This is not necessarily the same as the max size that can be written to an update file as writes can contain more than object data, you should use the size of the update file for that purpose.

Currently only provided by PLPKS on the pseries platform.

/sys/firmware/secvar/config/signed_update_algorithms

Defined on file *sysfs-secvar*

Bitmask of flags indicating which algorithms the hypervisor supports for signed update of objects, represented as a 16 byte hexadecimal ASCII string. Consult the hypervisor documentation for what these flags mean.

Currently only provided by PLPKS on the pseries platform.

/sys/firmware/secvar/config/supported_policies

Defined on file *sysfs-secvar*

Bitmask of supported policy flags by the hypervisor, represented as an 8 byte hexadecimal ASCII string. Consult the hypervisor documentation for what these flags are.

Currently only provided by PLPKS on the pseries platform.

/sys/firmware/secvar/config/total_size

Defined on file *sysfs-secvar*

Total size of the PLPKS in bytes, represented in ASCII decimal format.

Currently only provided by PLPKS on the pseries platform.

/sys/firmware/secvar/config/used_space

Defined on file *sysfs-secvar*

Current space consumed by the key store, in bytes, represented in ASCII decimal format.

Currently only provided by PLPKS on the pseries platform.

/sys/firmware/secvar/config/version

Defined on file *sysfs-secvar*

Config version as reported by the hypervisor in ASCII decimal format.

Currently only provided by PLPKS on the pseries platform.

/sys/firmware/secvar/format

Defined on file *sysfs-secvar*

A string indicating which backend is in use by the firmware. This determines the format of the variable and the accepted format of variable updates.

On powernv/OPAL, this value is provided by the OPAL firmware and is expected to be "ibm,edk2-compat-v1".

On pseries/PLPKS, this is generated by the kernel based on the version number in the SB_VERSION variable in the keystore, and has the form "ibm,plpks-sb-v<version>", or "ibm,plpks-sb-unknown" if there is no SB_VERSION variable.

/sys/firmware/secvar/vars

Defined on file *sysfs-secvar*

This directory lists all the secure variables that are supported by the firmware.

/sys/firmware/secvar/vars/<variable name>

Defined on file *sysfs-secvar*

Each secure variable is represented as a directory named as <variable_name>. The variable name is unique and is in ASCII representation. The data and size can be determined by reading their respective attribute files.

/sys/firmware/secvar/vars/<variable_name>/data

Defined on file *sysfs-secvar*

A read-only file containing the value of the variable. The size of the file represents the maximum size of the variable data.

/sys/firmware/secvar/vars/<variable_name>/size

Defined on file *sysfs-secvar*

An integer representation of the size of the content of the variable. In other words, it represents the size of the data.

/sys/firmware/secvar/vars/<variable_name>/update

Defined on file *sysfs-secvar*

A write-only file that is used to submit the new value for the variable. The size of the file represents the maximum size of the variable data that can be written.

/sys/firmware/sgi_uv/

Defined on file *sysfs-firmware-sgi_uv*

The /sys/firmware/sgi_uv directory contains information about the UV platform.

Under that directory are a number of read-only attributes:

```
archtype
hub_type
hubless
partition_id
coherence_id
uv_type
```

The archtype entry contains the UV architecture type that is used to select arch-dependent addresses and features. It can be set via the OEM_ID in the ACPI MADT table or by UVsystab entry both passed from UV BIOS.

The hub_type entry is used to select the type of hub which is similar to uv_type but encoded in a binary format. Include the file uv_hub.h to get the definitions.

The hubless entry basically is present and set only if there is no hub. In this case the hub_type entry is not present.

The partition_id entry contains the partition id. UV systems can be partitioned into multiple physical machines, which each partition running a unique copy of the operating system. Each partition will have a unique partition id.

The coherence_id entry contains the coherence id. A partitioned UV system can have one or more coherence domains. The coherence id indicates which coherence domain this partition is in.

The uv_type entry contains the hub revision number. This value can be used to identify the UV system version:

```
"0.*" = Hubless UV ('*' is subtype)
"3.0" = UV2
"5.0" = UV3
"7.0" = UV4
"7.1" = UV4a
"9.0" = UV5
```

The /sys/firmware/sgi_uv directory also contains two directories:

```
hubs/
pcibuses/
```

The hubs directory contains a number of hub objects, each representing a UV Hub visible to the BIOS. Each hub object's name is appended by a unique ordinal value (ex. /sys/firmware/sgi_uv/hubs/hub_5)

Each hub object directory contains a number of read-only attributes:

```
cnode
location
name
nasid
shared
this_partition
```

The cnode entry contains the cnode number of the corresponding hub. If a cnode value is not applicable, the value returned will be -1.

The location entry contains the location string of the corresponding hub. This value is used to physically identify a hub within a system.

The name entry contains the name of the corresponding hub. This name can be two variants:

```
"UVHub x.x" = A 'node' ASIC, connecting a CPU to the interconnect
fabric. The 'x.x' value represents the ASIC revision.
(ex. 'UVHub 5.0')

"NLxRouter" = A 'router ASIC, only connecting other ASICs to
the interconnect fabric. The 'x' value representing
the fabric technology version. (ex. 'NL8Router')
```

The nasid entry contains the nasid number of the corresponding hub. If a nasid value is not applicable, the value returned will be -1.

The shared entry contains a boolean value describing whether the corresponding hub is shared between system partitions.

The this_partition entry contains a boolean value describing whether the corresponding hub is local to the current partition.

Each hub object directory also contains a number of port objects, each representing a fabric port on the corresponding hub. A port object's name is appended by a unique ordinal value (ex. /sys/firmware/sgi_uv/hubs/hub_5/port_3)

Each port object directory contains a number of read-only attributes:

```
conn_hub
conn_port
```

The conn_hub entry contains a value representing the unique ordinal value of the hub on the other end of the fabric cable plugged into the port. If the port is disconnected, the value returned will be -1.

The conn_port entry contains a value representing the unique ordinal value of the port on the other end of the fabric cable plugged into the port. If the port is disconnected, the value returned will be -1.

Ex:

A value of '3' is read from:
/sys/firmware/sgi_uv/hubs/hub_5/port_3/conn_hub

and a value of '6' is read from:
/sys/firmware/sgi_uv/hubs/hub_5/port_3/conn_port

representing that this port is connected to:
/sys/firmware/sgi_uv/hubs/hub_3/port_6

The pcibuses directory contains a number of PCI bus objects. Each PCI bus object's name is appended by its PCI bus address. (ex. pcibus_0003:80)

Each pcibus object has a number of possible read-only attributes:

```
type
location
slot
ppb_addr
iio_stack
```

The type entry contains a value describing the type of IO at the corresponding PCI bus address. Known possible values across all UV versions are:

```
BASE IO
PCIe IO
PCIe SLOT
NODE IO
Riser
PPB
```

The location entry contains the location string of the UV Hub of the CPU physically connected to the corresponding PCI bus.

The slot entry contains the physical slot number of the corresponding PCI bus. This value is used to physically locate PCI cards within a system.

The ppb_addr entry contains the PCI address string of the bridged PCI bus. This entry is only present when the PCI bus object type is 'PPB'.

The iio_stack entry contains a value describing the IIO stack number that the corresponding PCI bus object is connected to.

/sys/firmware/turris-mox-rwtm/board_version

Defined on file *sysfs-firmware-turris-mox-rwtm*

(Read) Board version burned into eFuses of this Turris Mox board. Format: %i

/sys/firmware/turris-mox-rwtm/mac_address*

Defined on file *sysfs-firmware-turris-mox-rwtm*

(Read) MAC addresses burned into eFuses of this Turris Mox board. Format: %pM

/sys/firmware/turris-mox-rwtm/pubkey

Defined on file *sysfs-firmware-turris-mox-rwtm*

(Read) ECDSA public key (in pubkey hex compressed form) computed as pair to the ECDSA private key burned into eFuses of this Turris Mox Board. Format: string

/sys/firmware/turris-mox-rwtm/ram_size

Defined on file *sysfs-firmware-turris-mox-rwtm*

(Read) RAM size in MiB of this Turris Mox board as was detected during manufacturing and burned into eFuses. Can be 512 or 1024. Format: %i

/sys/firmware/turris-mox-rwtm/serial_number

Defined on file *sysfs-firmware-turris-mox-rwtm*

(Read) Serial number burned into eFuses of this Turris Mox device. Format: %016X

5.2.36 Symbols under /sys/fs

/sys/fs/erofs/<disk>/sync_decompress

Defined on file *sysfs-fs-erofs*

Control strategy of sync decompression:

- 0 (default, auto): enable for readpage, and enable for readahead on atomic contexts only.
- 1 (force on): enable for readpage and readahead.
- 2 (force off): disable for all situations.

/sys/fs/erofs/features/

Defined on file *sysfs-fs-erofs*

Shows all enabled kernel features. Supported features: zero_padding, compr_cfgs, big_pcluster, chunked_file, device_table, compr_head2, sb_chksum, ztailpacking, dedupe, fragments.

/sys/fs/ext4/<disk>/delayed_allocation_blocks

Defined on file *sysfs-fs-ext4*

This file is read-only and shows the number of blocks that are dirty in the page cache, but which do not have their location in the filesystem allocated yet.

/sys/fs/ext4/<disk>/extent_max_zeroout_kb

Defined on file *sysfs-fs-ext4*

The maximum number of kilobytes which will be zeroed out in preference to creating a new uninitialized extent when manipulating an inode's extent tree. Note that using a larger value

will increase the variability of time necessary to complete a random write operation (since a 4k random write might turn into a much larger write due to the zeroout operation).

/sys/fs/ext4/<disk>/inode_goal

Defined on file *sysfs-fs-ext4*

Tuning parameter which (if non-zero) controls the goal inode used by the inode allocator in preference to all other allocation heuristics. This is intended for debugging use only, and should be 0 on production systems.

/sys/fs/ext4/<disk>/inode_readahead_blks

Defined on file *sysfs-fs-ext4*

Tuning parameter which controls the maximum number of inode table blocks that ext4's inode table readahead algorithm will pre-read into the buffer cache

/sys/fs/ext4/<disk>/journal_task

Defined on file *sysfs-fs-ext4*

This file is read-only and shows the pid of journal thread in current pid-namespace or 0 if task is unreachable.

/sys/fs/ext4/<disk>/lifetime_write_kbytes

Defined on file *sysfs-fs-ext4*

This file is read-only and shows the number of kilobytes of data that have been written to this filesystem since it was created.

/sys/fs/ext4/<disk>/max_writeback_mb_bump

Defined on file *sysfs-fs-ext4*

The maximum number of megabytes the writeback code will try to write out before move on to another inode.

/sys/fs/ext4/<disk>/mb_group_prealloc

Defined on file *sysfs-fs-ext4*

The multiblock allocator will round up allocation requests to a multiple of this tuning parameter if the stripe size is not set in the ext4 superblock

/sys/fs/ext4/<disk>/mb_max_to_scan

Defined on file *sysfs-fs-ext4*

The maximum number of extents the multiblock allocator will search to find the best extent

/sys/fs/ext4/<disk>/mb_min_to_scan

Defined on file *sysfs-fs-ext4*

The minimum number of extents the multiblock allocator will search to find the best extent

/sys/fs/ext4/<disk>/mb_order2_req

Defined on file *sysfs-fs-ext4*

Tuning parameter which controls the minimum size for requests (as a power of 2) where the buddy cache is used

/sys/fs/ext4/<disk>/mb_stats

Defined on file *sysfs-fs-ext4*

Controls whether the multiblock allocator should collect statistics, which are shown during the unmount. 1 means to collect statistics, 0 means not to collect statistics

/sys/fs/ext4/<disk>/mb_stream_req

Defined on file *sysfs-fs-ext4*

Files which have fewer blocks than this tunable parameter will have their blocks allocated out of a block group specific preallocation pool, so that small files are packed closely together. Each large file will have its blocks allocated out of its own unique preallocation pool.

/sys/fs/ext4/<disk>/session_write_kbytes

Defined on file *sysfs-fs-ext4*

This file is read-only and shows the number of kilobytes of data that have been written to this filesystem since it was mounted.

/sys/fs/f2fs/<disk>/atgc_age_threshold

Defined on file *sysfs-fs-f2fs*

When ATGC is on, it controls age threshold to bypass GCing young candidates whose age is not beyond the threshold, by default it was initialized as 604800 seconds (equals to 7 days).

/sys/fs/f2fs/<disk>/atgc_age_weight

Defined on file *sysfs-fs-f2fs*

When ATGC is on, it controls age weight to balance weight proportion in between aging and valid blocks, the value should be in range of [0, 100], by default it was initialized as 60(%).

/sys/fs/f2fs/<disk>/atgc_candidate_count

Defined on file *sysfs-fs-f2fs*

When ATGC is on, it controls candidate count in order to limit total number of potential victim in all candidates, by default it was initialized as 10 (sections).

/sys/fs/f2fs/<disk>/atgc_candidate_ratio

Defined on file *sysfs-fs-f2fs*

When ATGC is on, it controls candidate ratio in order to limit total number of potential victim in all candidates, the value should be in range of [0, 100], by default it was initialized as 20(%).

/sys/fs/f2fs/<disk>/avg_vblocks

Defined on file *sysfs-fs-f2fs*

Average number of valid blocks. Available when CONFIG_F2FS_STAT_FS=y.

/sys/fs/f2fs/<disk>/ckpt_thread_ioprio

Defined on file *sysfs-fs-f2fs*

Give a way to change checkpoint merge daemon's io priority. Its default value is "be,3", which means "BE" I/O class and I/O priority "3". We can select the class between "rt" and "be", and set the I/O priority within valid range of it. "," delimiter is necessary in between I/O class and priority number.

/sys/fs/f2fs/<disk>/committed_atomic_block

Defined on file *sysfs-fs-f2fs*

Show the accumulated total committed atomic write block count after boot. If you write "0" here, you can initialize to "0".

/sys/fs/f2fs/<disk>/compr_new_inode

Defined on file *sysfs-fs-f2fs*

Show the count of inode newly enabled for compression since mount. Note that when the compression is disabled for the files, this count doesn't decrease. If you write "0" here, you can initialize compr_new_inode to "0".

/sys/fs/f2fs/<disk>/compr_saved_block

Defined on file *sysfs-fs-f2fs*

Show the saved block count with compression since mount. Note that when the compressed blocks are deleted, this count doesn't decrease. If you write "0" here, you can initialize compr_written_block and compr_saved_block to "0".

/sys/fs/f2fs/<disk>/compr_written_block

Defined on file *sysfs-fs-f2fs*

Show the block count written after compression since mount. Note that when the compressed blocks are deleted, this count doesn't decrease. If you write "0" here, you can initialize compr_written_block and compr_saved_block to "0".

/sys/fs/f2fs/<disk>/compress_percent

Defined on file *sysfs-fs-f2fs*

When compress cache is on, it controls cached page percent(compress pages / free_ram) in order to limit caching compress page. If cached page percent exceed threshold, then deny caching compress page. The value should be in range of (0, 100], by default it was initialized as 20(%).

/sys/fs/f2fs/<disk>/compress_watermark

Defined on file *sysfs-fs-f2fs*

When compress cache is on, it controls free memory watermark in order to limit caching compress page. If free memory is lower than watermark, then deny caching compress page. The value should be in range of (0, 100], by default it was initialized as 20(%).

/sys/fs/f2fs/<disk>/cp_background_calls

Defined on file *sysfs-fs-f2fs*

Number of checkpoint operations performed in the background to free segments. Available when CONFIG_F2FS_STAT_FS=y.

/sys/fs/f2fs/<disk>/cp_foreground_calls

Defined on file *sysfs-fs-f2fs*

Number of checkpoint operations performed on demand. Available when CONFIG_F2FS_STAT_FS=y.

/sys/fs/f2fs/<disk>/cp_interval

Defined on file *sysfs-fs-f2fs*

Controls the checkpoint timing, set to 60 seconds by default.

/sys/fs/f2fs/<disk>/current_atomic_write

Defined on file *sysfs-fs-f2fs*

Show the total current atomic write block count, which is not committed yet. This is a read-only entry.

/sys/fs/f2fs/<disk>/current_reserved_blocks

Defined on file *sysfs-fs-f2fs*

Shows current reserved blocks in system, it may be temporarily smaller than target_reserved_blocks, but will gradually increase to target_reserved_blocks when more free blocks are freed by user later.

/sys/fs/f2fs/<disk>/data_io_flag

Defined on file *sysfs-fs-f2fs*

Give a way to attach REQ_META|FUA to data writes given temperature-based bits. Now the bits indicate:

REQ_META			REQ_FUA		
5	4	3	2	1	0
Cold	Warm	Hot	Cold	Warm	Hot

/sys/fs/f2fs/<disk>/dir_level

Defined on file *sysfs-fs-f2fs*

Controls the directory level for large directory. If a directory has a number of files, it can reduce the file lookup latency by increasing this dir_level value. Otherwise, it needs to decrease this value to reduce the space overhead. The default value is 0.

/sys/fs/f2fs/<disk>/dirty_nats_ratio

Defined on file *sysfs-fs-f2fs*

Controls dirty nat entries ratio threshold, if current ratio exceeds configured threshold, checkpoint will be triggered for flushing dirty nat entries.

/sys/fs/f2fs/<disk>/dirty_segments

Defined on file *sysfs-fs-f2fs*

Shows the number of dirty segments.

/sys/fs/f2fs/<disk>/discard_granularity

Defined on file *sysfs-fs-f2fs*

Controls discard granularity of inner discard thread. Inner thread will not issue discards with size that is smaller than granularity. The unit size is one block(4KB), now only support configuring in range of [1, 512]. Default value is 16. For small devices, default value is 1.

/sys/fs/f2fs/<disk>/discard_idle_interval

Defined on file *sysfs-fs-f2fs*

Controls the idle timing of discard thread given this time interval. Default is 5 secs.

/sys/fs/f2fs/<disk>/discard_io_aware

Defined on file *sysfs-fs-f2fs*

It controls to enable/disable IO aware feature for background discard. By default, the value is 1 which indicates IO aware is on.

/sys/fs/f2fs/<disk>/discard_io_aware_gran

Defined on file *sysfs-fs-f2fs*

Controls background discard granularity of inner discard thread when is not in idle. Inner thread will not issue discards with size that is smaller than granularity. The unit size is one block(4KB), now only support configuring in range of [0, 512]. Default: 512

/sys/fs/f2fs/<disk>/discard_urgent_util

Defined on file *sysfs-fs-f2fs*

When space utilization exceeds this, do background DISCARD aggressively. Does DISCARD forcibly in a period of given min_discard_issue_time when the number of discards is not 0 and set discard granularity to 1. Default: 80

/sys/fs/f2fs/<disk>/encoding

Defined on file *sysfs-fs-f2fs*

Displays name and version of the encoding set for the filesystem. If no encoding is set, displays (none)

/sys/fs/f2fs/<disk>/extension_list

Defined on file *sysfs-fs-f2fs*

Used to control configure extension list: - Query: cat */sys/fs/f2fs/<disk>/extension_list* - Add: echo '[h/c]extension' > */sys/fs/f2fs/<disk>/extension_list* - Del: echo '[h/c]!extension' > */sys/fs/f2fs/<disk>/extension_list* - [h] means add/del hot file extension - [c] means add/del cold file extension

/sys/fs/f2fs/<disk>/fault_rate

Defined on file *sysfs-fs-f2fs*

Enable fault injection in all supported types with specified injection rate.

/sys/fs/f2fs/<disk>/fault_type

Defined on file *sysfs-fs-f2fs*

Support configuring fault injection type, should be enabled with fault_injection option, fault type value is shown below, it supports single or combined type.

Type_Name	Type_Value
FAULT_KMALLOC	0x000000001
FAULT_KVMALLOC	0x000000002
FAULT_PAGE_ALLOC	0x000000004
FAULT_PAGE_GET	0x000000008
FAULT_ALLOC_BIO	0x000000010 (obsolete)
FAULT_ALLOC_NID	0x000000020
FAULT_ORPHAN	0x000000040
FAULT_BLOCK	0x000000080
FAULT_DIR_DEPTH	0x000000100
FAULT_EVICT_INODE	0x000000200
FAULT_TRUNCATE	0x000000400
FAULT_READ_IO	0x000000800
FAULT_CHECKPOINT	0x000001000
FAULT_DISCARD	0x000002000
FAULT_WRITE_IO	0x000004000
FAULT_SLAB_ALLOC	0x000008000
FAULT_DQUOT_INIT	0x000010000
FAULT_LOCK_OP	0x000020000
FAULT_BLKADDR	0x000040000

/sys/fs/f2fs/<disk>/feature_list/

Defined on file *sysfs-fs-f2fs*

Expand */sys/fs/f2fs/<disk>/features* to meet sysfs rule. Supported on-disk features: encryption, block_zoned (aka blkzoned), extra_attr, project_quota (aka projquota), inode_checksum, flexible_inline_xattr, quota_ino, inode_crtime, lost_found, verity, sb_checksum, casefold, readonly, compression. Note that, pin_file is moved into */sys/fs/f2fs/features/*.

/sys/fs/f2fs/<disk>/features

Defined on file *sysfs-fs-f2fs*

<deprecated: should use /sys/fs/f2fs/<disk>/feature_list/> Shows all enabled features in current device. Supported features: encryption, blkzoned, extra_attr, projquota, inode_checksum, flexible_inline_xattr, quota_ino, inode_crtime, lost_found, verity, sb_checksum, casefold, readonly, compression, pin_file.

/sys/fs/f2fs/<disk>/free_segments

Defined on file *sysfs-fs-f2fs*

Number of free segments in disk.

/sys/fs/f2fs/<disk>/gc_background_calls

Defined on file *sysfs-fs-f2fs*

Number of garbage collection operations triggered in background. Available when CONFIG_F2FS_STAT_FS=y.

/sys/fs/f2fs/<disk>/gc_foreground_calls

Defined on file *sysfs-fs-f2fs*

Number of garbage collection operations performed on demand. Available when CONFIG_F2FS_STAT_FS=y.

/sys/fs/f2fs/<disk>/gc_idle

Defined on file *sysfs-fs-f2fs*

Controls the victim selection policy for garbage collection. Setting gc_idle = 0(default) will disable this option. Setting:

gc_idle = 1	will select the Cost Benefit approach & setting
gc_idle = 2	will select the greedy approach & setting
gc_idle = 3	will select the age-threshold based approach.

/sys/fs/f2fs/<disk>/gc_idle_interval

Defined on file *sysfs-fs-f2fs*

Controls the idle timing for gc path. Set to 5 seconds by default.

/sys/fs/f2fs/<disk>/gc_max_sleep_time

Defined on file *sysfs-fs-f2fs*

Controls the maximum sleep time for gc_thread. Time is in milliseconds.

/sys/fs/f2fs/<disk>/gc_min_sleep_time

Defined on file *sysfs-fs-f2fs*

Controls the minimum sleep time for gc_thread. Time is in milliseconds.

/sys/fs/f2fs/<disk>/gc_mode

Defined on file *sysfs-fs-f2fs*

Show the current gc_mode as a string. This is a read-only entry.

/sys/fs/f2fs/<disk>/gc_no_gc_sleep_time

Defined on file *sysfs-fs-f2fs*

Controls the default sleep time for gc_thread. Time is in milliseconds.

/sys/fs/f2fs/<disk>/gc_pin_file_thresh

Defined on file *sysfs-fs-f2fs*

This indicates how many GC can be failed for the pinned file. If it exceeds this, F2FS doesn't guarantee its pinning state. 2048 trials is set by default.

/sys/fs/f2fs/<disk>/gc_reclaimed_segments

Defined on file *sysfs-fs-f2fs*

Show how many segments have been reclaimed by GC during a specific GC mode (0: GC normal, 1: GC idle CB, 2: GC idle greedy, 3: GC idle AT, 4: GC urgent high, 5: GC urgent low 6: GC urgent mid) You can re-initialize this value to "0".

/sys/fs/f2fs/<disk>/gc_remaining_trials

Defined on file *sysfs-fs-f2fs*

You can set the trial count limit for GC urgent and idle mode with this value. If GC thread gets to the limit, the mode will turn back to GC normal mode. By default, the value is zero, which means there is no limit like before.

/sys/fs/f2fs/<disk>/gc_segment_mode

Defined on file *sysfs-fs-f2fs*

You can control for which gc mode the "gc_reclaimed_segments" node shows. Refer to the description of the modes in "gc_reclaimed_segments".

/sys/fs/f2fs/<disk>/gc_urgent

Defined on file *sysfs-fs-f2fs*

Do background GC aggressively when set. Set to 0 by default. gc urgent high(1): does GC forcibly in a period of given gc_urgent_sleep_time and ignores I/O idling check. uses greedy GC approach and turns SSR mode on. gc urgent low(2): lowers the bar of checking I/O idling in order to process outstanding discard commands and GC a little bit aggressively. uses cost benefit GC approach. gc urgent mid(3): does GC forcibly in a period of given gc_urgent_sleep_time and executes a mid level of I/O idling check. uses cost benefit GC approach.

/sys/fs/f2fs/<disk>/gc_urgent_sleep_time

Defined on file *sysfs-fs-f2fs*

Controls sleep time of GC urgent mode. Set to 500ms by default.

/sys/fs/f2fs/<disk>/hot_data_age_threshold

Defined on file *sysfs-fs-f2fs*

When DATA SEPARATION is on, it controls the age threshold to indicate the data blocks as hot. By default it was initialized as 262144 blocks (equals to 1GB).

/sys/fs/f2fs/<disk>/idle_interval

Defined on file *sysfs-fs-f2fs*

Controls the idle timing of system, if there is no FS operation during given interval. Set to 5 seconds by default.

/sys/fs/f2fs/<disk>/inject_rate

Defined on file *sysfs-fs-f2fs*

Controls the injection rate of arbitrary faults.

/sys/fs/f2fs/<disk>/inject_type

Defined on file *sysfs-fs-f2fs*

Controls the injection type of arbitrary faults.

/sys/fs/f2fs/<disk>/iostat_enable

Defined on file *sysfs-fs-f2fs*

Controls to enable/disable IO stat.

/sys/fs/f2fs/<disk>/iostat_period_ms

Defined on file *sysfs-fs-f2fs*

Give a way to change iostat_period time. 3secs by default. The new iostat trace gives stats gap given the period.

/sys/fs/f2fs/<disk>/ipu_policy

Defined on file *sysfs-fs-f2fs*

Controls the in-place-update policy. updates in f2fs. User can set:

value	policy	description
0x00	DISABLE	disable IPU(=default option in LFS mode)
0x01	FORCE	all the time
0x02	SSR	if SSR mode is activated
0x04	UTIL	if FS utilization is over threshold
0x08	SSR_UTIL	if SSR mode is activated and FS utilization is over threshold
0x10	FSYNC	activated in fsync path only for high performance flash storages. IPU will be triggered only if the # of dirty pages over min_fsync_blocks. (=default option)
0x20	ASYNC	do IPU given by asynchronous write requests
0x40	NOCACHE	disable IPU bio cache
0x80	HONOR_OPU_WRITE	use OPU write prior to IPU write if inode has FI_OPU_WRITE flag

Refer segment.h for details.

/sys/fs/f2fs/<disk>/last_age_weight

Defined on file *sysfs-fs-f2fs*

When DATA SEPARATION is on, it controls the weight of last data block age.

/sys/fs/f2fs/<disk>/lifetime_write_kbytes

Defined on file *sysfs-fs-f2fs*

Shows total written kbytes issued to disk.

/sys/fs/f2fs/<disk>/main_blkaddr

Defined on file *sysfs-fs-f2fs*

Shows first block address of MAIN area.

/sys/fs/f2fs/<disk>/max_discard_issue_time

Defined on file *sysfs-fs-f2fs*

Controls the interval the discard thread will wait when there are no discard operations to be issued.

/sys/fs/f2fs/<disk>/max_discard_request

Defined on file *sysfs-fs-f2fs*

Controls the number of discards a thread will issue at a time. Higher number will allow the discard thread to finish its work faster, at the cost of higher latency for incoming I/O.

/sys/fs/f2fs/<disk>/max_fragment_chunk

Defined on file *sysfs-fs-f2fs*

With "mode=fragment:block" mount options, we can scatter block allocation. f2fs will allocate 1..<max_fragment_chunk> blocks in a chunk and make a hole in the length of 1..<max_fragment_hole> by turns. This value can be set between 1..512 and the default value is 4.

/sys/fs/f2fs/<disk>/max_fragment_hole

Defined on file *sysfs-fs-f2fs*

With "mode=fragment:block" mount options, we can scatter block allocation. f2fs will allocate 1..<max_fragment_chunk> blocks in a chunk and make a hole in the length of 1..<max_fragment_hole> by turns. This value can be set between 1..512 and the default value is 4.

/sys/fs/f2fs/<disk>/max_io_bytes

Defined on file *sysfs-fs-f2fs*

This gives a control to limit the bio size in f2fs. Default is zero, which will follow underlying block layer limit, whereas, if it has a certain bytes value, f2fs won't submit a bio larger than that size.

/sys/fs/f2fs/<disk>/max_ordered_discard

Defined on file *sysfs-fs-f2fs*

Controls the maximum ordered discard, the unit size is one block(4KB). Set it to 16 by default.

/sys/fs/f2fs/<disk>/max_roll_forward_node_blocks

Defined on file *sysfs-fs-f2fs*

Controls max # of node block writes to be used for roll forward recovery. This can limit the roll forward recovery time.

/sys/fs/f2fs/<disk>/max_small_discards

Defined on file *sysfs-fs-f2fs*

Controls the issue rate of discard commands that consist of small blocks less than 2MB. The candidates to be discarded are cached during checkpoint, and issued by issue_discard thread after checkpoint. It is enabled by default.

/sys/fs/f2fs/<disk>/max_victim_search

Defined on file *sysfs-fs-f2fs*

Controls the number of trials to find a victim segment when conducting SSR and cleaning operations. The default value is 4096 which covers 8GB block address range.

/sys/fs/f2fs/<disk>/mid_discard_issue_time

Defined on file *sysfs-fs-f2fs*

Controls the interval the discard thread will wait between issuing discard requests when there are discards to be issued and an I/O aware interruption occurs.

/sys/fs/f2fs/<disk>/migration_granularity

Defined on file *sysfs-fs-f2fs*

Controls migration granularity of garbage collection on large section, it can let GC move partial segment{s} of one section in one GC cycle, so that dispersing heavy overhead GC to multiple lightweight one.

/sys/fs/f2fs/<disk>/min_discard_issue_time

Defined on file *sysfs-fs-f2fs*

Controls the interval the discard thread will wait between issuing discard requests when there are discards to be issued and no I/O aware interruptions occur.

/sys/fs/f2fs/<disk>/min_fsync_blocks

Defined on file *sysfs-fs-f2fs*

Controls the dirty page count condition for the in-place-update policies.

/sys/fs/f2fs/<disk>/min_hot_blocks

Defined on file *sysfs-fs-f2fs*

Controls the dirty page count condition for redefining hot data.

/sys/fs/f2fs/<disk>/min_ipu_util

Defined on file *sysfs-fs-f2fs*

Controls the FS utilization condition for the in-place-update policies. It is used by F2FS_IPU_UTIL and F2FS_IPU_SSR_UTIL policies.

/sys/fs/f2fs/<disk>/min_seq_blocks

Defined on file *sysfs-fs-f2fs*

Controls the dirty page count condition for batched sequential writes in writepages.

/sys/fs/f2fs/<disk>/min_ssr_sections

Defined on file *sysfs-fs-f2fs*

Controls the free section threshold to trigger SSR allocation. If this is large, SSR mode will be enabled early.

/sys/fs/f2fs/<disk>/mounted_time_sec

Defined on file *sysfs-fs-f2fs*

Show the mounted time in secs of this partition.

/sys/fs/f2fs/<disk>/moved_blocks_background

Defined on file *sysfs-fs-f2fs*

Number of blocks moved by garbage collection in background. Available when CONFIG_F2FS_STAT_FS=y.

/sys/fs/f2fs/<disk>/moved_blocks_foreground

Defined on file *sysfs-fs-f2fs*

Number of blocks moved by garbage collection in foreground. Available when CONFIG_F2FS_STAT_FS=y.

/sys/fs/f2fs/<disk>/node_io_flag

Defined on file *sysfs-fs-f2fs*

Give a way to attach REQ_META|FUA to node writes given temperature-based bits. Now the bits indicate:

REQ_META			REQ_FUA		
5	4	3	2	1	0
Cold	Warm	Hot	Cold	Warm	Hot

/sys/fs/f2fs/<disk>/ovp_segments

Defined on file *sysfs-fs-f2fs*

Shows the number of overprovision segments.

/sys/fs/f2fs/<disk>/peak_atomic_write

Defined on file *sysfs-fs-f2fs*

Show the peak value of total current atomic write block count after boot. If you write "0" here, you can initialize to "0".

/sys/fs/f2fs/<disk>/pending_discard

Defined on file *sysfs-fs-f2fs*

Shows the number of pending discard commands in the queue.

/sys/fs/f2fs/<disk>/ra_nid_pages

Defined on file *sysfs-fs-f2fs*

Controls the count of nid pages to be readaheaded. When building free nids, F2FS reads NAT blocks ahead for speed up. Default is 0.

/sys/fs/f2fs/<disk>/ram_thresh

Defined on file *sysfs-fs-f2fs*

Controls the memory footprint used by free nids and cached nat entries. By default, 1 is set, which indicates 10 MB / 1 GB RAM.

/sys/fs/f2fs/<disk>/readdir_ra

Defined on file *sysfs-fs-f2fs*

Controls readahead inode block in readdir. Enabled by default.

/sys/fs/f2fs/<disk>/reclaim_segments

Defined on file *sysfs-fs-f2fs*

This parameter controls the number of prefree segments to be reclaimed. If the number of prefree segments is larger than the number of segments in the proportion to the percentage over total volume size, f2fs tries to conduct checkpoint to reclaim the prefree segments to free segments. By default, 5% over total # of segments.

/sys/fs/f2fs/<disk>/reserved_blocks

Defined on file *sysfs-fs-f2fs*

Controls target reserved blocks in system, the threshold is soft, it could exceed current available user space.

/sys/fs/f2fs/<disk>/revoked_atomic_block

Defined on file *sysfs-fs-f2fs*

Show the accumulated total revoked atomic write block count after boot. If you write ”0” here, you can initialize to ”0”.

/sys/fs/f2fs/<disk>/seq_file_ra_mul

Defined on file *sysfs-fs-f2fs*

You can control the multiplier value of bdi device readahead window size between 2 (default) and 256 for POSIX_FADV_SEQUENTIAL advise option.

/sys/fs/f2fs/<disk>/stat/cp_status

Defined on file *sysfs-fs-f2fs*

Show status of f2fs checkpoint in real time.

cp flag	value
CP_UMOUNT_FLAG	0x00000001
CP_ORPHAN_PRESENT_FLAG	0x00000002
CP_COMPACT_SUM_FLAG	0x00000004
CP_ERROR_FLAG	0x00000008
CP_FSCK_FLAG	0x00000010
CP_FASTBOOT_FLAG	0x00000020
CP_CRC_RECOVERY_FLAG	0x00000040
CP_NAT_BITS_FLAG	0x00000080
CP_TRIMMED_FLAG	0x00000100
CP_NOCRC_RECOVERY_FLAG	0x00000200
CP_LARGE_NAT_BITMAP_FLAG	0x00000400
CP_QUOTA_NEED_FSCK_FLAG	0x00000800
CP_DISABLED_FLAG	0x00001000
CP_DISABLED_QUICK_FLAG	0x00002000
CP_RESIZEFS_FLAG	0x00004000

/sys/fs/f2fs/<disk>/stat/issued_discard

Defined on file *sysfs-fs-f2fs*

Shows the number of issued discard.

/sys/fs/f2fs/<disk>/stat/queued_discard

Defined on file *sysfs-fs-f2fs*

Shows the number of queued discard.

/sys/fs/f2fs/<disk>/stat/sb_status

Defined on file *sysfs-fs-f2fs*

Show status of f2fs superblock in real time.

value	sb status macro	description
0x1	SBI_IS_DIRTY	dirty flag for checkpoint
0x2	SBI_IS_CLOSE	specify unmounting
0x4	SBI_NEED_FSCK	need fsck.f2fs to fix
0x8	SBI_POR_DOING	recovery is doing or not
0x10	SBI_NEED_SB_WRITE	need to recover superblock
0x20	SBI_NEED_CP	need to checkpoint
0x40	SBI_IS_SHUTDOWN	shutdown by ioctl
0x80	SBI_IS_RECOVERED	recovered orphan/data
0x100	SBI_CP_DISABLED	CP was disabled last mount
0x200	SBI_CP_DISABLED_QUICK	CP was disabled quickly
0x400	SBI_QUOTA_NEED_FLUSH	need to flush quota info in CP
0x800	SBI_QUOTA_SKIP_FLUSH	skip flushing quota in current CP
0x1000	SBI_QUOTA_NEED_REPAIR	quota file may be corrupted
0x2000	SBI_IS_RESIZEFS	resizefs is in process
0x4000	SBI_IS_FREEZING	freefs is in process

/sys/fs/f2fs/<disk>/stat/undiscard_blks

Defined on file *sysfs-fs-f2fs*

Shows the total number of undiscard blocks.

/sys/fs/f2fs/<disk>/umount_discard_timeout

Defined on file *sysfs-fs-f2fs*

Set timeout to issue discard commands during umount. Default: 5 secs

/sys/fs/f2fs/<disk>/unusable

Defined on file *sysfs-fs-f2fs*

If checkpoint=disable, it displays the number of blocks that are unusable. If checkpoint=enable it displays the number of blocks that would be unusable if checkpoint=disable were to be set.

/sys/fs/f2fs/<disk>/unusable_blocks_per_sec

Defined on file *sysfs-fs-f2fs*

Shows the number of unusable blocks in a section which was defined by the zone capacity reported by underlying zoned device.

/sys/fs/f2fs/<disk>/warm_data_age_threshold

Defined on file *sysfs-fs-f2fs*

When DATA SEPARATION is on, it controls the age threshold to indicate the data blocks as warm. By default it was initialized as 2621440 blocks (equals to 10GB).

/sys/fs/f2fs/features/

Defined on file *sysfs-fs-f2fs*

Shows all enabled kernel features. Supported features: encryption, block_zoned, extra_attr, project_quota, inode_checksum, flexible_inline_xattr, quota_ino, inode_crtime, lost_found, verity, sb_checksum, casefold, readonly, compression, test_dummy_encryption_v2, atomic_write, pin_file, encrypted_casefold.

/sys/fs/nilfs2/<device>/README

Defined on file *sysfs-fs-nilfs2*

Describe attributes of /sys/fs/nilfs2/<device> group.

/sys/fs/nilfs2/<device>/blocksize

Defined on file *sysfs-fs-nilfs2*

Show volume's block size in bytes.

/sys/fs/nilfs2/<device>/checkpoints/README

Defined on file *sysfs-fs-nilfs2*

Describe attributes of /sys/fs/nilfs2/<device>/checkpoints group.

/sys/fs/nilfs2/<device>/checkpoints/checkpoints_number

Defined on file *sysfs-fs-nilfs2*

Show number of checkpoints on volume.

/sys/fs/nilfs2/<device>/checkpoints/last_seg_checkpoint

Defined on file *sysfs-fs-nilfs2*

Show checkpoint number of the latest segment.

/sys/fs/nilfs2/<device>/checkpoints/next_checkpoint

Defined on file *sysfs-fs-nilfs2*

Show next checkpoint number.

/sys/fs/nilfs2/<device>/checkpoints/snapshots_number

Defined on file *sysfs-fs-nilfs2*

Show number of snapshots on volume.

/sys/fs/nilfs2/<device>/device_size

Defined on file *sysfs-fs-nilfs2*

Show volume size in bytes.

/sys/fs/nilfs2/<device>/free_blocks

Defined on file *sysfs-fs-nilfs2*

Show count of free blocks on volume.

/sys/fs/nilfs2/<device>/mounted_snapshots/<id>/README

Defined on file *sysfs-fs-nilfs2*

Describe attributes of /sys/fs/nilfs2/<device>/mounted_snapshots/<id> group.

/sys/fs/nilfs2/<device>/mounted_snapshots/<id>/blocks_count

Defined on file *sysfs-fs-nilfs2*

Show number of blocks for snapshot.

/sys/fs/nilfs2/<device>/mounted_snapshots/<id>/inodes_count

Defined on file *sysfs-fs-nilfs2*

Show number of inodes for snapshot.

/sys/fs/nilfs2/<device>/mounted_snapshots/README

Defined on file *sysfs-fs-nilfs2*

Describe content of /sys/fs/nilfs2/<device>/mounted_snapshots group.

/sys/fs/nilfs2/<device>/revision

Defined on file *sysfs-fs-nilfs2*

Show NILFS file system revision on volume. This value informs about metadata structures' revision on mounted volume.

/sys/fs/nilfs2/<device>/segctor/README

Defined on file *sysfs-fs-nilfs2*

Describe attributes of /sys/fs/nilfs2/<device>/segctor group.

/sys/fs/nilfs2/<device>/segctor/current_last_full_seg

Defined on file *sysfs-fs-nilfs2*

Show index number of the latest full segment.

/sys/fs/nilfs2/<device>/segctor/current_seg_sequence

Defined on file *sysfs-fs-nilfs2*

Show segment sequence counter.

/sys/fs/nilfs2/<device>/segctor/dirty_data_blocks_count

Defined on file *sysfs-fs-nilfs2*

Show number of dirty data blocks.

/sys/fs/nilfs2/<device>/segctor/last_nongc_write_time

Defined on file *sysfs-fs-nilfs2*

Show write time of the last segment not for cleaner operation in human-readable format.

/sys/fs/nilfs2/<device>/segctor/last_nongc_write_time_secs

Defined on file *sysfs-fs-nilfs2*

Show write time of the last segment not for cleaner operation in seconds.

/sys/fs/nilfs2/<device>/segctor/last_pseg_block

Defined on file *sysfs-fs-nilfs2*

Show start block number of the latest segment.

/sys/fs/nilfs2/<device>/segctor/last_seg_checkpoint

Defined on file *sysfs-fs-nilfs2*

Show checkpoint number of the latest segment.

/sys/fs/nilfs2/<device>/segctor/last_seg_sequence

Defined on file *sysfs-fs-nilfs2*

Show sequence value of the latest segment.

/sys/fs/nilfs2/<device>/segctor/last_seg_write_time

Defined on file *sysfs-fs-nilfs2*

Show write time of the last segment in human-readable format.

/sys/fs/nilfs2/<device>/segctor/last_seg_write_time_secs

Defined on file *sysfs-fs-nilfs2*

Show write time of the last segment in seconds.

/sys/fs/nilfs2/<device>/segctor/next_checkpoint

Defined on file *sysfs-fs-nilfs2*

Show next checkpoint number.

/sys/fs/nilfs2/<device>/segctor/next_full_seg

Defined on file *sysfs-fs-nilfs2*

Show index number of the full segment index to be used next.

/sys/fs/nilfs2/<device>/segctor/next_pseg_offset

Defined on file *sysfs-fs-nilfs2*

Show offset of next partial segment in the current full segment.

/sys/fs/nilfs2/<device>/segments/README

Defined on file *sysfs-fs-nilfs2*

Describe attributes of /sys/fs/nilfs2/<device>/segments group.

/sys/fs/nilfs2/<device>/segments/blocks_per_segment

Defined on file *sysfs-fs-nilfs2*

Show number of blocks in segment.

/sys/fs/nilfs2/<device>/segments/clean_segments

Defined on file *sysfs-fs-nilfs2*

Show count of clean segments.

/sys/fs/nilfs2/<device>/segments/dirty_segments

Defined on file *sysfs-fs-nilfs2*

Show count of dirty segments.

/sys/fs/nilfs2/<device>/segments/segments_number

Defined on file *sysfs-fs-nilfs2*

Show number of segments on a volume.

/sys/fs/nilfs2/<device>/superblock/README

Defined on file *sysfs-fs-nilfs2*

Describe attributes of /sys/fs/nilfs2/<device>/superblock group.

/sys/fs/nilfs2/<device>/superblock/sb_update_frequency

Defined on file *sysfs-fs-nilfs2*

Show/Set interval of periodical update of superblock (in seconds).

/sys/fs/nilfs2/<device>/superblock/sb_write_count

Defined on file *sysfs-fs-nilfs2*

Show current write count of super block.

/sys/fs/nilfs2/<device>/superblock/sb_write_time

Defined on file *sysfs-fs-nilfs2*

Show last write time of super block in human-readable format.

/sys/fs/nilfs2/<device>/superblock/sb_write_time_secs

Defined on file *sysfs-fs-nilfs2*

Show last write time of super block in seconds.

/sys/fs/nilfs2/<device>/uuid

Defined on file *sysfs-fs-nilfs2*

Show volume's UUID (Universally Unique Identifier).

/sys/fs/nilfs2/<device>/volume_name

Defined on file *sysfs-fs-nilfs2*

Show volume's label.

/sys/fs/nilfs2/features/README

Defined on file *sysfs-fs-nilfs2*

Describe attributes of /sys/fs/nilfs2/features group.

/sys/fs/nilfs2/features/revision

Defined on file *sysfs-fs-nilfs2*

Show current revision of NILFS file system driver. This value informs about file system revision that driver is ready to support.

/sys/fs/ocfs2/

Defined on file *sysfs-ocfs2*

The /sys/fs/ocfs2 directory contains knobs used by the ocfs2-tools to interact with the filesystem.

/sys/fs/ocfs2/active_cluster_plugin

Defined on file *sysfs-ocfs2*

The */sys/fs/ocfs2/active_cluster_plugin* displays which cluster plugin is currently in use by the filesystem. The active plugin will appear in the loaded_cluster_plugins file as well. Only one plugin can be used at a time.

Reading from this file returns the name of the active plugin on a single line.

This file is read-only. Which plugin is active depends on the cluster stack in use. The contents may change when all filesystems are unmounted and the cluster stack is changed.

/sys/fs/ocfs2/cluster_stack

Defined on file *sysfs-ocfs2*

The */sys/fs/ocfs2/cluster_stack* file contains the name of current ocfs2 cluster stack. This value is set by userspace tools when bringing the cluster stack online.

Cluster stack names are 4 characters in length.

When the 'o2cb' cluster stack is used, the 'o2cb' cluster plugin is active. All other cluster stacks use the 'user' cluster plugin.

Reading from this file returns the name of the current cluster stack on a single line.

Writing a new stack name to this file changes the current cluster stack unless there are mounted ocfs2 filesystems. If there are mounted filesystems, attempts to change the stack return an error.

Users:

ocfs2-tools <ocfs2-tools-devel@lists.linux.dev>

/sys/fs/ocfs2/loaded_cluster_plugins

Defined on file *sysfs-ocfs2*

The */sys/fs/ocfs2/loaded_cluster_plugins* file describes the available plugins to support ocfs2 cluster operation. A cluster plugin is required to use ocfs2 in a cluster. There are currently two available plugins:

- **'o2cb' - The classic o2cb cluster stack that ocfs2 has**
  used since its inception.
- **'user' - A plugin supporting userspace cluster software**
  in conjunction with fs/dlm.

Reading from this file returns the names of all loaded plugins, one per line.

This file is read-only. Its contents may change as plugins are loaded or removed.

/sys/fs/ocfs2/max_locking_protocol

Defined on file *sysfs-ocfs2*

The */sys/fs/ocfs2/max_locking_protocol* file displays version of ocfs2 locking supported by the filesystem. This version covers how ocfs2 uses distributed locking between cluster nodes.

The protocol version has a major and minor number. Two cluster nodes can interoperate if they have an identical major number and an overlapping minor number - thus, a node with version 1.10 can interoperate with a node sporting version 1.8, as long as both use the 1.8 protocol.

Reading from this file returns a single line, the major number and minor number joined by a period, eg "1.10".

This file is read-only. The value is compiled into the driver.

/sys/fs/pstore/..
/dev/pstore/..

Defined on file *pstore*

Generic interface to platform dependent persistent storage.

Platforms that provide a mechanism to preserve some data across system reboots can register with this driver to provide a generic interface to show records captured in the dying moments. In the case of a panic the last part of the console log is captured, but other interesting data can also be saved:

```
# mount -t pstore -o kmsg_bytes=8000 - /sys/fs/pstore

$ ls -l /sys/fs/pstore/
total 0
-r--r--r-- 1 root root 7896 Nov 30 15:38 dmesg-erst-1
```

Different users of this interface will result in different filename prefixes. Currently two are defined:

- "dmesg" - saved console log
- "mce" - architecture dependent data from fatal h/w error

Once the information in a file has been read, removing the file will signal to the underlying persistent storage device that it can reclaim the space for later re-use:

```
$ rm /sys/fs/pstore/dmesg-erst-1
```

The expectation is that all files in /sys/fs/pstore/ will be saved elsewhere and erased from persistent store soon after boot to free up space ready for the next catastrophe.

The 'kmsg_bytes' mount option changes the target amount of data saved on each oops/panic. Pstore saves (possibly multiple) files based on the record size of the underlying persistent storage until at least this amount is reached. Default is 10 Kbytes.

Pstore only supports one backend at a time. If multiple backends are available, the preferred backend may be set by passing the pstore.backend= argument to the kernel at boot time.

/sys/fs/ubifsX_Y/error_crc

Defined on file *sysfs-fs-ubifs*

Exposes crc errors: every node embeds a crc checksum.

This counter keeps track of the number of accesses of nodes with a bad crc checksum.

The counter is reset to 0 with a remount.

/sys/fs/ubifsX_Y/error_magic

Defined on file *sysfs-fs-ubifs*

Exposes magic errors: every node starts with a magic number.

This counter keeps track of the number of accesses of nodes with a corrupted magic number.

The counter is reset to 0 with a remount.

/sys/fs/ubifsX_Y/error_node

Defined on file *sysfs-fs-ubifs*

Exposes node errors. Every node embeds its type.

This counter keeps track of the number of accesses of nodes with a corrupted node type.

The counter is reset to 0 with a remount.

/sys/fs/xfs/<disk>/log/log_head_lsn

Defined on file *sysfs-fs-xfs*

The log sequence number (LSN) of the current head of the log. The LSN is exported in "cycle:basic block" format.

Users: xfstests

/sys/fs/xfs/<disk>/log/log_tail_lsn

Defined on file *sysfs-fs-xfs*

The log sequence number (LSN) of the current tail of the log. The LSN is exported in "cycle:basic block" format.

/sys/fs/xfs/<disk>/log/reserve_grant_head

Defined on file *sysfs-fs-xfs*

The current state of the log reserve grant head. It represents the total log reservation of all currently outstanding transactions. The grant head is exported in "cycle:bytes" format.

Users: xfstests

/sys/fs/xfs/<disk>/log/write_grant_head

Defined on file *sysfs-fs-xfs*

The current state of the log write grant head. It represents the total log reservation of all currently outstanding transactions, including regrants due to rolling transactions. The grant head is exported in "cycle:bytes" format.

Users: xfstests

5.2.37 Symbols under /sys/hypervisor

/sys/hypervisor/guest_type

Defined on file *sysfs-hypervisor-xen*

If running under Xen: Type of guest: "Xen": standard guest type on arm "HVM": fully virtualized guest (x86) "PV": paravirtualized guest (x86) "PVH": fully virtualized guest without legacy emulation (x86)

/sys/hypervisor/pmu/pmu_features

Defined on file *sysfs-hypervisor-xen*

If running under Xen: Describes Xen PMU features (as an integer). A set bit indicates that the corresponding feature is enabled. See include/xen/interface/xenpmu.h for available features

/sys/hypervisor/pmu/pmu_mode

Defined on file *sysfs-hypervisor-xen*

If running under Xen: Describes mode that Xen's performance-monitoring unit (PMU) uses. Accepted values are:

"off"	PMU is disabled
"self"	The guest can profile itself
"hv"	The guest can profile itself and, if it is privileged (e.g. dom0), the hypervisor
"all"	The guest can profile itself, the hypervisor and all other guests. Only available to privileged guests.

/sys/hypervisor/properties/buildid

Defined on file *sysfs-hypervisor-xen*

If running under Xen: Build id of the hypervisor, needed for hypervisor live patching. Might return "<denied>" in case of special security settings in the hypervisor.

5.2.38 Symbols under /sys/kernel

/sys/kernel/address_bit

Defined on file *sysfs-kernel-address_bits*

The address size of the running kernel in bits.

Access: Read

Users: util-linux

/sys/kernel/boot_params

Defined on file *sysfs-kernel-boot_params*

The */sys/kernel/boot_params* directory contains two files: "data" and "version" and one subdirectory "setup_data". It is used to export the kernel boot parameters of an x86 platform to userspace for kexec and debugging purpose.

If there's no setup_data in boot_params the subdirectory will not be created.

"data" file is the binary representation of struct boot_params.

"version" file is the string representation of boot protocol version.

"setup_data" subdirectory contains the setup_data data structure in boot_params. setup_data is maintained in kernel as a link list. In "setup_data" subdirectory there's one subdirectory for each link list node named with the number of the list nodes. The list node subdirectory contains two files "type" and "data". "type" file is the string representation of setup_data type. "data" file is the binary representation of setup_data payload.

The whole boot_params directory structure is like below:

```
/sys/kernel/boot_params
|__ data
|__ setup_data
|   |__ 0
|   |   |__ data
|   |   |__ type
|   |__ 1
|       |__ data
|       |__ type
|__ version
```

Users: Kexec

/sys/kernel/btf

Defined on file *sysfs-kernel-btf*

Contains BTF type information and related data for kernel and kernel modules.

/sys/kernel/btf/<module-name>

Defined on file *sysfs-kernel-btf*

Read-only binary attribute exposing kernel module's BTF type information as an add-on to the kernel's BTF (*/sys/kernel/btf/vmlinux*).

/sys/kernel/btf/vmlinux

Defined on file *sysfs-kernel-btf*

Read-only binary attribute exposing kernel's own BTF type information with description of all internal kernel types. See /bpf/btf for detailed description of format itself.

/sys/kernel/config/most_<component>

Defined on file *configfs-most*

Interface is used to configure and connect device channels to component drivers.

Attributes are visible only when configfs is mounted. To mount configfs in /sys/kernel/config directory use: # mount -t configfs none /sys/kernel/config/

/sys/kernel/config/most_cdev/<link>

Defined on file *configfs-most*

The attributes:

buffer_size
: configure the buffer size for this channel

subbuffer_size
: configure the sub-buffer size for this channel (needed for synchronous and isochronous data)

num_buffers
: configure number of buffers used for this channel

datatype
: configure type of data that will travel over this channel

direction
: configure whether this link will be an input or output

dbr_size
: configure DBR data buffer size (this is used for MediaLB communication only)

packets_per_xact
configure the number of packets that will be collected from the network before being transmitted via USB (this is used for USB communication only)

device
name of the device the link is to be attached to

channel
name of the channel the link is to be attached to

comp_params
pass parameters needed by some components

create_link
write '1' to this attribute to trigger the creation of the link. In case of speculative configuration, the creation is post-poned until a physical device is being attached to the bus.

destroy_link
write '1' to this attribute to destroy an active link

/sys/kernel/config/most_net/<link>

Defined on file *configfs-most*

The attributes:

buffer_size
configure the buffer size for this channel

subbuffer_size
configure the sub-buffer size for this channel (needed for synchronous and isochronous data)

num_buffers
configure number of buffers used for this channel

datatype
configure type of data that will travel over this channel

direction
configure whether this link will be an input or output

dbr_size
configure DBR data buffer size (this is used for MediaLB communication only)

packets_per_xact
configure the number of packets that will be collected from the network before being transmitted via USB (this is used for USB communication only)

device
name of the device the link is to be attached to

channel
name of the channel the link is to be attached to

comp_params
pass parameters needed by some components

create_link
write '1' to this attribute to trigger the creation of the link. In case of speculative configuration, the creation is post-poned until a physical device is being attached to the bus.

destroy_link
write '1' to this attribute to destroy an active link

/sys/kernel/config/most_sound/<card>

Defined on file *configfs-most*

The attributes:

create_card
write '1' to this attribute to trigger the registration of the sound card with the ALSA subsystem.

/sys/kernel/config/most_sound/<card>/<link>

Defined on file *configfs-most*

The attributes:

buffer_size
configure the buffer size for this channel

subbuffer_size
configure the sub-buffer size for this channel (needed for synchronous and isochronous data)

num_buffers
configure number of buffers used for this channel

datatype
configure type of data that will travel over this channel

direction
configure whether this link will be an input or output

dbr_size
configure DBR data buffer size (this is used for MediaLB communication only)

packets_per_xact
configure the number of packets that will be collected from the network before being transmitted via USB (this is used for USB communication only)

device
name of the device the link is to be attached to

channel
name of the channel the link is to be attached to

comp_params
pass parameters needed by some components

create_link
write '1' to this attribute to trigger the creation of the link. In case of speculative configuration, the creation is post-poned until a physical device is being attached to the bus.

destroy_link
write '1' to this attribute to destroy an active link

/sys/kernel/config/most_video/<link>

Defined on file *configfs-most*

The attributes:

buffer_size
configure the buffer size for this channel

subbuffer_size
configure the sub-buffer size for this channel (needed for synchronous and isochronous data)

num_buffers
configure number of buffers used for this channel

datatype
configure type of data that will travel over this channel

direction
configure whether this link will be an input or output

dbr_size
configure DBR data buffer size (this is used for MediaLB communication only)

packets_per_xact
configure the number of packets that will be collected from the network before being transmitted via USB (this is used for USB communication only)

device
name of the device the link is to be attached to

channel
name of the channel the link is to be attached to

comp_params
pass parameters needed by some components

create_link
write '1' to this attribute to trigger the creation of the link. In case of speculative configuration, the creation is post-poned until a physical device is being attached to the bus.

destroy_link
write '1' to this attribute to destroy an active link

/sys/kernel/config/tsm/report/$name/auxblob

Defined on file *configfs-tsm*

(RO) Optional supplemental data that a TSM may emit, visibility of this attribute depends on TSM, and may be empty if no auxiliary data is available.

When @provider is ”sev_guest” this file contains the ”cert_table” from SEV-ES Guest-Hypervisor Communication Block Standardization v2.03 Section 4.1.8.1 MSG_REPORT_REQ. https://www.amd.com/content/dam/amd/en/documents/epyc-technical-docs/specifications/56421.pdf

/sys/kernel/config/tsm/report/$name/generation

Defined on file *configfs-tsm*

(RO) The value in this attribute increments each time @inblob or any option is written. Userspace can detect conflicts by checking generation before writing to any attribute and making sure the number of writes matches expectations after reading @outblob, or it can prevent conflicts by creating a report instance per requesting context.

/sys/kernel/config/tsm/report/$name/inblob

Defined on file *configfs-tsm*

(WO) Up to 64 bytes of user specified binary data. For replay protection this should include a nonce, but the kernel does not place any restrictions on the content.

/sys/kernel/config/tsm/report/$name/outblob

Defined on file *configfs-tsm*

(RO) Binary attestation report generated from @inblob and other options The format of the report is implementation specific where the implementation is conveyed via the @provider attribute.

/sys/kernel/config/tsm/report/$name/privlevel

Defined on file *configfs-tsm*

(WO) Attribute is visible if a TSM implementation provider supports the concept of attestation reports for TVMs running at different privilege levels, like SEV-SNP "VMPL", specify the privilege level via this attribute. The minimum acceptable value is conveyed via @privlevel_floor and the maximum acceptable value is TSM_PRIVLEVEL_MAX (3).

/sys/kernel/config/tsm/report/$name/privlevel_floor

Defined on file *configfs-tsm*

(RO) Indicates the minimum permissible value that can be written to @privlevel.

/sys/kernel/config/tsm/report/$name/provider

Defined on file *configfs-tsm*

(RO) A name for the format-specification of @outblob like "sev_guest" [1] or "tdx_guest" [2] in the near term, or a common standard format in the future.

[1]: SEV Secure Nested Paging Firmware ABI Specification Revision 1.55 Table 22 https://www.amd.com/content/dam/amd/en/documents/epyc-technical-docs/specifications/56860.pdf

[2]: Intel® Trust Domain Extensions Data Center Attestation Primitives : Quote Generation Library and Quote Verification Library Revision 0.8 Appendix 4,5 https://download.01.org/intel-sgx/latest/dcap-latest/linux/docs/Intel_TDX_DCAP_Quoting_Library_API.pdf

/sys/kernel/cpu_byteorder

Defined on file *sysfs-kernel-cpu_byteorder*

The endianness of the running kernel.

Access: Read

Valid values:
"little", "big"

Users: util-linux

/sys/kernel/debug/<cros-ec-device>/console_log

Defined on file *debugfs-cros-ec*

If the EC supports the CONSOLE_READ command type, this file can be used to grab the EC logs. The kernel polls for the log and keeps its own buffer but userspace should grab this and write it out to some logs.

/sys/kernel/debug/<cros-ec-device>/last_resume_result

Defined on file *debugfs-cros-ec*

Some ECs have a feature where they will track transitions to the (Intel) processor's SLP_S0 line, in order to detect cases where a system failed to go into S0ix. When the system resumes, an EC with this feature will return a summary of SLP_S0 transitions that occurred. The last_resume_result file returns the most recent response from the AP's resume message to the EC.

The bottom 31 bits contain a count of the number of SLP_S0 transitions that occurred since the suspend message was received. Bit 31 is set if the EC attempted to wake the system due to a timeout when watching for SLP_S0 transitions. Callers can use this to detect a wake from the EC due to S0ix timeouts. The result will be zero if no suspend transitions have been attempted, or the EC does not support this feature.

Output will be in the format: "0x%08xn".

/sys/kernel/debug/<cros-ec-device>/panicinfo

Defined on file *debugfs-cros-ec*

This file dumps the EC panic information from the previous reboot. This file will only exist if the PANIC_INFO command type is supported by the EC.

/sys/kernel/debug/<cros-ec-device>/pdinfo

Defined on file *debugfs-cros-ec*

This file provides the port role, muxes and power debug information for all the USB PD/type-C ports available. If the are no ports available, this file will be just an empty file.

/sys/kernel/debug/<cros-ec-device>/suspend_timeout_ms

Defined on file *debugfs-cros-ec*

Some ECs have a feature where they will track transitions of a hardware-controlled sleep line, such as Intel's SLP_S0 line, in order to detect cases where a system failed to go into deep sleep states. The suspend_timeout_ms file controls the amount of time in milliseconds the EC will wait before declaring a sleep timeout event and attempting to wake the system.

Supply 0 to use the default value coded into EC firmware. Supply 65535 (EC_HOST_SLEEP_TIMEOUT_INFINITE) to disable the EC sleep failure detection mechanism. Values in between 0 and 65535 indicate the number of milliseconds the EC should wait after a sleep transition before declaring a timeout. This includes both the duration after a sleep command was received but before the hardware line changed, as well as the duration between when the hardware line changed and the kernel sent an EC resume command.

Output will be in the format: "%un".

/sys/kernel/debug/<cros-ec-device>/uptime

Defined on file *debugfs-cros-ec*

A u32 providing the time since EC booted in ms. This is is used for synchronizing the AP host time with the EC log. An error is returned if the command is not supported by the EC or there is a communication problem.

/sys/kernel/debug/accel/<parent_device>/addr

Defined on file *debugfs-driver-habanalabs*

Sets the device address to be used for read or write through PCI bar, or the device VA of a host mapped memory to be read or written directly from the host. The latter option is allowed only when the IOMMU is disabled. The acceptable value is a string that starts with "0x"

/sys/kernel/debug/accel/<parent_device>/clk_gate

Defined on file *debugfs-driver-habanalabs*

This setting is now deprecated as clock gating is handled solely by the f/w

/sys/kernel/debug/accel/<parent_device>/command_buffers

Defined on file *debugfs-driver-habanalabs*

Displays a list with information about the currently allocated command buffers

/sys/kernel/debug/accel/<parent_device>/command_submission

Defined on file *debugfs-driver-habanalabs*

Displays a list with information about the currently active command submissions

/sys/kernel/debug/accel/<parent_device>/command_submission_jobs

Defined on file *debugfs-driver-habanalabs*

Displays a list with detailed information about each JOB (CB) of each active command submission

/sys/kernel/debug/accel/<parent_device>/data32

Defined on file *debugfs-driver-habanalabs*

Allows the root user to read or write directly through the device's PCI bar. Writing to this file generates a write transaction while reading from the file generates a read transaction. This custom interface is needed (instead of using the generic Linux user-space PCI mapping) because the DDR bar is very small compared to the DDR memory and only the driver can move the bar before and after the transaction.

If the IOMMU is disabled, it also allows the root user to read or write from the host a device VA of a host mapped memory

/sys/kernel/debug/accel/<parent_device>/data64

Defined on file *debugfs-driver-habanalabs*

Allows the root user to read or write 64 bit data directly through the device's PCI bar. Writing to this file generates a write transaction while reading from the file generates a read transaction. This custom interface is needed (instead of using the generic Linux user-space PCI mapping) because the DDR bar is very small compared to the DDR memory and only the driver can move the bar before and after the transaction.

If the IOMMU is disabled, it also allows the root user to read or write from the host a device VA of a host mapped memory

/sys/kernel/debug/accel/<parent_device>/data_dma

Defined on file *debugfs-driver-habanalabs*

Allows the root user to read from the device's internal memory (DRAM/SRAM) through a DMA engine. This property is a binary blob that contains the result of the DMA transfer. This custom interface is needed (instead of using the generic Linux user-space PCI mapping) because the amount of internal memory is huge (>32GB) and reading it via the PCI bar will take a very long time. This interface doesn't support concurrency in the same device. In GAUDI and GOYA, this action can cause undefined behavior in case it is done while the device is executing user workloads. Only supported on GAUDI at this stage.

/sys/kernel/debug/accel/<parent_device>/device

Defined on file *debugfs-driver-habanalabs*

Enables the root user to set the device to specific state. Valid values are ”disable”, ”enable”, ”suspend”, ”resume”. User can read this property to see the valid values

/sys/kernel/debug/accel/<parent_device>/device_release_watchdog_timeout

Defined on file *debugfs-driver-habanalabs*

The watchdog timeout value in seconds for a device release upon certain error cases, after which the device is reset.

/sys/kernel/debug/accel/<parent_device>/dma_size

Defined on file *debugfs-driver-habanalabs*

Specify the size of the DMA transaction when using DMA to read from the device's internal memory. The value can not be larger than 128MB. Writing to this value initiates the DMA transfer. When the write is finished, the user can read the "data_dma" blob

/sys/kernel/debug/accel/<parent_device>/dump_razwi_events

Defined on file *debugfs-driver-habanalabs*

Dumps all razwi events to dmesg if exist. After reading the status register of an existing event the routine will clear the status register. Usage: cat dump_razwi_events

/sys/kernel/debug/accel/<parent_device>/dump_security_violations

Defined on file *debugfs-driver-habanalabs*

Dumps all security violations to dmesg. This will also ack all security violations meanings those violations will not be dumped next time user calls this API

/sys/kernel/debug/accel/<parent_device>/engines

Defined on file *debugfs-driver-habanalabs*

Displays the status registers values of the device engines and their derived idle status

/sys/kernel/debug/accel/<parent_device>/i2c_addr

Defined on file *debugfs-driver-habanalabs*

Sets I2C device address for I2C transaction that is generated by the device's CPU, Not available when device is loaded with secured firmware

/sys/kernel/debug/accel/<parent_device>/i2c_bus

Defined on file *debugfs-driver-habanalabs*

Sets I2C bus address for I2C transaction that is generated by the device's CPU, Not available when device is loaded with secured firmware

/sys/kernel/debug/accel/<parent_device>/i2c_data

Defined on file *debugfs-driver-habanalabs*

Triggers an I2C transaction that is generated by the device's CPU. Writing to this file generates a write transaction while reading from the file generates a read transaction, Not available when device is loaded with secured firmware

/sys/kernel/debug/accel/<parent_device>/i2c_len

Defined on file *debugfs-driver-habanalabs*

Sets I2C length in bytes for I2C transaction that is generated by the device's CPU, Not available when device is loaded with secured firmware

/sys/kernel/debug/accel/<parent_device>/i2c_reg

Defined on file *debugfs-driver-habanalabs*

Sets I2C register id for I2C transaction that is generated by the device's CPU, Not available when device is loaded with secured firmware

/sys/kernel/debug/accel/<parent_device>/led0

Defined on file *debugfs-driver-habanalabs*

Sets the state of the first S/W led on the device, Not available when device is loaded with secured firmware

/sys/kernel/debug/accel/<parent_device>/led1

Defined on file *debugfs-driver-habanalabs*

Sets the state of the second S/W led on the device, Not available when device is loaded with secured firmware

/sys/kernel/debug/accel/<parent_device>/led2

Defined on file *debugfs-driver-habanalabs*

Sets the state of the third S/W led on the device, Not available when device is loaded with secured firmware

/sys/kernel/debug/accel/<parent_device>/memory_scrub

Defined on file *debugfs-driver-habanalabs*

Allows the root user to scrub the dram memory. The scrubbing value can be set using the debugfs file memory_scrub_val.

/sys/kernel/debug/accel/<parent_device>/memory_scrub_val

Defined on file *debugfs-driver-habanalabs*

The value to which the dram will be set to when the user scrubs the dram using 'memory_scrub' debugfs file and the scrubbing value when using module param 'memory_scrub'

/sys/kernel/debug/accel/<parent_device>/mmu

Defined on file *debugfs-driver-habanalabs*

Displays the hop values and physical address for a given ASID and virtual address. The user should write the ASID and VA into the file and then read the file to get the result. e.g. to display info about VA 0x1000 for ASID 1 you need to do: echo "1 0x1000" > /sys/kernel/debug/accel/0/mmu

/sys/kernel/debug/accel/<parent_device>/mmu_error

Defined on file *debugfs-driver-habanalabs*

Check and display page fault or access violation mmu errors for all MMUs specified in mmu_cap_mask. e.g. to display error info for MMU hw cap bit 9, you need to do: echo "0x200" > /sys/kernel/debug/accel/0/mmu_error cat /sys/kernel/debug/accel/0/mmu_error

/sys/kernel/debug/accel/<parent_device>/monitor_dump

Defined on file *debugfs-driver-habanalabs*

Allows the root user to dump monitors status from the device's protected config space. This property is a binary blob that contains the result of the monitors registers dump. This custom interface is needed (instead of using the generic Linux user-space PCI mapping) because this space is protected and cannot be accessed using PCI read. This interface doesn't support concurrency in the same device. Only supported on GAUDI.

/sys/kernel/debug/accel/<parent_device>/monitor_dump_trig

Defined on file *debugfs-driver-habanalabs*

Triggers dump of monitor data. The value to trigger the operation must be 1. Triggering the monitor dump operation initiates dump of current registers values of all monitors. When the write is finished, the user can read the "monitor_dump" blob

/sys/kernel/debug/accel/<parent_device>/set_power_state

Defined on file *debugfs-driver-habanalabs*

Sets the PCI power state. Valid values are "1" for D0 and "2" for D3Hot

/sys/kernel/debug/accel/<parent_device>/skip_reset_on_timeout

Defined on file *debugfs-driver-habanalabs*

Sets the skip reset on timeout option for the device. Value of "0" means device will be reset in case some CS has timed out, otherwise it will not be reset.

/sys/kernel/debug/accel/<parent_device>/state_dump

Defined on file *debugfs-driver-habanalabs*

Gets the state dump occurring on a CS timeout or failure. State dump is used for debug and is created each time in case of a problem in a CS execution, before reset. Reading from the node

returns the newest state dump available. Writing an integer X discards X state dumps, so that the next read would return X+1-st newest state dump.

/sys/kernel/debug/accel/<parent_device>/stop_on_err

Defined on file *debugfs-driver-habanalabs*

Sets the stop-on_error option for the device engines. Value of "0" is for disable, otherwise enable. Relevant only for GOYA and GAUDI.

/sys/kernel/debug/accel/<parent_device>/timeout_locked

Defined on file *debugfs-driver-habanalabs*

Sets the command submission timeout value in seconds.

/sys/kernel/debug/accel/<parent_device>/userptr

Defined on file *debugfs-driver-habanalabs*

Displays a list with information about the current user pointers (user virtual addresses) that are pinned and mapped to DMA addresses

/sys/kernel/debug/accel/<parent_device>/userptr_lookup

Defined on file *debugfs-driver-habanalabs*

Allows to search for specific user pointers (user virtual addresses) that are pinned and mapped to DMA addresses, and see their resolution to the specific dma address.

/sys/kernel/debug/accel/<parent_device>/vm

Defined on file *debugfs-driver-habanalabs*

Displays a list with information about all the active virtual address mappings per ASID and all user mappings of HW blocks

/sys/kernel/debug/cec/*/error-inj

Defined on file *debugfs-cec-error-inj*

The CEC Framework allows for CEC error injection commands through debugfs. Drivers that support this will create an error-inj file through which the error injection commands can be given.

The basic syntax is as follows:

Leading spaces/tabs are ignored. If the next character is a '#' or the end of the line was reached, then the whole line is ignored. Otherwise a command is expected.

It is up to the driver to decide what commands to implement. The only exception is that the command 'clear' without any arguments must be implemented and that it will remove all current error injection commands.

This ensures that you can always do 'echo clear >error-inj' to clear any error injections without having to know the details of the driver-specific commands.

Note that the output of 'error-inj' shall be valid as input to 'error-inj'. So this must work:

```
$ cat error-inj >einj.txt
$ cat einj.txt >error-inj
```

Other than these basic rules described above this ABI is not considered stable and may change in the future.

Drivers that implement this functionality must document the commands as part of the CEC documentation and must keep that documentation up to date when changes are made.

The following CEC error injection implementations exist:

- /userspace-api/media/cec/cec-pin-error-inj

/sys/kernel/debug/cxl/memX/inject_poison

Defined on file *debugfs-cxl*

(WO) When a Device Physical Address (DPA) is written to this attribute, the memdev driver sends an inject poison command to the device for the specified address. The DPA must be 64-byte aligned and the length of the injected poison is 64-bytes. If successful, the device returns poison when the address is accessed through the CXL.mem bus. Injecting poison adds the address to the device's Poison List and the error source is set to Injected. In addition, the device adds a poison creation event to its internal Informational Event log, updates the Event Status register, and if configured, interrupts the host. It is not an error to inject poison into an address that already has poison present and no error is returned. The inject_poison attribute is only visible for devices supporting the capability.

/sys/kernel/debug/dcc/.../[list-number]/config

Defined on file *debugfs-driver-dcc*

This stores the addresses of the registers which can be read in case of a hardware crash or manual software triggers. The input addresses type can be one of following dcc instructions: read, write, read-write, and loop type. The lists need to be configured sequentially and not in a overlapping manner; e.g. users can jump to list x only after list y is configured and enabled. The input format for each type is as follows:

i) Read instruction

```
echo R <addr> <n> <bus> >/sys/kernel/debug/dcc/../[list-number]/config
```

where:

<addr>
The address to be read.

<n>
The addresses word count, starting from address <1>. Each word is 32 bits (4 bytes). If omitted, defaulted to 1.

<bus type>
The bus type, which can be either 'apb' or 'ahb'. The default is 'ahb' if leaved out.

ii) Write instruction

```
echo W <addr> <n> <bus type> > /sys/kernel/debug/dcc/../[list-number]/
↪config
```

where:

<addr>
The address to be written.

<n>
The value to be written at <addr>.

<bus type>
The bus type, which can be either 'apb' or 'ahb'.

iii) Read-write instruction

```
echo RW <addr> <n> <mask> > /sys/kernel/debug/dcc/../[list-number]/config
```

where:

<addr>
The address to be read and written.

<n>
The value to be written at <addr>.

<mask>
The value mask.

iv) Loop instruction

```
echo L <loop count> <address count> <address>... > /sys/kernel/debug/dcc/..
↪/[list-number]/config
```

where:

<loop count>
Number of iterations

<address count>
total number of addresses to be written

<address>
Space-separated list of addresses.

/sys/kernel/debug/dcc/.../[list-number]/enable

Defined on file *debugfs-driver-dcc*

This debugfs interface is used for enabling the the dcc hardware. A file named "enable" is in the directory list number where users can enable/disable the specific list by writing boolean (1 or 0) to the file.

On enabling the dcc, all the addresses specified by the user for the corresponding list is written into dcc sram which is read by the dcc hardware on manual or crash induced triggers. Lists must be configured and enabled sequentially, e.g. list 2 can only be enabled when list 1 have so.

/sys/kernel/debug/dcc/.../config_reset

Defined on file *debugfs-driver-dcc*

This file is used to reset the configuration of a dcc driver to the default configuration. When '1' is written to the file, all the previous addresses stored in the driver gets removed and users need to reconfigure addresses again.

/sys/kernel/debug/dcc/.../ready

Defined on file *debugfs-driver-dcc*

This file is used to check the status of the dcc hardware if it's ready to receive user configurations. A 'Y' here indicates dcc is ready.

/sys/kernel/debug/dcc/.../trigger

Defined on file *debugfs-driver-dcc*

This is the debugfs interface for manual software triggers. The trigger can be invoked by writing '1' to the file.

/sys/kernel/debug/dell-wmi-ddv-<wmi_device_name>/fan_sensor_information

Defined on file *debugfs-dell-wmi-ddv*

This file contains the contents of the fan sensor information buffer, which contains fan sensor entries and a terminating character (0xFF).

Each fan sensor entry contains:

- fan type (single byte)
- fan speed in RPM (two bytes, little endian)

See /wmi/devices/dell-wmi-ddv for details.

/sys/kernel/debug/dell-wmi-ddv-<wmi_device_name>/thermal_sensor_information

Defined on file *debugfs-dell-wmi-ddv*

This file contains the contents of the thermal sensor information buffer, which contains thermal sensor entries and a terminating character (0xFF).

Each thermal sensor entry contains:

- thermal type (single byte)
- current temperature (single byte)
- min. temperature (single byte)

- max. temperature (single byte)
- unknown field (single byte)

See /wmi/devices/dell-wmi-ddv for details.

/sys/kernel/debug/ec/*/{gpe,use_global_lock,io}

Defined on file *debugfs-ec*

General information like which GPE is assigned to the EC and whether the global lock should get used. Knowing the EC GPE one can watch the amount of HW events related to the EC here (XY -> GPE number from */sys/kernel/debug/ec/*/gpe*): /sys/firmware/acpi/interrupts/gpeXY

The io file is binary and a userspace tool located here: ftp://ftp.suse.com/pub/people/trenn/sources/ec/ should get used to read out the 256 Embedded Controller registers or writing to them.

CAUTION:

Do not write to the Embedded Controller if you don't know what you are doing! Rebooting afterwards also is a good idea. This can influence the way your machine is cooled and fans may not get switched on again after you did a wrong write.

/sys/kernel/debug/genwqe/genwqe<n>_card/curr_dbg_uid0

Defined on file *debugfs-driver-genwqe*

Internal chip state of UID0 (unit id 0). Only available for PF.

/sys/kernel/debug/genwqe/genwqe<n>_card/curr_dbg_uid1

Defined on file *debugfs-driver-genwqe*

Internal chip state of UID1. Only available for PF.

/sys/kernel/debug/genwqe/genwqe<n>_card/curr_dbg_uid2

Defined on file *debugfs-driver-genwqe*

Internal chip state of UID2. Only available for PF.

/sys/kernel/debug/genwqe/genwqe<n>_card/curr_regs

Defined on file *debugfs-driver-genwqe*

Dump of the current error registers. Only available for PF.

/sys/kernel/debug/genwqe/genwqe<n>_card/ddcb_info

Defined on file *debugfs-driver-genwqe*

DDCB queue dump used for debugging queueing problems.

/sys/kernel/debug/genwqe/genwqe<n>_card/err_inject

Defined on file *debugfs-driver-genwqe*

Possibility to inject error cases to ensure that the drivers error handling code works well.

/sys/kernel/debug/genwqe/genwqe<n>_card/info

Defined on file *debugfs-driver-genwqe*

Comprehensive summary of bitstream version and software version. Used bitstream and bitstream clocking information.

/sys/kernel/debug/genwqe/genwqe<n>_card/jobtimer

Defined on file *debugfs-driver-genwqe*

Dump job timeout register values for PF and VFs. Only available for PF.

/sys/kernel/debug/genwqe/genwqe<n>_card/prev_dbg_uid0

Defined on file *debugfs-driver-genwqe*

Internal chip state of UID0 before card was reset. Only available for PF.

/sys/kernel/debug/genwqe/genwqe<n>_card/prev_dbg_uid1

Defined on file *debugfs-driver-genwqe*

Internal chip state of UID1 before card was reset. Only available for PF.

/sys/kernel/debug/genwqe/genwqe<n>_card/prev_dbg_uid2

Defined on file *debugfs-driver-genwqe*

Internal chip state of UID2 before card was reset. Only available for PF.

/sys/kernel/debug/genwqe/genwqe<n>_card/prev_regs

Defined on file *debugfs-driver-genwqe*

Dump of the error registers before the last reset of the card occurred. Only available for PF.

/sys/kernel/debug/genwqe/genwqe<n>_card/queue_working_time

Defined on file *debugfs-driver-genwqe*

Dump queue working time register values for PF and VFs. Only available for PF.

/sys/kernel/debug/genwqe/genwqe<n>_card/vf<0..14>_jobtimeout_msec

Defined on file *debugfs-driver-genwqe*

Default VF timeout 250ms. Testing might require 1000ms. Using 0 will use the cards default value (whatever that is).

The timeout depends on the max number of available cards in the system and the maximum allowed queue size.

The driver ensures that the settings are done just before the VFs get enabled. Changing the timeouts in flight is not possible. Only available for PF.

/sys/kernel/debug/hisi_hpre/<bdf>/alg_qos

Defined on file *debugfs-hisi-hpre*

The <bdf> is related the function for PF and VF. HPRE driver supports to configure each function's QoS, the driver supports to write <bdf> value to alg_qos in the host. Such as "echo <bdf> value > alg_qos". The qos value is 1~1000, means 1/1000~1000/1000 of total QoS. The driver reading alg_qos to get related QoS in the host and VM, Such as "cat alg_qos".

/sys/kernel/debug/hisi_hpre/<bdf>/cluster[0-3]/cluster_ctrl

Defined on file *debugfs-hisi-hpre*

Write the HPRE core selection in the cluster into this file, and then we can read the debug information of the core. Only available for PF.

/sys/kernel/debug/hisi_hpre/<bdf>/cluster[0-3]/regs

Defined on file *debugfs-hisi-hpre*

Dump debug registers from the HPRE cluster. Only available for PF.

/sys/kernel/debug/hisi_hpre/<bdf>/current_qm

Defined on file *debugfs-hisi-hpre*

One HPRE controller has one PF and multiple VFs, each function has a QM. Select the QM which below qm refers to. Only available for PF.

/sys/kernel/debug/hisi_hpre/<bdf>/hpre_dfx/diff_regs

Defined on file *debugfs-hisi-hpre*

HPRE debug registers(regs) read hardware register value. This node is used to show the change of the register values. This node can be help users to check the change of register values.

/sys/kernel/debug/hisi_hpre/<bdf>/hpre_dfx/invalid_req_cnt

Defined on file *debugfs-hisi-hpre*

Dump the total number of invalid requests being received. Available for both PF and VF, and take no other effect on HPRE.

/sys/kernel/debug/hisi_hpre/<bdf>/hpre_dfx/over_thrhld_cnt

Defined on file *debugfs-hisi-hpre*

Dump the total number of time out requests. Available for both PF and VF, and take no other effect on HPRE.

/sys/kernel/debug/hisi_hpre/<bdf>/hpre_dfx/overtime_thrhld

Defined on file *debugfs-hisi-hpre*

Set the threshold time for counting the request which is processed longer than the threshold. 0: disable(default), 1: 1 microsecond. Available for both PF and VF, and take no other effect on HPRE.

/sys/kernel/debug/hisi_hpre/<bdf>/hpre_dfx/recv_cnt

Defined on file *debugfs-hisi-hpre*

Dump the total number of received requests. Available for both PF and VF, and take no other effect on HPRE.

/sys/kernel/debug/hisi_hpre/<bdf>/hpre_dfx/send_busy_cnt

Defined on file *debugfs-hisi-hpre*

Dump the total number of requests sent with returning busy. Available for both PF and VF, and take no other effect on HPRE.

/sys/kernel/debug/hisi_hpre/<bdf>/hpre_dfx/send_cnt

Defined on file *debugfs-hisi-hpre*

Dump the total number of sent requests. Available for both PF and VF, and take no other effect on HPRE.

/sys/kernel/debug/hisi_hpre/<bdf>/hpre_dfx/send_fail_cnt

Defined on file *debugfs-hisi-hpre*

Dump the total number of completed but error requests. Available for both PF and VF, and take no other effect on HPRE.

/sys/kernel/debug/hisi_hpre/<bdf>/qm/abnormal_irq

Defined on file *debugfs-hisi-hpre*

Dump the number of interrupts for QM abnormal event. Available for both PF and VF, and take no other effect on HPRE.

/sys/kernel/debug/hisi_hpre/<bdf>/qm/aeq_irq

Defined on file *debugfs-hisi-hpre*

Dump the number of QM async event queue interrupts. Available for both PF and VF, and take no other effect on HPRE.

/sys/kernel/debug/hisi_hpre/<bdf>/qm/clear_enable

Defined on file *debugfs-hisi-hpre*

QM debug registers(regs) read clear control. 1 means enable register read clear, otherwise 0. Writing to this file has no functional effect, only enable or disable counters clear after reading of these registers. Only available for PF.

/sys/kernel/debug/hisi_hpre/<bdf>/qm/create_qp_err

Defined on file *debugfs-hisi-hpre*

Dump the number of queue allocation errors. Available for both PF and VF, and take no other effect on HPRE.

/sys/kernel/debug/hisi_hpre/<bdf>/qm/current_q

Defined on file *debugfs-hisi-hpre*

One QM may contain multiple queues. Select specific queue to show its debug registers in above regs. Only available for PF.

/sys/kernel/debug/hisi_hpre/<bdf>/qm/diff_regs

Defined on file *debugfs-hisi-hpre*

QM debug registers(regs) read hardware register value. This node is used to show the change of the qm register values. This node can be help users to check the change of register values.

/sys/kernel/debug/hisi_hpre/<bdf>/qm/err_irq

Defined on file *debugfs-hisi-hpre*

Dump the number of invalid interrupts for QM task completion. Available for both PF and VF, and take no other effect on HPRE.

/sys/kernel/debug/hisi_hpre/<bdf>/qm/mb_err

Defined on file *debugfs-hisi-hpre*

Dump the number of failed QM mailbox commands. Available for both PF and VF, and take no other effect on HPRE.

/sys/kernel/debug/hisi_hpre/<bdf>/qm/regs

Defined on file *debugfs-hisi-hpre*

Dump debug registers from the QM. Available for PF and VF in host. VF in guest currently only has one debug register.

/sys/kernel/debug/hisi_hpre/<bdf>/qm/status

Defined on file *debugfs-hisi-hpre*

Dump the status of the QM. Two states: work, stop. Available for both PF and VF, and take no other effect on HPRE.

/sys/kernel/debug/hisi_hpre/<bdf>/rdclr_en

Defined on file *debugfs-hisi-hpre*

HPRE cores debug registers read clear control. 1 means enable register read clear, otherwise 0. Writing to this file has no functional effect, only enable or disable counters clear after reading of these registers. Only available for PF.

/sys/kernel/debug/hisi_hpre/<bdf>/regs

Defined on file *debugfs-hisi-hpre*

Dump debug registers from the HPRE. Only available for PF.

/sys/kernel/debug/hisi_sec2/<bdf>/alg_qos

Defined on file *debugfs-hisi-sec*

The <bdf> is related the function for PF and VF. SEC driver supports to configure each function's QoS, the driver supports to write <bdf> value to alg_qos in the host. Such as "echo <bdf> value > alg_qos". The qos value is 1~1000, means 1/1000~1000/1000 of total QoS. The driver reading alg_qos to get related QoS in the host and VM, Such as "cat alg_qos".

/sys/kernel/debug/hisi_sec2/<bdf>/clear_enable

Defined on file *debugfs-hisi-sec*

Enabling/disabling of clear action after reading the SEC debug registers. 0: disable, 1: enable. Only available for PF, and take no other effect on SEC.

/sys/kernel/debug/hisi_sec2/<bdf>/current_qm

Defined on file *debugfs-hisi-sec*

One SEC controller has one PF and multiple VFs, each function has a QM. This file can be used to select the QM which below qm refers to. Only available for PF.

/sys/kernel/debug/hisi_sec2/<bdf>/qm/abnormal_irq

Defined on file *debugfs-hisi-sec*

Dump the number of interrupts for QM abnormal event. Available for both PF and VF, and take no other effect on SEC.

/sys/kernel/debug/hisi_sec2/<bdf>/qm/aeq_irq

Defined on file *debugfs-hisi-sec*

Dump the number of QM async event queue interrupts. Available for both PF and VF, and take no other effect on SEC.

/sys/kernel/debug/hisi_sec2/<bdf>/qm/clear_enable

Defined on file *debugfs-hisi-sec*

Enabling/disabling of clear action after reading the SEC's QM debug registers. 0: disable, 1: enable. Only available for PF, and take no other effect on SEC.

/sys/kernel/debug/hisi_sec2/<bdf>/qm/create_qp_err

Defined on file *debugfs-hisi-sec*

Dump the number of queue allocation errors. Available for both PF and VF, and take no other effect on SEC.

/sys/kernel/debug/hisi_sec2/<bdf>/qm/current_q

Defined on file *debugfs-hisi-sec*

One QM of SEC may contain multiple queues. Select specific queue to show its debug registers in above 'regs'. Only available for PF.

/sys/kernel/debug/hisi_sec2/<bdf>/qm/diff_regs

Defined on file *debugfs-hisi-sec*

QM debug registers(regs) read hardware register value. This node is used to show the change of the qm register values. This node can be help users to check the change of register values.

/sys/kernel/debug/hisi_sec2/<bdf>/qm/err_irq

Defined on file *debugfs-hisi-sec*

Dump the number of invalid interrupts for QM task completion. Available for both PF and VF, and take no other effect on SEC.

/sys/kernel/debug/hisi_sec2/<bdf>/qm/mb_err

Defined on file *debugfs-hisi-sec*

Dump the number of failed QM mailbox commands. Available for both PF and VF, and take no other effect on SEC.

/sys/kernel/debug/hisi_sec2/<bdf>/qm/qm_regs

Defined on file *debugfs-hisi-sec*

Dump of QM related debug registers. Available for PF and VF in host. VF in guest currently only has one debug register.

/sys/kernel/debug/hisi_sec2/<bdf>/qm/status

Defined on file *debugfs-hisi-sec*

Dump the status of the QM. Two states: work, stop. Available for both PF and VF, and take no other effect on SEC.

/sys/kernel/debug/hisi_sec2/<bdf>/sec_dfx/diff_regs

Defined on file *debugfs-hisi-sec*

SEC debug registers(regs) read hardware register value. This node is used to show the change of the register values. This node can be help users to check the change of register values.

/sys/kernel/debug/hisi_sec2/<bdf>/sec_dfx/done_flag_cnt

Defined on file *debugfs-hisi-sec*

Dump the total number of completed but marked error requests to be received. Available for both PF and VF, and take no other effect on SEC.

/sys/kernel/debug/hisi_sec2/<bdf>/sec_dfx/err_bd_cnt

Defined on file *debugfs-hisi-sec*

Dump the total number of BD type error requests to be received. Available for both PF and VF, and take no other effect on SEC.

/sys/kernel/debug/hisi_sec2/<bdf>/sec_dfx/invalid_req_cnt

Defined on file *debugfs-hisi-sec*

Dump the total number of invalid requests being received. Available for both PF and VF, and take no other effect on SEC.

/sys/kernel/debug/hisi_sec2/<bdf>/sec_dfx/recv_cnt

Defined on file *debugfs-hisi-sec*

Dump the total number of received requests. Available for both PF and VF, and take no other effect on SEC.

/sys/kernel/debug/hisi_sec2/<bdf>/sec_dfx/send_busy_cnt

Defined on file *debugfs-hisi-sec*

Dump the total number of requests sent with returning busy. Available for both PF and VF, and take no other effect on SEC.

/sys/kernel/debug/hisi_sec2/<bdf>/sec_dfx/send_cnt

Defined on file *debugfs-hisi-sec*

Dump the total number of sent requests. Available for both PF and VF, and take no other effect on SEC.

/sys/kernel/debug/hisi_zip/<bdf>/alg_qos

Defined on file *debugfs-hisi-zip*

The <bdf> is related the function for PF and VF. ZIP driver supports to configure each function's QoS, the driver supports to write <bdf> value to alg_qos in the host. Such as "echo <bdf> value > alg_qos". The qos value is 1~1000, means 1/1000~1000/1000 of total QoS. The driver reading alg_qos to get related QoS in the host and VM, Such as "cat alg_qos".

/sys/kernel/debug/hisi_zip/<bdf>/clear_enable

Defined on file *debugfs-hisi-zip*

Compression/decompression core debug registers read clear control. 1 means enable register read clear, otherwise 0. Writing to this file has no functional effect, only enable or disable counters clear after reading of these registers. Only available for PF.

/sys/kernel/debug/hisi_zip/<bdf>/comp_core[01]/regs

Defined on file *debugfs-hisi-zip*

Dump of compression cores related debug registers. Only available for PF.

/sys/kernel/debug/hisi_zip/<bdf>/current_qm

Defined on file *debugfs-hisi-zip*

One ZIP controller has one PF and multiple VFs, each function has a QM. Select the QM which below qm refers to. Only available for PF.

/sys/kernel/debug/hisi_zip/<bdf>/decomp_core[0-5]/regs

Defined on file *debugfs-hisi-zip*

Dump of decompression cores related debug registers. Only available for PF.

/sys/kernel/debug/hisi_zip/<bdf>/qm/abnormal_irq

Defined on file *debugfs-hisi-zip*

Dump the number of interrupts for QM abnormal event. Available for both PF and VF, and take no other effect on ZIP.

/sys/kernel/debug/hisi_zip/<bdf>/qm/aeq_irq

Defined on file *debugfs-hisi-zip*

Dump the number of QM async event queue interrupts. Available for both PF and VF, and take no other effect on ZIP.

/sys/kernel/debug/hisi_zip/<bdf>/qm/clear_enable

Defined on file *debugfs-hisi-zip*

QM debug registers(regs) read clear control. 1 means enable register read clear, otherwise 0. Writing to this file has no functional effect, only enable or disable counters clear after reading of these registers. Only available for PF.

/sys/kernel/debug/hisi_zip/<bdf>/qm/create_qp_err

Defined on file *debugfs-hisi-zip*

Dump the number of queue allocation errors. Available for both PF and VF, and take no other effect on ZIP.

/sys/kernel/debug/hisi_zip/<bdf>/qm/current_q

Defined on file *debugfs-hisi-zip*

One QM may contain multiple queues. Select specific queue to show its debug registers in above regs. Only available for PF.

/sys/kernel/debug/hisi_zip/<bdf>/qm/diff_regs

Defined on file *debugfs-hisi-zip*

QM debug registers(regs) read hardware register value. This node is used to show the change of the qm registers value. This node can be help users to check the change of register values.

/sys/kernel/debug/hisi_zip/<bdf>/qm/err_irq

Defined on file *debugfs-hisi-zip*

Dump the number of invalid interrupts for QM task completion. Available for both PF and VF, and take no other effect on ZIP.

/sys/kernel/debug/hisi_zip/<bdf>/qm/mb_err

Defined on file *debugfs-hisi-zip*

Dump the number of failed QM mailbox commands. Available for both PF and VF, and take no other effect on ZIP.

/sys/kernel/debug/hisi_zip/<bdf>/qm/regs

Defined on file *debugfs-hisi-zip*

Dump of QM related debug registers. Available for PF and VF in host. VF in guest currently only has one debug register.

/sys/kernel/debug/hisi_zip/<bdf>/qm/status

Defined on file *debugfs-hisi-zip*

Dump the status of the QM. Two states: work, stop. Available for both PF and VF, and take no other effect on ZIP.

/sys/kernel/debug/hisi_zip/<bdf>/zip_dfx/diff_regs

Defined on file *debugfs-hisi-zip*

ZIP debug registers(regs) read hardware register value. This node is used to show the change of the registers value. this node can be help users to check the change of register values.

/sys/kernel/debug/hisi_zip/<bdf>/zip_dfx/err_bd_cnt

Defined on file *debugfs-hisi-zip*

Dump the total number of BD type error requests to be received. Available for both PF and VF, and take no other effect on ZIP.

/sys/kernel/debug/hisi_zip/<bdf>/zip_dfx/recv_cnt

Defined on file *debugfs-hisi-zip*

Dump the total number of received requests. Available for both PF and VF, and take no other effect on ZIP.

/sys/kernel/debug/hisi_zip/<bdf>/zip_dfx/send_busy_cnt

Defined on file *debugfs-hisi-zip*

Dump the total number of requests received with returning busy. Available for both PF and VF, and take no other effect on ZIP.

/sys/kernel/debug/hisi_zip/<bdf>/zip_dfx/send_cnt

Defined on file *debugfs-hisi-zip*

Dump the total number of sent requests. Available for both PF and VF, and take no other effect on ZIP.

/sys/kernel/debug/hyperv/<UUID>/delay/fuzz_test_buffer_interrupt_delay

Defined on file *debugfs-hyperv*

Fuzz testing buffer interrupt delay value between 0 - 1000
microseconds (inclusive).

Users: Debugging tools

/sys/kernel/debug/hyperv/<UUID>/delay/fuzz_test_message_delay

Defined on file *debugfs-hyperv*

Fuzz testing message delay value between 0 - 1000 microseconds
(inclusive).

Users: Debugging tools

/sys/kernel/debug/hyperv/<UUID>/fuzz_test_state

Defined on file *debugfs-hyperv*

Fuzz testing status of a vmbus device, whether its in an ON state or a OFF state

Users: Debugging tools

/sys/kernel/debug/ideapad/cfg

Defined on file *debugfs-ideapad*

cfg shows the return value of _CFG method in VPC2004 device. It tells machine capability and what graphic component within the machine.

/sys/kernel/debug/ideapad/status

Defined on file *debugfs-ideapad*

status shows infos we can read and tells its meaning and value.

/sys/kernel/debug/memX/clear_poison

Defined on file *debugfs-cxl*

(WO) When a Device Physical Address (DPA) is written to this attribute, the memdev driver sends a clear poison command to the device for the specified address. Clearing poison removes the address from the device's Poison List and writes 0 (zero) for 64 bytes starting at address. It is not an error to clear poison from an address that does not have poison set. If the device cannot clear poison from the address, -ENXIO is returned. The clear_poison attribute is only visible for devices supporting the capability.

/sys/kernel/debug/moxtet/input

Defined on file *debugfs-moxtet*

(Read) Read input from the shift registers, in hexadecimal. Returns N+1 bytes, where N is the number of Moxtet connected modules. The first byte is from the CPU board itself.

Example:

```
101214
```

10	CPU board with SD card
12	2 = PCIe module, 1 = IRQ not active
14	4 = Peridot module, 1 = IRQ not active

/sys/kernel/debug/moxtet/output

Defined on file *debugfs-moxtet*

(RW) Read last written value to the shift registers, in hexadecimal, or write values to the shift registers, also in hexadecimal.

Example:

```
0102
```

01	01 was last written, or is to be written, to the first module's shift register
02	the same for second module

/sys/kernel/debug/nx-crypto/*

Defined on file *debugfs-pfo-nx-crypto*

These debugfs interfaces are built by the nx-crypto driver, built in arch/powerpc/crypto/nx.

Error Detection

errors:
A u32 providing a total count of errors since the driver was loaded. The only errors counted here are those returned from the hcall, H_COP_OP.

last_error:
The most recent non-zero return code from the H_COP_OP hcall. -EBUSY is not recorded here (the hcall will retry until -EBUSY goes away).

last_error_pid:
The process ID of the process who received the most recent error from the hcall.

Device Use

aes_bytes:
The total number of bytes encrypted using AES in any of the driver's supported modes.

aes_ops:
The total number of AES operations submitted to the hardware.

sha256_bytes:
The total number of bytes hashed by the hardware using SHA-256.

sha256_ops:
The total number of SHA-256 operations submitted to the hardware.

sha512_bytes:
The total number of bytes hashed by the hardware using SHA-512.

sha512_ops:
The total number of SHA-512 operations submitted to the hardware.

/sys/kernel/debug/olpc-ec/cmd

Defined on file *debugfs-olpc*

A generic interface for executing OLPC Embedded Controller commands and reading their responses.

To execute a command, write data with the format: CC:N A A A A CC is the (hex) command, N is the count of expected reply bytes, and A A A A are optional (hex) arguments.

To read the response (if any), read from the generic node after executing a command. Hex reply bytes will be returned, *whether or not* they came from the immediately previous command.

/sys/kernel/debug/pktcdvd/pktcdvd[0-7]

Defined on file *debugfs-pktcdvd*

The pktcdvd module (packet writing driver) creates these files in debugfs:

/sys/kernel/debug/pktcdvd/pktcdvd[0-7]/

info	0444	Lots of driver statistics and infos.

Example:

```
cat /sys/kernel/debug/pktcdvd/pktcdvd0/info
```

/sys/kernel/debug/powerpc/memtrace

Defined on file *ppc-memtrace*

This folder contains the relevant debugfs files for the hardware trace macro to use. CONFIG_PPC64_HARDWARE_TRACING must be set.

/sys/kernel/debug/powerpc/memtrace/<node-id>

Defined on file *ppc-memtrace*

This directory contains information about the removed memory from the specific NUMA node.

/sys/kernel/debug/powerpc/memtrace/<node-id>/size

Defined on file *ppc-memtrace*

This contains the size of the memory removed from the node.

/sys/kernel/debug/powerpc/memtrace/<node-id>/start

Defined on file *ppc-memtrace*

This contains the start address of the removed memory.

/sys/kernel/debug/powerpc/memtrace/<node-id>/trace

Defined on file *ppc-memtrace*

This is where the hardware trace macro will output the trace it generates.

/sys/kernel/debug/powerpc/memtrace/enable

Defined on file *ppc-memtrace*

Write an integer containing the size in bytes of the memory you want removed from each NUMA node to this file - it must be aligned to the memblock size. This amount of RAM will be removed from each NUMA node in the kernel mappings and the following debugfs files will be created. Once memory is successfully removed from each node, the following files are created. To re-add memory to the kernel, echo 0 into this file (it will be automatically onlined).

/sys/kernel/debug/qat_<device>_<BDF>/cnv_errors

Defined on file *debugfs-driver-qat*

(RO) Read returns, for each Acceleration Engine (AE), the number of errors and the type of the last error detected by the device when performing verified compression. Reported counters:

```
<N>: Number of Compress and Verify (CnV) errors and type
     of the last CnV error detected by Acceleration
     Engine N.
```

/sys/kernel/debug/qat_<device>_<BDF>/fw_counters

Defined on file *debugfs-driver-qat*

(RO) Read returns the number of requests sent to the FW and the number of responses received from the FW for each Acceleration Engine Reported firmware counters:

```
<N>: Number of requests sent from Acceleration Engine N to FW and responses
     Acceleration Engine N received from FW
```

/sys/kernel/debug/qat_<device>_<BDF>/heartbeat/config

Defined on file *debugfs-driver-qat*

(RW) Read returns value of the Heartbeat update period. Write to the file changes this period value.

This period should reflect planned polling interval of device health status. High frequency Heartbeat monitoring wastes CPU cycles but minimizes the customer's system downtime. Also, if there are large service requests that take some time to complete, high frequency Heartbeat

monitoring could result in false reports of unresponsiveness and in those cases, period needs to be increased.

This parameter is effective only for c3xxx, c62x, dh895xcc devices. 4xxx has this value internally fixed to 200ms.

Default value is set to 500. Minimal allowed value is 200. All values are expressed in milliseconds.

/sys/kernel/debug/qat_<device>_<BDF>/heartbeat/queries_failed

Defined on file *debugfs-driver-qat*

(RO) Read returns the number of times the device became unresponsive.

Attribute returns value of the counter which is incremented when status query results negative.

/sys/kernel/debug/qat_<device>_<BDF>/heartbeat/queries_sent

Defined on file *debugfs-driver-qat*

(RO) Read returns the number of times the control process checked if the device is responsive.

Attribute returns value of the counter which is incremented on every status query.

/sys/kernel/debug/qat_<device>_<BDF>/heartbeat/status

Defined on file *debugfs-driver-qat*

(RO) Read returns the device health status.

Returns 0 when device is healthy or -1 when is unresponsive or the query failed to send.

The driver does not monitor for Heartbeat. It is left for a user to poll the status periodically.

/sys/kernel/debug/qat_<device>_<BDF>/pm_status

Defined on file *debugfs-driver-qat*

(RO) Read returns power management information specific to the QAT device.

This attribute is only available for qat_4xxx devices.

/sys/kernel/debug/qat_<device>_<BDF>/telemetry/control

Defined on file *debugfs-driver-qat_telemetry*

(RW) Enables/disables the reporting of telemetry metrics.

Allowed values to write:

- 0: disable telemetry
- 1: enable telemetry
- 2, 3, 4: enable telemetry and calculate minimum, maximum and average for each counter over 2, 3 or 4 samples

Returned values:

- 1-4: telemetry is enabled and running
- 0: telemetry is disabled

Example.

Writing '3' to this file starts the collection of telemetry metrics. Samples are collected every second and stored in a circular buffer of size 3. These values are then used to calculate the minimum, maximum and average for each counter. After enabling, counters can be retrieved through the `device_data` file:

```
echo 3 > /sys/kernel/debug/qat_4xxx_0000:6b:00.0/telemetry/control
```

Writing '0' to this file stops the collection of telemetry metrics:

```
echo 0 > /sys/kernel/debug/qat_4xxx_0000:6b:00.0/telemetry/control
```

This attribute is only available for qat_4xxx devices.

/sys/kernel/debug/qat_<device>_<BDF>/telemetry/device_data

Defined on file *debugfs-driver-qat_telemetry*

(RO) Reports device telemetry counters. Reads report metrics about performance and utilization of a QAT device:

Field	Description
sample_cnt	number of acquisitions of telemetry data from the device. Reads are performed every 1000 ms.
pci_trans_cnt	number of PCIe partial transactions
max_rd_lat	maximum logged read latency [ns] (could be any read operation)
rd_lat_acc_avg	average read latency [ns]
max_gp_lat	max get to put latency [ns] (only takes samples for AE0)
gp_lat_acc_avg	average get to put latency [ns]
bw_in	PCIe, write bandwidth [Mbps]
bw_out	PCIe, read bandwidth [Mbps]
at_page_req_lat_avg	Address Translator(AT), average page request latency [ns]
at_trans_lat_avg	AT, average page translation latency [ns]
at_max_tlb_used	AT, maximum uTLB used
util_cpr<N>	utilization of Compression slice N [%]
exec_cpr<N>	execution count of Compression slice N
util_xlt<N>	utilization of Translator slice N [%]
exec_xlt<N>	execution count of Translator slice N
util_dcpr<N>	utilization of Decompression slice N [%]
exec_dcpr<N>	execution count of Decompression slice N
util_pke<N>	utilization of PKE N [%]
exec_pke<N>	execution count of PKE N
util_ucs<N>	utilization of UCS slice N [%]

exec_wcp<N>	execution count of Wireless Cipher slice N
util_cph<N>	utilization of Cipher slice N [%]
exec_cph<N>	execution count of Cipher slice N
util_ath<N>	utilization of Authentication slice N [%]
exec_ath<N>	execution count of Authentication slice N

The telemetry report file can be read with the following command:

```
cat /sys/kernel/debug/qat_4xxx_0000:6b:00.0/telemetry/device_data
```

If `control` is set to 1, only the current values of the counters are displayed:

```
<counter_name> <current>
```

If `control` is 2, 3 or 4, counters are displayed in the following format:

```
<counter_name> <current> <min> <max> <avg>
```

If a device lacks of a specific accelerator, the corresponding attribute is not reported.

This attribute is only available for qat_4xxx devices.

/sys/kernel/debug/qat_<device>_<BDF>/telemetry/rp_<A/B/C/D>_data

Defined on file *debugfs-driver-qat_telemetry*

(RW) Selects up to 4 Ring Pairs (RP) to monitor, one per file, and report telemetry counters related to each.

Allowed values to write:

- 0 to `<num_rps - 1>`: Ring pair to be monitored. The value of `num_rps` can be retrieved through `/sys/bus/pci/devices/<BDF>/qat/num_rps`. See *testing/sysfs-driver-qat*.

Reads report metrics about performance and utilization of the selected RP:

Field	Description
sample_cnt	number of acquisitions of telemetry data from the device. Reads are performed every 1000 ms
rp_num	RP number associated with slot <A/B/C/D>
service_type	service associated to the RP
pci_trans_cnt	number of PCIe partial transactions
gp_lat_acc_avg	average get to put latency [ns]
bw_in	PCIe, write bandwidth [Mbps]
bw_out	PCIe, read bandwidth [Mbps]
at_glob_devtlb_hit	Message descriptor DevTLB hit rate
at_glob_devtlb_miss	Message descriptor DevTLB miss rate
tl_at_payld_devtlb_hit	Payload DevTLB hit rate
tl_at_payld_devtlb_miss	Payload DevTLB miss rate

Example.

Writing the value '32' to the file `rp_C_data` starts the collection of telemetry metrics for ring pair 32:

```
echo 32 > /sys/kernel/debug/qat_4xxx_0000:6b:00.0/telemetry/rp_C_data
```

Once a ring pair is selected, statistics can be read accessing the file:

```
cat /sys/kernel/debug/qat_4xxx_0000:6b:00.0/telemetry/rp_C_data
```

If `control` is set to 1, only the current values of the counters are displayed:

```
<counter_name> <current>
```

If `control` is 2, 3 or 4, counters are displayed in the following format:

```
<counter_name> <current> <min> <max> <avg>
```

On QAT GEN4 devices there are 64 RPs on a PF, so the allowed values are 0..63. This number is absolute to the device. If Virtual Functions (VF) are used, the ring pair number can be derived from the Bus, Device, Function of the VF:

PCI BDF/VF	RP0	RP1	RP2	RP3
0000:6b:0.1	RP 0	RP 1	RP 2	RP 3
0000:6b:0.2	RP 4	RP 5	RP 6	RP 7
0000:6b:0.3	RP 8	RP 9	RP 10	RP 11
0000:6b:0.4	RP 12	RP 13	RP 14	RP 15
0000:6b:0.5	RP 16	RP 17	RP 18	RP 19
0000:6b:0.6	RP 20	RP 21	RP 22	RP 23
0000:6b:0.7	RP 24	RP 25	RP 26	RP 27
0000:6b:1.0	RP 28	RP 29	RP 30	RP 31
0000:6b:1.1	RP 32	RP 33	RP 34	RP 35
0000:6b:1.2	RP 36	RP 37	RP 38	RP 39
0000:6b:1.3	RP 40	RP 41	RP 42	RP 43
0000:6b:1.4	RP 44	RP 45	RP 46	RP 47
0000:6b:1.5	RP 48	RP 49	RP 50	RP 51
0000:6b:1.6	RP 52	RP 53	RP 54	RP 55
0000:6b:1.7	RP 56	RP 57	RP 58	RP 59
0000:6b:2.0	RP 60	RP 61	RP 62	RP 63

The mapping is only valid for the BDFs of VFs on the host.

The service provided on a ring-pair varies depending on the configuration. The configuration for a given device can be queried and set using `cfg_services`. See *testing/sysfs-driver-qat* for details.

The following table reports how ring pairs are mapped to VFs on the PF 0000:6b:0.0 configured for *sym;asym* or *asym;sym*:

PCI BDF/VF	RP0/service	RP1/service	RP2/service	RP3/service
0000:6b:0.1	RP 0 asym	RP 1 sym	RP 2 asym	RP 3 sym
0000:6b:0.2	RP 4 asym	RP 5 sym	RP 6 asym	RP 7 sym
0000:6b:0.3	RP 8 asym	RP 9 sym	RP10 asym	RP11 sym
...	...	...	...	...

All VFs follow the same pattern.

The following table reports how ring pairs are mapped to VFs on the PF 0000:6b:0.0 configured for *dc*:

PCI BDF/VF	RP0/service	RP1/service	RP2/service	RP3/service
0000:6b:0.1	RP 0 dc	RP 1 dc	RP 2 dc	RP 3 dc
0000:6b:0.2	RP 4 dc	RP 5 dc	RP 6 dc	RP 7 dc
0000:6b:0.3	RP 8 dc	RP 9 dc	RP10 dc	RP11 dc
...	...	...	...	...

The mapping of a RP to a service can be retrieved using `rp2srv` from sysfs. See *testing/sysfs-driver-qat* for details.

This attribute is only available for qat_4xxx devices.

/sys/kernel/debug/scmi/<n>/atomic_threshold_us

Defined on file *debugfs-scmi*

An optional time value, expressed in microseconds, representing, on this SCMI instance <n>, the threshold above which any SCMI command, advertised to have an higher-than-threshold execution latency, should not be considered for atomic mode of operation, even if requested.

Users: Debugging, any userspace test suite

/sys/kernel/debug/scmi/<n>/instance_name

Defined on file *debugfs-scmi*

The name of the underlying SCMI instance <n> described by all the debugfs accessors rooted at /sys/kernel/debug/scmi/<n>, expressed as the full name of the top DT SCMI node under which this SCMI instance is rooted.

Users: Debugging, any userspace test suite

/sys/kernel/debug/scmi/<n>/raw/channels/<m>/message

Defined on file *debugfs-scmi-raw*

SCMI Raw synchronous message injection/snooping facility; write a complete SCMI synchronous command message (header included) in little-endian binary format to have it sent to the configured backend SCMI server for instance <n> through the <m> transport channel. Any subsequently received response can be read from this same entry if it arrived on channel <m> within the configured timeout. Each write to the entry causes one command request to be built and sent while the replies are read back one message at time (receiving an EOF at each message boundary). Channel identifier <m> matches the SCMI protocol number which has been associated with this transport channel in the DT description, with base protocol number 0x10 being the default channel for this instance. Note that these per-channel entries rooted at <..>/channels exist only if the transport is configured to have more than one default channel.

Users: Debugging, any userspace test suite

/sys/kernel/debug/scmi/<n>/raw/channels/<m>/message_async

Defined on file *debugfs-scmi-raw*

SCMI Raw asynchronous message injection/snooping facility; write a complete SCMI asynchronous command message (header included) in little-endian binary format to have it sent to the configured backend SCMI server for instance <n> through the <m> transport channel. Any subsequently received response can be read from this same entry if it arrived on channel <m> within the configured timeout. Any additional delayed response received afterwards can be read from this same entry too if it arrived within the configured timeout. Each write to the entry causes one command request to be built and sent while the replies are read back one message at time (receiving an EOF at each message boundary). Channel identifier <m> matches the SCMI protocol number which has been associated with this transport channel in the DT description, with base protocol number 0x10 being the default channel for this instance. Note that these per-channel entries rooted at <..>/channels exist only if the transport is configured to have more than one default channel.

Users: Debugging, any userspace test suite

/sys/kernel/debug/scmi/<n>/raw/errors

Defined on file *debugfs-scmi-raw*

SCMI Raw message errors facility; any kind of timed-out or generally unexpectedly received SCMI message, for instance <n>, can be read from this entry. Each read gives back one message at time (receiving an EOF at each message boundary).

Users: Debugging, any userspace test suite

/sys/kernel/debug/scmi/<n>/raw/message

Defined on file *debugfs-scmi-raw*

SCMI Raw synchronous message injection/snooping facility; write a complete SCMI synchronous command message (header included) in little-endian binary format to have it sent to the configured backend SCMI server for instance <n>. Any subsequently received response can be read from this same entry if it arrived within the configured timeout. Each write to the entry causes one command request to be built and sent while the replies are read back one message at time (receiving an EOF at each message boundary).

Users: Debugging, any userspace test suite

/sys/kernel/debug/scmi/<n>/raw/message_async

Defined on file *debugfs-scmi-raw*

SCMI Raw asynchronous message injection/snooping facility; write a complete SCMI asynchronous command message (header included) in little-endian binary format to have it sent to the configured backend SCMI server for instance <n>. Any subsequently received response can be read from this same entry if it arrived within the configured timeout. Any additional delayed response received afterwards can be read from this same entry too if it arrived within the configured timeout. Each write to the entry causes one command request to be built and sent while the replies are read back one message at time (receiving an EOF at each message boundary).

Users: Debugging, any userspace test suite

/sys/kernel/debug/scmi/<n>/raw/notification

Defined on file *debugfs-scmi-raw*

SCMI Raw notification snooping facility; any notification emitted by the backend SCMI server, for instance <n>, can be read from this entry. Each read gives back one message at time (receiving an EOF at each message boundary).

Users: Debugging, any userspace test suite

/sys/kernel/debug/scmi/<n>/raw/reset

Defined on file *debugfs-scmi-raw*

SCMI Raw stack reset facility; writing a value to this entry causes the internal queues of any kind of received message, still pending to be read out for instance <n>, to be immediately flushed. Can be used to reset and clean the SCMI Raw stack between to different test-run.

Users: Debugging, any userspace test suite

/sys/kernel/debug/scmi/<n>/transport/is_atomic

Defined on file *debugfs-scmi*

A boolean stating if the transport configured on the underlying SCMI instance <n> is capable of atomic mode of operation.

Users: Debugging, any userspace test suite

/sys/kernel/debug/scmi/<n>/transport/max_msg_size

Defined on file *debugfs-scmi*

Max message size of allowed SCMI messages for the currently configured SCMI transport for instance <n>.

Users: Debugging, any userspace test suite

/sys/kernel/debug/scmi/<n>/transport/max_rx_timeout_ms

Defined on file *debugfs-scmi*

Timeout in milliseconds allowed for SCMI synchronous replies for the currently configured SCMI transport for instance <n>.

Users: Debugging, any userspace test suite

/sys/kernel/debug/scmi/<n>/transport/rx_max_msg

Defined on file *debugfs-scmi*

Max number of concurrently allowed in-flight SCMI messages for the currently configured SCMI transport for instance <n> on the RX channels.

Users: Debugging, any userspace test suite

/sys/kernel/debug/scmi/<n>/transport/tx_max_msg

Defined on file *debugfs-scmi*

Max number of concurrently allowed in-flight SCMI messages for the currently configured SCMI transport for instance <n> on the TX channels.

Users: Debugging, any userspace test suite

/sys/kernel/debug/scmi/<n>/transport/type

Defined on file *debugfs-scmi*

A string representing the type of transport configured for this SCMI instance <n>.

Users: Debugging, any userspace test suite

/sys/kernel/debug/tpmi-<n>/pfs_dump

Defined on file *debugfs-tpmi*

The PFS (PM Feature Structure) table, shows details of each power management feature. This includes: tpmi_id, number of entries, entry size, offset, vsec offset, lock status and disabled status.

Users: Debugging, any user space test suite

/sys/kernel/debug/tpmi-<n>/tpmi-id-<n>/mem_dump

Defined on file *debugfs-tpmi*

Shows the memory dump of the MMIO region for a TPMI ID.

Users: Debugging, any user space test suite

/sys/kernel/debug/tpmi-<n>/tpmi-id-<n>/mem_write

Defined on file *debugfs-tpmi*

Allows to write at any offset. It doesn't check for Read/Write access as hardware will not allow to write at read-only memory. This write is at offset multiples of 4. The format is instance,offset,contents. Example: echo 0,0x20,0xff > mem_write echo 1,64,64 > mem_write

Users: Debugging, any user space test suite

/sys/kernel/debug/turris-mox-rwtm/do_sign

Defined on file *debugfs-turris-mox-rwtm*

(Write)	Message to sign with the ECDSA private key stored in device's OTP. The message must be exactly 64 bytes (since this is intended for SHA-512 hashes).
(Read)	The resulting signature, 136 bytes. This contains the R and S values of the ECDSA signature, both in big-endian format.

/sys/kernel/debug/vfio

Defined on file *debugfs-vfio*

This debugfs file directory is used for debugging of vfio devices, it's a common directory for all vfio devices. Vfio core will create a device subdirectory under this directory.

/sys/kernel/debug/vfio/<device>/migration

Defined on file *debugfs-vfio*

This debugfs file directory is used for debugging of vfio devices that support live migration. The debugfs of each vfio device that supports live migration could be created under this directory.

/sys/kernel/debug/vfio/<device>/migration/state

Defined on file *debugfs-vfio*

Read the live migration status of the vfio device. The contents of the state file reflects the migration state relative to those defined in the vfio_device_mig_state enum

/sys/kernel/debug/wilco_ec/h1_gpio

Defined on file *debugfs-wilco-ec*

As part of Chrome OS's FAFT (Fully Automated Firmware Testing) tests, we need to ensure that the H1 chip is properly setting some GPIO lines. The h1_gpio attribute exposes the state of the lines: - ENTRY_TO_FACT_MODE in BIT(0) - SPI_CHROME_SEL in BIT(1)

Output will formatted with "0x%02xn".

/sys/kernel/debug/wilco_ec/raw

Defined on file *debugfs-wilco-ec*

Write and read raw mailbox commands to the EC.

You can write a hexadecimal sentence to raw, and that series of bytes will be sent to the EC. Then, you can read the bytes of response by reading from raw.

For writing, bytes 0-1 indicate the message type, one of enum wilco_ec_msg_type. Byte 2+ consist of the data passed in the request, starting at MBOX[0]. At least three bytes are required for writing, two for the type and at least a single byte of data.

Example:

```
// Request EC info type 3 (EC firmware build date)
// Corresponds with sending type 0x00f0 with
// MBOX = [38, 00, 03, 00]
$ echo 00 f0 38 00 03 00 > /sys/kernel/debug/wilco_ec/raw
// View the result. The decoded ASCII result "12/21/18" is
// included after the raw hex.
// Corresponds with MBOX = [00, 00, 31, 32, 2f, 32, 31, 38, ...]
$ cat /sys/kernel/debug/wilco_ec/raw
00 00 31 32 2f 32 31 2f 31 38 00 38 00 01 00 2f 00  ..12/21/18.8...
```

Note that the first 16 bytes of the received MBOX[] will be printed, even if some of the data is junk, and skipping bytes 17 to 32. It is up to you to know how many of the first bytes of data are the actual response.

/sys/kernel/dmabuf/buffers

Defined on file *sysfs-kernel-dmabuf-buffers*

The */sys/kernel/dmabuf/buffers* directory contains a snapshot of the internal state of every DMA-BUF. /sys/kernel/dmabuf/buffers/<inode_number> will contain the statistics for the DMA-BUF with the unique inode number <inode_number>

Users: kernel memory tuning/debugging tools

/sys/kernel/dmabuf/buffers/<inode_number>/exporter_name

Defined on file *sysfs-kernel-dmabuf-buffers*

This file is read-only and contains the name of the exporter of the DMA-BUF.

/sys/kernel/dmabuf/buffers/<inode_number>/size

Defined on file *sysfs-kernel-dmabuf-buffers*

This file is read-only and specifies the size of the DMA-BUF in bytes.

/sys/kernel/fadump/*

Defined on file *sysfs-kernel-fadump*

The /sys/kernel/fadump/* is a collection of FADump sysfs file provide information about the configuration status of Firmware Assisted Dump (FADump).

/sys/kernel/fadump/enabled

Defined on file *sysfs-kernel-fadump*

read only Primarily used to identify whether the FADump is enabled in the kernel or not. User: Kdump service

/sys/kernel/fadump/mem_reserved

Defined on file *sysfs-kernel-fadump*

read only Provide information about the amount of memory reserved by FADump to save the crash dump in bytes.

/sys/kernel/fadump/registered

Defined on file *sysfs-kernel-fadump*

read/write Helps to control the dump collect feature from userspace. Setting 1 to this file enables the system to collect the dump and 0 to disable it. User: Kdump service

/sys/kernel/fadump/release_mem

Defined on file *sysfs-kernel-fadump*

write only This is a special sysfs file and only available when the system is booted to capture the vmcore using FADump. It is used to release the memory reserved by FADump to save the crash dump.

/sys/kernel/fscaps

Defined on file *sysfs-kernel-fscaps*

Shows whether file system capabilities are honored when executing a binary

/sys/kernel/iommu_groups/

Defined on file *sysfs-kernel-iommu_groups*

/sys/kernel/iommu_groups/ contains a number of sub- directories, each representing an IOMMU group. The name of the sub-directory matches the iommu_group_id() for the group, which is an integer value. Within each subdirectory is another directory named "devices" with links to the sysfs devices contained in this group. The group directory also optionally contains a "name" file if the IOMMU driver has chosen to register a more common name for the group.

/sys/kernel/iommu_groups/<grp_id>/type

Defined on file *sysfs-kernel-iommu_groups*

/sys/kernel/iommu_groups/<grp_id>/type shows the type of default domain in use by iommu for this group. See include/linux/iommu.h for possible read values. A privileged user could request kernel to change the group type by writing to this file. Valid write values:

DMA	All the DMA transactions from the device in this group are translated by the iommu.
DMA-FQ	As above, but using batched invalidation to lazily remove translations after use. This may offer reduced overhead at the cost of reduced memory protection.
identity	All the DMA transactions from the device in this group are not translated by the iommu. Maximum performance but zero protection.
auto	Change to the type the device was booted with.

The default domain type of a group may be modified only when

- The device in the group is not bound to any device driver. So, the users must unbind the appropriate driver before changing the default domain type.

Unbinding a device driver will take away the driver's control over the device and if done on devices that host root file system could lead to catastrophic effects (the users might need to reboot the machine to get it to normal state). So, it's expected that the users understand what they're doing.

/sys/kernel/iommu_groups/reserved_regions

Defined on file *sysfs-kernel-iommu_groups*

/sys/kernel/iommu_groups/reserved_regions list IOVA regions that are reserved. Not necessarily all reserved regions are listed. This is typically used to output direct-mapped, MSI, non mappable regions. Each region is described on a single line: the 1st field is the base IOVA, the second is the end IOVA and the third field describes the type of the region.

Since kernel 5.3, in case an RMRR is used only by graphics or USB devices it is now exposed as "direct-relaxable" instead of "direct". In device assignment use case, for instance, those RMRR are considered to be relaxable and safe.

/sys/kernel/irq

Defined on file *sysfs-kernel-irq*

Directory containing information about the system's IRQs. Specifically, data from the associated struct irq_desc. The information here is similar to that in /proc/interrupts but in a more machine-friendly format. This directory contains one subdirectory for each Linux IRQ number.

/sys/kernel/irq/<irq>/actions

Defined on file *sysfs-kernel-irq*

The IRQ action chain. A comma-separated list of zero or more device names associated with this interrupt.

/sys/kernel/irq/<irq>/chip_name

Defined on file *sysfs-kernel-irq*

Human-readable chip name supplied by the associated device driver.

/sys/kernel/irq/<irq>/hwirq

Defined on file *sysfs-kernel-irq*

When interrupt translation domains are used, this file contains the underlying hardware IRQ number used for this Linux IRQ.

/sys/kernel/irq/<irq>/name

Defined on file *sysfs-kernel-irq*

Human-readable flow handler name as defined by the irq chip driver.

/sys/kernel/irq/<irq>/per_cpu_count

Defined on file *sysfs-kernel-irq*

The number of times the interrupt has fired since boot. This is a comma-separated list of counters; one per CPU in CPU id order. NOTE: This file consistently shows counters for all CPU ids. This differs from the behavior of /proc/interrupts which only shows counters for online CPUs.

/sys/kernel/irq/<irq>/type

Defined on file *sysfs-kernel-irq*

The type of the interrupt. Either the string 'level' or 'edge'.

/sys/kernel/irq/<irq>/wakeup

Defined on file *sysfs-kernel-irq*

The wakeup state of the interrupt. Either the string 'enabled' or 'disabled'.

/sys/kernel/livepatch

Defined on file *sysfs-kernel-livepatch*

Interface for kernel live patching

The */sys/kernel/livepatch* directory contains subdirectories for each loaded live patch module.

/sys/kernel/livepatch/<patch>

Defined on file *sysfs-kernel-livepatch*

The patch directory contains subdirectories for each kernel object (vmlinux or a module) in which it patched functions.

/sys/kernel/livepatch/<patch>/<object>

Defined on file *sysfs-kernel-livepatch*

The object directory contains subdirectories for each function that is patched within the object.

/sys/kernel/livepatch/<patch>/<object>/<function,sympos>

Defined on file *sysfs-kernel-livepatch*

The function directory contains attributes regarding the properties and state of the patched function.

The directory name contains the patched function name and a sympos number corresponding to the nth occurrence of the symbol name in kallsyms for the patched object.

There are currently no such attributes.

/sys/kernel/livepatch/<patch>/<object>/patched

Defined on file *sysfs-kernel-livepatch*

An attribute which indicates whether the object is currently patched.

/sys/kernel/livepatch/<patch>/enabled

Defined on file *sysfs-kernel-livepatch*

A writable attribute that indicates whether the patched code is currently applied. Writing 0 will disable the patch while writing 1 will re-enable the patch.

/sys/kernel/livepatch/<patch>/force

Defined on file *sysfs-kernel-livepatch*

A writable attribute that allows administrator to affect the course of an existing transition. Writing 1 clears TIF_PATCH_PENDING flag of all tasks and thus forces the tasks to the patched or unpatched state. Administrator should not use this feature without a clearance from a patch distributor. Removal (rmmod) of patch modules is permanently disabled when the feature is used. See /livepatch/livepatch for more information.

/sys/kernel/livepatch/<patch>/transition

Defined on file *sysfs-kernel-livepatch*

An attribute which indicates whether the patch is currently in transition.

/sys/kernel/mm

Defined on file *sysfs-kernel-mm*

/sys/kernel/mm/ should contain any and all VM related information in /sys/kernel/.

/sys/kernel/mm/cma/

Defined on file *sysfs-kernel-mm-cma*

/sys/kernel/mm/cma/ contains a subdirectory for each CMA heap name (also sometimes called CMA areas).

Each CMA heap subdirectory (that is, each /sys/kernel/mm/cma/<cma-heap-name> directory) contains the following items:

alloc_pages_success alloc_pages_fail

/sys/kernel/mm/cma/<cma-heap-name>/alloc_pages_fail

Defined on file *sysfs-kernel-mm-cma*

the number of pages CMA API failed to allocate

/sys/kernel/mm/cma/<cma-heap-name>/alloc_pages_success

Defined on file *sysfs-kernel-mm-cma*

the number of pages CMA API succeeded to allocate

/sys/kernel/mm/damon/

Defined on file *sysfs-kernel-mm-damon*

Interface for Data Access MONitoring (DAMON). Contains files for controlling DAMON. For more details on DAMON itself, please refer to *DAMON: Data Access MONitor*.

/sys/kernel/mm/damon/admin/

Defined on file *sysfs-kernel-mm-damon*

Interface for privileged users of DAMON. Contains files for controlling DAMON that aimed to be used by privileged users.

/sys/kernel/mm/damon/admin/kdamonds/<K>/contexts/<C>/avail_operations

Defined on file *sysfs-kernel-mm-damon*

Reading this file returns the available monitoring operations sets on the currently running kernel.

/sys/kernel/mm/damon/admin/kdamonds/<K>/contexts/<C>/monitoring_attrs/intervals/agg

Defined on file *sysfs-kernel-mm-damon*

Writing a value to this file sets the aggregation interval of the DAMON context in microseconds as the value. Reading this file returns the value.

/sys/kernel/mm/damon/admin/kdamonds/<K>/contexts/<C>/monitoring_attrs/intervals/san

Defined on file *sysfs-kernel-mm-damon*

Writing a value to this file sets the sampling interval of the DAMON context in microseconds as the value. Reading this file returns the value.

/sys/kernel/mm/damon/admin/kdamonds/<K>/contexts/<C>/monitoring_attrs/intervals/upd

Defined on file *sysfs-kernel-mm-damon*

Writing a value to this file sets the update interval of the DAMON context in microseconds as the value. Reading this file returns the value.

/sys/kernel/mm/damon/admin/kdamonds/<K>/contexts/<C>/monitoring_attrs/nr_regions/m

Defined on file *sysfs-kernel-mm-damon*

Writing a value to this file sets the maximum number of monitoring regions of the DAMON context as the value. Reading this file returns the value.

/sys/kernel/mm/damon/admin/kdamonds/<K>/contexts/<C>/monitoring_attrs/nr_regions/m

Defined on file *sysfs-kernel-mm-damon*

Writing a value to this file sets the minimum number of monitoring regions of the DAMON context as the value. Reading this file returns the value.

/sys/kernel/mm/damon/admin/kdamonds/<K>/contexts/<C>/operations

Defined on file *sysfs-kernel-mm-damon*

Writing a keyword for a monitoring operations set ('vaddr' for virtual address spaces monitoring, 'fvaddr' for fixed virtual address ranges monitoring, and 'paddr' for the physical address space monitoring) to this file makes the context to use the operations set. Reading the file returns the keyword for the operations set the context is set to use.

Note that only the operations sets that listed in 'avail_operations' file are valid inputs.

/sys/kernel/mm/damon/admin/kdamonds/<K>/contexts/<C>/schemes/<S>/access_pattern/a

Defined on file *sysfs-kernel-mm-damon*

Writing to and reading from this file sets and gets the maximum 'age' of the scheme's target regions.

/sys/kernel/mm/damon/admin/kdamonds/<K>/contexts/<C>/schemes/<S>/access_pattern/a

Defined on file *sysfs-kernel-mm-damon*

Writing to and reading from this file sets and gets the minimum 'age' of the scheme's target regions.

/sys/kernel/mm/damon/admin/kdamonds/<K>/contexts/<C>/schemes/<S>/access_pattern/n

Defined on file *sysfs-kernel-mm-damon*

Writing to and reading from this file sets and gets the maximum 'nr_accesses' of the scheme's target regions.

/sys/kernel/mm/damon/admin/kdamonds/<K>/contexts/<C>/schemes/<S>/access_pattern/n

Defined on file *sysfs-kernel-mm-damon*

Writing to and reading from this file sets and gets the manimum 'nr_accesses' of the scheme's target regions.

/sys/kernel/mm/damon/admin/kdamonds/<K>/contexts/<C>/schemes/<S>/access_pattern/s

Defined on file *sysfs-kernel-mm-damon*

Writing to and reading from this file sets and gets the maximum size of the scheme's target regions in bytes.

/sys/kernel/mm/damon/admin/kdamonds/<K>/contexts/<C>/schemes/<S>/access_pattern/s

Defined on file *sysfs-kernel-mm-damon*

Writing to and reading from this file sets and gets the minimum size of the scheme's target regions in bytes.

/sys/kernel/mm/damon/admin/kdamonds/<K>/contexts/<C>/schemes/<S>/action

Defined on file *sysfs-kernel-mm-damon*

Writing to and reading from this file sets and gets the action of the scheme.

/sys/kernel/mm/damon/admin/kdamonds/<K>/contexts/<C>/schemes/<S>/apply_interval_u

Defined on file *sysfs-kernel-mm-damon*

Writing a value to this file sets the action apply interval of the scheme in microseconds. Reading this file returns the value.

/sys/kernel/mm/damon/admin/kdamonds/<K>/contexts/<C>/schemes/<S>/filters/<F>/addr

Defined on file *sysfs-kernel-mm-damon*

If 'addr' is written to the 'type' file, writing to or reading from this file sets or gets the end address of the address range for the filter.

/sys/kernel/mm/damon/admin/kdamonds/<K>/contexts/<C>/schemes/<S>/filters/<F>/addr

Defined on file *sysfs-kernel-mm-damon*

If 'addr' is written to the 'type' file, writing to or reading from this file sets or gets the start address of the address range for the filter.

/sys/kernel/mm/damon/admin/kdamonds/<K>/contexts/<C>/schemes/<S>/filters/<F>/matc

Defined on file *sysfs-kernel-mm-damon*

Writing 'Y' or 'N' to this file sets whether to filter out pages that do or do not match to the 'type' and 'memcg_path', respectively. Filter out means the action of the scheme will not be applied to.

/sys/kernel/mm/damon/admin/kdamonds/<K>/contexts/<C>/schemes/<S>/filters/<F>/mem

Defined on file *sysfs-kernel-mm-damon*

If 'memcg' is written to the 'type' file, writing to and reading from this file sets and gets the path to the memory cgroup of the interest.

/sys/kernel/mm/damon/admin/kdamonds/<K>/contexts/<C>/schemes/<S>/filters/<F>/targe

Defined on file *sysfs-kernel-mm-damon*

If 'target' is written to the 'type' file, writing to or reading from this file sets or gets the index of the DAMON monitoring target of the interest.

/sys/kernel/mm/damon/admin/kdamonds/<K>/contexts/<C>/schemes/<S>/filters/<F>/type

Defined on file *sysfs-kernel-mm-damon*

Writing to and reading from this file sets and gets the type of the memory of the interest. 'anon' for anonymous pages, 'memcg' for specific memory cgroup, 'addr' for address range (an open-ended interval), or 'target' for DAMON monitoring target can be written and read.

/sys/kernel/mm/damon/admin/kdamonds/<K>/contexts/<C>/schemes/<S>/filters/nr_filters

Defined on file *sysfs-kernel-mm-damon*

Writing a number 'N' to this file creates the number of directories for setting filters of the scheme named '0' to 'N-1' under the filters/ directory.

/sys/kernel/mm/damon/admin/kdamonds/<K>/contexts/<C>/schemes/<S>/quotas/bytes

Defined on file *sysfs-kernel-mm-damon*

Writing to and reading from this file sets and gets the size quota of the scheme in bytes.

/sys/kernel/mm/damon/admin/kdamonds/<K>/contexts/<C>/schemes/<S>/quotas/goals/<G

Defined on file *sysfs-kernel-mm-damon*

Writing to and reading from this file sets and gets the current value of the goal metric.

/sys/kernel/mm/damon/admin/kdamonds/<K>/contexts/<C>/schemes/<S>/quotas/goals/<G

Defined on file *sysfs-kernel-mm-damon*

Writing to and reading from this file sets and gets the target value of the goal metric.

/sys/kernel/mm/damon/admin/kdamonds/<K>/contexts/<C>/schemes/<S>/quotas/goals/nr_

Defined on file *sysfs-kernel-mm-damon*

Writing a number 'N' to this file creates the number of directories for setting automatic tuning of the scheme's aggressiveness named '0' to 'N-1' under the goals/ directory.

/sys/kernel/mm/damon/admin/kdamonds/<K>/contexts/<C>/schemes/<S>/quotas/ms

Defined on file *sysfs-kernel-mm-damon*

Writing to and reading from this file sets and gets the time quota of the scheme in milliseconds.

/sys/kernel/mm/damon/admin/kdamonds/<K>/contexts/<C>/schemes/<S>/quotas/reset_int

Defined on file *sysfs-kernel-mm-damon*

Writing to and reading from this file sets and gets the quotas charge reset interval of the scheme in milliseconds.

/sys/kernel/mm/damon/admin/kdamonds/<K>/contexts/<C>/schemes/<S>/quotas/weights/

Defined on file *sysfs-kernel-mm-damon*

Writing to and reading from this file sets and gets the under-quota limit regions prioritization weight for 'age' in permil.

/sys/kernel/mm/damon/admin/kdamonds/<K>/contexts/<C>/schemes/<S>/quotas/weights/

Defined on file *sysfs-kernel-mm-damon*

Writing to and reading from this file sets and gets the under-quota limit regions prioritization weight for 'nr_accesses' in permil.

/sys/kernel/mm/damon/admin/kdamonds/<K>/contexts/<C>/schemes/<S>/quotas/weights/

Defined on file *sysfs-kernel-mm-damon*

Writing to and reading from this file sets and gets the under-quota limit regions prioritization weight for 'size' in permil.

/sys/kernel/mm/damon/admin/kdamonds/<K>/contexts/<C>/schemes/<S>/stats/nr_applied

Defined on file *sysfs-kernel-mm-damon*

Reading this file returns the number of regions that the action of the scheme has successfully applied.

/sys/kernel/mm/damon/admin/kdamonds/<K>/contexts/<C>/schemes/<S>/stats/nr_tried

Defined on file *sysfs-kernel-mm-damon*

Reading this file returns the number of regions that the action of the scheme has tried to be applied.

/sys/kernel/mm/damon/admin/kdamonds/<K>/contexts/<C>/schemes/<S>/stats/qt_exceeds

Defined on file *sysfs-kernel-mm-damon*

Reading this file returns the number of the exceed events of the scheme's quotas.

/sys/kernel/mm/damon/admin/kdamonds/<K>/contexts/<C>/schemes/<S>/stats/sz_applied

Defined on file *sysfs-kernel-mm-damon*

Reading this file returns the total size of regions that the action of the scheme has successfully applied in bytes.

/sys/kernel/mm/damon/admin/kdamonds/<K>/contexts/<C>/schemes/<S>/stats/sz_tried

Defined on file *sysfs-kernel-mm-damon*

Reading this file returns the total size of regions that the action of the scheme has tried to be applied in bytes.

/sys/kernel/mm/damon/admin/kdamonds/<K>/contexts/<C>/schemes/<S>/tried_regions/<

Defined on file *sysfs-kernel-mm-damon*

Reading this file returns the 'age' of a memory region that corresponding DAMON-based Operation Scheme's action has tried to be applied.

/sys/kernel/mm/damon/admin/kdamonds/<K>/contexts/<C>/schemes/<S>/tried_regions/<I

Defined on file *sysfs-kernel-mm-damon*

Reading this file returns the end address of a memory region that corresponding DAMON-based Operation Scheme's action has tried to be applied.

/sys/kernel/mm/damon/admin/kdamonds/<K>/contexts/<C>/schemes/<S>/tried_regions/<I

Defined on file *sysfs-kernel-mm-damon*

Reading this file returns the 'nr_accesses' of a memory region that corresponding DAMON-based Operation Scheme's action has tried to be applied.

/sys/kernel/mm/damon/admin/kdamonds/<K>/contexts/<C>/schemes/<S>/tried_regions/<I

Defined on file *sysfs-kernel-mm-damon*

Reading this file returns the start address of a memory region that corresponding DAMON-based Operation Scheme's action has tried to be applied.

/sys/kernel/mm/damon/admin/kdamonds/<K>/contexts/<C>/schemes/<S>/tried_regions/to

Defined on file *sysfs-kernel-mm-damon*

Reading this file returns the total amount of memory that corresponding DAMON-based Operation Scheme's action has tried to be applied.

/sys/kernel/mm/damon/admin/kdamonds/<K>/contexts/<C>/schemes/<S>/watermarks/hig

Defined on file *sysfs-kernel-mm-damon*

Writing to and reading from this file sets and gets the high watermark of the scheme in permil.

/sys/kernel/mm/damon/admin/kdamonds/<K>/contexts/<C>/schemes/<S>/watermarks/inte

Defined on file *sysfs-kernel-mm-damon*

Writing to and reading from this file sets and gets the metric check interval of the watermarks for the scheme in microseconds.

/sys/kernel/mm/damon/admin/kdamonds/<K>/contexts/<C>/schemes/<S>/watermarks/low

Defined on file *sysfs-kernel-mm-damon*

Writing to and reading from this file sets and gets the low watermark of the scheme in permil.

/sys/kernel/mm/damon/admin/kdamonds/<K>/contexts/<C>/schemes/<S>/watermarks/met

Defined on file *sysfs-kernel-mm-damon*

Writing to and reading from this file sets and gets the metric of the watermarks for the scheme. The writable/readable keywords for this file are 'none' for disabling the watermarks feature, or 'free_mem_rate' for the system's global free memory rate in permil.

/sys/kernel/mm/damon/admin/kdamonds/<K>/contexts/<C>/schemes/<S>/watermarks/mid

Defined on file *sysfs-kernel-mm-damon*

Writing to and reading from this file sets and gets the mid watermark of the scheme in permil.

/sys/kernel/mm/damon/admin/kdamonds/<K>/contexts/<C>/schemes/nr_schemes

Defined on file *sysfs-kernel-mm-damon*

Writing a number 'N' to this file creates the number of directories for controlling each DAMON-based operation scheme of the context named '0' to 'N-1' under the schemes/ directory.

/sys/kernel/mm/damon/admin/kdamonds/<K>/contexts/<C>/targets/<T>/pid_target

Defined on file *sysfs-kernel-mm-damon*

Writing to and reading from this file sets and gets the pid of the target process if the context is for virtual address spaces monitoring, respectively.

/sys/kernel/mm/damon/admin/kdamonds/<K>/contexts/<C>/targets/<T>/regions/<R>/end

Defined on file *sysfs-kernel-mm-damon*

Writing to and reading from this file sets and gets the end address of the monitoring region.

/sys/kernel/mm/damon/admin/kdamonds/<K>/contexts/<C>/targets/<T>/regions/<R>/star

Defined on file *sysfs-kernel-mm-damon*

Writing to and reading from this file sets and gets the start address of the monitoring region.

/sys/kernel/mm/damon/admin/kdamonds/<K>/contexts/<C>/targets/<T>/regions/nr_region

Defined on file *sysfs-kernel-mm-damon*

Writing a number 'N' to this file creates the number of directories for setting each DAMON target memory region of the context named '0' to 'N-1' under the regions/ directory. In case of the virtual address space monitoring, DAMON automatically sets the target memory region based on the target processes' mappings.

/sys/kernel/mm/damon/admin/kdamonds/<K>/contexts/<C>/targets/nr_targets

Defined on file *sysfs-kernel-mm-damon*

Writing a number 'N' to this file creates the number of directories for controlling each DAMON target of the context named '0' to 'N-1' under the contexts/ directory.

/sys/kernel/mm/damon/admin/kdamonds/<K>/contexts/nr_contexts

Defined on file *sysfs-kernel-mm-damon*

Writing a number 'N' to this file creates the number of directories for controlling each DAMON context named '0' to 'N-1' under the contexts/ directory.

/sys/kernel/mm/damon/admin/kdamonds/<K>/pid

Defined on file *sysfs-kernel-mm-damon*

Reading this file returns the pid of the kdamond if it is running.

/sys/kernel/mm/damon/admin/kdamonds/<K>/state

Defined on file *sysfs-kernel-mm-damon*

Writing 'on' or 'off' to this file makes the kdamond starts or stops, respectively. Reading the file returns the keywords based on the current status. Writing 'commit' to this file makes the kdamond reads the user inputs in the sysfs files except 'state' again. Writing 'commit_schemes_quota_goals' to this file makes the kdamond reads the quota goal files again. Writing 'update_schemes_stats' to the file updates contents of schemes stats files of the kdamond. Writing 'update_schemes_tried_regions' to the file updates contents of 'tried_regions' directory of every scheme directory of this kdamond. Writing 'update_schemes_tried_bytes' to the file updates only '.../tried_regions/total_bytes' files of this kdamond. Writing 'clear_schemes_tried_regions' to the file removes contents of the 'tried_regions' directory.

/sys/kernel/mm/damon/admin/kdamonds/nr_kdamonds

Defined on file *sysfs-kernel-mm-damon*

Writing a number 'N' to this file creates the number of directories for controlling each DAMON worker thread (kdamond) named '0' to 'N-1' under the kdamonds/ directory.

/sys/kernel/mm/hugepages/

Defined on file *sysfs-kernel-mm-hugepages*

/sys/kernel/mm/hugepages/ contains a number of subdirectories of the form hugepages-<size>kB, where <size> is the page size of the hugepages supported by the kernel/CPU combination.

Under these directories are a number of files:

- nr_hugepages
- nr_overcommit_hugepages
- free_hugepages

- surplus_hugepages
- resv_hugepages

See *HugeTLB Pages* for details.

/sys/kernel/mm/ksm

Defined on file *sysfs-kernel-mm-ksm*

Interface for Kernel Samepage Merging (KSM)

/sys/kernel/mm/ksm/full_scans
/sys/kernel/mm/ksm/pages_shared
/sys/kernel/mm/ksm/pages_sharing
/sys/kernel/mm/ksm/pages_to_scan
/sys/kernel/mm/ksm/pages_unshared
/sys/kernel/mm/ksm/pages_volatile
/sys/kernel/mm/ksm/run
/sys/kernel/mm/ksm/sleep_millisecs

Defined on file *sysfs-kernel-mm-ksm*

Kernel Samepage Merging daemon sysfs interface

full_scans: how many times all mergeable areas have been scanned.

pages_shared: how many shared pages are being used.

pages_sharing: how many more sites are sharing them i.e. how much saved.

pages_to_scan: how many present pages to scan before ksmd goes to sleep.

pages_unshared: how many pages unique but repeatedly checked for merging.

pages_volatile: how many pages changing too fast to be placed in a tree.

run: write 0 to disable ksm, read 0 while ksm is disabled.

- write 1 to run ksm, read 1 while ksm is running.
- write 2 to disable ksm and unmerge all its pages.

sleep_millisecs: how many milliseconds ksm should sleep between scans.

See /mm/ksm for more information.

/sys/kernel/mm/ksm/general_profit

Defined on file *sysfs-kernel-mm-ksm*

Measure how effective KSM is. general_profit: how effective is KSM. The formula for the calculation is in *Kernel Samepage Merging*.

/sys/kernel/mm/ksm/merge_across_nodes

Defined on file *sysfs-kernel-mm-ksm*

Control merging pages across different NUMA nodes.

When it is set to 0 only pages from the same node are merged, otherwise pages from all nodes can be merged together (default).

/sys/kernel/mm/numa/

Defined on file *sysfs-kernel-mm-numa*

Interface for NUMA

/sys/kernel/mm/numa/demotion_enabled

Defined on file *sysfs-kernel-mm-numa*

Enable/disable demoting pages during reclaim

Page migration during reclaim is intended for systems with tiered memory configurations. These systems have multiple types of memory with varied performance characteristics instead of plain NUMA systems where the same kind of memory is found at varied distances. Allowing page migration during reclaim enables these systems to migrate pages from fast tiers to slow tiers when the fast tier is under pressure. This migration is performed before swap. It may move data to a NUMA node that does not fall into the cpuset of the allocating process which might be construed to violate the guarantees of cpusets. This should not be enabled on systems which need strict cpuset location guarantees.

/sys/kernel/mm/swap/

Defined on file *sysfs-kernel-mm-swap*

Interface for swapping

/sys/kernel/mm/swap/vma_ra_enabled

Defined on file *sysfs-kernel-mm-swap*

Enable/disable VMA based swap readahead.

If set to true, the VMA based swap readahead algorithm will be used for swappable anonymous pages mapped in a VMA, and the global swap readahead algorithm will be still used for tmpfs etc. other users. If set to false, the global swap readahead algorithm will be used for all swappable pages.

/sys/kernel/oops_count

Defined on file *sysfs-kernel-oops_count*

Shows how many times the system has Oopsed since last boot.

/sys/kernel/profiling

Defined on file *sysfs-profiling*

/sys/kernel/profiling is the runtime equivalent of the boot-time profile= option.

You can get the same effect running:

```
echo 2 > /sys/kernel/profiling
```

as you would by issuing profile=2 on the boot command line.

/sys/kernel/reboot

Defined on file *sysfs-kernel-reboot*

Interface to set the kernel reboot behavior, similarly to what can be done via the reboot= cmd-line option. (see *The kernel's command-line parameters*)

/sys/kernel/reboot/cpu

Defined on file *sysfs-kernel-reboot*

CPU number to use to reboot.

/sys/kernel/reboot/force

Defined on file *sysfs-kernel-reboot*

Don't wait for any other CPUs on reboot and avoid anything that could hang.

/sys/kernel/reboot/mode

Defined on file *sysfs-kernel-reboot*

Reboot mode. Valid values are: cold warm hard soft gpio

/sys/kernel/reboot/type

Defined on file *sysfs-kernel-reboot*

Reboot type. Valid values are: bios acpi kbd triple efi pci

/sys/kernel/security/*/evm/evm_xattrs

Defined on file *evm*

Shows the set of extended attributes used to calculate or validate the EVM signature, and allows additional attributes to be added at runtime. Any signatures generated after additional attributes are added (and on files possessing those additional attributes) will only be valid if the same additional attributes are configured on system boot. Writing a single period (.) will lock the xattr list from any further modification.

/sys/kernel/security/*/ima/policy

Defined on file *ima_policy*

The Trusted Computing Group(TCG) runtime Integrity Measurement Architecture(IMA) maintains a list of hash values of executables and other sensitive system files loaded into the run-time of this system. At runtime, the policy can be constrained based on LSM specific data. Policies are loaded into the securityfs file ima/policy by opening the file, writing the rules one at a time and then closing the file. The new policy takes effect after the file ima/policy is closed.

IMA appraisal, if configured, uses these file measurements for local measurement appraisal.

```
rule format: action [condition ...]

action: measure | dont_measure | appraise | dont_appraise |
        audit | hash | dont_hash
condition:= base | lsm  [option]
      base:   [[func=] [mask=] [fsmagic=] [fsuuid=] [fsname=]
              [uid=] [euid=] [gid=] [egid=]
              [fowner=] [fgroup=]]
      lsm:    [[subj_user=] [subj_role=] [subj_type=]
               [obj_user=] [obj_role=] [obj_type=]]
      option: [digest_type=] [template=] [permit_directio]
              [appraise_type=] [appraise_flag=]
              [appraise_algos=] [keyrings=]
base:
      func:= [BPRM_CHECK][MMAP_CHECK][CREDS_CHECK][FILE_CHECK][MODULE_CHECK]
              [FIRMWARE_CHECK]
              [KEXEC_KERNEL_CHECK] [KEXEC_INITRAMFS_CHECK]
              [KEXEC_CMDLINE] [KEY_CHECK] [CRITICAL_DATA]
              [SETXATTR_CHECK][MMAP_CHECK_REQPROT]
      mask:= [[^]MAY_READ] [[^]MAY_WRITE] [[^]MAY_APPEND]
             [[^]MAY_EXEC]
      fsmagic:= hex value
      fsuuid:= file system UUID (e.g 8bcbe394-4f13-4144-be8e-5aa9ea2ce2f6)
      uid:= decimal value
      euid:= decimal value
      gid:= decimal value
      egid:= decimal value
      fowner:= decimal value
      fgroup:= decimal value
lsm:  are LSM specific
option:
      appraise_type:= [imasig] | [imasig|modsig] | [sigv3]
          where 'imasig' is the original or the signature
              format v2.
          where 'modsig' is an appended signature,
          where 'sigv3' is the signature format v3. (Currently
              limited to fsverity digest based signatures
              stored in security.ima xattr. Requires
              specifying "digest_type=verity" first.)

      appraise_flag:= [check_blacklist] (deprecated)
      Setting the check_blacklist flag is no longer necessary.
      All appraisal functions set it by default.
      digest_type:= verity
```

```
          Require fs-verity's file digest instead of the
          regular IMA file hash.
      keyrings:= list of keyrings
      (eg, .builtin_trusted_keys|.ima). Only valid
      when action is "measure" and func is KEY_CHECK.
      template:= name of a defined IMA template type
      (eg, ima-ng). Only valid when action is "measure".
      pcr:= decimal value
      label:= [selinux]|[kernel_info]|[data_label]
      data_label:= a unique string used for grouping and limiting critical␣
↪data.
      For example, "selinux" to measure critical data for SELinux.
      appraise_algos:= comma-separated list of hash algorithms
      For example, "sha256,sha512" to only accept to appraise
      files where the security.ima xattr was hashed with one
      of these two algorithms.

default policy:
      # PROC_SUPER_MAGIC
      dont_measure fsmagic=0x9fa0
      dont_appraise fsmagic=0x9fa0
      # SYSFS_MAGIC
      dont_measure fsmagic=0x62656572
      dont_appraise fsmagic=0x62656572
      # DEBUGFS_MAGIC
      dont_measure fsmagic=0x64626720
      dont_appraise fsmagic=0x64626720
      # TMPFS_MAGIC
      dont_measure fsmagic=0x01021994
      dont_appraise fsmagic=0x01021994
      # RAMFS_MAGIC
      dont_appraise fsmagic=0x858458f6
      # DEVPTS_SUPER_MAGIC
      dont_measure fsmagic=0x1cd1
      dont_appraise fsmagic=0x1cd1
      # BINFMTFS_MAGIC
      dont_measure fsmagic=0x42494e4d
      dont_appraise fsmagic=0x42494e4d
      # SECURITYFS_MAGIC
      dont_measure fsmagic=0x73636673
      dont_appraise fsmagic=0x73636673
      # SELINUX_MAGIC
      dont_measure fsmagic=0xf97cff8c
      dont_appraise fsmagic=0xf97cff8c
      # CGROUP_SUPER_MAGIC
      dont_measure fsmagic=0x27e0eb
      dont_appraise fsmagic=0x27e0eb
      # NSFS_MAGIC
      dont_measure fsmagic=0x6e736673
      dont_appraise fsmagic=0x6e736673
```

```
measure func=BPRM_CHECK
measure func=FILE_MMAP mask=MAY_EXEC
measure func=FILE_CHECK mask=MAY_READ uid=0
measure func=MODULE_CHECK
measure func=FIRMWARE_CHECK
appraise fowner=0
```

The default policy measures all executables in bprm_check, all files mmapped executable in file_mmap, and all files open for read by root in do_filp_open. The default appraisal policy appraises all files owned by root.

Examples of LSM specific definitions:

SELinux:

```
dont_measure obj_type=var_log_t
dont_appraise obj_type=var_log_t
dont_measure obj_type=auditd_log_t
dont_appraise obj_type=auditd_log_t
measure subj_user=system_u func=FILE_CHECK mask=MAY_READ
measure subj_role=system_r func=FILE_CHECK mask=MAY_READ
```

Smack:

```
measure subj_user=_ func=FILE_CHECK mask=MAY_READ
```

Example of measure rules using alternate PCRs:

```
measure func=KEXEC_KERNEL_CHECK pcr=4
measure func=KEXEC_INITRAMFS_CHECK pcr=5
```

Example of appraise rule allowing modsig appended signatures:

appraise func=KEXEC_KERNEL_CHECK appraise_type=imasig|modsig

Example of measure rule using KEY_CHECK to measure all keys:

measure func=KEY_CHECK

Example of measure rule using KEY_CHECK to only measure keys added to .builtin_trusted_keys or .ima keyring:

measure func=KEY_CHECK keyrings=.builtin_trusted_keys|.ima

Example of the special SETXATTR_CHECK appraise rule, that restricts the hash algorithms allowed when writing to the security.ima xattr of a file:

appraise func=SETXATTR_CHECK appraise_algos=sha256,sha384,sha512

Example of a 'measure' rule requiring fs-verity's digests with indication of type of digest in the measurement list.

measure func=FILE_CHECK digest_type=verity
template=ima-ngv2

Example of 'measure' and 'appraise' rules requiring fs-verity signatures (format version 3) stored in security.ima xattr.

The 'measure' rule specifies the 'ima-sigv3' template option, which includes the indication of type of digest and the file signature in the measurement list.

measure func=BPRM_CHECK digest_type=verity
template=ima-sigv3

The 'appraise' rule specifies the type and signature format version (sigv3) required.

appraise func=BPRM_CHECK digest_type=verity
appraise_type=sigv3

All of these policy rules could, for example, be constrained either based on a filesystem's UUID (fsuuid) or based on LSM labels.

/sys/kernel/security/evm
/sys/kernel/security/*/evm

Defined on file *evm*

EVM protects a file's security extended attributes(xattrs) against integrity attacks. The initial method maintains an HMAC-sha1 value across the extended attributes, storing the value as the extended attribute 'security.evm'.

EVM supports two classes of security.evm. The first is an HMAC-sha1 generated locally with a trusted/encrypted key stored in the Kernel Key Retention System. The second is a digital signature generated either locally or remotely using an asymmetric key. These keys are loaded onto root's keyring using keyctl, and EVM is then enabled by echoing a value to <securityfs>/evm made up of the following bits:

Bit	Effect
0	Enable HMAC validation and creation
1	Enable digital signature validation
2	Permit modification of EVM-protected metadata at runtime. Not supported if HMAC validation and creation is enabled (deprecated).
31	Disable further runtime modification of EVM policy

For example:

```
echo 1 ><securityfs>/evm
```

will enable HMAC validation and creation

```
echo 0x80000003 ><securityfs>/evm
```

will enable HMAC and digital signature validation and HMAC creation and disable all further modification of policy.

```
echo 0x80000006 ><securityfs>/evm
```

will enable digital signature validation, permit modification of EVM-protected metadata and disable all further modification of policy. This option is now deprecated in favor of:

```
echo 0x80000002 ><securityfs>/evm
```

as the outstanding issues that prevent the usage of EVM portable signatures have been solved.

Echoing a value is additive, the new value is added to the existing initialization flags.

For example, after:

```
echo 2 ><securityfs>/evm
```

another echo can be performed:

```
echo 1 ><securityfs>/evm
```

and the resulting value will be 3.

Note that once an HMAC key has been loaded, it will no longer be possible to enable metadata modification. Signaling that an HMAC key has been loaded will clear the corresponding flag. For example, if the current value is 6 (2 and 4 set):

```
echo 1 ><securityfs>/evm
```

will set the new value to 3 (4 cleared).

Loading an HMAC key is the only way to disable metadata modification.

Until key loading has been signaled EVM can not create or validate the 'security.evm' xattr, but returns INTEGRITY_UNKNOWN. Loading keys and signaling EVM should be done as early as possible. Normally this is done in the initramfs, which has already been measured as part of the trusted boot. For more information on creating and loading existing trusted/encrypted keys, refer to: /security/keys/trusted-encrypted. Both dracut (via 97masterkey and 98integrity) and systemd (via core/ima-setup) have support for loading keys at boot time.

/sys/kernel/slab

Defined on file *sysfs-kernel-slab*

The */sys/kernel/slab* directory contains a snapshot of the internal state of the SLUB allocator for each cache. Certain files may be modified to change the behavior of the cache (and any cache it aliases, if any).

Users: kernel memory tuning tools

/sys/kernel/slab/<cache>/aliases

Defined on file *sysfs-kernel-slab*

The aliases file is read-only and specifies how many caches have merged into this cache.

/sys/kernel/slab/<cache>/align

Defined on file *sysfs-kernel-slab*

The align file is read-only and specifies the cache's object alignment in bytes.

/sys/kernel/slab/<cache>/alloc_calls

Defined on file *sysfs-kernel-slab*

The alloc_calls file is read-only and lists the kernel code locations from which allocations for this cache were performed. The alloc_calls file only contains information if debugging is enabled for that cache (see /mm/slub).

/sys/kernel/slab/<cache>/alloc_fastpath

Defined on file *sysfs-kernel-slab*

The alloc_fastpath file shows how many objects have been allocated using the fast path. It can be written to clear the current count. Available when CONFIG_SLUB_STATS is enabled.

/sys/kernel/slab/<cache>/alloc_from_partial

Defined on file *sysfs-kernel-slab*

The alloc_from_partial file shows how many times a cpu slab has been full and it has been refilled by using a slab from the list of partially used slabs. It can be written to clear the current count. Available when CONFIG_SLUB_STATS is enabled.

/sys/kernel/slab/<cache>/alloc_refill

Defined on file *sysfs-kernel-slab*

The alloc_refill file shows how many times the per-cpu freelist was empty but there were objects available as the result of remote cpu frees. It can be written to clear the current count. Available when CONFIG_SLUB_STATS is enabled.

/sys/kernel/slab/<cache>/alloc_slab

Defined on file *sysfs-kernel-slab*

The alloc_slab file is shows how many times a new slab had to be allocated from the page allocator. It can be written to clear the current count. Available when CONFIG_SLUB_STATS is enabled.

/sys/kernel/slab/<cache>/alloc_slowpath

Defined on file *sysfs-kernel-slab*

The alloc_slowpath file shows how many objects have been allocated using the slow path because of a refill or allocation from a partial or new slab. It can be written to clear the current count. Available when CONFIG_SLUB_STATS is enabled.

/sys/kernel/slab/<cache>/cache_dma

Defined on file *sysfs-kernel-slab*

The cache_dma file is read-only and specifies whether objects are from ZONE_DMA. Available when CONFIG_ZONE_DMA is enabled.

/sys/kernel/slab/<cache>/cpu_partial

Defined on file *sysfs-kernel-slab*

This read-only file shows the number of per cpu partial pages to keep around.

/sys/kernel/slab/<cache>/cpu_slabs

Defined on file *sysfs-kernel-slab*

The cpu_slabs file is read-only and displays how many cpu slabs are active and their NUMA locality.

/sys/kernel/slab/<cache>/cpuslab_flush

Defined on file *sysfs-kernel-slab*

The file cpuslab_flush shows how many times a cache's cpu slabs have been flushed as the result of destroying or shrinking a cache, a cpu going offline, or as the result of forcing an allocation from a certain node. It can be written to clear the current count. Available when CONFIG_SLUB_STATS is enabled.

/sys/kernel/slab/<cache>/ctor

Defined on file *sysfs-kernel-slab*

The ctor file is read-only and specifies the cache's object constructor function, which is invoked for each object when a new slab is allocated.

/sys/kernel/slab/<cache>/deactivate_empty

Defined on file *sysfs-kernel-slab*

The deactivate_empty file shows how many times an empty cpu slab was deactivated. It can be written to clear the current count. Available when CONFIG_SLUB_STATS is enabled.

/sys/kernel/slab/<cache>/deactivate_full

Defined on file *sysfs-kernel-slab*

The deactivate_full file shows how many times a full cpu slab was deactivated. It can be written to clear the current count. Available when CONFIG_SLUB_STATS is enabled.

/sys/kernel/slab/<cache>/deactivate_remote_frees

Defined on file *sysfs-kernel-slab*

The deactivate_remote_frees file shows how many times a cpu slab has been deactivated and contained free objects that were freed remotely. It can be written to clear the current count. Available when CONFIG_SLUB_STATS is enabled.

/sys/kernel/slab/<cache>/deactivate_to_head

Defined on file *sysfs-kernel-slab*

The deactivate_to_head file shows how many times a partial cpu slab was deactivated and added to the head of its node's partial list. It can be written to clear the current count. Available when CONFIG_SLUB_STATS is enabled.

/sys/kernel/slab/<cache>/deactivate_to_tail

Defined on file *sysfs-kernel-slab*

The deactivate_to_tail file shows how many times a partial cpu slab was deactivated and added to the tail of its node's partial list. It can be written to clear the current count. Available when CONFIG_SLUB_STATS is enabled.

/sys/kernel/slab/<cache>/destroy_by_rcu

Defined on file *sysfs-kernel-slab*

The destroy_by_rcu file is read-only and specifies whether slabs (not objects) are freed by rcu.

/sys/kernel/slab/<cache>/free_add_partial

Defined on file *sysfs-kernel-slab*

The free_add_partial file shows how many times an object has been freed in a full slab so that it had to added to its node's partial list. It can be written to clear the current count. Available when CONFIG_SLUB_STATS is enabled.

/sys/kernel/slab/<cache>/free_calls

Defined on file *sysfs-kernel-slab*

The free_calls file is read-only and lists the locations of object frees if slab debugging is enabled (see /mm/slub).

/sys/kernel/slab/<cache>/free_fastpath

Defined on file *sysfs-kernel-slab*

The free_fastpath file shows how many objects have been freed using the fast path because it was an object from the cpu slab. It can be written to clear the current count. Available when CONFIG_SLUB_STATS is enabled.

/sys/kernel/slab/<cache>/free_frozen

Defined on file *sysfs-kernel-slab*

The free_frozen file shows how many objects have been freed to a frozen slab (i.e. a remote cpu slab). It can be written to clear the current count. Available when CONFIG_SLUB_STATS is enabled.

/sys/kernel/slab/<cache>/free_remove_partial

Defined on file *sysfs-kernel-slab*

The free_remove_partial file shows how many times an object has been freed to a now-empty slab so that it had to be removed from its node's partial list. It can be written to clear the current count. Available when CONFIG_SLUB_STATS is enabled.

/sys/kernel/slab/<cache>/free_slab

Defined on file *sysfs-kernel-slab*

The free_slab file shows how many times an empty slab has been freed back to the page allocator. It can be written to clear the current count. Available when CONFIG_SLUB_STATS is enabled.

/sys/kernel/slab/<cache>/free_slowpath

Defined on file *sysfs-kernel-slab*

The free_slowpath file shows how many objects have been freed using the slow path (i.e. to a full or partial slab). It can be written to clear the current count. Available when CONFIG_SLUB_STATS is enabled.

/sys/kernel/slab/<cache>/hwcache_align

Defined on file *sysfs-kernel-slab*

The hwcache_align file is read-only and specifies whether objects are aligned on cachelines.

/sys/kernel/slab/<cache>/min_partial

Defined on file *sysfs-kernel-slab*

The min_partial file specifies how many empty slabs shall remain on a node's partial list to avoid the overhead of allocating new slabs. Such slabs may be reclaimed by utilizing the shrink file.

/sys/kernel/slab/<cache>/object_size

Defined on file *sysfs-kernel-slab*

The object_size file is read-only and specifies the cache's object size.

/sys/kernel/slab/<cache>/objects

Defined on file *sysfs-kernel-slab*

The objects file is read-only and displays how many objects are active and from which nodes they are from.

/sys/kernel/slab/<cache>/objects_partial

Defined on file *sysfs-kernel-slab*

The objects_partial file is read-only and displays how many objects are on partial slabs and from which nodes they are from.

/sys/kernel/slab/<cache>/objs_per_slab

Defined on file *sysfs-kernel-slab*

The file objs_per_slab is read-only and specifies how many objects may be allocated from a single slab of the order specified in */sys/kernel/slab/<cache>/order*.

/sys/kernel/slab/<cache>/order

Defined on file *sysfs-kernel-slab*

The order file specifies the page order at which new slabs are allocated. It is writable and can be changed to increase the number of objects per slab. If a slab cannot be allocated because of fragmentation, SLUB will retry with the minimum order possible depending on its characteristics.

When debug_guardpage_minorder=N (N > 0) parameter is specified (see *The kernel's command-line parameters*), the minimum possible order is used and this sysfs entry can not be used to change the order at run time.

/sys/kernel/slab/<cache>/order_fallback

Defined on file *sysfs-kernel-slab*

The order_fallback file shows how many times an allocation of a new slab has not been possible at the cache's order and instead fallen back to its minimum possible order. It can be written to clear the current count.

Available when CONFIG_SLUB_STATS is enabled.

/sys/kernel/slab/<cache>/partial

Defined on file *sysfs-kernel-slab*

The partial file is read-only and displays how long many partial slabs there are and how long each node's list is.

/sys/kernel/slab/<cache>/poison

Defined on file *sysfs-kernel-slab*

The poison file specifies whether objects should be poisoned when a new slab is allocated.

/sys/kernel/slab/<cache>/reclaim_account

Defined on file *sysfs-kernel-slab*

The reclaim_account file specifies whether the cache's objects are reclaimable (and grouped by their mobility).

/sys/kernel/slab/<cache>/red_zone

Defined on file *sysfs-kernel-slab*

The red_zone file specifies whether the cache's objects are red zoned.

/sys/kernel/slab/<cache>/remote_node_defrag_ratio

Defined on file *sysfs-kernel-slab*

The file remote_node_defrag_ratio specifies the percentage of times SLUB will attempt to refill the cpu slab with a partial slab from a remote node as opposed to allocating a new slab on the local node. This reduces the amount of wasted memory over the entire system but can be expensive.

Available when CONFIG_NUMA is enabled.

/sys/kernel/slab/<cache>/sanity_checks

Defined on file *sysfs-kernel-slab*

The sanity_checks file specifies whether expensive checks should be performed on free and, at minimum, enables double free checks. Caches that enable sanity_checks cannot be merged with caches that do not.

/sys/kernel/slab/<cache>/shrink

Defined on file *sysfs-kernel-slab*

The shrink file is used to reclaim unused slab cache memory from a cache. Empty per-cpu or partial slabs are freed and the partial list is sorted so the slabs with the fewest available objects are used first. It only accepts a value of "1" on write for shrinking the cache. Other input values are considered invalid. Shrinking slab caches might be expensive and can adversely impact other running applications. So it should be used with care.

/sys/kernel/slab/<cache>/slab_size

Defined on file *sysfs-kernel-slab*

The slab_size file is read-only and specifies the object size with metadata (debugging information and alignment) in bytes.

/sys/kernel/slab/<cache>/slabs

Defined on file *sysfs-kernel-slab*

The slabs file is read-only and displays how long many slabs there are (both cpu and partial) and from which nodes they are from.

/sys/kernel/slab/<cache>/slabs_cpu_partial

Defined on file *sysfs-kernel-slab*

This read-only file shows the number of partialli allocated frozen slabs.

/sys/kernel/slab/<cache>/store_user

Defined on file *sysfs-kernel-slab*

The store_user file specifies whether the location of allocation or free should be tracked for a cache.

/sys/kernel/slab/<cache>/total_objects

Defined on file *sysfs-kernel-slab*

The total_objects file is read-only and displays how many total objects a cache has and from which nodes they are from.

/sys/kernel/slab/<cache>/trace

Defined on file *sysfs-kernel-slab*

The trace file specifies whether object allocations and frees should be traced.

/sys/kernel/slab/<cache>/usersize

Defined on file *sysfs-kernel-slab*

The usersize file is read-only and contains the usercopy region size.

/sys/kernel/slab/<cache>/validate

Defined on file *sysfs-kernel-slab*

Writing to the validate file causes SLUB to traverse all of its cache's objects and check the validity of metadata.

/sys/kernel/vmcoreinfo

Defined on file *sysfs-kernel-vmcoreinfo*

Shows physical address and size of vmcoreinfo ELF note. First value contains physical address of note in hex and second value contains the size of note in hex. This ELF note info is parsed by second kernel and exported to user space as part of ELF note in /proc/vmcore file. This note contains various information like struct size, symbol values, page size etc.

/sys/kernel/warn_count

Defined on file *sysfs-kernel-warn_count*

Shows how many times the system has Warned since last boot.

5.2.39 Symbols under /sys/module

/sys/module/*/initstate

Defined on file *sysfs-module*

Show the initialization state(live, coming, going) of the module.

/sys/module/*/taint

Defined on file *sysfs-module*

Module taint flags:

P	proprietary module
O	out-of-tree module
F	force-loaded module
C	staging driver module
E	unsigned module

/sys/module/*/{coresize,initsize}

Defined on file *sysfs-module*

Module size in bytes.

/sys/module/ehci_hcd/drivers/.../uframe_periodic_max

Defined on file *sysfs-module*

Maximum time allowed for periodic transfers per microframe (µs)

Note:

USB 2.0 sets maximum allowed time for periodic transfers per microframe to be 80%, that is 100 microseconds out of 125 microseconds (full microframe).

However there are cases, when 80% max isochronous bandwidth is too limiting. For example two video streams could require 110 microseconds of isochronous bandwidth per microframe to work together.

Through this setting it is possible to raise the limit so that the host controller would allow allocating more than 100 microseconds of periodic bandwidth per microframe.

Beware, non-standard modes are usually not thoroughly tested by hardware designers, and the hardware can malfunction when this setting differ from default 100.

/sys/module/grant_table/parameters/free_per_iteration

Defined on file *sysfs-module*

Read and write number of grant entries to attempt to free per iteration.

Note: Future versions of Xen and Linux may provide a better interface for controlling the rate of deferred grant reclaim or may not need it at all.

Users: Qubes OS (https://www.qubes-os.org)

/sys/module/pch_phub/drivers/.../pch_firmware

Defined on file *sysfs-module*

Write/read Option ROM data.

/sys/module/pch_phub/drivers/.../pch_mac

Defined on file *sysfs-module*

Write/read GbE MAC address.

/sys/module/xen_blkback/parameters/buffer_squeeze_duration_ms

Defined on file *sysfs-driver-xen-blkback*

When memory pressure is reported to blkback this option controls the duration in milliseconds that blkback will not cache any page not backed by a grant mapping. The default is 10ms.

/sys/module/xen_blkback/parameters/feature_persistent

Defined on file *sysfs-driver-xen-blkback*

Whether to enable the persistent grants feature or not. Note that this option only takes effect on newly connected backends. The default is Y (enable).

/sys/module/xen_blkback/parameters/max_buffer_pages

Defined on file *sysfs-driver-xen-blkback*

Maximum number of free pages to keep in each block backend buffer.

/sys/module/xen_blkback/parameters/max_persistent_grants

Defined on file *sysfs-driver-xen-blkback*

Maximum number of grants to map persistently in blkback. If the frontend tries to use more than max_persistent_grants, the LRU kicks in and starts removing 5% of max_persistent_grants every 100ms.

/sys/module/xen_blkback/parameters/persistent_grant_unused_seconds

Defined on file *sysfs-driver-xen-blkback*

How long a persistent grant is allowed to remain allocated without being in use. The time is in seconds, 0 means indefinitely long. The default is 60 seconds.

/sys/module/xen_blkfront/parameters/feature_persistent

Defined on file *sysfs-driver-xen-blkfront*

Whether to enable the persistent grants feature or not. Note that this option only takes effect on newly connected frontends. The default is Y (enable).

/sys/module/xen_blkfront/parameters/max_indirect_segments

Defined on file *sysfs-driver-xen-blkfront*

Maximum number of segments that the frontend will negotiate with the backend for indirect descriptors. The default value is 32 - higher value means more potential throughput but more memory usage. The backend picks the minimum of the frontend and its default backend value.

5.2.40 Symbols under /sys/power

/sys/power/

Defined on file *sysfs-power*

The /sys/power directory will contain files that will provide a unified interface to the power management subsystem.

/sys/power/autosleep

Defined on file *sysfs-power*

The */sys/power/autosleep* file can be written one of the strings returned by reads from */sys/power/state*. If that happens, a work item attempting to trigger a transition of the system to the sleep state represented by that string is queued up. This attempt will only succeed if there are no active wakeup sources in the system at that time. After every execution, regardless of whether or not the attempt to put the system to sleep has succeeded, the work item requeues itself until user space writes "off" to */sys/power/autosleep*.

Reading from this file causes the last string successfully written to it to be returned.

/sys/power/disk

Defined on file *sysfs-power*

The */sys/power/disk* file controls the operating mode of the suspend-to-disk mechanism. Reading from this file returns the name of the method by which the system will be put to sleep on the next suspend. There are four methods supported:

'firmware' - means that the memory image will be saved to disk by some firmware, in which case we also assume that the firmware will handle the system suspend.

'platform' - the memory image will be saved by the kernel and the system will be put to sleep by the platform driver (e.g. ACPI or other PM registers).

'shutdown' - the memory image will be saved by the kernel and the system will be powered off.

'reboot' - the memory image will be saved by the kernel and the system will be rebooted.

Additionally, */sys/power/disk* can be used to turn on one of the two testing modes of the suspend-to-disk mechanism: 'testproc' or 'test'. If the suspend-to-disk mechanism is in the 'testproc' mode, writing 'disk' to */sys/power/state* will cause the kernel to disable nonboot CPUs and freeze tasks, wait for 5 seconds, unfreeze tasks and enable nonboot CPUs. If it is in the 'test' mode, writing 'disk' to */sys/power/state* will cause the kernel to disable nonboot CPUs and freeze tasks, shrink memory, suspend devices, wait for 5 seconds, resume devices, unfreeze tasks and enable nonboot CPUs. Then, we are able to look in the log messages and work out, for example, which code is being slow and which device drivers are misbehaving.

The suspend-to-disk method may be chosen by writing to this file one of the accepted strings:

- 'firmware'
- 'platform'
- 'shutdown'
- 'reboot'
- 'testproc'
- 'test'

It will only change to 'firmware' or 'platform' if the system supports that.

/sys/power/image_size

Defined on file *sysfs-power*

The */sys/power/image_size* file controls the size of the image created by the suspend-to-disk mechanism. It can be written a string representing a non-negative integer that will be used as an upper limit of the image size, in bytes. The kernel's suspend-to-disk code will do its best to ensure the image size will not exceed this number. However, if it turns out to be impossible, the kernel will try to suspend anyway using the smallest image possible. In particular, if ”0” is written to this file, the suspend image will be as small as possible.

Reading from this file will display the current image size limit, which is set to around 2/5 of available RAM by default.

/sys/power/mem_sleep

Defined on file *sysfs-power*

The */sys/power/mem_sleep* file controls the operating mode of system suspend. Reading from it returns the available modes as ”s2idle” (always present), ”shallow” and ”deep” (present if supported). The mode that will be used on subsequent attempts to suspend the system (by writing ”mem” to the */sys/power/state* file described above) is enclosed in square brackets.

Writing one of the above strings to this file causes the mode represented by it to be used on subsequent attempts to suspend the system.

See *System Sleep States* for more information.

/sys/power/pm_async

Defined on file *sysfs-power*

The */sys/power/pm_async* file controls the switch allowing the user space to enable or disable asynchronous suspend and resume of devices. If enabled, this feature will cause some device drivers' suspend and resume callbacks to be executed in parallel with each other and with the main suspend thread. It is enabled if this file contains "1", which is the default. It may be disabled by writing "0" to this file, in which case all devices will be suspended and resumed synchronously.

/sys/power/pm_debug_messages

Defined on file *sysfs-power*

The */sys/power/pm_debug_messages* file controls the printing of debug messages from the system suspend/hiberbation infrastructure to the kernel log.

Writing a "1" to this file enables the debug messages and writing a "0" (default) to it disables them. Reads from this file return the current value.

/sys/power/pm_print_times

Defined on file *sysfs-power*

The */sys/power/pm_print_times* file allows user space to control whether the time taken by devices to suspend and resume is printed. These prints are useful for hunting down devices that take too long to suspend or resume.

Writing a "1" enables this printing while writing a "0" disables it. The default value is "0". Reading from this file will display the current value.

/sys/power/pm_trace

Defined on file *sysfs-power*

The */sys/power/pm_trace* file controls the code which saves the last PM event point in the RTC across reboots, so that you can debug a machine that just hangs during suspend (or more commonly, during resume). Namely, the RTC is only used to save the last PM event point if this file contains '1'. Initially it contains '0' which may be changed to '1' by writing a string representing a nonzero integer into it.

To use this debugging feature you should attempt to suspend the machine, then reboot it and run:

```
dmesg -s 1000000 | grep 'hash matches'
```

If you do not get any matches (or they appear to be false positives), it is possible that the last PM event point referred to a device created by a loadable kernel module. In this case cat /sys/power/pm_trace_dev_match (see below) after your system is started up and the kernel modules are loaded.

CAUTION: Using it will cause your machine's real-time (CMOS) clock to be set to a random invalid time after a resume.

What; /sys/power/pm_trace_dev_match The /sys/power/pm_trace_dev_match file contains the name of the device associated with the last PM event point saved in the RTC across reboots when pm_trace has been used. More precisely it contains the list of current devices (including those registered by loadable kernel modules since boot) which match the device hash in the RTC at boot, with a newline after each one.

The advantage of this file over the hash matches printed to the kernel log (see */sys/power/pm_trace*), is that it includes devices created after boot by loadable kernel modules.

Due to the small hash size necessary to fit in the RTC, it is possible that more than one device matches the hash, in which case further investigation is required to determine which device is causing the problem. Note that genuine RTC clock values (such as when pm_trace has not been used), can still match a device and output its name here.

/sys/power/pm_wakeup_irq

Defined on file *sysfs-power*

The */sys/power/pm_wakeup_irq* file reports to user space the IRQ number of the first wakeup interrupt (that is, the first interrupt from an IRQ line armed for system wakeup) seen by the kernel during the most recent system suspend/resume cycle.

This output is useful for system wakeup diagnostics of spurious wakeup interrupts.

/sys/power/reserved_size

Defined on file *sysfs-power*

The */sys/power/reserved_size* file allows user space to control the amount of memory reserved for allocations made by device drivers during the ”device freeze” stage of hibernation. It can be written a string representing a non-negative integer that will be used as the amount of memory to reserve for allocations made by device drivers' ”freeze” callbacks, in bytes.

Reading from this file will display the current value, which is set to 1 MB by default.

/sys/power/resume_offset

Defined on file *sysfs-power*

This file is used for telling the kernel an offset into a disk to use when hibernating the system such as with a swap file.

Reads from this file will display the current offset the kernel will be using on the next hibernation attempt.

Using this sysfs file will override any values that were set using the kernel command line for disk offset.

/sys/power/state

Defined on file *sysfs-power*

The */sys/power/state* file controls system sleep states. Reading from this file returns the available sleep state labels, which may be "mem" (suspend), "standby" (power-on suspend), "freeze" (suspend-to-idle) and "disk" (hibernation).

Writing one of the above strings to this file causes the system to transition into the corresponding state, if available.

See *System Sleep States* for more information.

/sys/power/suspend_stats

Defined on file *sysfs-power*

The */sys/power/suspend_stats* directory contains suspend related statistics.

/sys/power/suspend_stats/fail

Defined on file *sysfs-power*

The */sys/power/suspend_stats/fail* file contains the number of times entering system sleep state failed.

/sys/power/suspend_stats/failed_freeze

Defined on file *sysfs-power*

The */sys/power/suspend_stats/failed_freeze* file contains the number of times freezing processes failed.

/sys/power/suspend_stats/failed_prepare

Defined on file *sysfs-power*

The */sys/power/suspend_stats/failed_prepare* file contains the number of times preparing all non-sysdev devices for a system PM transition failed.

/sys/power/suspend_stats/failed_resume

Defined on file *sysfs-power*

The */sys/power/suspend_stats/failed_resume* file contains the number of times executing "resume" callbacks of non-sysdev devices failed.

/sys/power/suspend_stats/failed_resume_early

Defined on file *sysfs-power*

The */sys/power/suspend_stats/failed_resume_early* file contains the number of times executing "early resume" callbacks of devices failed.

/sys/power/suspend_stats/failed_resume_noirq

Defined on file *sysfs-power*

The */sys/power/suspend_stats/failed_resume_noirq* file contains the number of times executing "noirq resume" callbacks of devices failed.

/sys/power/suspend_stats/failed_suspend

Defined on file *sysfs-power*

The */sys/power/suspend_stats/failed_suspend* file contains the number of times executing "suspend" callbacks of all non-sysdev devices failed.

/sys/power/suspend_stats/failed_suspend_late

Defined on file *sysfs-power*

The */sys/power/suspend_stats/failed_suspend_late* file contains the number of times executing "late suspend" callbacks of all devices failed.

/sys/power/suspend_stats/failed_suspend_noirq

Defined on file *sysfs-power*

The */sys/power/suspend_stats/failed_suspend_noirq* file contains the number of times executing "noirq suspend" callbacks of all devices failed.

/sys/power/suspend_stats/last_failed_dev

Defined on file *sysfs-power*

The */sys/power/suspend_stats/last_failed_dev* file contains the last device for which a suspend/resume callback failed.

/sys/power/suspend_stats/last_failed_errno

Defined on file *sysfs-power*

The */sys/power/suspend_stats/last_failed_errno* file contains the errno of the last failed attempt at entering system sleep state.

/sys/power/suspend_stats/last_failed_step

Defined on file *sysfs-power*

The */sys/power/suspend_stats/last_failed_step* file contains the last failed step in the suspend/resume path.

/sys/power/suspend_stats/last_hw_sleep

Defined on file *sysfs-power*

The */sys/power/suspend_stats/last_hw_sleep* file contains the duration of time spent in a hardware sleep state in the most recent system suspend-resume cycle. This number is measured in microseconds.

/sys/power/suspend_stats/max_hw_sleep

Defined on file *sysfs-power*

The */sys/power/suspend_stats/max_hw_sleep* file contains the maximum amount of time that the hardware can report for time spent in a hardware sleep state. When sleep cycles are longer than this time, the values for 'total_hw_sleep' and 'last_hw_sleep' may not be accurate. This number is measured in microseconds.

/sys/power/suspend_stats/success

Defined on file *sysfs-power*

The */sys/power/suspend_stats/success* file contains the number of times entering system sleep state succeeded.

/sys/power/suspend_stats/total_hw_sleep

Defined on file *sysfs-power*

The */sys/power/suspend_stats/total_hw_sleep* file contains the aggregate of time spent in a hardware sleep state since the kernel was booted. This number is measured in microseconds.

/sys/power/sync_on_suspend

Defined on file *sysfs-power*

This file controls whether or not the kernel will sync() filesystems during system suspend (after freezing user space and before suspending devices).

Writing a ”1” to this file enables the sync() and writing a ”0” disables it. Reads from the file return the current value. The default is ”1” if the build-time ”SUSPEND_SKIP_SYNC” config flag is unset, or ”0” otherwise.

/sys/power/wake_lock

Defined on file *sysfs-power*

The */sys/power/wake_lock* file allows user space to create wakeup source objects and activate them on demand (if one of those wakeup sources is active, reads from the */sys/power/wakeup_count* file block or return false). When a string without white space is written to */sys/power/wake_lock*, it will be assumed to represent a wakeup source name. If there is a wakeup source object with that name, it will be activated (unless active already). Otherwise, a new wakeup source object will be registered, assigned the given name and activated. If a string written to */sys/power/wake_lock* contains white space, the part of the string preceding the white space will be regarded as a wakeup source name and handled as descrived above. The other part of the string will be regarded as a timeout (in nanoseconds) such that the wakeup

source will be automatically deactivated after it has expired. The timeout, if present, is set regardless of the current state of the wakeup source object in question.

Reads from this file return a string consisting of the names of wakeup sources created with the help of it that are active at the moment, separated with spaces.

/sys/power/wake_unlock

Defined on file *sysfs-power*

The */sys/power/wake_unlock* file allows user space to deactivate wakeup sources created with the help of */sys/power/wake_lock*. When a string is written to */sys/power/wake_unlock*, it will be assumed to represent the name of a wakeup source to deactivate.

If a wakeup source object of that name exists and is active at the moment, it will be deactivated.

Reads from this file return a string consisting of the names of wakeup sources created with the help of */sys/power/wake_lock* that are inactive at the moment, separated with spaces.

/sys/power/wakeup_count

Defined on file *sysfs-power*

The */sys/power/wakeup_count* file allows user space to put the system into a sleep state while taking into account the concurrent arrival of wakeup events. Reading from it returns the current number of registered wakeup events and it blocks if some wakeup events are being processed at the time the file is read from. Writing to it will only succeed if the current number of wakeup events is equal to the written value and, if successful, will make the kernel abort a subsequent transition to a sleep state if any wakeup events are reported after the write has returned.

5.2.41 Raise a uevent when a USB Host Controller has died

Raise a uevent when a USB Host Controller has died

Defined on file *usb-uevent*

When the USB Host Controller has entered a state where it is no longer functional a uevent will be raised. The uevent will contain ACTION=offline and ERROR=DEAD.

Here is an example taken using udevadm monitor -p:

```
KERNEL[130.428945] offline  /devices/pci0000:00/0000:00:10.0/usb2 (usb)
ACTION=offline
BUSNUM=002
DEVNAME=/dev/bus/usb/002/001
DEVNUM=001
DEVPATH=/devices/pci0000:00/0000:00:10.0/usb2
DEVTYPE=usb_device
DRIVER=usb
ERROR=DEAD
MAJOR=189
MINOR=128
```

```
PRODUCT=1d6b/2/414
SEQNUM=2168
SUBSYSTEM=usb
TYPE=9/0/1
```

Users: chromium-os-dev@chromium.org

5.2.42 Raise a uevent when a USB charger is inserted or removed

Raise a uevent when a USB charger is inserted or removed

Defined on file *usb-charger-uevent*

There are two USB charger states:

- USB_CHARGER_ABSENT
- USB_CHARGER_PRESENT

There are five USB charger types:

USB_CHARGER_UNKNOWN_TYPE	Charger type is unknown
USB_CHARGER_SDP_TYPE	Standard Downstream Port
USB_CHARGER_CDP_TYPE	Charging Downstream Port
USB_CHARGER_DCP_TYPE	Dedicated Charging Port
USB_CHARGER_ACA_TYPE	Accessory Charging Adapter

https://www.usb.org/document-library/battery-charging-v12-spec-and-adopters-agreement

Here are two examples taken using `udevadm monitor -p` when USB charger is online:

```
UDEV  change   /devices/soc0/usbphynop1 (platform)
ACTION=change
DEVPATH=/devices/soc0/usbphynop1
DRIVER=usb_phy_generic
MODALIAS=of:Nusbphynop1T(null)Cusb-nop-xceiv
OF_COMPATIBLE_0=usb-nop-xceiv
OF_COMPATIBLE_N=1
OF_FULLNAME=/usbphynop1
OF_NAME=usbphynop1
SEQNUM=2493
SUBSYSTEM=platform
USB_CHARGER_STATE=USB_CHARGER_PRESENT
USB_CHARGER_TYPE=USB_CHARGER_SDP_TYPE
USEC_INITIALIZED=227422826
```

USB charger is offline:

```
KERNEL change   /devices/soc0/usbphynop1 (platform)
ACTION=change
DEVPATH=/devices/soc0/usbphynop1
```

```
DRIVER=usb_phy_generic
MODALIAS=of:Nusbphynop1T(null)Cusb-nop-xceiv
OF_COMPATIBLE_0=usb-nop-xceiv
OF_COMPATIBLE_N=1
OF_FULLNAME=/usbphynop1
OF_NAME=usbphynop1
SEQNUM=2494
SUBSYSTEM=platform
USB_CHARGER_STATE=USB_CHARGER_ABSENT
USB_CHARGER_TYPE=USB_CHARGER_UNKNOWN_TYPE
```

5.2.43 nvdimm

nvdimm

Defined on file *sysfs-bus-nvdimm*

The libnvdimm sub-system implements a common sysfs interface for platform nvdimm resources. See Documentation/driver-api/nvdimm/.

5.2.44 Symbols under security/secrets

security/secrets/coco

Defined on file *securityfs-secrets-coco*

Exposes confidential computing (coco) EFI secrets to userspace via securityfs.

EFI can declare memory area used by confidential computing platforms (such as AMD SEV and SEV-ES) for secret injection by the Guest Owner during VM's launch. The secrets are encrypted by the Guest Owner and decrypted inside the trusted enclave, and therefore are not readable by the untrusted host.

The efi_secret module exposes the secrets to userspace. Each secret appears as a file under <securityfs>/secrets/coco, where the filename is the GUID of the entry in the secrets table. This module is loaded automatically by the EFI driver if the EFI secret area is populated.

Two operations are supported for the files: read and unlink. Reading the file returns the content of secret entry. Unlinking the file overwrites the secret data with zeroes and removes the entry from the filesystem. A secret cannot be read after it has been unlinked.

For example, listing the available secrets:

```
# modprobe efi_secret
# ls -l /sys/kernel/security/secrets/coco
-r--r----- 1 root root 0 Jun 28 11:54 736870e5-84f0-4973-92ec-06879ce3da0b
-r--r----- 1 root root 0 Jun 28 11:54 83c83f7f-1356-4975-8b7e-d3a0b54312c6
-r--r----- 1 root root 0 Jun 28 11:54 9553f55d-3da2-43ee-ab5d-ff17f78864d2
-r--r----- 1 root root 0 Jun 28 11:54 e6f5a162-d67f-4750-a67c-5d065f2a9910
```

Reading the secret data by reading a file:

```
# cat /sys/kernel/security/secrets/coco/e6f5a162-d67f-4750-a67c-5d065f2a9910
the-content-of-the-secret-data
```

Wiping a secret by unlinking a file:

```
# rm /sys/kernel/security/secrets/coco/e6f5a162-d67f-4750-a67c-5d065f2a9910
# ls -l /sys/kernel/security/secrets/coco
-r--r----- 1 root root 0 Jun 28 11:54 736870e5-84f0-4973-92ec-06879ce3da0b
-r--r----- 1 root root 0 Jun 28 11:54 83c83f7f-1356-4975-8b7e-d3a0b54312c6
-r--r----- 1 root root 0 Jun 28 11:54 9553f55d-3da2-43ee-ab5d-ff17f78864d2
```

Note: The binary format of the secrets table injected by the Guest Owner is described in drivers/virt/coco/efi_secret/efi_secret.c under "Structure of the EFI secret area".

5.2.45 File testing/configfs-acpi

Has the following ABI:

- */config/acpi*
- */config/acpi/table*

5.2.46 File testing/configfs-iio

Has the following ABI:

- */config/iio*
- */config/iio/triggers*
- */config/iio/triggers/hrtimers*
- */config/iio/devices*
- */config/iio/devices/dummy*

5.2.47 File testing/configfs-most

Has the following ABI:

- */sys/kernel/config/most_<component>*
- */sys/kernel/config/most_cdev/<link>*
- */sys/kernel/config/most_video/<link>*
- */sys/kernel/config/most_net/<link>*
- */sys/kernel/config/most_sound/<card>*
- */sys/kernel/config/most_sound/<card>/<link>*

5.2.48 File testing/configfs-rdma_cm

Has the following ABI:

- */config/rdma_cm*
- */config/rdma_cm/<hca>/ports/<port-num>/default_roce_mode*
- */config/rdma_cm/<hca>/ports/<port-num>/default_roce_tos*

5.2.49 File testing/configfs-spear-pcie-gadget

Has the following ABI:

- */config/pcie-gadget*

5.2.50 File testing/configfs-stp-policy

Has the following ABI:

- */config/stp-policy*
- */config/stp-policy/<device>.<policy>*
- */config/stp-policy/<device>.<policy>/device*
- */config/stp-policy/<device>.<policy>/<node>*
- */config/stp-policy/<device>.<policy>/<node>/masters*
- */config/stp-policy/<device>.<policy>/<node>/channels*

5.2.51 File testing/configfs-stp-policy-p_sys-t

Has the following ABI:

- */config/stp-policy/<device>:p_sys-t.<policy>/<node>/uuid*
- */config/stp-policy/<device>:p_sys-t.<policy>/<node>/do_len*
- */config/stp-policy/<device>:p_sys-t.<policy>/<node>/ts_interval*
- */config/stp-policy/<device>:p_sys-t.<policy>/<node>/clocksync_interval*

5.2.52 File testing/configfs-tsm

Has the following ABI:

- */sys/kernel/config/tsm/report/$name/inblob*
- */sys/kernel/config/tsm/report/$name/outblob*
- */sys/kernel/config/tsm/report/$name/auxblob*
- */sys/kernel/config/tsm/report/$name/provider*
- */sys/kernel/config/tsm/report/$name/generation*
- */sys/kernel/config/tsm/report/$name/privlevel*

- */sys/kernel/config/tsm/report/$name/privlevel_floor*

5.2.53 File testing/configfs-usb-gadget

Has the following ABI:

- */config/usb-gadget*
- */config/usb-gadget/gadget*
- */config/usb-gadget/gadget/configs*
- */config/usb-gadget/gadget/configs/config*
- */config/usb-gadget/gadget/configs/config/strings*
- */config/usb-gadget/gadget/configs/config/strings/language*

- */config/usb-gadget/gadget/strings*
- */config/usb-gadget/gadget/strings/language*
- */config/usb-gadget/gadget/os_desc*
- */config/usb-gadget/gadget/webusb*

5.2.54 File testing/configfs-usb-gadget-acm

Has the following ABI:

- */config/usb-gadget/gadget/functions/acm.name*

5.2.55 File testing/configfs-usb-gadget-ecm

Has the following ABI:

- */config/usb-gadget/gadget/functions/ecm.name*

5.2.56 File testing/configfs-usb-gadget-eem

Has the following ABI:

- */config/usb-gadget/gadget/functions/eem.name*

5.2.57 File testing/configfs-usb-gadget-ffs

Has the following ABI:

- */config/usb-gadget/gadget/functions/ffs.name*

5.2.58 File testing/configfs-usb-gadget-hid

Has the following ABI:

- */config/usb-gadget/gadget/functions/hid.name*

5.2.59 File testing/configfs-usb-gadget-loopback

Has the following ABI:

- */config/usb-gadget/gadget/functions/Loopback.name*

5.2.60 File testing/configfs-usb-gadget-mass-storage

Has the following ABI:

- */config/usb-gadget/gadget/functions/mass_storage.name*
- */config/usb-gadget/gadget/functions/mass_storage.name/lun.name*

5.2.61 File testing/configfs-usb-gadget-midi

Has the following ABI:

- */config/usb-gadget/gadget/functions/midi.name*

5.2.62 File testing/configfs-usb-gadget-midi2

Has the following ABI:

- */config/usb-gadget/gadget/functions/midi2.name*
- */config/usb-gadget/gadget/functions/midi2.name/ep.number*
- */config/usb-gadget/gadget/functions/midi2.name/ep.number/block.number*

5.2.63 File testing/configfs-usb-gadget-ncm

Has the following ABI:

- */config/usb-gadget/gadget/functions/ncm.name*

5.2.64 File testing/configfs-usb-gadget-obex

Has the following ABI:

- */config/usb-gadget/gadget/functions/obex.name*

5.2.65 File testing/configfs-usb-gadget-phonet

Has the following ABI:

- */config/usb-gadget/gadget/functions/phonet.name*

5.2.66 File testing/configfs-usb-gadget-printer

Has the following ABI:

- */config/usb-gadget/gadget/functions/printer.name*

5.2.67 File testing/configfs-usb-gadget-rndis

Has the following ABI:

- */config/usb-gadget/gadget/functions/rndis.name*

5.2.68 File testing/configfs-usb-gadget-serial

Has the following ABI:

- */config/usb-gadget/gadget/functions/gser.name*

5.2.69 File testing/configfs-usb-gadget-sourcesink

Has the following ABI:

- */config/usb-gadget/gadget/functions/SourceSink.name*

5.2.70 File testing/configfs-usb-gadget-subset

Has the following ABI:

- */config/usb-gadget/gadget/functions/geth.name*

5.2.71 File testing/configfs-usb-gadget-tcm

Has the following ABI:

- */config/usb-gadget/gadget/functions/tcm.name*

5.2.72 File testing/configfs-usb-gadget-uac1

Has the following ABI:

- */config/usb-gadget/gadget/functions/uac1.name*

5.2.73 File testing/configfs-usb-gadget-uac1_legacy

Has the following ABI:

- */config/usb-gadget/gadget/functions/uac1_legacy.name*

5.2.74 File testing/configfs-usb-gadget-uac2

Has the following ABI:

- */config/usb-gadget/gadget/functions/uac2.name*

5.2.75 File testing/configfs-usb-gadget-uvc

Has the following ABI:

- */config/usb-gadget/gadget/functions/uvc.name*
- */config/usb-gadget/gadget/functions/uvc.name/control*
- */config/usb-gadget/gadget/functions/uvc.name/control/class*

- */sys/kernel/debug/hisi_hpre/<bdf>/alg_qos*
- */sys/kernel/debug/hisi_hpre/<bdf>/regs*
- */sys/kernel/debug/hisi_hpre/<bdf>/qm/regs*

- */sys/kernel/debug/hisi_hpre/<bdf>/qm/current_q*
- */sys/kernel/debug/hisi_hpre/<bdf>/qm/clear_enable*
- */sys/kernel/debug/hisi_hpre/<bdf>/qm/err_irq*
- */sys/kernel/debug/hisi_hpre/<bdf>/qm/aeq_irq*
- */sys/kernel/debug/hisi_hpre/<bdf>/qm/abnormal_irq*
- */sys/kernel/debug/hisi_hpre/<bdf>/qm/create_qp_err*
- */sys/kernel/debug/hisi_hpre/<bdf>/qm/mb_err*
- */sys/kernel/debug/hisi_hpre/<bdf>/qm/status*
- */sys/kernel/debug/hisi_hpre/<bdf>/qm/diff_regs*
- */sys/kernel/debug/hisi_hpre/<bdf>/hpre_dfx/diff_regs*
- */sys/kernel/debug/hisi_hpre/<bdf>/hpre_dfx/send_cnt*
- */sys/kernel/debug/hisi_hpre/<bdf>/hpre_dfx/recv_cnt*
- */sys/kernel/debug/hisi_hpre/<bdf>/hpre_dfx/send_busy_cnt*
- */sys/kernel/debug/hisi_hpre/<bdf>/hpre_dfx/send_fail_cnt*
- */sys/kernel/debug/hisi_hpre/<bdf>/hpre_dfx/invalid_req_cnt*
- */sys/kernel/debug/hisi_hpre/<bdf>/hpre_dfx/overtime_thrhld*
- */sys/kernel/debug/hisi_hpre/<bdf>/hpre_dfx/over_thrhld_cnt*

5.2.87 File testing/debugfs-hisi-sec

Has the following ABI:

- */sys/kernel/debug/hisi_sec2/<bdf>/clear_enable*
- */sys/kernel/debug/hisi_sec2/<bdf>/current_qm*
- */sys/kernel/debug/hisi_sec2/<bdf>/alg_qos*
- */sys/kernel/debug/hisi_sec2/<bdf>/qm/qm_regs*
- */sys/kernel/debug/hisi_sec2/<bdf>/qm/current_q*
- */sys/kernel/debug/hisi_sec2/<bdf>/qm/clear_enable*
- */sys/kernel/debug/hisi_sec2/<bdf>/qm/err_irq*
- */sys/kernel/debug/hisi_sec2/<bdf>/qm/aeq_irq*
- */sys/kernel/debug/hisi_sec2/<bdf>/qm/abnormal_irq*
- */sys/kernel/debug/hisi_sec2/<bdf>/qm/create_qp_err*
- */sys/kernel/debug/hisi_sec2/<bdf>/qm/mb_err*
- */sys/kernel/debug/hisi_sec2/<bdf>/qm/status*
- */sys/kernel/debug/hisi_sec2/<bdf>/qm/diff_regs*
- */sys/kernel/debug/hisi_sec2/<bdf>/sec_dfx/diff_regs*

- */sys/kernel/debug/hisi_sec2/<bdf>/sec_dfx/send_cnt*
- */sys/kernel/debug/hisi_sec2/<bdf>/sec_dfx/recv_cnt*
- */sys/kernel/debug/hisi_sec2/<bdf>/sec_dfx/send_busy_cnt*
- */sys/kernel/debug/hisi_sec2/<bdf>/sec_dfx/err_bd_cnt*
- */sys/kernel/debug/hisi_sec2/<bdf>/sec_dfx/invalid_req_cnt*
- */sys/kernel/debug/hisi_sec2/<bdf>/sec_dfx/done_flag_cnt*

5.2.88 File testing/debugfs-hisi-zip

Has the following ABI:

- */sys/kernel/debug/hisi_zip/<bdf>/comp_core[01]/regs*
- */sys/kernel/debug/hisi_zip/<bdf>/decomp_core[0-5]/regs*
- */sys/kernel/debug/hisi_zip/<bdf>/clear_enable*
- */sys/kernel/debug/hisi_zip/<bdf>/current_qm*
- */sys/kernel/debug/hisi_zip/<bdf>/alg_qos*
- */sys/kernel/debug/hisi_zip/<bdf>/qm/regs*
- */sys/kernel/debug/hisi_zip/<bdf>/qm/current_q*
- */sys/kernel/debug/hisi_zip/<bdf>/qm/clear_enable*
- */sys/kernel/debug/hisi_zip/<bdf>/qm/err_irq*
- */sys/kernel/debug/hisi_zip/<bdf>/qm/aeq_irq*
- */sys/kernel/debug/hisi_zip/<bdf>/qm/abnormal_irq*
- */sys/kernel/debug/hisi_zip/<bdf>/qm/create_qp_err*
- */sys/kernel/debug/hisi_zip/<bdf>/qm/mb_err*
- */sys/kernel/debug/hisi_zip/<bdf>/qm/status*
- */sys/kernel/debug/hisi_zip/<bdf>/qm/diff_regs*
- */sys/kernel/debug/hisi_zip/<bdf>/zip_dfx/diff_regs*
- */sys/kernel/debug/hisi_zip/<bdf>/zip_dfx/send_cnt*
- */sys/kernel/debug/hisi_zip/<bdf>/zip_dfx/recv_cnt*
- */sys/kernel/debug/hisi_zip/<bdf>/zip_dfx/send_busy_cnt*
- */sys/kernel/debug/hisi_zip/<bdf>/zip_dfx/err_bd_cnt*

5.2.89 File testing/debugfs-hyperv

Has the following ABI:

- */sys/kernel/debug/hyperv/<UUID>/fuzz_test_state*
- */sys/kernel/debug/hyperv/<UUID>/delay/fuzz_test_buffer_interrupt_delay*
- */sys/kernel/debug/hyperv/<UUID>/delay/fuzz_test_message_delay*

5.2.90 File testing/debugfs-ideapad

Has the following ABI:

- */sys/kernel/debug/ideapad/cfg*
- */sys/kernel/debug/ideapad/status*

5.2.91 File testing/debugfs-moxtet

Has the following ABI:

- */sys/kernel/debug/moxtet/input*
- */sys/kernel/debug/moxtet/output*

5.2.92 File testing/debugfs-olpc

Has the following ABI:

- */sys/kernel/debug/olpc-ec/cmd*

5.2.93 File testing/debugfs-pfo-nx-crypto

Has the following ABI:

- */sys/kernel/debug/nx-crypto/**

5.2.94 File testing/debugfs-pktcdvd

Has the following ABI:

- */sys/kernel/debug/pktcdvd/pktcdvd[0-7]*

5.2.95 File testing/debugfs-scmi

Has the following ABI:

- */sys/kernel/debug/scmi/<n>/instance_name*
- */sys/kernel/debug/scmi/<n>/atomic_threshold_us*
- */sys/kernel/debug/scmi/<n>/transport/type*
- */sys/kernel/debug/scmi/<n>/transport/is_atomic*
- */sys/kernel/debug/scmi/<n>/transport/max_rx_timeout_ms*
- */sys/kernel/debug/scmi/<n>/transport/max_msg_size*
- */sys/kernel/debug/scmi/<n>/transport/tx_max_msg*
- */sys/kernel/debug/scmi/<n>/transport/rx_max_msg*

5.2.96 File testing/debugfs-scmi-raw

Has the following ABI:

- */sys/kernel/debug/scmi/<n>/raw/message*
- */sys/kernel/debug/scmi/<n>/raw/message_async*
- */sys/kernel/debug/scmi/<n>/raw/errors*
- */sys/kernel/debug/scmi/<n>/raw/notification*
- */sys/kernel/debug/scmi/<n>/raw/reset*
- */sys/kernel/debug/scmi/<n>/raw/channels/<m>/message*
- */sys/kernel/debug/scmi/<n>/raw/channels/<m>/message_async*

5.2.97 File testing/debugfs-tpmi

Has the following ABI:

- */sys/kernel/debug/tpmi-<n>/pfs_dump*
- */sys/kernel/debug/tpmi-<n>/tpmi-id-<n>/mem_dump*
- */sys/kernel/debug/tpmi-<n>/tpmi-id-<n>/mem_write*

5.2.98 File testing/debugfs-turris-mox-rwtm

Has the following ABI:

- */sys/kernel/debug/turris-mox-rwtm/do_sign*

5.2.99 File testing/debugfs-vfio

Has the following ABI:

- */sys/kernel/debug/vfio*
- */sys/kernel/debug/vfio/<device>/migration*
- */sys/kernel/debug/vfio/<device>/migration/state*

5.2.100 File testing/debugfs-wilco-ec

Has the following ABI:

- */sys/kernel/debug/wilco_ec/h1_gpio*
- */sys/kernel/debug/wilco_ec/raw*

5.2.101 File testing/dell-smbios-wmi

Has the following ABI:

- */dev/wmi/dell-smbios*

5.2.102 File testing/dev-kmsg

Has the following ABI:

- */dev/kmsg*

5.2.103 File testing/devlink-resource-mlxsw

Has the following ABI:

- */kvd/*
- */kvd/linear*
- */kvd/hash_single*
- */kvd/hash_double*

5.2.104 File testing/evm

Has the following ABI:

- */sys/kernel/security/evm*
- */sys/kernel/security/*/evm*
- */sys/kernel/security/*/evm/evm_xattrs*

5.2.105 File testing/gpio-cdev

Has the following ABI:

- */dev/gpiochip[0-9]+*

5.2.106 File testing/ima_policy

Has the following ABI:

- */sys/kernel/security/*/ima/policy*

5.2.107 File testing/ppc-memtrace

Has the following ABI:

- */sys/kernel/debug/powerpc/memtrace*
- */sys/kernel/debug/powerpc/memtrace/enable*
- */sys/kernel/debug/powerpc/memtrace/<node-id>*
- */sys/kernel/debug/powerpc/memtrace/<node-id>/size*
- */sys/kernel/debug/powerpc/memtrace/<node-id>/start*
- */sys/kernel/debug/powerpc/memtrace/<node-id>/trace*

5.2.108 File testing/procfs-attr-current

Has the following ABI:

- */proc/*/attr/current*

5.2.109 File testing/procfs-attr-exec

Has the following ABI:

- */proc/*/attr/exec*

5.2.110 File testing/procfs-attr-prev

Has the following ABI:

- */proc/*/attr/prev*

5.2.111 File testing/procfs-diskstats

Has the following ABI:

- */proc/diskstats*

5.2.112 File testing/procfs-smaps_rollup

Has the following ABI:

- */proc/pid/smaps_rollup*

5.2.113 File testing/pstore

Has the following ABI:

- */sys/fs/pstore/..*
- */dev/pstore/..*

5.2.114 File testing/rtc-cdev

Has the following ABI:

- */dev/rtcX*

5.2.115 File testing/securityfs-secrets-coco

Has the following ABI:

- *security/secrets/coco*

5.2.116 File testing/sysfs-amd-pmc

Has the following ABI:

- */sys/bus/platform/drivers/amd_pmc/*/smu_fw_version*
- */sys/bus/platform/drivers/amd_pmc/*/smu_program*

5.2.117 File testing/sysfs-amd-pmf

Has the following ABI:

- */sys/devices/platform/*/cnqf_enable*

5.2.118 File testing/sysfs-ata

Has the following ABI:

- */sys/class/ata_**
- */sys/class/ata_port/ataX/nr_pmp_links*
- */sys/class/ata_port/ataX/idle_irq*
- */sys/class/ata_port/ataX/port_no*
- */sys/class/ata_link/linkX[.Y]/hw_sata_spd_limit*
- */sys/class/ata_link/linkX[.Y]/sata_spd_limit*
- */sys/class/ata_link/linkX[.Y]/sata_spd*
- */sys/class/ata_device/devX[.Y].Z/spdn_cnt*
- */sys/class/ata_device/devX[.Y].Z/gscr*
- */sys/class/ata_device/devX[.Y].Z/ering*
- */sys/class/ata_device/devX[.Y].Z/id*
- */sys/class/ata_device/devX[.Y].Z/pio_mode*
- */sys/class/ata_device/devX[.Y].Z/xfer_mode*
- */sys/class/ata_device/devX[.Y].Z/dma_mode*
- */sys/class/ata_device/devX[.Y].Z/class*
- */sys/class/ata_device/devX[.Y].Z/trim*

5.2.119 File testing/sysfs-block-aoe

Has the following ABI:

- */sys/block/etherd*/mac*
- */sys/block/etherd*/netif*
- */sys/block/etherd*/state*
- */sys/block/etherd*/firmware-version*
- */sys/block/etherd*/payload*

5.2.120 File testing/sysfs-block-bcache

Has the following ABI:

- */sys/block/<disk>/bcache/unregister*
- */sys/block/<disk>/bcache/clear_stats*
- */sys/block/<disk>/bcache/cache*
- */sys/block/<disk>/bcache/cache_hits*
- */sys/block/<disk>/bcache/cache_misses*

- */sys/block/<disk>/bcache/cache_hit_ratio*
- */sys/block/<disk>/bcache/sequential_cutoff*
- */sys/block/<disk>/bcache/bypassed*
- */sys/block/<disk>/bcache/writeback*
- */sys/block/<disk>/bcache/writeback_running*
- */sys/block/<disk>/bcache/writeback_delay*
- */sys/block/<disk>/bcache/writeback_percent*
- */sys/block/<disk>/bcache/synchronous*
- */sys/block/<disk>/bcache/discard*
- */sys/block/<disk>/bcache/bucket_size*
- */sys/block/<disk>/bcache/nbuckets*
- */sys/block/<disk>/bcache/tree_depth*
- */sys/block/<disk>/bcache/btree_cache_size*
- */sys/block/<disk>/bcache/written*
- */sys/block/<disk>/bcache/btree_written*

5.2.121 File testing/sysfs-block-device

Has the following ABI:

- */sys/block/*/device/sw_activity*
- */sys/block/*/device/unload_heads*
- */sys/block/*/device/ncq_prio_enable*
- */sys/block/*/device/sas_ncq_prio_enable*
- */sys/block/*/device/ncq_prio_supported*
- */sys/block/*/device/sas_ncq_prio_supported*
- */sys/block/*/device/cdl_supported*
- */sys/block/*/device/cdl_enable*

5.2.122 File testing/sysfs-block-dm

Has the following ABI:

- */sys/block/dm-<num>/dm/name*
- */sys/block/dm-<num>/dm/uuid*
- */sys/block/dm-<num>/dm/suspended*
- */sys/block/dm-<num>/dm/rq_based_seq_io_merge_deadline*
- */sys/block/dm-<num>/dm/use_blk_mq*

5.2.123 File testing/sysfs-block-loop

Has the following ABI:

- */sys/block/loopX/loop/autoclear*
- */sys/block/loopX/loop/backing_file*
- */sys/block/loopX/loop/offset*
- */sys/block/loopX/loop/sizelimit*
- */sys/block/loopX/loop/partscan*
- */sys/block/loopX/loop/dio*

5.2.124 File testing/sysfs-block-rnbd

Has the following ABI:

- */sys/block/rnbd<N>/rnbd/unmap_device*
- */sys/block/rnbd<N>/rnbd/state*
- */sys/block/rnbd<N>/rnbd/session*
- */sys/block/rnbd<N>/rnbd/mapping_path*
- */sys/block/rnbd<N>/rnbd/access_mode*
- */sys/block/rnbd<N>/rnbd/resize*
- */sys/block/rnbd<N>/rnbd/remap_device*
- */sys/block/rnbd<N>/rnbd/nr_poll_queues*

5.2.125 File testing/sysfs-block-rssd

Has the following ABI:

- */sys/block/rssd*/status*

5.2.126 File testing/sysfs-block-zram

Has the following ABI:

- */sys/block/zram<id>/disksize*
- */sys/block/zram<id>/initstate*
- */sys/block/zram<id>/reset*
- */sys/block/zram<id>/max_comp_streams*
- */sys/block/zram<id>/comp_algorithm*
- */sys/block/zram<id>/mem_used_max*
- */sys/block/zram<id>/mem_limit*
- */sys/block/zram<id>/compact*

- */sys/block/zram<id>/io_stat*
- */sys/block/zram<id>/mm_stat*
- */sys/block/zram<id>/debug_stat*
- */sys/block/zram<id>/backing_dev*
- */sys/block/zram<id>/idle*
- */sys/block/zram<id>/writeback*
- */sys/block/zram<id>/bd_stat*
- */sys/block/zram<id>/writeback_limit_enable*
- */sys/block/zram<id>/writeback_limit*
- */sys/block/zram<id>/recomp_algorithm*
- */sys/block/zram<id>/recompress*

5.2.127 File testing/sysfs-bus-acpi

Has the following ABI:

- */sys/bus/acpi/devices/.../path*
- */sys/bus/acpi/devices/.../modalias*
- */sys/bus/acpi/devices/.../hid*
- */sys/bus/acpi/devices/.../description*
- */sys/bus/acpi/devices/.../adr*
- */sys/bus/acpi/devices/.../uid*
- */sys/bus/acpi/devices/.../eject*
- */sys/bus/acpi/devices/.../status*
- */sys/bus/acpi/devices/.../hrv*

5.2.128 File testing/sysfs-bus-amba

Has the following ABI:

- */sys/bus/amba/devices/.../driver_override*

5.2.129 File testing/sysfs-bus-bcma

Has the following ABI:

- */sys/bus/bcma/devices/.../manuf*
- */sys/bus/bcma/devices/.../id*
- */sys/bus/bcma/devices/.../rev*
- */sys/bus/bcma/devices/.../class*

5.2.130 File testing/sysfs-bus-cdx

Has the following ABI:

- */sys/bus/cdx/rescan*
- */sys/bus/cdx/devices/.../vendor*
- */sys/bus/cdx/devices/.../device*
- */sys/bus/cdx/devices/.../subsystem_vendor*
- */sys/bus/cdx/devices/.../subsystem_device*
- */sys/bus/cdx/devices/.../class*
- */sys/bus/cdx/devices/.../revision*
- */sys/bus/cdx/devices/.../enable*
- */sys/bus/cdx/devices/.../reset*
- */sys/bus/cdx/devices/.../remove*
- */sys/bus/cdx/devices/.../resource<N>*
- */sys/bus/cdx/devices/.../modalias*

5.2.131 File testing/sysfs-bus-coreboot

Has the following ABI:

- */sys/bus/coreboot*
- */sys/bus/coreboot/devices/cbmem-<id>*
- */sys/bus/coreboot/devices/cbmem-<id>/address*
- */sys/bus/coreboot/devices/cbmem-<id>/size*
- */sys/bus/coreboot/devices/cbmem-<id>/mem*

5.2.132 File testing/sysfs-bus-coresight-devices-cti

Has the following ABI:

- */sys/bus/coresight/devices/<cti-name>/enable*
- */sys/bus/coresight/devices/<cti-name>/powered*
- */sys/bus/coresight/devices/<cti-name>/ctmid*
- */sys/bus/coresight/devices/<cti-name>/nr_trigger_cons*
- */sys/bus/coresight/devices/<cti-name>/triggers<N>/name*
- */sys/bus/coresight/devices/<cti-name>/triggers<N>/in_signals*
- */sys/bus/coresight/devices/<cti-name>/triggers<N>/in_types*
- */sys/bus/coresight/devices/<cti-name>/triggers<N>/out_signals*
- */sys/bus/coresight/devices/<cti-name>/triggers<N>/out_types*
- */sys/bus/coresight/devices/<cti-name>/regs/inout_sel*
- */sys/bus/coresight/devices/<cti-name>/regs/inen*
- */sys/bus/coresight/devices/<cti-name>/regs/outen*
- */sys/bus/coresight/devices/<cti-name>/regs/gate*
- */sys/bus/coresight/devices/<cti-name>/regs/asicctl*
- */sys/bus/coresight/devices/<cti-name>/regs/intack*
- */sys/bus/coresight/devices/<cti-name>/regs/appset*
- */sys/bus/coresight/devices/<cti-name>/regs/appclear*
- */sys/bus/coresight/devices/<cti-name>/regs/apppulse*
- */sys/bus/coresight/devices/<cti-name>/regs/chinstatus*
- */sys/bus/coresight/devices/<cti-name>/regs/choutstatus*
- */sys/bus/coresight/devices/<cti-name>/regs/triginstatus*
- */sys/bus/coresight/devices/<cti-name>/regs/trigoutstatus*
- */sys/bus/coresight/devices/<cti-name>/channels/trigin_attach*
- */sys/bus/coresight/devices/<cti-name>/channels/trigin_detach*
- */sys/bus/coresight/devices/<cti-name>/channels/trigout_attach*
- */sys/bus/coresight/devices/<cti-name>/channels/trigout_detach*
- */sys/bus/coresight/devices/<cti-name>/channels/chan_gate_enable*
- */sys/bus/coresight/devices/<cti-name>/channels/chan_gate_disable*
- */sys/bus/coresight/devices/<cti-name>/channels/chan_set*
- */sys/bus/coresight/devices/<cti-name>/channels/chan_clear*
- */sys/bus/coresight/devices/<cti-name>/channels/chan_pulse*
- */sys/bus/coresight/devices/<cti-name>/channels/trigout_filtered*

- */sys/bus/coresight/devices/<cti-name>/channels/trig_filter_enable*
- */sys/bus/coresight/devices/<cti-name>/channels/chan_inuse*
- */sys/bus/coresight/devices/<cti-name>/channels/chan_free*
- */sys/bus/coresight/devices/<cti-name>/channels/chan_xtrigs_sel*
- */sys/bus/coresight/devices/<cti-name>/channels/chan_xtrigs_in*
- */sys/bus/coresight/devices/<cti-name>/channels/chan_xtrigs_out*
- */sys/bus/coresight/devices/<cti-name>/channels/chan_xtrigs_reset*

5.2.133 File testing/sysfs-bus-coresight-devices-etb10

Has the following ABI:

- */sys/bus/coresight/devices/<memory_map>.etb/enable_sink*
- */sys/bus/coresight/devices/<memory_map>.etb/trigger_cntr*
- */sys/bus/coresight/devices/<memory_map>.etb/mgmt/rdp*
- */sys/bus/coresight/devices/<memory_map>.etb/mgmt/sts*
- */sys/bus/coresight/devices/<memory_map>.etb/mgmt/rrp*
- */sys/bus/coresight/devices/<memory_map>.etb/mgmt/rwp*
- */sys/bus/coresight/devices/<memory_map>.etb/mgmt/trg*
- */sys/bus/coresight/devices/<memory_map>.etb/mgmt/ctl*
- */sys/bus/coresight/devices/<memory_map>.etb/mgmt/ffsr*
- */sys/bus/coresight/devices/<memory_map>.etb/mgmt/ffcr*

5.2.134 File testing/sysfs-bus-coresight-devices-etm3x

Has the following ABI:

- */sys/bus/coresight/devices/<memory_map>.[etm|ptm]/enable_source*
- */sys/bus/coresight/devices/<memory_map>.[etm|ptm]/addr_idx*
- */sys/bus/coresight/devices/<memory_map>.[etm|ptm]/addr_acctype*
- */sys/bus/coresight/devices/<memory_map>.[etm|ptm]/addr_range*
- */sys/bus/coresight/devices/<memory_map>.[etm|ptm]/addr_single*
- */sys/bus/coresight/devices/<memory_map>.[etm|ptm]/addr_start*

- */sys/bus/cxl/devices/regionZ/commit*
- */sys/bus/cxl/devices/memX/trigger_poison_list*

5.2.145 File testing/sysfs-bus-dfl

Has the following ABI:

- */sys/bus/dfl/devices/dfl_dev.X/type*
- */sys/bus/dfl/devices/dfl_dev.X/feature_id*

5.2.146 File testing/sysfs-bus-dfl-devices-emif

Has the following ABI:

- */sys/bus/dfl/devices/dfl_dev.X/infX_cal_fail*
- */sys/bus/dfl/devices/dfl_dev.X/infX_init_done*
- */sys/bus/dfl/devices/dfl_dev.X/infX_clear*

5.2.147 File testing/sysfs-bus-dfl-devices-n3000-nios

Has the following ABI:

- */sys/bus/dfl/devices/dfl_dev.X/fec_mode*
- */sys/bus/dfl/devices/dfl_dev.X/retimer_A_mode*
- */sys/bus/dfl/devices/dfl_dev.X/retimer_B_mode*
- */sys/bus/dfl/devices/dfl_dev.X/nios_fw_version*

5.2.148 File testing/sysfs-bus-event_source-devices-caps

Has the following ABI:

- */sys/bus/event_source/devices/<dev>/caps*

5.2.149 File testing/sysfs-bus-event_source-devices-dfl_fme

Has the following ABI:

- */sys/bus/event_source/devices/dfl_fmeX/format*
- */sys/bus/event_source/devices/dfl_fmeX/cpumask*
- */sys/bus/event_source/devices/dfl_fmeX/events*

5.2.150 File testing/sysfs-bus-event_source-devices-dsa

Has the following ABI:

- */sys/bus/event_source/devices/dsa*/format*
- */sys/bus/event_source/devices/dsa*/cpumask*

5.2.151 File testing/sysfs-bus-event_source-devices-events

Has the following ABI:

- */sys/devices/cpu/events/*
- */sys/bus/event_source/devices/<pmu>/events/<event>*
- */sys/bus/event_source/devices/<pmu>/events/<event>.unit*
- */sys/bus/event_source/devices/<pmu>/events/<event>.scale*

5.2.152 File testing/sysfs-bus-event_source-devices-format

Has the following ABI:

- */sys/bus/event_source/devices/<dev>/format*

5.2.153 File testing/sysfs-bus-event_source-devices-hv_24x7

Has the following ABI:

- */sys/bus/event_source/devices/hv_24x7/format*
- */sys/bus/event_source/devices/hv_24x7/interface/catalog*
- */sys/bus/event_source/devices/hv_24x7/interface/catalog_length*
- */sys/bus/event_source/devices/hv_24x7/interface/catalog_version*
- */sys/devices/hv_24x7/interface/sockets*
- */sys/devices/hv_24x7/interface/chipspersocket*
- */sys/devices/hv_24x7/interface/coresperchip*
- */sys/devices/hv_24x7/cpumask*
- */sys/bus/event_source/devices/hv_24x7/event_descs/<event-name>*
- */sys/bus/event_source/devices/hv_24x7/event_long_descs/<event-name>*

5.2.154 File testing/sysfs-bus-event_source-devices-hv_gpci

Has the following ABI:

- */sys/bus/event_source/devices/hv_gpci/format*
- */sys/bus/event_source/devices/hv_gpci/interface/collect_privileged*
- */sys/bus/event_source/devices/hv_gpci/interface/ga*
- */sys/bus/event_source/devices/hv_gpci/interface/expanded*
- */sys/bus/event_source/devices/hv_gpci/interface/lab*
- */sys/bus/event_source/devices/hv_gpci/interface/version*
- */sys/bus/event_source/devices/hv_gpci/interface/kernel_version*
- */sys/devices/hv_gpci/cpumask*

- */sys/devices/hv_gpci/interface/processor_bus_topology*
- */sys/devices/hv_gpci/interface/processor_config*
- */sys/devices/hv_gpci/interface/affinity_domain_via_virtual_processor*
- */sys/devices/hv_gpci/interface/affinity_domain_via_domain*
- */sys/devices/hv_gpci/interface/affinity_domain_via_partition*

5.2.155 File testing/sysfs-bus-event_source-devices-iommu

Has the following ABI:

- */sys/bus/event_source/devices/dmar*/format*
- */sys/bus/event_source/devices/dmar*/cpumask*

5.2.156 File testing/sysfs-bus-event_source-devices-uncore

Has the following ABI:

- */sys/bus/event_source/devices/uncore_*/alias*

5.2.157 File testing/sysfs-bus-fcoe

Has the following ABI:

- */sys/bus/fcoe/*
- */sys/bus/fcoe/devices/ctlr_X*
- */sys/bus/fcoe/devices/fcf_X*

5.2.158 File testing/sysfs-bus-fsi

Has the following ABI:

- */sys/bus/platform/devices/../fsi-master/fsi0/rescan*
- */sys/bus/platform/devices/../fsi-master/fsi0/break*
- */sys/bus/platform/devices/../fsi-master/fsi0/slave@00:00/term*
- */sys/bus/platform/devices/../fsi-master/fsi0/slave@00:00/raw*
- */sys/bus/platform/devices/../cfam_reset*

5.2.159 File testing/sysfs-bus-fsi-devices-sbefifo

Has the following ABI:

- */sys/bus/fsi/devices/XX.XX.00:06/sbefifoX/timeout*

5.2.160 File testing/sysfs-bus-fsl-mc

Has the following ABI:

- */sys/bus/fsl-mc/drivers/.../bind*
- */sys/bus/fsl-mc/drivers/.../unbind*

5.2.161 File testing/sysfs-bus-hsi

Has the following ABI:

- */sys/bus/hsi*
- */sys/bus/hsi/devices/.../modalias*

5.2.162 File testing/sysfs-bus-i2c-devices-bq32k

Has the following ABI:

- */sys/bus/i2c/devices/.../trickle_charge_bypass*

5.2.163 File testing/sysfs-bus-i2c-devices-fsa9480

Has the following ABI:

- */sys/bus/i2c/devices/.../device*
- */sys/bus/i2c/devices/.../switch*

5.2.164 File testing/sysfs-bus-i2c-devices-hm6352

Has the following ABI:

- */sys/bus/i2c/devices/.../heading0_input*
- */sys/bus/i2c/devices/.../power_state*
- */sys/bus/i2c/devices/.../calibration*

5.2.165 File testing/sysfs-bus-i2c-devices-lm3533

Has the following ABI:

- */sys/bus/i2c/devices/.../output_hvled[n]*
- */sys/bus/i2c/devices/.../output_lvled[n]*

5.2.166 File testing/sysfs-bus-i2c-devices-pca954x

Has the following ABI:

- */sys/bus/i2c/.../idle_state*

5.2.167 File testing/sysfs-bus-i3c

Has the following ABI:

- */sys/bus/i3c/devices/i3c-<bus-id>*
- */sys/bus/i3c/devices/i3c-<bus-id>/current_master*
- */sys/bus/i3c/devices/i3c-<bus-id>/mode*
- */sys/bus/i3c/devices/i3c-<bus-id>/i3c_scl_frequency*
- */sys/bus/i3c/devices/i3c-<bus-id>/i2c_scl_frequency*

5.2.198 File testing/sysfs-bus-iio-frequency-admv1014

Has the following ABI:

- */sys/bus/iio/devices/iio:deviceX/in_altvoltage0_i_calibscale_coarse*
- */sys/bus/iio/devices/iio:deviceX/in_altvoltage0_q_calibscale_coarse*
- */sys/bus/iio/devices/iio:deviceX/in_altvoltage0_i_calibscale_fine*
- */sys/bus/iio/devices/iio:deviceX/in_altvoltage0_q_calibscale_fine*

5.2.199 File testing/sysfs-bus-iio-gyro-bmg160

Has the following ABI:

- */sys/bus/iio/devices/triggerX/name = "bmg160-any-motion-devX"*

5.2.200 File testing/sysfs-bus-iio-health-afe440x

Has the following ABI:

- */sys/bus/iio/devices/iio:deviceX/in_intensityY_raw*
- */sys/bus/iio/devices/iio:deviceX/in_intensityY_offset*
- */sys/bus/iio/devices/iio:deviceX/in_intensityY_resistance*
- */sys/bus/iio/devices/iio:deviceX/in_intensityY_capacitance*

5.2.201 File testing/sysfs-bus-iio-humidity

Has the following ABI:

- */sys/bus/iio/devices/iio:deviceX/out_current_heater_raw*
- */sys/bus/iio/devices/iio:deviceX/out_current_heater_raw_available*

5.2.202 File testing/sysfs-bus-iio-impedance-analyzer-ad5933

Has the following ABI:

- */sys/bus/iio/devices/iio:deviceX/out_altvoltageY_frequency_start*
- */sys/bus/iio/devices/iio:deviceX/out_altvoltageY_frequency_increment*
- */sys/bus/iio/devices/iio:deviceX/out_altvoltageY_frequency_points*
- */sys/bus/iio/devices/iio:deviceX/out_altvoltageY_settling_cycles*

5.2.203 File testing/sysfs-bus-iio-ina2xx-adc

Has the following ABI:

- */sys/bus/iio/devices/iio:deviceX/in_allow_async_readout*
- */sys/bus/iio/devices/iio:deviceX/in_shunt_resistor*

5.2.204 File testing/sysfs-bus-iio-isl29501

Has the following ABI:

- */sys/bus/iio/devices/iio:deviceX/in_proximity0_agc_gain*
- */sys/bus/iio/devices/iio:deviceX/in_proximity0_agc_gain_bias*
- */sys/bus/iio/devices/iio:deviceX/in_proximity0_calib_phase_temp_a*
- */sys/bus/iio/devices/iio:deviceX/in_proximity0_calib_phase_temp_b*
- */sys/bus/iio/devices/iio:deviceX/in_proximity0_calib_phase_light_a*
- */sys/bus/iio/devices/iio:deviceX/in_proximity0_calib_phase_light_b*

5.2.205 File testing/sysfs-bus-iio-light-isl29018

Has the following ABI:

- */sys/bus/iio/devices/iio:deviceX/proximity_on_chip_ambient_infrared_suppression*

5.2.206 File testing/sysfs-bus-iio-light-lm3533-als

Has the following ABI:

- */sys/.../events/in_illuminance0_thresh_either_en*
- */sys/.../events/in_illuminance0_threshY_hysteresis*
- */sys/.../events/illuminance_threshY_falling_value*
- */sys/.../events/illuminance_threshY_raising_value*
- */sys/bus/iio/devices/iio:deviceX/in_illuminance0_zone*
- */sys/bus/iio/devices/iio:deviceX/out_currentY_currentZ_raw*

5.2.207 File testing/sysfs-bus-iio-light-si1133

Has the following ABI:

- */sys/bus/iio/devices/iio:deviceX/in_intensity_ir_small_raw*
- */sys/bus/iio/devices/iio:deviceX/in_intensity_ir_large_raw*
- */sys/bus/iio/devices/iio:deviceX/in_intensity_large_raw*

5.2.208 File testing/sysfs-bus-iio-light-tsl2583

Has the following ABI:

- */sys/bus/iio/devices/device[n]/in_illuminance_calibrate*
- */sys/bus/iio/devices/device[n]/in_illuminance_lux_table*
- */sys/bus/iio/devices/device[n]/in_illuminance_input_target*

5.2.209 File testing/sysfs-bus-iio-light-tsl2772

Has the following ABI:

- */sys/bus/iio/devices/device[n]/in_illuminance0_calibrate*
- */sys/bus/iio/devices/device[n]/in_proximity0_calibrate*

5.2.210 File testing/sysfs-bus-iio-magnetometer-hmc5843

Has the following ABI:

- */sys/bus/iio/devices/iio:deviceX/meas_conf*
- */sys/bus/iio/devices/iio:deviceX/meas_conf_available*

5.2.211 File testing/sysfs-bus-iio-meas-spec

Has the following ABI:

- */sys/bus/iio/devices/iio:deviceX/battery_low*

5.2.212 File testing/sysfs-bus-iio-mpu6050

Has the following ABI:

- */sys/bus/iio/devices/iio:deviceX/in_gyro_matrix*
- */sys/bus/iio/devices/iio:deviceX/in_accel_matrix*
- */sys/bus/iio/devices/iio:deviceX/in_magn_matrix*

5.2.213 File testing/sysfs-bus-iio-potentiometer-mcp4531

Has the following ABI:

- */sys/bus/iio/devices/iio:deviceX/out_resistance_raw_available*

5.2.214 File testing/sysfs-bus-iio-proximity

Has the following ABI:

- */sys/bus/iio/devices/iio:deviceX/in_proximity_nearlevel*
- */sys/bus/iio/devices/iio:deviceX/sensor_sensitivity*

5.2.215 File testing/sysfs-bus-iio-proximity-as3935

Has the following ABI:

- */sys/bus/iio/devices/iio:deviceX/in_proximity_input*

5.2.216 File testing/sysfs-bus-iio-resolver-ad2s1210

Has the following ABI:

- */sys/bus/iio/devices/iio:deviceX/events/in_altvoltage0_mag_rising_reset_max*
- */sys/bus/iio/devices/iio:deviceX/events/in_altvoltage0_mag_rising_reset_max_available*
- */sys/bus/iio/devices/iio:deviceX/events/in_altvoltage0_mag_rising_reset_min*
- */sys/bus/iio/devices/iio:deviceX/events/in_altvoltage0_mag_rising_reset_min_available*

5.2.217 File testing/sysfs-bus-iio-sps30

Has the following ABI:

- */sys/bus/iio/devices/iio:deviceX/start_cleaning*
- */sys/bus/iio/devices/iio:deviceX/cleaning_period*
- */sys/bus/iio/devices/iio:deviceX/cleaning_period_available*

5.2.218 File testing/sysfs-bus-iio-sx9310

Has the following ABI:

- */sys/bus/iio/devices/iio:deviceX/in_proximity3_comb_raw*

5.2.219 File testing/sysfs-bus-iio-sx9324

Has the following ABI:

- */sys/bus/iio/devices/iio:deviceX/in_proximity<id>_setup*

5.2.220 File testing/sysfs-bus-iio-thermocouple

Has the following ABI:

- */sys/bus/iio/devices/iio:deviceX/fault_ovuv*
- */sys/bus/iio/devices/iio:deviceX/fault_oc*

5.2.221 File testing/sysfs-bus-iio-timer-stm32

Has the following ABI:

- */sys/bus/iio/devices/triggerX/master_mode_available*
- */sys/bus/iio/devices/triggerX/master_mode*
- */sys/bus/iio/devices/iio:deviceX/in_count0_preset*
- */sys/bus/iio/devices/iio:deviceX/in_count_enable_mode_available*
- */sys/bus/iio/devices/iio:deviceX/in_count0_enable_mode*
- */sys/bus/iio/devices/iio:deviceX/in_count_trigger_mode_available*
- */sys/bus/iio/devices/iio:deviceX/in_count0_trigger_mode*

5.2.222 File testing/sysfs-bus-iio-trigger-sysfs

Has the following ABI:

- */sys/bus/iio/devices/triggerX/trigger_now*
- */sys/bus/iio/devices/triggerX/name*
- */sys/bus/iio/devices/iio_sysfs_trigger/add_trigger*
- */sys/bus/iio/devices/iio_sysfs_trigger/remove_trigger*

5.2.223 File testing/sysfs-bus-iio-vf610

Has the following ABI:

- */sys/bus/iio/devices/iio:deviceX/in_conversion_mode*
- */sys/bus/iio/devices/iio:deviceX/out_conversion_mode*

5.2.224 File testing/sysfs-bus-intel_th-devices-gth

Has the following ABI:

- */sys/bus/intel_th/devices/<intel_th_id>-gth/masters/**
- */sys/bus/intel_th/devices/<intel_th_id>-gth/outputs/[0-7]_port*
- */sys/bus/intel_th/devices/<intel_th_id>-gth/outputs/[0-7]_drop*
- */sys/bus/intel_th/devices/<intel_th_id>-gth/outputs/[0-7]_null*
- */sys/bus/intel_th/devices/<intel_th_id>-gth/outputs/[0-7]_flush*
- */sys/bus/intel_th/devices/<intel_th_id>-gth/outputs/[0-7]_reset*
- */sys/bus/intel_th/devices/<intel_th_id>-gth/outputs/[0-7]_smcfreq*

5.2.225 File testing/sysfs-bus-intel_th-devices-msc

Has the following ABI:

- */sys/bus/intel_th/devices/<intel_th_id>-msc<msc-id>/wrap*
- */sys/bus/intel_th/devices/<intel_th_id>-msc<msc-id>/mode*
- */sys/bus/intel_th/devices/<intel_th_id>-msc<msc-id>/nr_pages*
- */sys/bus/intel_th/devices/<intel_th_id>-msc<msc-id>/win_switch*
- */sys/bus/intel_th/devices/<intel_th_id>-msc<msc-id>/stop_on_full*

5.2.226 File testing/sysfs-bus-intel_th-devices-pti

Has the following ABI:

- */sys/bus/intel_th/devices/<intel_th_id>-pti/mode*
- */sys/bus/intel_th/devices/<intel_th_id>-pti/freerunning_clock*
- */sys/bus/intel_th/devices/<intel_th_id>-pti/clock_divider*

5.2.227 File testing/sysfs-bus-intel_th-output-devices

Has the following ABI:

- */sys/bus/intel_th/devices/<intel_th_id>-<device><id>/active*
- */sys/bus/intel_th/devices/<intel_th_id>-msc<msc-id>/port*

5.2.228 File testing/sysfs-bus-mcb

Has the following ABI:

- */sys/bus/mcb/devices/mcb:X*
- */sys/bus/mcb/devices/mcb:X/revision*
- */sys/bus/mcb/devices/mcb:X/minor*
- */sys/bus/mcb/devices/mcb:X/model*
- */sys/bus/mcb/devices/mcb:X/name*

5.2.229 File testing/sysfs-bus-mdio

Has the following ABI:

- */sys/bus/mdio_bus/devices/.../statistics/*
- */sys/class/mdio_bus/.../statistics/*
- */sys/bus/mdio_bus/devices/.../statistics/transfers*
- */sys/class/mdio_bus/.../transfers*
- */sys/bus/mdio_bus/devices/.../statistics/errors*
- */sys/class/mdio_bus/.../statistics/errors*
- */sys/bus/mdio_bus/devices/.../statistics/writes*
- */sys/class/mdio_bus/.../statistics/writes*
- */sys/bus/mdio_bus/devices/.../statistics/reads*
- */sys/class/mdio_bus/.../statistics/reads*
- */sys/bus/mdio_bus/devices/.../statistics/transfers_<addr>*
- */sys/class/mdio_bus/.../statistics/transfers_<addr>*
- */sys/bus/mdio_bus/devices/.../statistics/errors_<addr>*

- */sys/class/mdio_bus/.../statistics/errors_<addr>*
- */sys/bus/mdio_bus/devices/.../statistics/writes_<addr>*
- */sys/class/mdio_bus/.../statistics/writes_<addr>*
- */sys/bus/mdio_bus/devices/.../statistics/reads_<addr>*
- */sys/class/mdio_bus/.../statistics/reads_<addr>*

5.2.230 File testing/sysfs-bus-media

Has the following ABI:

- */sys/bus/media/devices/.../model*

5.2.231 File testing/sysfs-bus-mei

Has the following ABI:

- */sys/bus/mei/devices/.../modalias*
- */sys/bus/mei/devices/.../name*
- */sys/bus/mei/devices/.../uuid*
- */sys/bus/mei/devices/.../version*
- */sys/bus/mei/devices/.../max_conn*
- */sys/bus/mei/devices/.../fixed*
- */sys/bus/mei/devices/.../vtag*
- */sys/bus/mei/devices/.../max_len*

5.2.232 File testing/sysfs-bus-mmc

Has the following ABI:

- */sys/bus/mmc/devices/.../rev*

5.2.233 File testing/sysfs-bus-most

Has the following ABI:

- */sys/bus/most/devices/<dev>/description*
- */sys/bus/most/devices/<dev>/interface*
- */sys/bus/most/devices/<dev>/dci*
- */sys/bus/most/devices/<dev>/dci/arb_address*
- */sys/bus/most/devices/<dev>/dci/arb_value*
- */sys/bus/most/devices/<dev>/dci/mep_eui48_hi*
- */sys/bus/most/devices/<dev>/dci/mep_eui48_lo*

- /sys/bus/most/devices/<dev>/dci/mep_eui48_mi
- /sys/bus/most/devices/<dev>/dci/mep_filter
- /sys/bus/most/devices/<dev>/dci/mep_hash0
- /sys/bus/most/devices/<dev>/dci/mep_hash1
- /sys/bus/most/devices/<dev>/dci/mep_hash2
- /sys/bus/most/devices/<dev>/dci/mep_hash3
- /sys/bus/most/devices/<dev>/dci/ni_state
- /sys/bus/most/devices/<dev>/dci/node_address
- /sys/bus/most/devices/<dev>/dci/node_position
- /sys/bus/most/devices/<dev>/dci/packet_bandwidth
- /sys/bus/most/devices/<dev>/dci/sync_ep
- /sys/bus/most/devices/<dev>/<channel>/
- /sys/bus/most/devices/<dev>/<channel>/available_datatypes
- /sys/bus/most/devices/<dev>/<channel>/available_directions
- /sys/bus/most/devices/<dev>/<channel>/number_of_packet_buffers
- /sys/bus/most/devices/<dev>/<channel>/number_of_stream_buffers
- /sys/bus/most/devices/<dev>/<channel>/size_of_packet_buffer
- /sys/bus/most/devices/<dev>/<channel>/size_of_stream_buffer
- /sys/bus/most/devices/<dev>/<channel>/set_number_of_buffers
- /sys/bus/most/devices/<dev>/<channel>/set_buffer_size
- /sys/bus/most/devices/<dev>/<channel>/set_direction
- /sys/bus/most/devices/<dev>/<channel>/set_datatype
- /sys/bus/most/devices/<dev>/<channel>/set_subbuffer_size
- /sys/bus/most/devices/<dev>/<channel>/set_packets_per_xact
- /sys/bus/most/devices/<dev>/<channel>/channel_starving
- /sys/bus/most/drivers/most_core/components
- /sys/bus/most/drivers/most_core/links

5.2.234 File testing/sysfs-bus-moxtet-devices

Has the following ABI:

- /sys/bus/moxtet/devices/moxtet-<name>.<addr>/module_description
- /sys/bus/moxtet/devices/moxtet-<name>.<addr>/module_id
- /sys/bus/moxtet/devices/moxtet-<name>.<addr>/module_name

5.2.235 File testing/sysfs-bus-nfit

For all of the nmem device attributes under `nfit/*`, see the 'NVDIMM Firmware Interface Table (NFIT)' section in the ACPI specification (http://www.uefi.org/specifications) for more details.

Has the following ABI:

- */sys/bus/nd/devices/nmemX/nfit/serial*
- */sys/bus/nd/devices/nmemX/nfit/handle*
- */sys/bus/nd/devices/nmemX/nfit/device*
- */sys/bus/nd/devices/nmemX/nfit/rev_id*
- */sys/bus/nd/devices/nmemX/nfit/phys_id*
- */sys/bus/nd/devices/nmemX/nfit/flags*
- */sys/bus/nd/devices/nmemX/nfit/format*
- */sys/bus/nd/devices/nmemX/nfit/format1*
- */sys/bus/nd/devices/nmemX/nfit/formats*
- */sys/bus/nd/devices/nmemX/nfit/vendor*
- */sys/bus/nd/devices/nmemX/nfit/dsm_mask*
- */sys/bus/nd/devices/nmemX/nfit/family*
- */sys/bus/nd/devices/nmemX/nfit/id*
- */sys/bus/nd/devices/nmemX/nfit/subsystem_vendor*
- */sys/bus/nd/devices/nmemX/nfit/subsystem_rev_id*
- */sys/bus/nd/devices/nmemX/nfit/subsystem_device*
- */sys/bus/nd/devices/ndbusX/nfit/revision*
- */sys/bus/nd/devices/ndbusX/nfit/scrub*
- */sys/bus/nd/devices/ndbusX/nfit/hw_error_scrub*
- */sys/bus/nd/devices/ndbusX/nfit/dsm_mask*
- */sys/bus/nd/devices/ndbusX/nfit/firmware_activate_noidle*
- */sys/bus/nd/devices/regionX/nfit/range_index*

5.2.236 File testing/sysfs-bus-nvdimm

Has the following ABI:

- *nvdimm*
- */sys/bus/event_source/devices/nmemX/format*
- */sys/bus/event_source/devices/nmemX/events*
- */sys/bus/event_source/devices/nmemX/cpumask*
- */sys/bus/nd/devices/nmemX/cxl/id*

- */sys/bus/nd/devices/nmemX/cxl/provider*

5.2.237 File testing/sysfs-bus-optee-devices

Has the following ABI:

- */sys/bus/tee/devices/optee-ta-<uuid>/*
- */sys/bus/tee/devices/optee-ta-<uuid>/need_supplicant*

5.2.238 File testing/sysfs-bus-papr-pmem

Has the following ABI:

- */sys/bus/nd/devices/nmemX/papr/flags*
- */sys/bus/nd/devices/nmemX/papr/perf_stats*
- */sys/bus/nd/devices/nmemX/papr/health_bitmap_inject*

5.2.239 File testing/sysfs-bus-pci

Has the following ABI:

- */sys/bus/pci/drivers/.../bind*
- */sys/devices/pciX/.../bind*
- */sys/bus/pci/drivers/.../unbind*
- */sys/devices/pciX/.../unbind*
- */sys/bus/pci/drivers/.../new_id*
- */sys/devices/pciX/.../new_id*
- */sys/bus/pci/drivers/.../remove_id*
- */sys/devices/pciX/.../remove_id*
- */sys/bus/pci/rescan*
- */sys/bus/pci/devices/.../msi_bus*
- */sys/bus/pci/devices/.../msi_irqs/*
- */sys/bus/pci/devices/.../msi_irqs/<N>*
- */sys/bus/pci/devices/.../irq*
- */sys/bus/pci/devices/.../remove*
- */sys/bus/pci/devices/.../pci_bus/.../rescan*
- */sys/bus/pci/devices/.../rescan*
- */sys/bus/pci/devices/.../reset_method*
- */sys/bus/pci/devices/.../reset*
- */sys/bus/pci/devices/.../vpd*

- */sys/bus/pci/devices/.../virtfn<N>*
- */sys/bus/pci/devices/.../dep_link*
- */sys/bus/pci/devices/.../physfn*
- */sys/bus/pci/devices/.../modalias*
- */sys/bus/pci/slots/.../module*
- */sys/bus/pci/devices/.../label*
- */sys/bus/pci/devices/.../index*
- */sys/bus/pci/devices/.../acpi_index*
- */sys/bus/pci/devices/.../d3cold_allowed*
- */sys/bus/pci/devices/.../sriov_totalvfs*
- */sys/bus/pci/devices/.../sriov_numvfs*
- */sys/bus/pci/devices/.../driver_override*
- */sys/bus/pci/devices/.../numa_node*
- */sys/bus/pci/devices/.../revision*
- */sys/bus/pci/devices/.../sriov_drivers_autoprobe*
- */sys/bus/pci/devices/.../p2pmem/size*
- */sys/bus/pci/devices/.../p2pmem/available*
- */sys/bus/pci/devices/.../p2pmem/published*
- */sys/bus/pci/devices/.../p2pmem/allocate*
- */sys/bus/pci/devices/.../link/clkpm*
- */sys/bus/pci/devices/.../power_state*
- */sys/bus/pci/devices/.../sriov_vf_total_msix*
- */sys/bus/pci/devices/.../sriov_vf_msix_count*
- */sys/bus/pci/devices/.../resourceN_resize*

5.2.240 File testing/sysfs-bus-pci-devices-aer_stats

PCIe Device AER statistics

These attributes show up under all the devices that are AER capable. These statistical counters indicate the errors "as seen/reported by the device". Note that this may mean that if an endpoint is causing problems, the AER counters may increment at its link partner (e.g. root port) because the errors may be "seen" / reported by the link partner and not the problematic endpoint itself (which may report all counters as 0 as it never saw any problems).

Has the following ABI:

- */sys/bus/pci/devices/<dev>/aer_dev_correctable*
- */sys/bus/pci/devices/<dev>/aer_dev_fatal*
- */sys/bus/pci/devices/<dev>/aer_dev_nonfatal*

- */sys/bus/pci/devices/<dev>/aer_stats/aer_rootport_total_err_cor*
- */sys/bus/pci/devices/<dev>/aer_stats/aer_rootport_total_err_fatal*
- */sys/bus/pci/devices/<dev>/aer_stats/aer_rootport_total_err_nonfatal*

5.2.241 File testing/sysfs-bus-pci-devices-catpt

Has the following ABI:

- */sys/devices/pci0000:00/<dev>/fw_version*
- */sys/devices/pci0000:00/<dev>/fw_info*

5.2.242 File testing/sysfs-bus-pci-devices-cciss

Has the following ABI:

- */sys/bus/pci/devices/<dev>/ccissX/cXdY/model*
- */sys/bus/pci/devices/<dev>/ccissX/cXdY/rev*
- */sys/bus/pci/devices/<dev>/ccissX/cXdY/unique_id*
- */sys/bus/pci/devices/<dev>/ccissX/cXdY/vendor*
- */sys/bus/pci/devices/<dev>/ccissX/cXdY/block:cciss!cXdY*
- */sys/bus/pci/devices/<dev>/ccissX/rescan*
- */sys/bus/pci/devices/<dev>/ccissX/cXdY/lunid*
- */sys/bus/pci/devices/<dev>/ccissX/cXdY/raid_level*
- */sys/bus/pci/devices/<dev>/ccissX/cXdY/usage_count*
- */sys/bus/pci/devices/<dev>/ccissX/resettable*
- */sys/bus/pci/devices/<dev>/ccissX/transport_mode*

5.2.243 File testing/sysfs-bus-pci-devices-pvpanic

Has the following ABI:

- */sys/devices/pci0000:00/*/QEMU0001:00/capability for MMIO*
- */sys/devices/pci0000:00/*/QEMU0001:00/events*

5.2.244 File testing/sysfs-bus-pci-drivers-ehci_hcd

Has the following ABI:

- */sys/bus/pci/drivers/ehci_hcd/.../companion*

5.2.245 File testing/sysfs-bus-pci-drivers-janz-cmodio

Has the following ABI:

- */sys/bus/pci/drivers/janz-cmodio/.../modulbus_number*

5.2.246 File testing/sysfs-bus-pci-drivers-xhci_hcd

Has the following ABI:

- */sys/bus/pci/drivers/xhci_hcd/.../dbc*
- */sys/bus/pci/drivers/xhci_hcd/.../dbc_idVendor*
- */sys/bus/pci/drivers/xhci_hcd/.../dbc_idProduct*
- */sys/bus/pci/drivers/xhci_hcd/.../dbc_bcdDevice*
- */sys/bus/pci/drivers/xhci_hcd/.../dbc_bInterfaceProtocol*

5.2.247 File testing/sysfs-bus-peci

Has the following ABI:

- */sys/bus/peci/rescan*
- */sys/bus/peci/devices/<controller_id>-<device_addr>/remove*

5.2.248 File testing/sysfs-bus-platform

Has the following ABI:

- */sys/bus/platform/devices/.../driver_override*
- */sys/bus/platform/devices/.../numa_node*
- */sys/bus/platform/devices/.../msi_irqs/*
- */sys/bus/platform/devices/.../msi_irqs/<N>*
- */sys/bus/platform/devices/.../modalias*

5.2.249 File testing/sysfs-bus-platform-devices-ampere-smpro

Has the following ABI:

- */sys/bus/platform/devices/smpro-errmon.*/error_[core|mem|pcie|other]_[ce|ue]*
- */sys/bus/platform/devices/smpro-errmon.*/overflow_[core|mem|pcie|other]_[ce|ue]*
- */sys/bus/platform/devices/smpro-errmon.*/[error|warn]_[smpro|pmpro]*
- */sys/bus/platform/devices/smpro-errmon.*/event_[vrd_warn_fault|vrd_hot|dimm_hot|dimm_2x_re*
- */sys/bus/platform/devices/smpro-errmon.*/event_dimm[0-15]_syndrome*
- */sys/bus/platform/devices/smpro-misc.*/boot_progress*
- */sys/bus/platform/devices/smpro-misc*/soc_power_limit*

5.2.250 File testing/sysfs-bus-platform-devices-occ-hwmon

Has the following ABI:

- */sys/bus/platform/devices/occ-hwmon.X/ffdc*

5.2.251 File testing/sysfs-bus-platform-onboard-usb-hub

Has the following ABI:

- */sys/bus/platform/devices/<dev>/always_powered_in_suspend*

5.2.252 File testing/sysfs-bus-rapidio

Has the following ABI:

- */sys/bus/rapidio/devices/<nn>:<d>:<iiii>*
- */sys/bus/rapidio/devices/<nn>:<d>:<iiii>/did*
- */sys/bus/rapidio/devices/<nn>:<d>:<iiii>/vid*
- */sys/bus/rapidio/devices/<nn>:<d>:<iiii>/device_rev*
- */sys/bus/rapidio/devices/<nn>:<d>:<iiii>/asm_did*
- */sys/bus/rapidio/devices/<nn>:<d>:<iiii>/asm_rev*
- */sys/bus/rapidio/devices/<nn>:<d>:<iiii>/asm_vid*
- */sys/bus/rapidio/devices/<nn>:<d>:<iiii>/destid*
- */sys/bus/rapidio/devices/<nn>:<d>:<iiii>/lprev*
- */sys/bus/rapidio/devices/<nn>:<d>:<iiii>/modalias*
- */sys/bus/rapidio/devices/<nn>:<d>:<iiii>/config*
- */sys/bus/rapidio/devices/<nn>:<s>:<iiii>/routes*
- */sys/bus/rapidio/devices/<nn>:<s>:<iiii>/destid*
- */sys/bus/rapidio/devices/<nn>:<s>:<iiii>/hopcount*

- */sys/bus/rapidio/devices/<nn>:<s>:<iiii>/lnext*
- */sys/bus/rapidio/devices/<nn>:<s>:<iiii>/errlog*
- */sys/bus/rapidio/scan*

5.2.253 File testing/sysfs-bus-rbd

Has the following ABI:

- */sys/bus/rbd/add*
- */sys/bus/rbd/remove*
- */sys/bus/rbd/add_single_major*
- */sys/bus/rbd/remove_single_major*
- */sys/bus/rbd/supported_features*
- */sys/bus/rbd/devices/<dev-id>/size*
- */sys/bus/rbd/devices/<dev-id>/major*
- */sys/bus/rbd/devices/<dev-id>/client_id*
- */sys/bus/rbd/devices/<dev-id>/pool*
- */sys/bus/rbd/devices/<dev-id>/name*
- */sys/bus/rbd/devices/<dev-id>/refresh*
- */sys/bus/rbd/devices/<dev-id>/current_snap*
- */sys/bus/rbd/devices/<dev-id>/pool_id*
- */sys/bus/rbd/devices/<dev-id>/image_id*
- */sys/bus/rbd/devices/<dev-id>/features*
- */sys/bus/rbd/devices/<dev-id>/parent*
- */sys/bus/rbd/devices/<dev-id>/minor*
- */sys/bus/rbd/devices/<dev-id>/snap_id*
- */sys/bus/rbd/devices/<dev-id>/config_info*
- */sys/bus/rbd/devices/<dev-id>/cluster_fsid*
- */sys/bus/rbd/devices/<dev-id>/client_addr*

5.2.254 File testing/sysfs-bus-rpmsg

Has the following ABI:

- */sys/bus/rpmsg/devices/.../name*
- */sys/bus/rpmsg/devices/.../src*
- */sys/bus/rpmsg/devices/.../dst*
- */sys/bus/rpmsg/devices/.../announce*

- */sys/bus/rpmsg/devices/.../driver_override*

5.2.255 File testing/sysfs-bus-siox

Has the following ABI:

- */sys/bus/siox/devices/siox-X/active*
- */sys/bus/siox/devices/siox-X/device_add*
- */sys/bus/siox/devices/siox-X/device_remove*
- */sys/bus/siox/devices/siox-X/poll_interval_ns*
- */sys/bus/siox/devices/siox-X-Y/connected*
- */sys/bus/siox/devices/siox-X-Y/inbytes*
- */sys/bus/siox/devices/siox-X-Y/status_errors*
- */sys/bus/siox/devices/siox-X-Y/type*
- */sys/bus/siox/devices/siox-X-Y/watchdog*
- */sys/bus/siox/devices/siox-X-Y/watchdog_errors*
- */sys/bus/siox/devices/siox-X-Y/outbytes*

5.2.256 File testing/sysfs-bus-soundwire-master

Has the following ABI:

- */sys/bus/soundwire/devices/sdw-master-<N>/revision*

5.2.257 File testing/sysfs-bus-soundwire-slave

Has the following ABI:

- */sys/bus/soundwire/devices/sdw:.../status*
- */sys/bus/soundwire/devices/sdw:.../dev-properties/mipi_revision*
- */sys/bus/soundwire/devices/sdw:.../dp0/max_word*
- */sys/bus/soundwire/devices/sdw:.../dp<N>_src/max_word*

5.2.258 File testing/sysfs-bus-spi-devices-spi-nor

Has the following ABI:

- */sys/bus/spi/devices/.../spi-nor/jedec_id*
- */sys/bus/spi/devices/.../spi-nor/manufacturer*
- */sys/bus/spi/devices/.../spi-nor/partname*
- */sys/bus/spi/devices/.../spi-nor/sfdp*

5.2.259 File testing/sysfs-bus-surface_aggregator-tabletsw

Has the following ABI:

- */sys/bus/surface_aggregator/devices/01:0e:01:00:01/state*
- */sys/bus/surface_aggregator/devices/01:26:01:00:01/state*

5.2.260 File testing/sysfs-bus-thunderbolt

Has the following ABI:

- */sys/bus/thunderbolt/devices/.../domainX/boot_acl*
- */sys/bus/thunderbolt/devices/.../domainX/deauthorization*
- */sys/bus/thunderbolt/devices/.../domainX/iommu_dma_protection*
- */sys/bus/thunderbolt/devices/.../domainX/security*
- */sys/bus/thunderbolt/devices/.../authorized*
- */sys/bus/thunderbolt/devices/.../boot*
- */sys/bus/thunderbolt/devices/.../generation*
- */sys/bus/thunderbolt/devices/.../key*
- */sys/bus/thunderbolt/devices/.../device*
- */sys/bus/thunderbolt/devices/.../device_name*
- */sys/bus/thunderbolt/devices/.../maxhopid*
- */sys/bus/thunderbolt/devices/.../rx_speed*
- */sys/bus/thunderbolt/devices/.../rx_lanes*
- */sys/bus/thunderbolt/devices/.../tx_speed*
- */sys/bus/thunderbolt/devices/.../tx_lanes*
- */sys/bus/thunderbolt/devices/.../vendor*
- */sys/bus/thunderbolt/devices/.../vendor_name*
- */sys/bus/thunderbolt/devices/.../unique_id*
- */sys/bus/thunderbolt/devices/.../nvm_version*
- */sys/bus/thunderbolt/devices/.../nvm_authenticate*
- */sys/bus/thunderbolt/devices/.../nvm_authenticate_on_disconnect*
- */sys/bus/thunderbolt/devices/<xdomain>.<service>/key*
- */sys/bus/thunderbolt/devices/<xdomain>.<service>/modalias*
- */sys/bus/thunderbolt/devices/<xdomain>.<service>/prtcid*
- */sys/bus/thunderbolt/devices/<xdomain>.<service>/prtcvers*
- */sys/bus/thunderbolt/devices/<xdomain>.<service>/prtcrevs*
- */sys/bus/thunderbolt/devices/<xdomain>.<service>/prtcstns*

- */sys/bus/thunderbolt/devices/usb4_portX/connector*
- */sys/bus/thunderbolt/devices/usb4_portX/link*
- */sys/bus/thunderbolt/devices/usb4_portX/offline*
- */sys/bus/thunderbolt/devices/usb4_portX/rescan*
- */sys/bus/thunderbolt/devices/<device>:<port>.<index>/device*
- */sys/bus/thunderbolt/devices/<device>:<port>.<index>/nvm_authenticate*
- */sys/bus/thunderbolt/devices/<device>:<port>.<index>/nvm_version*
- */sys/bus/thunderbolt/devices/<device>:<port>.<index>/vendor*

5.2.261 File testing/sysfs-bus-typec

Has the following ABI:

- */sys/bus/typec/devices/.../active*
- */sys/bus/typec/devices/.../description*
- */sys/bus/typec/devices/.../mode*
- */sys/bus/typec/devices/.../svid*
- */sys/bus/typec/devices/.../vdo*

5.2.262 File testing/sysfs-bus-usb

Has the following ABI:

- */sys/bus/usb/devices/<INTERFACE>/authorized*
- */sys/bus/usb/devices/usbX/interface_authorized_default*
- */sys/bus/usb/device/.../authorized*
- */sys/bus/usb/drivers/.../new_id*
- */sys/bus/usb-serial/drivers/.../new_id*
- */sys/bus/usb/drivers/.../remove_id*
- */sys/bus/usb/devices/.../power/usb2_hardware_lpm*
- */sys/bus/usb/devices/.../power/usb3_hardware_lpm_u1*
- */sys/bus/usb/devices/.../ltm_capable*
- */sys/bus/usb/devices/<INTERFACE>/wireless_status*
- */sys/bus/usb/devices/.../<hub_interface>/port<X>*
- */sys/bus/usb/devices/.../<hub_interface>/port<X>/connect_type*
- */sys/bus/usb/devices/.../<hub_interface>/port<X>/location*
- */sys/bus/usb/devices/.../<hub_interface>/port<X>/quirks*
- */sys/bus/usb/devices/.../<hub_interface>/port<X>/over_current_count*

- */sys/bus/usb/devices/.../<hub_interface>/port<X>/usb3_lpm_permit*
- */sys/bus/usb/devices/.../<hub_interface>/port<X>/connector*
- */sys/bus/usb/devices/.../<hub_interface>/port<X>/disable*
- */sys/bus/usb/devices/.../<hub_interface>/port<X>/early_stop*
- */sys/bus/usb/devices/.../<hub_interface>/port<X>/state*
- */sys/bus/usb/devices/.../power/usb2_lpm_l1_timeout*
- */sys/bus/usb/devices/.../power/usb2_lpm_besl*
- */sys/bus/usb/devices/.../rx_lanes*
- */sys/bus/usb/devices/.../tx_lanes*
- */sys/bus/usb/devices/.../typec*
- */sys/bus/usb/devices/usbX/bAlternateSetting*
- */sys/bus/usb/devices/usbX/bcdDevice*
- */sys/bus/usb/devices/usbX/bConfigurationValue*
- */sys/bus/usb/devices/usbX/bDeviceClass*
- */sys/bus/usb/devices/usbX/bDeviceProtocol*
- */sys/bus/usb/devices/usbX/bDeviceSubClass*
- */sys/bus/usb/devices/usbX/bInterfaceClass*
- */sys/bus/usb/devices/usbX/bInterfaceNumber*
- */sys/bus/usb/devices/usbX/bInterfaceProtocol*
- */sys/bus/usb/devices/usbX/bInterfaceSubClass*
- */sys/bus/usb/devices/usbX/bmAttributes*
- */sys/bus/usb/devices/usbX/bMaxPacketSize0*
- */sys/bus/usb/devices/usbX/bMaxPower*
- */sys/bus/usb/devices/usbX/bNumConfigurations*
- */sys/bus/usb/devices/usbX/bNumEndpoints*
- */sys/bus/usb/devices/usbX/bNumInterfaces*
- */sys/bus/usb/devices/usbX/busnum*
- */sys/bus/usb/devices/usbX/configuration*
- */sys/bus/usb/devices/usbX/descriptors*
- */sys/bus/usb/devices/usbX/idProduct*
- */sys/bus/usb/devices/usbX/idVendor*
- */sys/bus/usb/devices/usbX/devspec*
- */sys/bus/usb/devices/usbX/avoid_reset_quirk*
- */sys/bus/usb/devices/usbX/devnum*

- */sys/bus/usb/devices/usbX/devpath*
- */sys/bus/usb/devices/usbX/manufacturer*
- */sys/bus/usb/devices/usbX/maxchild*
- */sys/bus/usb/devices/usbX/persist*
- */sys/bus/usb/devices/usbX/product*
- */sys/bus/usb/devices/usbX/speed*
- */sys/bus/usb/devices/usbX/supports_autosuspend*
- */sys/bus/usb/devices/usbX/urbnum*
- */sys/bus/usb/devices/usbX/version*
- */sys/bus/usb/devices/usbX/power/autosuspend*
- */sys/bus/usb/devices/usbX/power/active_duration*
- */sys/bus/usb/devices/usbX/power/connected_duration*
- */sys/bus/usb/devices/usbX/power/level*
- */sys/bus/usb/devices/usbX/ep_<N>/bEndpointAddress*
- */sys/bus/usb/devices/usbX/ep_<N>/bInterval*
- */sys/bus/usb/devices/usbX/ep_<N>/bLength*
- */sys/bus/usb/devices/usbX/ep_<N>/bmAttributes*
- */sys/bus/usb/devices/usbX/ep_<N>/direction*
- */sys/bus/usb/devices/usbX/ep_<N>/interval*
- */sys/bus/usb/devices/usbX/ep_<N>/type*
- */sys/bus/usb/devices/usbX/ep_<N>/wMaxPacketSize*

5.2.263 File testing/sysfs-bus-usb-devices-usbsevseg

Has the following ABI:

- */sys/bus/usb/.../powered*
- */sys/bus/usb/.../mode_msb*
- */sys/bus/usb/.../mode_lsb*
- */sys/bus/usb/.../textmode*
- */sys/bus/usb/.../text*
- */sys/bus/usb/.../decimals*

5.2.264 File testing/sysfs-bus-usb-lvstest

Link Layer Validation Device is a standard device for testing of Super Speed Link Layer tests. These nodes are available in sysfs only when lvs driver is bound with root hub device.

Has the following ABI:

- */sys/bus/usb/devices/.../get_dev_desc*
- */sys/bus/usb/devices/.../u1_timeout*
- */sys/bus/usb/devices/.../u2_timeout*
- */sys/bus/usb/devices/.../hot_reset*
- */sys/bus/usb/devices/.../u3_entry*
- */sys/bus/usb/devices/.../u3_exit*
- */sys/bus/usb/devices/.../enable_compliance*
- */sys/bus/usb/devices/.../warm_reset*

5.2.265 File testing/sysfs-bus-vdpa

Has the following ABI:

- */sys/bus/vdpa/drivers_autoprobe*
- */sys/bus/vdpa/driver_probe*
- */sys/bus/vdpa/drivers/.../bind*
- */sys/bus/vdpa/drivers/.../unbind*
- */sys/bus/vdpa/devices/.../driver_override*

5.2.266 File testing/sysfs-bus-vfio-mdev

Has the following ABI:

- */sys/.../<device>/mdev_supported_types/*
- */sys/.../<device>/mdev_supported_types/<type-id>/*
- */sys/.../mdev_supported_types/<type-id>/create*
- */sys/.../mdev_supported_types/<type-id>/devices/*
- */sys/.../mdev_supported_types/<type-id>/available_instances*
- */sys/.../mdev_supported_types/<type-id>/device_api*
- */sys/.../mdev_supported_types/<type-id>/name*
- */sys/.../mdev_supported_types/<type-id>/description*
- */sys/.../<device>/<UUID>/*
- */sys/.../<device>/<UUID>/mdev_type*
- */sys/.../<device>/<UUID>/remove*

5.2.267 File testing/sysfs-bus-vmbus

Has the following ABI:

- */sys/bus/vmbus/devices/.../driver_override*

5.2.268 File testing/sysfs-c2port

Has the following ABI:

- */sys/class/c2port/*
- */sys/class/c2port/c2portX*
- */sys/class/c2port/c2portX/access*
- */sys/class/c2port/c2portX/dev_id*
- */sys/class/c2port/c2portX/flash_access*
- */sys/class/c2port/c2portX/flash_block_size*
- */sys/class/c2port/c2portX/flash_blocks_num*
- */sys/class/c2port/c2portX/flash_data*
- */sys/class/c2port/c2portX/flash_erase*
- */sys/class/c2port/c2portX/reset*
- */sys/class/c2port/c2portX/rev_id*

5.2.269 File testing/sysfs-cfq-target-latency

Has the following ABI:

- */sys/block/<device>/iosched/target_latency*

5.2.270 File testing/sysfs-class

Has the following ABI:

- */sys/class/*

5.2.271 File testing/sysfs-class-backlight

Has the following ABI:

- */sys/class/backlight/<backlight>/scale*
- */sys/class/backlight/<backlight>/ambient_light_level*
- */sys/class/backlight/<backlight>/ambient_light_zone*
- */sys/class/backlight/<backlight>/<ambient light zone>_max*
- */sys/class/backlight/<backlight>/<ambient light zone>_dim*

5.2.272 File testing/sysfs-class-backlight-driver-lm3533

Has the following ABI:

- */sys/class/backlight/<backlight>/als_channel*
- */sys/class/backlight/<backlight>/als_en*
- */sys/class/backlight/<backlight>/id*
- */sys/class/backlight/<backlight>/linear*
- */sys/class/backlight/<backlight>/pwm*

5.2.273 File testing/sysfs-class-backlight-lm3639

sysfs interface for Texas Instruments lm3639 backlight + flash led driver chip

Has the following ABI:

- */sys/class/backlight/<backlight>/bled_mode*

5.2.274 File testing/sysfs-class-bdi

Has the following ABI:

- */sys/class/bdi/<bdi>/*
- */sys/class/bdi/<bdi>/read_ahead_kb*
- */sys/class/bdi/<bdi>/min_ratio*
- */sys/class/bdi/<bdi>/min_ratio_fine*
- */sys/class/bdi/<bdi>/max_ratio*
- */sys/class/bdi/<bdi>/max_ratio_fine*
- */sys/class/bdi/<bdi>/min_bytes*
- */sys/class/bdi/<bdi>/max_bytes*
- */sys/class/bdi/<bdi>/strict_limit*
- */sys/class/bdi/<bdi>/stable_pages_required*

5.2.275 File testing/sysfs-class-bsr

Has the following ABI:

- */sys/class/bsr/bsr*/bsr_size*
- */sys/class/bsr/bsr*/bsr_length*
- */sys/class/bsr/bsr*/bsr_stride*

5.2.276 File testing/sysfs-class-chromeos

Has the following ABI:

- */sys/class/chromeos/<ec-device-name>/flashinfo*
- */sys/class/chromeos/<ec-device-name>/kb_wake_angle*
- */sys/class/chromeos/<ec-device-name>/reboot*
- */sys/class/chromeos/<ec-device-name>/version*

5.2.277 File testing/sysfs-class-chromeos-driver-cros-ec-lightbar

Has the following ABI:

- */sys/class/chromeos/<ec-device-name>/lightbar/brightness*
- */sys/class/chromeos/<ec-device-name>/lightbar/interval_msec*
- */sys/class/chromeos/<ec-device-name>/lightbar/led_rgb*
- */sys/class/chromeos/<ec-device-name>/lightbar/program*
- */sys/class/chromeos/<ec-device-name>/lightbar/sequence*
- */sys/class/chromeos/<ec-device-name>/lightbar/userspace_control*
- */sys/class/chromeos/<ec-device-name>/lightbar/version*

5.2.278 File testing/sysfs-class-chromeos-driver-cros-ec-vbc

Has the following ABI:

- */sys/class/chromeos/<ec-device-name>/vbc/vboot_context*

5.2.279 File testing/sysfs-class-cxl

Please note that attributes that are shared between devices are stored in the directory pointed to by the symlink device/. For example, the real path of the attribute /sys/class/cxl/afu0.0s/irqs_max is /sys/class/cxl/afu0.0s/device/irqs_max, i.e. /sys/class/cxl/afu0.0/irqs_max.

Slave contexts (eg. /sys/class/cxl/afu0.0s):

Has the following ABI:

- */sys/class/cxl/<afu>/afu_err_buf*
- */sys/class/cxl/<afu>/irqs_max*
- */sys/class/cxl/<afu>/irqs_min*
- */sys/class/cxl/<afu>/mmio_size*
- */sys/class/cxl/<afu>/modes_supported*
- */sys/class/cxl/<afu>/mode*
- */sys/class/cxl/<afu>/prefault_mode*

- */sys/class/cxl/<afu>/reset*
- */sys/class/cxl/<afu>/api_version*
- */sys/class/cxl/<afu>/api_version_compatible*
- */sys/class/cxl/<afu>/cr<config num>/vendor*
- */sys/class/cxl/<afu>/cr<config num>/device*
- */sys/class/cxl/<afu>/cr<config num>/class*
- */sys/class/cxl/<afu>/cr<config num>/config*
- */sys/class/cxl/<afu>m/mmio_size*
- */sys/class/cxl/<afu>m/pp_mmio_len*
- */sys/class/cxl/<afu>m/pp_mmio_off*
- */sys/class/cxl/<card>/caia_version*
- */sys/class/cxl/<card>/psl_revision*
- */sys/class/cxl/<card>/base_image*
- */sys/class/cxl/<card>/image_loaded*
- */sys/class/cxl/<card>/load_image_on_perst*
- */sys/class/cxl/<card>/reset*
- */sys/class/cxl/<card>/perst_reloads_same_image*
- */sys/class/cxl/<card>/psl_timebase_synced*
- */sys/class/cxl/<card>/tunneled_ops_supported*

5.2.280 File testing/sysfs-class-devfreq

Has the following ABI:

- */sys/class/devfreq/.../*
- */sys/class/devfreq/.../name*
- */sys/class/devfreq/.../governor*
- */sys/class/devfreq/.../cur_freq*
- */sys/class/devfreq/.../target_freq*
- */sys/class/devfreq/.../trans_stat*
- */sys/class/devfreq/.../available_frequencies*
- */sys/class/devfreq/.../available_governors*
- */sys/class/devfreq/.../min_freq*
- */sys/class/devfreq/.../max_freq*
- */sys/class/devfreq/.../polling_interval*
- */sys/class/devfreq/.../userspace/set_freq*

- */sys/class/devfreq/.../timer*

5.2.281 File testing/sysfs-class-devfreq-event

Has the following ABI:

- */sys/class/devfreq-event/event<x>/*
- */sys/class/devfreq-event/event<x>/name*
- */sys/class/devfreq-event/event<x>/enable_count*

5.2.282 File testing/sysfs-class-devlink

Has the following ABI:

- */sys/class/devlink/.../*
- */sys/class/devlink/.../auto_remove_on*
- */sys/class/devlink/.../consumer*
- */sys/class/devlink/.../runtime_pm*
- */sys/class/devlink/.../status*
- */sys/class/devlink/.../supplier*
- */sys/class/devlink/.../sync_state_only*

5.2.283 File testing/sysfs-class-extcon

Has the following ABI:

- */sys/class/extcon/.../*
- */sys/class/extcon/.../name*
- */sys/class/extcon/.../state*
- */sys/class/extcon/.../cable.X/name*
- */sys/class/extcon/.../cable.X/state*
- */sys/class/extcon/.../mutually_exclusive/..*

5.2.284 File testing/sysfs-class-fc

Has the following ABI:

- */sys/class/fc/fc_udev_device/appid_store*

5.2.285 File testing/sysfs-class-fc_host

Has the following ABI:

- */sys/class/fc_host/hostX/statistics/fpin_cn_yyy*
- */sys/class/fc_host/hostX/statistics/fpin_li_yyy*
- */sys/class/fc_host/hostX/statistics/fpin_dn_yyy*

5.2.286 File testing/sysfs-class-fc_remote_ports

Has the following ABI:

- */sys/class/fc_remote_ports/rport-X:Y-Z/statistics/fpin_cn_yyy*
- */sys/class/fc_remote_ports/rport-X:Y-Z/statistics/fpin_li_yyy*
- */sys/class/fc_remote_ports/rport-X:Y-Z/statistics/fpin_dn_yyy*

5.2.287 File testing/sysfs-class-firmware

Has the following ABI:

- */sys/class/firmware/.../data*
- */sys/class/firmware/.../cancel*
- */sys/class/firmware/.../error*
- */sys/class/firmware/.../loading*
- */sys/class/firmware/.../remaining_size*
- */sys/class/firmware/.../status*
- */sys/class/firmware/.../timeout*

5.2.288 File testing/sysfs-class-firmware-attributes

Has the following ABI:

- */sys/class/firmware-attributes/*/attributes/*/*
- */sys/class/firmware-attributes/*/authentication/*
- */sys/class/firmware-attributes/*/attributes/pending_reboot*
- */sys/class/firmware-attributes/*/attributes/reset_bios*
- */sys/class/firmware-attributes/*/attributes/save_settings*
- */sys/class/firmware-attributes/*/attributes/debug_cmd*
- */sys/class/firmware-attributes/*/authentication/SPM/kek*
- */sys/class/firmware-attributes/*/authentication/SPM/sk*
- */sys/class/firmware-attributes/*/authentication/SPM/status*
- */sys/class/firmware-attributes/*/attributes/Sure_Start/audit_log_entries*

- */sys/class/firmware-attributes/*/attributes/Sure_Start/audit_log_entry_count*

5.2.289 File testing/sysfs-class-fpga-bridge

Has the following ABI:

- */sys/class/fpga_bridge/<bridge>/name*
- */sys/class/fpga_bridge/<bridge>/state*

5.2.290 File testing/sysfs-class-fpga-manager

Has the following ABI:

- */sys/class/fpga_manager/<fpga>/name*
- */sys/class/fpga_manager/<fpga>/state*
- */sys/class/fpga_manager/<fpga>/status*

5.2.291 File testing/sysfs-class-fpga-region

Has the following ABI:

- */sys/class/fpga_region/<region>/compat_id*

5.2.292 File testing/sysfs-class-gnss

Has the following ABI:

- */sys/class/gnss/gnss<N>/type*

5.2.293 File testing/sysfs-class-hwmon

Has the following ABI:

- */sys/class/hwmon/hwmonX/name*
- */sys/class/hwmon/hwmonX/label*
- */sys/class/hwmon/hwmonX/update_interval*
- */sys/class/hwmon/hwmonX/inY_min*
- */sys/class/hwmon/hwmonX/inY_lcrit*
- */sys/class/hwmon/hwmonX/inY_max*
- */sys/class/hwmon/hwmonX/inY_crit*
- */sys/class/hwmon/hwmonX/inY_input*
- */sys/class/hwmon/hwmonX/inY_average*
- */sys/class/hwmon/hwmonX/inY_lowest*
- */sys/class/hwmon/hwmonX/inY_highest*

- */sys/class/hwmon/hwmonX/inY_reset_history*
- */sys/class/hwmon/hwmonX/in_reset_history*
- */sys/class/hwmon/hwmonX/inY_label*
- */sys/class/hwmon/hwmonX/inY_enable*

5.2.294 File testing/sysfs-class-intel_pmt

Has the following ABI:

- */sys/class/intel_pmt/*
- */sys/class/intel_pmt/telem<x>*
- */sys/class/intel_pmt/telem<x>/telem*
- */sys/class/intel_pmt/telem<x>/guid*
- */sys/class/intel_pmt/telem<x>/size*
- */sys/class/intel_pmt/telem<x>/offset*
- */sys/class/intel_pmt/crashlog<x>*
- */sys/class/intel_pmt/crashlog<x>/crashlog*
- */sys/class/intel_pmt/crashlog<x>/guid*
- */sys/class/intel_pmt/crashlog<x>/size*
- */sys/class/intel_pmt/crashlog<x>/offset*
- */sys/class/intel_pmt/crashlog<x>/enable*
- */sys/class/intel_pmt/crashlog<x>/trigger*

5.2.295 File testing/sysfs-class-iommu

Has the following ABI:

- */sys/class/iommu/<iommu>/devices/*
- */sys/devices/.../iommu*

5.2.296 File testing/sysfs-class-iommu-amd-iommu

Has the following ABI:

- */sys/class/iommu/<iommu>/amd-iommu/cap*
- */sys/class/iommu/<iommu>/amd-iommu/features*

5.2.297 File testing/sysfs-class-iommu-intel-iommu

Has the following ABI:

- */sys/class/iommu/<iommu>/intel-iommu/address*
- */sys/class/iommu/<iommu>/intel-iommu/cap*
- */sys/class/iommu/<iommu>/intel-iommu/ecap*
- */sys/class/iommu/<iommu>/intel-iommu/version*

5.2.298 File testing/sysfs-class-lcd

Has the following ABI:

- */sys/class/lcd/<lcd>/lcd_power*
- */sys/class/lcd/<lcd>/contrast*
- */sys/class/lcd/<lcd>/max_contrast*

5.2.299 File testing/sysfs-class-led

Has the following ABI:

- */sys/class/leds/<led>/brightness*
- */sys/class/leds/<led>/max_brightness*
- */sys/class/leds/<led>/brightness_hw_changed*
- */sys/class/leds/<led>/trigger*
- */sys/class/leds/<led>/inverted*

5.2.300 File testing/sysfs-class-led-driver-aw200xx

Has the following ABI:

- */sys/class/leds/<led>/dim*

5.2.301 File testing/sysfs-class-led-driver-lm3533

Has the following ABI:

- */sys/class/leds/<led>/als_channel*
- */sys/class/leds/<led>/als_en*
- */sys/class/leds/<led>/falltime*
- */sys/class/leds/<led>/risetime*
- */sys/class/leds/<led>/id*
- */sys/class/leds/<led>/linear*
- */sys/class/leds/<led>/pwm*

5.2.302 File testing/sysfs-class-led-driver-turris-omnia

Has the following ABI:

- */sys/class/leds/<led>/device/brightness*
- */sys/class/leds/<led>/device/gamma_correction*

5.2.303 File testing/sysfs-class-led-flash

Has the following ABI:

- */sys/class/leds/<led>/flash_brightness*
- */sys/class/leds/<led>/max_flash_brightness*
- */sys/class/leds/<led>/flash_timeout*
- */sys/class/leds/<led>/max_flash_timeout*
- */sys/class/leds/<led>/flash_strobe*
- */sys/class/leds/<led>/flash_fault*

5.2.304 File testing/sysfs-class-led-multicolor

Has the following ABI:

- */sys/class/leds/<led>/multi_index*
- */sys/class/leds/<led>/multi_intensity*

5.2.305 File testing/sysfs-class-led-trigger-netdev

Has the following ABI:

- */sys/class/leds/<led>/device_name*
- */sys/class/leds/<led>/interval*
- */sys/class/leds/<led>/link*
- */sys/class/leds/<led>/tx*
- */sys/class/leds/<led>/rx*
- */sys/class/leds/<led>/offloaded*
- */sys/class/leds/<led>/link_10*
- */sys/class/leds/<led>/link_100*
- */sys/class/leds/<led>/link_1000*
- */sys/class/leds/<led>/link_2500*
- */sys/class/leds/<led>/link_5000*
- */sys/class/leds/<led>/link_10000*
- */sys/class/leds/<led>/half_duplex*

- */sys/class/leds/<led>/full_duplex*

5.2.306 File testing/sysfs-class-led-trigger-oneshot

Has the following ABI:

- */sys/class/leds/<led>/delay_on*
- */sys/class/leds/<led>/delay_off*
- */sys/class/leds/<led>/invert*
- */sys/class/leds/<led>/shot*

5.2.307 File testing/sysfs-class-led-trigger-pattern

Has the following ABI:

- */sys/class/leds/<led>/pattern*
- */sys/class/leds/<led>/hw_pattern*
- */sys/class/leds/<led>/repeat*

5.2.308 File testing/sysfs-class-led-trigger-tty

Has the following ABI:

- */sys/class/leds/<led>/ttyname*
- */sys/class/leds/<led>/rx*
- */sys/class/leds/<led>/tx*
- */sys/class/leds/<led>/cts*
- */sys/class/leds/<led>/dsr*
- */sys/class/leds/<led>/dcd*
- */sys/class/leds/<led>/rng*

5.2.309 File testing/sysfs-class-led-trigger-usbport

Has the following ABI:

- */sys/class/leds/<led>/ports/<port>*

5.2.310 File testing/sysfs-class-leds-gt683r

Has the following ABI:

- */sys/class/leds/<led>/gt683r/mode*

5.2.311 File testing/sysfs-class-mei

Has the following ABI:

- */sys/class/mei/*
- */sys/class/mei/mei<N>/*
- */sys/class/mei/mei<N>/fw_status*
- */sys/class/mei/mei<N>/hbm_ver*
- */sys/class/mei/mei<N>/hbm_ver_drv*
- */sys/class/mei/mei<N>/tx_queue_limit*
- */sys/class/mei/mei<N>/fw_ver*
- */sys/class/mei/mei<N>/dev_state*
- */sys/class/mei/mei<N>/trc*
- */sys/class/mei/mei<N>/kind*

5.2.312 File testing/sysfs-class-mic

Has the following ABI:

- */sys/class/mic/*
- */sys/class/mic/mic<X>*
- */sys/class/mic/mic<X>/family*
- */sys/class/mic/mic<X>/stepping*
- */sys/class/mic/mic<X>/state*
- */sys/class/mic/mic<X>/shutdown_status*
- */sys/class/mic/mic<X>/cmdline*
- */sys/class/mic/mic<X>/firmware*
- */sys/class/mic/mic<X>/ramdisk*
- */sys/class/mic/mic<X>/bootmode*
- */sys/class/mic/mic<X>/log_buf_addr*
- */sys/class/mic/mic<X>/log_buf_len*
- */sys/class/mic/mic<X>/heartbeat_enable*

5.2.313 File testing/sysfs-class-mtd

Has the following ABI:

- */sys/class/mtd/*
- */sys/class/mtd/mtdX/*
- */sys/class/mtd/mtdXro/*
- */sys/class/mtd/mtdX/dev*
- */sys/class/mtd/mtdXro/dev*
- */sys/class/mtd/mtdX/erasesize*
- */sys/class/mtd/mtdX/flags*
- */sys/class/mtd/mtdX/name*
- */sys/class/mtd/mtdX/numeraseregions*
- */sys/class/mtd/mtdX/oobsize*
- */sys/class/mtd/mtdX/size*
- */sys/class/mtd/mtdX/type*
- */sys/class/mtd/mtdX/writesize*
- */sys/class/mtd/mtdX/ecc_strength*
- */sys/class/mtd/mtdX/bitflip_threshold*
- */sys/class/mtd/mtdX/ecc_step_size*
- */sys/class/mtd/mtdX/ecc_failures*
- */sys/class/mtd/mtdX/corrected_bits*
- */sys/class/mtd/mtdX/bad_blocks*
- */sys/class/mtd/mtdX/bbt_blocks*
- */sys/class/mtd/mtdX/offset*
- */sys/class/mtd/mtdX/oobavail*

5.2.314 File testing/sysfs-class-mux

Has the following ABI:

- */sys/class/mux/*
- */sys/class/mux/muxchip<N>/*

5.2.315 File testing/sysfs-class-net

Has the following ABI:

- */sys/class/net/<iface>/name_assign_type*
- */sys/class/net/<iface>/addr_assign_type*
- */sys/class/net/<iface>/addr_len*
- */sys/class/net/<iface>/address*
- */sys/class/net/<bridge iface>/bridge/group_fwd_mask*
- */sys/class/net/<iface>/broadcast*
- */sys/class/net/<iface>/carrier*
- */sys/class/net/<iface>/dev_id*
- */sys/class/net/<iface>/dev_port*
- */sys/class/net/<iface>/dormant*
- */sys/class/net/<iface>/testing*
- */sys/class/net/<iface>/duplex*
- */sys/class/net/<iface>/flags*
- */sys/class/net/<iface>/ifalias*
- */sys/class/net/<iface>/ifindex*
- */sys/class/net/<iface>/iflink*
- */sys/class/net/<iface>/link_mode*
- */sys/class/net/<iface>/mtu*
- */sys/class/net/<iface>/netdev_group*
- */sys/class/net/<iface>/operstate*
- */sys/class/net/<iface>/phys_port_id*
- */sys/class/net/<iface>/phys_port_name*
- */sys/class/net/<iface>/speed*
- */sys/class/net/<iface>/tx_queue_len*
- */sys/class/net/<iface>/type*
- */sys/class/net/<iface>/phys_switch_id*
- */sys/class/net/<iface>/phydev*
- */sys/class/net/<iface>/carrier_changes*
- */sys/class/net/<iface>/carrier_up_count*
- */sys/class/net/<iface>/carrier_down_count*
- */sys/class/net/<iface>/threaded*

5.2.316 File testing/sysfs-class-net-cdc_ncm

Has the following ABI:

- */sys/class/net/<iface>/cdc_ncm/min_tx_pkt*
- */sys/class/net/<iface>/cdc_ncm/ndp_to_end*
- */sys/class/net/<iface>/cdc_ncm/rx_max*
- */sys/class/net/<iface>/cdc_ncm/tx_max*
- */sys/class/net/<iface>/cdc_ncm/tx_timer_usecs*
- */sys/class/net/<iface>/cdc_ncm/bmNtbFormatsSupported*
- */sys/class/net/<iface>/cdc_ncm/dwNtbInMaxSize*
- */sys/class/net/<iface>/cdc_ncm/wNdpInDivisor*
- */sys/class/net/<iface>/cdc_ncm/wNdpInPayloadRemainder*
- */sys/class/net/<iface>/cdc_ncm/wNdpInAlignment*
- */sys/class/net/<iface>/cdc_ncm/dwNtbOutMaxSize*
- */sys/class/net/<iface>/cdc_ncm/wNdpOutDivisor*
- */sys/class/net/<iface>/cdc_ncm/wNdpOutPayloadRemainder*
- */sys/class/net/<iface>/cdc_ncm/wNdpOutAlignment*
- */sys/class/net/<iface>/cdc_ncm/wNtbOutMaxDatagrams*

5.2.317 File testing/sysfs-class-net-dsa

Has the following ABI:

- */sys/class/net/<iface>/dsa/tagging*

5.2.318 File testing/sysfs-class-net-grcan

Has the following ABI:

- */sys/class/net/<iface>/grcan/enable0*
- */sys/class/net/<iface>/grcan/enable1*
- */sys/class/net/<iface>/grcan/select*

5.2.319 File testing/sysfs-class-net-janz-ican3

Has the following ABI:

- */sys/class/net/<iface>/termination*
- */sys/class/net/<iface>/fwinfo*

5.2.320 File testing/sysfs-class-net-peak_usb

Has the following ABI:

- */sys/class/net/<iface>/peak_usb/can_channel_id*

5.2.321 File testing/sysfs-class-net-phydev

Has the following ABI:

- */sys/class/mdio_bus/<bus>/<device>/attached_dev*
- */sys/class/mdio_bus/<bus>/<device>/phy_has_fixups*
- */sys/class/mdio_bus/<bus>/<device>/phy_id*
- */sys/class/mdio_bus/<bus>/<device>/phy_interface*
- */sys/class/mdio_bus/<bus>/<device>/phy_standalone*
- */sys/class/mdio_bus/<bus>/<device>/phy_dev_flags*

5.2.322 File testing/sysfs-class-net-qmi

Has the following ABI:

- */sys/class/net/<iface>/qmi/raw_ip*
- */sys/class/net/<iface>/qmi/add_mux*
- */sys/class/net/<iface>/qmi/del_mux*
- */sys/class/net/<qmimux iface>/qmap/mux_id*
- */sys/class/net/<iface>/qmi/pass_through*

5.2.323 File testing/sysfs-class-net-queues

Has the following ABI:

- */sys/class/net/<iface>/queues/rx-<queue>/rps_cpus*
- */sys/class/net/<iface>/queues/rx-<queue>/rps_flow_cnt*
- */sys/class/net/<iface>/queues/tx-<queue>/tx_timeout*
- */sys/class/net/<iface>/queues/tx-<queue>/tx_maxrate*
- */sys/class/net/<iface>/queues/tx-<queue>/xps_cpus*
- */sys/class/net/<iface>/queues/tx-<queue>/xps_rxqs*

- */sys/class/net/<iface>/queues/tx-<queue>/byte_queue_limits/hold_time*
- */sys/class/net/<iface>/queues/tx-<queue>/byte_queue_limits/inflight*
- */sys/class/net/<iface>/queues/tx-<queue>/byte_queue_limits/limit*
- */sys/class/net/<iface>/queues/tx-<queue>/byte_queue_limits/limit_max*
- */sys/class/net/<iface>/queues/tx-<queue>/byte_queue_limits/limit_min*

5.2.324 File testing/sysfs-class-net-statistics

Has the following ABI:

- */sys/class/net/<iface>/statistics/collisions*
- */sys/class/net/<iface>/statistics/multicast*
- */sys/class/net/<iface>/statistics/rx_bytes*
- */sys/class/net/<iface>/statistics/rx_compressed*
- */sys/class/net/<iface>/statistics/rx_crc_errors*
- */sys/class/net/<iface>/statistics/rx_dropped*
- */sys/class/net/<iface>/statistics/rx_errors*
- */sys/class/net/<iface>/statistics/rx_fifo_errors*
- */sys/class/net/<iface>/statistics/rx_frame_errors*
- */sys/class/net/<iface>/statistics/rx_length_errors*
- */sys/class/net/<iface>/statistics/rx_missed_errors*
- */sys/class/net/<iface>/statistics/rx_nohandler*
- */sys/class/net/<iface>/statistics/rx_over_errors*
- */sys/class/net/<iface>/statistics/rx_packets*
- */sys/class/net/<iface>/statistics/tx_aborted_errors*
- */sys/class/net/<iface>/statistics/tx_bytes*
- */sys/class/net/<iface>/statistics/tx_carrier_errors*
- */sys/class/net/<iface>/statistics/tx_compressed*
- */sys/class/net/<iface>/statistics/tx_dropped*
- */sys/class/net/<iface>/statistics/tx_errors*
- */sys/class/net/<iface>/statistics/tx_fifo_errors*
- */sys/class/net/<iface>/statistics/tx_heartbeat_errors*
- */sys/class/net/<iface>/statistics/tx_packets*
- */sys/class/net/<iface>/statistics/tx_window_errors*

5.2.325 File testing/sysfs-class-ocxl

Has the following ABI:

- */sys/class/ocxl/<afu name>/afu_version*
- */sys/class/ocxl/<afu name>/contexts*
- */sys/class/ocxl/<afu name>/pp_mmio_size*
- */sys/class/ocxl/<afu name>/global_mmio_size*
- */sys/class/ocxl/<afu name>/global_mmio_area*
- */sys/class/ocxl/<afu name>/reload_on_reset*

5.2.326 File testing/sysfs-class-pktcdvd

sysfs interface

The pktcdvd module (packet writing driver) creates the following files in the sysfs: (<devid> is in the format major:minor)

Has the following ABI:

- */sys/class/pktcdvd/add*
- */sys/class/pktcdvd/remove*
- */sys/class/pktcdvd/device_map*
- */sys/class/pktcdvd/pktcdvd[0-7]/dev*
- */sys/class/pktcdvd/pktcdvd[0-7]/uevent*
- */sys/class/pktcdvd/pktcdvd[0-7]/stat/packets_started*
- */sys/class/pktcdvd/pktcdvd[0-7]/stat/packets_finished*
- */sys/class/pktcdvd/pktcdvd[0-7]/stat/kb_written*
- */sys/class/pktcdvd/pktcdvd[0-7]/stat/kb_read*
- */sys/class/pktcdvd/pktcdvd[0-7]/stat/kb_read_gather*
- */sys/class/pktcdvd/pktcdvd[0-7]/stat/reset*
- */sys/class/pktcdvd/pktcdvd[0-7]/write_queue/size*
- */sys/class/pktcdvd/pktcdvd[0-7]/write_queue/congestion_off*
- */sys/class/pktcdvd/pktcdvd[0-7]/write_queue/congestion_on*

5.2.327 File testing/sysfs-class-power

General Properties

Has the following ABI:

- */sys/class/power_supply/<supply_name>/manufacturer*
- */sys/class/power_supply/<supply_name>/model_name*
- */sys/class/power_supply/<supply_name>/serial_number*
- */sys/class/power_supply/<supply_name>/type*
- */sys/class/power_supply/<supply_name>/current_avg*
- */sys/class/power_supply/<supply_name>/current_max*
- */sys/class/power_supply/<supply_name>/current_now*
- */sys/class/power_supply/<supply_name>/temp*
- */sys/class/power_supply/<supply_name>/temp_alert_max*
- */sys/class/power_supply/<supply_name>/temp_alert_min*
- */sys/class/power_supply/<supply_name>/temp_max*
- */sys/class/power_supply/<supply_name>/temp_min*
- */sys/class/power_supply/<supply_name>/voltage_max*
- */sys/class/power_supply/<supply_name>/voltage_min*
- */sys/class/power_supply/<supply_name>/voltage_now*
- */sys/class/power_supply/<supply_name>/capacity*
- */sys/class/power_supply/<supply_name>/capacity_alert_max*
- */sys/class/power_supply/<supply_name>/capacity_alert_min*
- */sys/class/power_supply/<supply_name>/capacity_error_margin*
- */sys/class/power_supply/<supply_name>/capacity_level*
- */sys/class/power_supply/<supply_name>/charge_control_limit*
- */sys/class/power_supply/<supply_name>/charge_control_limit_max*
- */sys/class/power_supply/<supply_name>/charge_control_start_threshold*
- */sys/class/power_supply/<supply_name>/charge_control_end_threshold*
- */sys/class/power_supply/<supply_name>/charge_type*
- */sys/class/power_supply/<supply_name>/charge_term_current*
- */sys/class/power_supply/<supply_name>/health*
- */sys/class/power_supply/<supply_name>/precharge_current*
- */sys/class/power_supply/<supply_name>/present*
- */sys/class/power_supply/<supply_name>/status*

- */sys/class/power_supply/ltc4162-l/force_telemetry*
- */sys/class/power_supply/ltc4162-l/arm_ship_mode*

5.2.329 File testing/sysfs-class-power-mp2629

Has the following ABI:

- */sys/class/power_supply/mp2629_battery/batt_impedance_compen*

5.2.330 File testing/sysfs-class-power-rt9467

Has the following ABI:

- */sys/class/power_supply/rt9467-*/sysoff_enable*

5.2.331 File testing/sysfs-class-power-rt9471

Has the following ABI:

- */sys/class/power_supply/rt9471-*/sysoff_enable*
- */sys/class/power_supply/rt9471-*/port_detect_enable*

5.2.332 File testing/sysfs-class-power-surface

Has the following ABI:

- */sys/class/power_supply/<supply_name>/alarm*

5.2.333 File testing/sysfs-class-power-twl4030

Has the following ABI:

- */sys/class/power_supply/twl4030_usb/mode*
- */sys/class/power_supply/twl4030_ac/mode*

5.2.334 File testing/sysfs-class-power-wilco

Has the following ABI:

- */sys/class/power_supply/wilco-charger/charge_type*
- */sys/class/power_supply/wilco-charger/charge_control_start_threshold*
- */sys/class/power_supply/wilco-charger/charge_control_end_threshold*

5.2.335 File testing/sysfs-class-powercap

Has the following ABI:

- */sys/class/powercap/*
- */sys/class/powercap/<control type>*
- */sys/class/powercap/<control type>/enabled*
- */sys/class/powercap/<control type>/<power zone>*
- */sys/class/powercap/<control type>/<power zone>/<child power zone>*
- */sys/class/powercap/.../<power zone>/name*
- */sys/class/powercap/.../<power zone>/energy_uj*
- */sys/class/powercap/.../<power zone>/max_energy_range_uj*
- */sys/class/powercap/.../<power zone>/power_uw*
- */sys/class/powercap/.../<power zone>/max_power_range_uw*
- */sys/class/powercap/.../<power zone>/constraint_X_name*
- */sys/class/powercap/.../<power zone>/constraint_X_power_limit_uw*
- */sys/class/powercap/.../<power zone>/constraint_X_time_window_us*
- */sys/class/powercap/<control type>/.../constraint_X_max_power_uw*
- */sys/class/powercap/<control type>/.../constraint_X_min_power_uw*
- */sys/class/powercap/.../<power zone>/constraint_X_max_time_window_us*
- */sys/class/powercap/.../<power zone>/constraint_X_min_time_window_us*
- */sys/class/powercap/.../<power zone>/enabled*

5.2.336 File testing/sysfs-class-pwm

Has the following ABI:

- */sys/class/pwm/*
- */sys/class/pwm/pwmchip<N>/*
- */sys/class/pwm/pwmchip<N>/npwm*
- */sys/class/pwm/pwmchip<N>/export*
- */sys/class/pwm/pwmchip<N>/unexport*
- */sys/class/pwm/pwmchip<N>/pwmX*
- */sys/class/pwm/pwmchip<N>/pwmX/period*
- */sys/class/pwm/pwmchip<N>/pwmX/duty_cycle*
- */sys/class/pwm/pwmchip<N>/pwmX/polarity*
- */sys/class/pwm/pwmchip<N>/pwmX/enable*
- */sys/class/pwm/pwmchip<N>/pwmX/capture*

5.2.337 File testing/sysfs-class-rapidio

Has the following ABI:

- */sys/class/rapidio_port*
- */sys/class/rapidio_port/rapidio<N>/sys_size*
- */sys/class/rapidio_port/rapidio<N>/port_destid*

5.2.338 File testing/sysfs-class-rc

Has the following ABI:

- */sys/class/rc/*
- */sys/class/rc/rc<N>/*
- */sys/class/rc/rc<N>/protocols*
- */sys/class/rc/rc<N>/filter*
- */sys/class/rc/rc<N>/filter_mask*
- */sys/class/rc/rc<N>/wakeup_protocols*
- */sys/class/rc/rc<N>/wakeup_filter*
- */sys/class/rc/rc<N>/wakeup_filter_mask*

5.2.339 File testing/sysfs-class-rc-nuvoton

Has the following ABI:

- */sys/class/rc/rc<N>/wakeup_data*

5.2.340 File testing/sysfs-class-regulator

Has the following ABI:

- */sys/class/regulator/.../state*
- */sys/class/regulator/.../status*
- */sys/class/regulator/.../type*
- */sys/class/regulator/.../microvolts*
- */sys/class/regulator/.../microamps*
- */sys/class/regulator/.../opmode*
- */sys/class/regulator/.../min_microvolts*
- */sys/class/regulator/.../max_microvolts*
- */sys/class/regulator/.../min_microamps*
- */sys/class/regulator/.../max_microamps*
- */sys/class/regulator/.../name*

- */sys/class/regulator/.../num_users*
- */sys/class/regulator/.../requested_microamps*
- */sys/class/regulator/.../parent*
- */sys/class/regulator/.../suspend_mem_microvolts*
- */sys/class/regulator/.../suspend_disk_microvolts*
- */sys/class/regulator/.../suspend_standby_microvolts*
- */sys/class/regulator/.../suspend_mem_mode*
- */sys/class/regulator/.../suspend_disk_mode*
- */sys/class/regulator/.../suspend_standby_mode*
- */sys/class/regulator/.../suspend_mem_state*
- */sys/class/regulator/.../suspend_disk_state*
- */sys/class/regulator/.../suspend_standby_state*
- */sys/class/regulator/.../bypass*
- */sys/class/regulator/.../under_voltage*
- */sys/class/regulator/.../over_current*
- */sys/class/regulator/.../regulation_out*
- */sys/class/regulator/.../fail*
- */sys/class/regulator/.../over_temp*
- */sys/class/regulator/.../under_voltage_warn*
- */sys/class/regulator/.../over_current_warn*
- */sys/class/regulator/.../over_voltage_warn*
- */sys/class/regulator/.../over_temp_warn*

5.2.341 File testing/sysfs-class-remoteproc

Has the following ABI:

- */sys/class/remoteproc/.../firmware*
- */sys/class/remoteproc/.../state*
- */sys/class/remoteproc/.../name*
- */sys/class/remoteproc/.../coredump*
- */sys/class/remoteproc/.../recovery*

5.2.342 File testing/sysfs-class-rnbd-client

Has the following ABI:

- */sys/class/rnbd-client*
- */sys/class/rnbd-client/ctl/map_device*
- */sys/class/rnbd-client/ctl/devices/*

5.2.343 File testing/sysfs-class-rnbd-server

Has the following ABI:

- */sys/class/rnbd-server*
- */sys/class/rnbd-server/ctl/*
- */sys/class/rnbd-server/ctl/devices/<device_name>/block_dev*
- */sys/class/rnbd-server/ctl/devices/<device_name>/sessions/*
- */sys/class/rnbd-server/ctl/devices/<device_name>/sessions/<session-name>/read_only*
- */sys/class/rnbd-server/ctl/devices/<device_name>/sessions/<session-name>/mapping_path*
- */sys/class/rnbd-server/ctl/devices/<device_name>/sessions/<session-name>/access_mode*
- */sys/class/rnbd-server/ctl/devices/<device_name>/sessions/<session-name>/force_close*

5.2.344 File testing/sysfs-class-rtc

Has the following ABI:

- */sys/class/rtc/*
- */sys/class/rtc/rtcX/*
- */sys/class/rtc/rtcX/date*
- */sys/class/rtc/rtcX/hctosys*
- */sys/class/rtc/rtcX/max_user_freq*
- */sys/class/rtc/rtcX/name*
- */sys/class/rtc/rtcX/range*
- */sys/class/rtc/rtcX/since_epoch*
- */sys/class/rtc/rtcX/time*
- */sys/class/rtc/rtcX/offset*
- */sys/class/rtc/rtcX/wakealarm*

5.2.345 File testing/sysfs-class-rtc-rtc0-device-rtc_calibration

Has the following ABI:

- */sys/class/rtc/rtc0/device/rtc_calibration*

5.2.346 File testing/sysfs-class-rtrs-client

Has the following ABI:

- */sys/class/rtrs-client*
- */sys/class/rtrs-client/<session-name>/add_path*
- */sys/class/rtrs-client/<session-name>/max_reconnect_attempts*
- */sys/class/rtrs-client/<session-name>/mp_policy*
- */sys/class/rtrs-client/<session-name>/paths/*
- */sys/class/rtrs-client/<session-name>/paths/<src@dst>/state*
- */sys/class/rtrs-client/<session-name>/paths/<src@dst>/reconnect*
- */sys/class/rtrs-client/<session-name>/paths/<src@dst>/disconnect*
- */sys/class/rtrs-client/<session-name>/paths/<src@dst>/remove_path*
- */sys/class/rtrs-client/<session-name>/paths/<src@dst>/hca_name*
- */sys/class/rtrs-client/<session-name>/paths/<src@dst>/hca_port*
- */sys/class/rtrs-client/<session-name>/paths/<src@dst>/src_addr*
- */sys/class/rtrs-client/<session-name>/paths/<src@dst>/dst_addr*
- */sys/class/rtrs-client/<session-name>/paths/<src@dst>/cur_latency*
- */sys/class/rtrs-client/<session-name>/paths/<src@dst>/stats/reset_all*
- */sys/class/rtrs-client/<session-name>/paths/<src@dst>/stats/cpu_migration*
- */sys/class/rtrs-client/<session-name>/paths/<src@dst>/stats/reconnects*
- */sys/class/rtrs-client/<session-name>/paths/<src@dst>/stats/rdma*

5.2.347 File testing/sysfs-class-rtrs-server

Has the following ABI:

- */sys/class/rtrs-server*
- */sys/class/rtrs-server/<session-name>/paths/*
- */sys/class/rtrs-server/<session-name>/paths/<src@dst>/disconnect*
- */sys/class/rtrs-server/<session-name>/paths/<src@dst>/hca_name*
- */sys/class/rtrs-server/<session-name>/paths/<src@dst>/hca_port*
- */sys/class/rtrs-server/<session-name>/paths/<src@dst>/src_addr*
- */sys/class/rtrs-server/<session-name>/paths/<src@dst>/dst_addr*

- */sys/class/rtrs-server/<session-name>/paths/<src@dst>/stats/rdma*

5.2.348 File testing/sysfs-class-scsi_host

Has the following ABI:

- */sys/class/scsi_host/hostX/isci_id*
- */sys/class/scsi_host/hostX/acciopath_status*
- */sys/class/scsi_host/hostX/link_power_management_policy*
- */sys/class/scsi_host/hostX/em_message*
- */sys/class/scsi_host/hostX/em_message_type*
- */sys/class/scsi_host/hostX/ahci_port_cmd*
- */sys/class/scsi_host/hostX/ahci_host_caps*
- */sys/class/scsi_host/hostX/ahci_host_cap2*
- */sys/class/scsi_host/hostX/ahci_host_version*
- */sys/class/scsi_host/hostX/em_buffer*
- */sys/class/scsi_host/hostX/em_message_supported*

5.2.349 File testing/sysfs-class-scsi_tape

Has the following ABI:

- */sys/class/scsi_tape/*/stats/in_flight*
- */sys/class/scsi_tape/*/stats/io_ns*
- */sys/class/scsi_tape/*/stats/other_cnt*
- */sys/class/scsi_tape/*/stats/read_byte_cnt*
- */sys/class/scsi_tape/*/stats/read_cnt*
- */sys/class/scsi_tape/*/stats/read_ns*
- */sys/class/scsi_tape/*/stats/write_byte_cnt*
- */sys/class/scsi_tape/*/stats/write_cnt*
- */sys/class/scsi_tape/*/stats/write_ms*
- */sys/class/scsi_tape/*/stats/resid_cnt*

5.2.350 File testing/sysfs-class-spi-eeprom

Has the following ABI:

- */sys/class/spi_master/spi<bus>/spi<bus>.<dev>/fram*
- */sys/class/spi_master/spi<bus>/spi<bus>.<dev>/sernum*

5.2.351 File testing/sysfs-class-stm

Has the following ABI:

- */sys/class/stm/<stm>/masters*
- */sys/class/stm/<stm>/channels*
- */sys/class/stm/<stm>/hw_override*

5.2.352 File testing/sysfs-class-stm_source

Has the following ABI:

- */sys/class/stm_source/<stm_source>/stm_source_link*

5.2.353 File testing/sysfs-class-switchtec

switchtec - Microsemi Switchtec PCI Switch Management Endpoint

For details on this subsystem look at /driver-api/switchtec.

Has the following ABI:

- */sys/class/switchtec*
- */sys/class/switchtec/switchtec[0-9]+/component_id*
- */sys/class/switchtec/switchtec[0-9]+/component_revision*
- */sys/class/switchtec/switchtec[0-9]+/component_vendor*
- */sys/class/switchtec/switchtec[0-9]+/device_version*
- */sys/class/switchtec/switchtec[0-9]+/fw_version*
- */sys/class/switchtec/switchtec[0-9]+/partition*
- */sys/class/switchtec/switchtec[0-9]+/partition_count*
- */sys/class/switchtec/switchtec[0-9]+/product_id*
- */sys/class/switchtec/switchtec[0-9]+/product_revision*
- */sys/class/switchtec/switchtec[0-9]+/product_vendor*

5.2.354 File testing/sysfs-class-thermal

Has the following ABI:

- */sys/class/thermal/thermal_zoneX/type*
- */sys/class/thermal/thermal_zoneX/temp*
- */sys/class/thermal/thermal_zoneX/mode*
- */sys/class/thermal/thermal_zoneX/policy*
- */sys/class/thermal/thermal_zoneX/available_policies*
- */sys/class/thermal/thermal_zoneX/trip_point_Y_temp*
- */sys/class/thermal/thermal_zoneX/trip_point_Y_type*
- */sys/class/thermal/thermal_zoneX/trip_point_Y_hyst*
- */sys/class/thermal/thermal_zoneX/cdevY*
- */sys/class/thermal/thermal_zoneX/cdevY_trip_point*
- */sys/class/thermal/thermal_zoneX/cdevY_weight*
- */sys/class/thermal/thermal_zoneX/emul_temp*
- */sys/class/thermal/thermal_zoneX/k_d*
- */sys/class/thermal/thermal_zoneX/k_i*
- */sys/class/thermal/thermal_zoneX/k_po*
- */sys/class/thermal/thermal_zoneX/k_pu*
- */sys/class/thermal/thermal_zoneX/integral_cutoff*
- */sys/class/thermal/thermal_zoneX/slope*
- */sys/class/thermal/thermal_zoneX/offset*
- */sys/class/thermal/thermal_zoneX/sustainable_power*
- */sys/class/thermal/cooling_deviceX/type*
- */sys/class/thermal/cooling_deviceX/max_state*
- */sys/class/thermal/cooling_deviceX/cur_state*
- */sys/class/thermal/cooling_deviceX/stats/reset*
- */sys/class/thermal/cooling_deviceX/stats/time_in_state_ms:*
- */sys/class/thermal/cooling_deviceX/stats/total_trans*
- */sys/class/thermal/cooling_deviceX/stats/trans_table*

5.2.355 File testing/sysfs-class-typec

USB Type-C port devices (eg. /sys/class/typec/port0/)

Has the following ABI:

- */sys/class/typec/<port>/data_role*
- */sys/class/typec/<port>/power_role*
- */sys/class/typec/<port>/port_type*
- */sys/class/typec/<port>/vconn_source*
- */sys/class/typec/<port>/power_operation_mode*
- */sys/class/typec/<port>/preferred_role*
- */sys/class/typec/<port>/supported_accessory_modes*
- */sys/class/typec/<port>/usb_power_delivery_revision*
- */sys/class/typec/<port>-{partner|cable}/usb_power_delivery_revision*
- */sys/class/typec/<port>/usb_typec_revision*
- */sys/class/typec/<port>/orientation*
- */sys/class/typec/<port>/select_usb_power_delivery*
- */sys/class/typec/<port>-partner/accessory_mode*
- */sys/class/typec/<port>-partner/supports_usb_power_delivery*
- */sys/class/typec/<port>-partner/number_of_alternate_modes*
- */sys/class/typec/<port>-partner/type*
- */sys/class/typec/<port>-partner/identity/*
- */sys/class/typec/<port>-cable/type*
- */sys/class/typec/<port>-cable/plug_type*
- */sys/class/typec/<port>-<plug>/number_of_alternate_modes*
- */sys/class/typec/<port>-{partner|cable}/identity/*
- */sys/class/typec/<port>-{partner|cable}/identity/id_header*
- */sys/class/typec/<port>-{partner|cable}/identity/cert_stat*
- */sys/class/typec/<port>-{partner|cable}/identity/product*
- */sys/class/typec/<port>-{partner|cable}/identity/product_type_vdo1*
- */sys/class/typec/<port>-{partner|cable}/identity/product_type_vdo2*
- */sys/class/typec/<port>-{partner|cable}/identity/product_type_vdo3*
- */sys/class/typec/<port>/<alt mode>/supported_roles*

5.2.356 File testing/sysfs-class-usb_power_delivery

Has the following ABI:

- */sys/class/usb_power_delivery*
- */sys/class/usb_power_delivery/.../revision*
- */sys/class/usb_power_delivery/.../version*
- */sys/class/usb_power_delivery/.../source-capabilities*
- */sys/class/usb_power_delivery/.../sink-capabilities*
- */sys/class/usb_power_delivery/.../<capability>/<position>:fixed_supply*
- */sys/class/usb_power_delivery/.../<capability>/1:fixed_supply/dual_role_power*
- */sys/class/usb_power_delivery/.../source-capabilities/1:fixed_supply/usb_suspend_supported*
- */sys/class/usb_power_delivery/.../sink-capabilities/1:fixed_supply/higher_capability*
- */sys/class/usb_power_delivery/.../<capability>/1:fixed_supply/unconstrained_power*
- */sys/class/usb_power_delivery/.../<capability>/1:fixed_supply/usb_communication_capable*
- */sys/class/usb_power_delivery/.../<capability>/1:fixed_supply/dual_role_data*
- */sys/class/usb_power_delivery/.../<capability>/1:fixed_supply/unchunked_extended_messages_su*
- */sys/class/usb_power_delivery/.../<capability>/<position>:fixed_supply/voltage*
- */sys/class/usb_power_delivery/.../source-capabilities/<position>:fixed_supply/peak_current*
- */sys/class/usb_power_delivery/.../source-capabilities/<position>:fixed_supply/maximum_current*
- */sys/class/usb_power_delivery/.../sink-capabilities/<position>:fixed_supply/operational_current*
- */sys/class/usb_power_delivery/.../sink-capabilities/<position>:fixed_supply/fast_role_swap_curre*
- */sys/class/usb_power_delivery/.../<capability>/<position>:variable_supply*
- */sys/class/usb_power_delivery/.../<capability>/<position>:variable_supply/maximum_voltage*

- */sys/class/usb_power_delivery/.../<capability>/<position>:programmable_supply/minimum_volta*
- */sys/class/usb_power_delivery/.../<capability>/<position>:programmable_supply/maximum_curr*

- */sys/class/usb_power_delivery/.../source-capabilities/<position>:programmable_supply/pps_pow*

5.2.357 File testing/sysfs-class-usb_role

Has the following ABI:

- */sys/class/usb_role/*
- */sys/class/usb_role/<switch>/role*

5.2.358 File testing/sysfs-class-vduse

Has the following ABI:

- */sys/class/vduse/*
- */sys/class/vduse/control/*
- */sys/class/vduse/<device-name>/*
- */sys/class/vduse/<device-name>/msg_timeout*

5.2.359 File testing/sysfs-class-wakeup

Has the following ABI:

- */sys/class/wakeup/*
- */sys/class/wakeup/.../name*
- */sys/class/wakeup/.../active_count*
- */sys/class/wakeup/.../event_count*
- */sys/class/wakeup/.../wakeup_count*
- */sys/class/wakeup/.../expire_count*
- */sys/class/wakeup/.../active_time_ms*
- */sys/class/wakeup/.../total_time_ms*
- */sys/class/wakeup/.../max_time_ms*
- */sys/class/wakeup/.../last_change_ms*
- */sys/class/wakeup/.../prevent_suspend_time_ms*

5.2.360 File testing/sysfs-class-watchdog

Has the following ABI:

- */sys/class/watchdog/watchdogn/bootstatus*
- */sys/class/watchdog/watchdogn/options*
- */sys/class/watchdog/watchdogn/fw_version*
- */sys/class/watchdog/watchdogn/identity*
- */sys/class/watchdog/watchdogn/nowayout*
- */sys/class/watchdog/watchdogn/state*
- */sys/class/watchdog/watchdogn/status*
- */sys/class/watchdog/watchdogn/timeleft*
- */sys/class/watchdog/watchdogn/timeout*
- */sys/class/watchdog/watchdogn/pretimeout*
- */sys/class/watchdog/watchdogn/pretimeout_avaialable_governors*
- */sys/class/watchdog/watchdogn/pretimeout_governor*
- */sys/class/watchdog/watchdog1/access_cs0*

5.2.361 File testing/sysfs-class-zram

Has the following ABI:

- */sys/class/zram-control/*
- */sys/class/zram-control/hot_add*
- */sys/class/zram-control/hot_remove*

5.2.362 File testing/sysfs-dev

Has the following ABI:

- */sys/dev*

5.2.363 File testing/sysfs-devices

Has the following ABI:

- */sys/devices*

5.2.364 File testing/sysfs-devices-consumer

Has the following ABI:

- */sys/devices/.../consumer:<consumer>*

5.2.365 File testing/sysfs-devices-coredump

Has the following ABI:

- */sys/devices/.../coredump*

5.2.366 File testing/sysfs-devices-edac

Has the following ABI:

- */sys/devices/system/edac/mc/mc*/reset_counters*
- */sys/devices/system/edac/mc/mc*/seconds_since_reset*
- */sys/devices/system/edac/mc/mc*/mc_name*
- */sys/devices/system/edac/mc/mc*/size_mb*
- */sys/devices/system/edac/mc/mc*/ue_count*
- */sys/devices/system/edac/mc/mc*/ue_noinfo_count*
- */sys/devices/system/edac/mc/mc*/ce_count*
- */sys/devices/system/edac/mc/mc*/ce_noinfo_count*
- */sys/devices/system/edac/mc/mc*/sdram_scrub_rate*
- */sys/devices/system/edac/mc/mc*/max_location*
- */sys/devices/system/edac/mc/mc*/(dimm|rank)*/size*
- */sys/devices/system/edac/mc/mc*/(dimm|rank)*/dimm_dev_type*
- */sys/devices/system/edac/mc/mc*/(dimm|rank)*/dimm_edac_mode*
- */sys/devices/system/edac/mc/mc*/(dimm|rank)*/dimm_label*
- */sys/devices/system/edac/mc/mc*/(dimm|rank)*/dimm_location*
- */sys/devices/system/edac/mc/mc*/(dimm|rank)*/dimm_mem_type*
- */sys/devices/system/edac/mc/mc*/(dimm|rank)*/dimm_ce_count*
- */sys/devices/system/edac/mc/mc*/(dimm|rank)*/dimm_ue_count*

5.2.367 File testing/sysfs-devices-firmware_node

Has the following ABI:

- */sys/devices/.../firmware_node/*
- */sys/devices/.../firmware_node/description*

5.2.368 File testing/sysfs-devices-hisi_ptt

Has the following ABI:

- */sys/devices/hisi_ptt<sicl_id>_<core_id>/tune*
- */sys/devices/hisi_ptt<sicl_id>_<core_id>/tune/qos_tx_cpl*
- */sys/devices/hisi_ptt<sicl_id>_<core_id>/tune/qos_tx_np*
- */sys/devices/hisi_ptt<sicl_id>_<core_id>/tune/qos_tx_p*
- */sys/devices/hisi_ptt<sicl_id>_<core_id>/tune/rx_alloc_buf_level*
- */sys/devices/hisi_ptt<sicl_id>_<core_id>/tune/tx_alloc_buf_level*
- */sys/devices/hisi_ptt<sicl_id>_<core_id>/root_port_filters*
- */sys/devices/hisi_ptt<sicl_id>_<core_id>/root_port_filters/multiselect*
- */sys/devices/hisi_ptt<sicl_id>_<core_id>/root_port_filters/<bdf>*
- */sys/devices/hisi_ptt<sicl_id>_<core_id>/requester_filters*
- */sys/devices/hisi_ptt<sicl_id>_<core_id>/requester_filters/multiselect*
- */sys/devices/hisi_ptt<sicl_id>_<core_id>/requester_filters/<bdf>*

5.2.369 File testing/sysfs-devices-lpss_ltr

Has the following ABI:

- */sys/devices/.../lpss_ltr/*
- */sys/devices/.../lpss_ltr/ltr_mode*
- */sys/devices/.../lpss_ltr/auto_ltr*
- */sys/devices/.../lpss_ltr/sw_ltr*

5.2.370 File testing/sysfs-devices-mapping

Has the following ABI:

- */sys/devices/uncore_iio_x/dieX*
- */sys/devices/uncore_upi_x/dieX*

5.2.371 File testing/sysfs-devices-memory

Has the following ABI:

- */sys/devices/system/memory*
- */sys/devices/system/memory/memoryX/removable*
- */sys/devices/system/memory/memoryX/phys_device*
- */sys/devices/system/memory/memoryX/phys_index*
- */sys/devices/system/memory/memoryX/state*
- */sys/devices/system/memory/memoryX/valid_zones*
- */sys/devices/system/memoryX/nodeY*
- */sys/devices/system/node/nodeX/memoryY*
- */sys/devices/system/memory/crash_hotplug*

5.2.372 File testing/sysfs-devices-mmc

Has the following ABI:

- */sys/devices/.../mmc_host/mmcX/mmcX:XXXX/enhanced_area_offset*
- */sys/devices/.../mmc_host/mmcX/mmcX:XXXX/enhanced_area_size*

5.2.373 File testing/sysfs-devices-online

Has the following ABI:

- */sys/devices/.../online*

5.2.374 File testing/sysfs-devices-physical_location

Has the following ABI:

- */sys/devices/.../physical_location*
- */sys/devices/.../physical_location/panel*
- */sys/devices/.../physical_location/vertical_position*
- */sys/devices/.../physical_location/horizontal_position*
- */sys/devices/.../physical_location/dock*
- */sys/devices/.../physical_location/lid*

5.2.375 File testing/sysfs-devices-platform-ACPI-TAD

ACPI Time and Alarm (TAD) device attributes.

Has the following ABI:

- */sys/bus/platform/devices/ACPI000E:00/caps*
- */sys/bus/platform/devices/ACPI000E:00/ac_alarm*
- */sys/bus/platform/devices/ACPI000E:00/ac_policy*
- */sys/bus/platform/devices/ACPI000E:00/ac_status*
- */sys/bus/platform/devices/ACPI000E:00/dc_alarm*
- */sys/bus/platform/devices/ACPI000E:00/dc_policy*
- */sys/bus/platform/devices/ACPI000E:00/dc_status*

5.2.376 File testing/sysfs-devices-platform-_UDC_-gadget

Has the following ABI:

- */sys/devices/platform/_UDC_/gadget/suspended*
- */sys/devices/platform/_UDC_/gadget/gadget-lunX/nofua*

5.2.377 File testing/sysfs-devices-platform-docg3

Has the following ABI:

- */sys/devices/platform/docg3/f[0-3]_dps[01]_is_keylocked*
- */sys/devices/platform/docg3/f[0-3]_dps[01]_protection_key*

5.2.378 File testing/sysfs-devices-platform-dock

Has the following ABI:

- */sys/devices/platform/dock.<N>/docked*
- */sys/devices/platform/dock.<N>/undock*
- */sys/devices/platform/dock.<N>/uid*
- */sys/devices/platform/dock.<N>/flags*
- */sys/devices/platform/dock.<N>/type*

5.2.379 File testing/sysfs-devices-platform-ipmi

Has the following ABI:

- */sys/devices/platform/ipmi_bmc.*/firmware_revision*
- */sys/devices/platform/ipmi_bmc.*/aux_firmware_revision*
- */sys/devices/platform/ipmi_bmc.*/revision*
- */sys/devices/platform/ipmi_bmc.*/provides_device_sdrs*
- */sys/devices/platform/ipmi_bmc.*/device_id*
- */sys/devices/platform/ipmi_bmc.*/additional_device_support*
- */sys/devices/platform/ipmi_bmc.*/ipmi_version*
- */sys/devices/platform/ipmi_bmc.*/manufacturer_id*
- */sys/devices/platform/ipmi_bmc.*/product_id*
- */sys/devices/platform/ipmi_bmc.*/guid*
- */sys/devices/platform/ipmi_si.*/type*
- */sys/devices/platform/ipmi_si.*/idles*
- */sys/devices/platform/ipmi_si.*/watchdog_pretimeouts*
- */sys/devices/platform/ipmi_si.*/complete_transactions*
- */sys/devices/platform/ipmi_si.*/events*
- */sys/devices/platform/ipmi_si.*/interrupts*
- */sys/devices/platform/ipmi_si.*/hosed_count*
- */sys/devices/platform/ipmi_si.*/long_timeouts*
- */sys/devices/platform/ipmi_si.*/flag_fetches*
- */sys/devices/platform/ipmi_si.*/attentions*
- */sys/devices/platform/ipmi_si.*/incoming_messages*
- */sys/devices/platform/ipmi_si.*/short_timeouts*
- */sys/devices/platform/ipmi_si.*/interrupts_enabled*
- */sys/devices/platform/ipmi_si.*/params*
- */sys/devices/platform/dmi-ipmi-ssif.*/type*
- */sys/devices/platform/dmi-ipmi-ssif.*/hosed*
- */sys/devices/platform/dmi-ipmi-ssif.*/alerts*
- */sys/devices/platform/dmi-ipmi-ssif.*/sent_messages*
- */sys/devices/platform/dmi-ipmi-ssif.*/sent_messages_parts*
- */sys/devices/platform/dmi-ipmi-ssif.*/received_messages*
- */sys/devices/platform/dmi-ipmi-ssif.*/received_message_parts*
- */sys/devices/platform/dmi-ipmi-ssif.*/events*

- */sys/devices/platform/dmi-ipmi-ssif.*/watchdog_pretimeouts*
- */sys/devices/platform/dmi-ipmi-ssif.*/flag_fetches*
- */sys/devices/platform/dmi-ipmi-ssif.*/send_retries*
- */sys/devices/platform/dmi-ipmi-ssif.*/receive_retries*
- */sys/devices/platform/dmi-ipmi-ssif.*/send_errors*
- */sys/devices/platform/dmi-ipmi-ssif.*/receive_errors*

5.2.380 File testing/sysfs-devices-platform-kunpeng_hccs

Has the following ABI:

- */sys/devices/platform/HISI04Bx:00/chipX/all_linked*
- */sys/devices/platform/HISI04Bx:00/chipX/linked_full_lane*
- */sys/devices/platform/HISI04Bx:00/chipX/crc_err_cnt*
- */sys/devices/platform/HISI04Bx:00/chipX/dieY/all_linked*
- */sys/devices/platform/HISI04Bx:00/chipX/dieY/linked_full_lane*
- */sys/devices/platform/HISI04Bx:00/chipX/dieY/crc_err_cnt*
- */sys/devices/platform/HISI04Bx:00/chipX/dieY/hccsN/type*
- */sys/devices/platform/HISI04Bx:00/chipX/dieY/hccsN/lane_mode*
- */sys/devices/platform/HISI04Bx:00/chipX/dieY/hccsN/enable*
- */sys/devices/platform/HISI04Bx:00/chipX/dieY/hccsN/cur_lane_num*
- */sys/devices/platform/HISI04Bx:00/chipX/dieY/hccsN/link_fsm*
- */sys/devices/platform/HISI04Bx:00/chipX/dieY/hccsN/lane_mask*
- */sys/devices/platform/HISI04Bx:00/chipX/dieY/hccsN/crc_err_cnt*

5.2.381 File testing/sysfs-devices-platform-sh_mobile_lcdc_fb

Has the following ABI:

- */sys/devices/platform/sh_mobile_lcdc_fb.[0-3]/graphics/fb[0-9]/ovl_alpha*
- */sys/devices/platform/sh_mobile_lcdc_fb.[0-3]/graphics/fb[0-9]/ovl_mode*
- */sys/devices/platform/sh_mobile_lcdc_fb.[0-3]/graphics/fb[0-9]/ovl_position*
- */sys/devices/platform/sh_mobile_lcdc_fb.[0-3]/graphics/fb[0-9]/ovl_rop3*

5.2.382 File testing/sysfs-devices-platform-soc-ipa

Has the following ABI:

- */sys/devices/platform/soc@X/XXXXXXX.ipa/*
- */.../XXXXXXX.ipa/version*
- */.../XXXXXXX.ipa/feature/*
- */.../XXXXXXX.ipa/feature/rx_offload*
- */.../XXXXXXX.ipa/feature/tx_offload*
- */.../XXXXXXX.ipa/endpoint_id/*
- */.../XXXXXXX.ipa/endpoint_id/modem_rx*
- */.../XXXXXXX.ipa/endpoint_id/modem_tx*
- */.../XXXXXXX.ipa/endpoint_id/monitor_rx*
- */.../XXXXXXX.ipa/modem/*
- */.../XXXXXXX.ipa/modem/rx_endpoint_id*
- */.../XXXXXXX.ipa/modem/tx_endpoint_id*

5.2.383 File testing/sysfs-devices-platform-stratix10-rsu

Intel Stratix10 Remote System Update (RSU) device attributes

Has the following ABI:

- */sys/devices/platform/stratix10-rsu.0/current_image*
- */sys/devices/platform/stratix10-rsu.0/fail_image*
- */sys/devices/platform/stratix10-rsu.0/state*
- */sys/devices/platform/stratix10-rsu.0/version*
- */sys/devices/platform/stratix10-rsu.0/error_location*
- */sys/devices/platform/stratix10-rsu.0/error_details*
- */sys/devices/platform/stratix10-rsu.0/retry_counter*
- */sys/devices/platform/stratix10-rsu.0/reboot_image*
- */sys/devices/platform/stratix10-rsu.0/notify*
- */sys/devices/platform/stratix10-rsu.0/dcmf0*
- */sys/devices/platform/stratix10-rsu.0/dcmf1*
- */sys/devices/platform/stratix10-rsu.0/dcmf2*
- */sys/devices/platform/stratix10-rsu.0/dcmf3*
- */sys/devices/platform/stratix10-rsu.0/max_retry*

5.2.384 File testing/sysfs-devices-platform-trackpoint

Has the following ABI:

- */sys/devices/platform/i8042/.../sensitivity*
- */sys/devices/platform/i8042/.../intertia*
- */sys/devices/platform/i8042/.../reach*
- */sys/devices/platform/i8042/.../draghys*
- */sys/devices/platform/i8042/.../mindrag*
- */sys/devices/platform/i8042/.../speed*
- */sys/devices/platform/i8042/.../thresh*
- */sys/devices/platform/i8042/.../upthresh*
- */sys/devices/platform/i8042/.../ztime*
- */sys/devices/platform/i8042/.../jenks*
- */sys/devices/platform/i8042/.../skipback*
- */sys/devices/platform/i8042/.../ext_dev*
- */sys/devices/platform/i8042/.../press_to_select*
- */sys/devices/platform/i8042/.../drift_time*

5.2.385 File testing/sysfs-devices-power

Has the following ABI:

- */sys/devices/.../power/*
- */sys/devices/.../power/wakeup*
- */sys/devices/.../power/control*
- */sys/devices/.../power/async*
- */sys/devices/.../power/wakeup_count*
- */sys/devices/.../power/wakeup_active_count*
- */sys/devices/.../power/wakeup_abort_count*
- */sys/devices/.../power/wakeup_expire_count*
- */sys/devices/.../power/wakeup_active*
- */sys/devices/.../power/wakeup_total_time_ms*
- */sys/devices/.../power/wakeup_max_time_ms*
- */sys/devices/.../power/wakeup_last_time_ms*
- */sys/devices/.../power/wakeup_prevent_sleep_time_ms*
- */sys/devices/.../power/autosuspend_delay_ms*
- */sys/devices/.../power/pm_qos_resume_latency_us*

- */sys/devices/.../power/pm_qos_latency_tolerance_us*
- */sys/devices/.../power/pm_qos_no_power_off*
- */sys/devices/.../power/runtime_status*
- */sys/devices/.../power/runtime_active_time*
- */sys/devices/.../power/runtime_suspended_time*
- */sys/devices/.../power/runtime_usage*
- */sys/devices/.../power/runtime_enabled*
- */sys/devices/.../power/runtime_active_kids*

5.2.386 File testing/sysfs-devices-power_resources_D0

Has the following ABI:

- */sys/devices/.../power_resources_D0/*

5.2.387 File testing/sysfs-devices-power_resources_D1

Has the following ABI:

- */sys/devices/.../power_resources_D1/*

5.2.388 File testing/sysfs-devices-power_resources_D2

Has the following ABI:

- */sys/devices/.../power_resources_D2/*

5.2.389 File testing/sysfs-devices-power_resources_D3hot

Has the following ABI:

- */sys/devices/.../power_resources_D3hot/*

5.2.390 File testing/sysfs-devices-power_resources_wakeup

Has the following ABI:

- */sys/devices/.../power_resources_wakeup/*

5.2.391 File testing/sysfs-devices-power_state

Has the following ABI:

- */sys/devices/.../power_state*

5.2.392 File testing/sysfs-devices-real_power_state

Has the following ABI:

- */sys/devices/.../real_power_state*

5.2.393 File testing/sysfs-devices-removable

Has the following ABI:

- */sys/devices/.../removable*

5.2.394 File testing/sysfs-devices-resource_in_use

Has the following ABI:

- */sys/devices/.../resource_in_use*

5.2.395 File testing/sysfs-devices-soc

Has the following ABI:

- */sys/devices/socX*
- */sys/devices/socX/machine*
- */sys/devices/socX/family*
- */sys/devices/socX/serial_number*
- */sys/devices/socX/soc_id*
- */sys/devices/socX/revision*
- */sys/devices/socX/process*
- */sys/bus/soc*

5.2.396 File testing/sysfs-devices-software_node

Has the following ABI:

- */sys/devices/.../software_node/*

5.2.397 File testing/sysfs-devices-state_synced

Has the following ABI:

- */sys/devices/.../state_synced*

5.2.398 File testing/sysfs-devices-sun

Has the following ABI:

- */sys/devices/.../sun*

5.2.399 File testing/sysfs-devices-supplier

Has the following ABI:

- */sys/devices/.../supplier:<supplier>*

5.2.400 File testing/sysfs-devices-system-cpu

Has the following ABI:

- */sys/devices/system/cpu/*
- */sys/devices/system/cpu/kernel_max*
- */sys/devices/system/cpu/probe*
- */sys/devices/system/cpu/cpuX/node*
- */sys/devices/system/cpu/cpuX/topology/core_siblings*
- */sys/devices/system/cpu/cpuidle/available_governors*
- */sys/devices/system/cpu/cpuX/cpuidle/state<N>/name*

- */sys/devices/system/cpu/cpuX/mte_tcf_preferred*
- */sys/devices/system/cpu/nohz_full*
- */sys/devices/system/cpu/isolated*
- */sys/devices/system/cpu/crash_hotplug*

5.2.401 File testing/sysfs-devices-system-ibm-rtl

Has the following ABI:

- */sys/devices/system/ibm_rtl/state*
- */sys/devices/system/ibm_rtl/version*

5.2.402 File testing/sysfs-devices-system-xen_cpu

Has the following ABI:

- */sys/devices/system/xen_cpu/*
- */sys/devices/system/xen_cpu/xen_cpu#/online*

5.2.403 File testing/sysfs-devices-vfio-dev

Has the following ABI:

- */sys/.../<device>/vfio-dev/vfioX/*

5.2.404 File testing/sysfs-devices-waiting_for_supplier

Has the following ABI:

- */sys/devices/.../waiting_for_supplier*

5.2.405 File testing/sysfs-devices-xenbus

Has the following ABI:

- */sys/devices/*/xenbus/event_channels*
- */sys/devices/*/xenbus/events*
- */sys/devices/*/xenbus/jiffies_eoi_delayed*
- */sys/devices/*/xenbus/spurious_events*
- */sys/devices/*/xenbus/spurious_threshold*

5.2.406 File testing/sysfs-driver-altera-cvp

Has the following ABI:

- */sys/bus/pci/drivers/altera-cvp/chkcfg*

5.2.407 File testing/sysfs-driver-aspeed-uart-routing

Has the following ABI:

- */sys/bus/platform/drivers/aspeed-uart-routing/*/uart**
- */sys/bus/platform/drivers/aspeed-uart-routing/*/io**

5.2.408 File testing/sysfs-driver-bd9571mwv-regulator

Has the following ABI:

- */sys/bus/i2c/devices/.../bd9571mwv-regulator.*.auto/backup_mode*

5.2.409 File testing/sysfs-driver-ccp

Has the following ABI:

- */sys/bus/pci/devices/<BDF>/fused_part*
- */sys/bus/pci/devices/<BDF>/debug_lock_on*
- */sys/bus/pci/devices/<BDF>/tsme_status*
- */sys/bus/pci/devices/<BDF>/anti_rollback_status*
- */sys/bus/pci/devices/<BDF>/rpmc_production_enabled*
- */sys/bus/pci/devices/<BDF>/rpmc_spirom_available*
- */sys/bus/pci/devices/<BDF>/hsp_tpm_available*
- */sys/bus/pci/devices/<BDF>/rom_armor_enforced*
- */sys/bus/pci/devices/<BDF>/bootloader_version*
- */sys/bus/pci/devices/<BDF>/tee_version*

5.2.410 File testing/sysfs-driver-chromeos-acpi

Has the following ABI:

- */sys/bus/platform/devices/GGL0001:*/BINF.2*
- */sys/bus/platform/devices/GGL0001:*/BINF.3*
- */sys/bus/platform/devices/GGL0001:*/CHSW*
- */sys/bus/platform/devices/GGL0001:*/FMAP*
- */sys/bus/platform/devices/GGL0001:*/FRID*
- */sys/bus/platform/devices/GGL0001:*/FWID*

- */sys/class/accel/accel<n>/device/soft_reset*
- */sys/class/accel/accel<n>/device/soft_reset_cnt*
- */sys/class/accel/accel<n>/device/status*
- */sys/class/accel/accel<n>/device/thermal_ver*
- */sys/class/accel/accel<n>/device/tpc_clk*
- */sys/class/accel/accel<n>/device/tpc_clk_curr*

- */sys/class/accel/accel<n>/device/uboot_ver*
- */sys/class/accel/accel<n>/device/vrm_ver*

5.2.416 File testing/sysfs-driver-hid

Has the following ABI:

- */sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/report_descriptor*
- */sys/class/bluetooth/hci<addr>/<hid-bus>:<vendor-id>:<product-id>.<num>/report_descriptor*
- */sys/class/hidraw/hidraw<num>/device/report_descriptor*
- */sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/country*
- */sys/class/bluetooth/hci<addr>/<hid-bus>:<vendor-id>:<product-id>.<num>/country*
- */sys/class/hidraw/hidraw<num>/device/country*

5.2.417 File testing/sysfs-driver-hid-corsair

Has the following ABI:

- */sys/bus/drivers/corsair/<dev>/macro_mode*
- */sys/bus/drivers/corsair/<dev>/current_profile*

5.2.418 File testing/sysfs-driver-hid-lenovo

Has the following ABI:

- */sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/press_to_select*
- */sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/dragging*
- */sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/release_to_select*
- */sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/select_right*
- */sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/sensitivity*
- */sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/press_speed*
- */sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/fn_lock*

5.2.419 File testing/sysfs-driver-hid-logitech-hidpp

Has the following ABI:

- */sys/bus/hid/drivers/logitech-hidpp-device/<dev>/range*
- */sys/bus/hid/drivers/logitech-hidpp-device/<dev>/builtin_power_supply*

5.2.420 File testing/sysfs-driver-hid-logitech-lg4ff

Has the following ABI:

- */sys/bus/hid/drivers/logitech/<dev>/range*
- */sys/bus/hid/drivers/logitech/<dev>/alternate_modes*
- */sys/bus/hid/drivers/logitech/<dev>/real_id*
- */sys/bus/hid/drivers/logitech/<dev>/combine_pedals*

5.2.421 File testing/sysfs-driver-hid-multitouch

Has the following ABI:

- */sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/quirks*

5.2.422 File testing/sysfs-driver-hid-ntrig

Has the following ABI:

- */sys/bus/hid/drivers/ntrig/<dev>/activate_slack*
- */sys/bus/hid/drivers/ntrig/<dev>/decativate_slack*
- */sys/bus/hid/drivers/ntrig/<dev>/activation_width*
- */sys/bus/hid/drivers/ntrig/<dev>/activation_height*
- */sys/bus/hid/drivers/ntrig/<dev>/min_width*
- */sys/bus/hid/drivers/ntrig/<dev>/min_height*
- */sys/bus/hid/drivers/ntrig/<dev>/sensor_physical_width*
- */sys/bus/hid/drivers/ntrig/<dev>/sensor_physical_height*
- */sys/bus/hid/drivers/ntrig/<dev>/sensor_logical_width*
- */sys/bus/hid/drivers/ntrig/<dev>/sensor_logical_height*

5.2.423 File testing/sysfs-driver-hid-picolcd

Has the following ABI:

- */sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/operation_mode*
- */sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/operation_mode_delay*
- */sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/fb_update_rate*

5.2.424 File testing/sysfs-driver-hid-prodikeys

Has the following ABI:

- */sys/bus/hid/drivers/prodikeys/.../channel*
- */sys/bus/hid/drivers/prodikeys/.../sustain*
- */sys/bus/hid/drivers/prodikeys/.../octave*

5.2.425 File testing/sysfs-driver-hid-roccat-kone

Has the following ABI:

- */sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/kone/roccatkone<minor>/actual_dpi*
- */sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/kone/roccatkone<minor>/actual_profile*
- */sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/kone/roccatkone<minor>/firmware_version*
- */sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/kone/roccatkone<minor>/profile[1-5]*
- */sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/kone/roccatkone<minor>/settings*
- */sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/kone/roccatkone<minor>/startup_profile*
- */sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/kone/roccatkone<minor>/tcu*
- */sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/kone/roccatkone<minor>/weight*

5.2.426 File testing/sysfs-driver-hid-srws1

Has the following ABI:

- */sys/class/leds/SRWS1::<serial>::RPM1*
- */sys/class/leds/SRWS1::<serial>::RPM2*
- */sys/class/leds/SRWS1::<serial>::RPM3*
- */sys/class/leds/SRWS1::<serial>::RPM4*
- */sys/class/leds/SRWS1::<serial>::RPM5*
- */sys/class/leds/SRWS1::<serial>::RPM6*
- */sys/class/leds/SRWS1::<serial>::RPM7*
- */sys/class/leds/SRWS1::<serial>::RPM8*
- */sys/class/leds/SRWS1::<serial>::RPM9*
- */sys/class/leds/SRWS1::<serial>::RPM10*
- */sys/class/leds/SRWS1::<serial>::RPM11*
- */sys/class/leds/SRWS1::<serial>::RPM12*
- */sys/class/leds/SRWS1::<serial>::RPM13*
- */sys/class/leds/SRWS1::<serial>::RPM14*
- */sys/class/leds/SRWS1::<serial>::RPM15*
- */sys/class/leds/SRWS1::<serial>::RPMALL*

5.2.427 File testing/sysfs-driver-hid-wiimote

Has the following ABI:

- */sys/bus/hid/drivers/wiimote/<dev>/led1*
- */sys/bus/hid/drivers/wiimote/<dev>/led2*
- */sys/bus/hid/drivers/wiimote/<dev>/led3*
- */sys/bus/hid/drivers/wiimote/<dev>/led4*
- */sys/bus/hid/drivers/wiimote/<dev>/extension*
- */sys/bus/hid/drivers/wiimote/<dev>/devtype*
- */sys/bus/hid/drivers/wiimote/<dev>/bboard_calib*
- */sys/bus/hid/drivers/wiimote/<dev>/pro_calib*

5.2.428 File testing/sysfs-driver-input-axp-pek

Has the following ABI:

- */sys/class/input/input(x)/device/startup*
- */sys/class/input/input(x)/device/shutdown*

5.2.429 File testing/sysfs-driver-input-cros-ec-keyb

Has the following ABI:

- */sys/class/input/input(x)/device/function_row_physmap*

5.2.430 File testing/sysfs-driver-input-exc3000

Has the following ABI:

- */sys/bus/i2c/devices/xxx/fw_version*
- */sys/bus/i2c/devices/xxx/model*
- */sys/bus/i2c/devices/xxx/type*

5.2.431 File testing/sysfs-driver-intc_sar

Has the following ABI:

- */sys/bus/platform/devices/INTC1092:00/intc_reg*
- */sys/bus/platform/devices/INTC1092:00/intc_data*

5.2.432 File testing/sysfs-driver-intel-i915-hwmon

Has the following ABI:

- */sys/bus/pci/drivers/i915/.../hwmon/hwmon<i>/in0_input*
- */sys/bus/pci/drivers/i915/.../hwmon/hwmon<i>/power1_max*
- */sys/bus/pci/drivers/i915/.../hwmon/hwmon<i>/power1_rated_max*
- */sys/bus/pci/drivers/i915/.../hwmon/hwmon<i>/power1_max_interval*
- */sys/bus/pci/drivers/i915/.../hwmon/hwmon<i>/power1_crit*
- */sys/bus/pci/drivers/i915/.../hwmon/hwmon<i>/curr1_crit*
- */sys/bus/pci/drivers/i915/.../hwmon/hwmon<i>/energy1_input*

5.2.433 File testing/sysfs-driver-intel-m10-bmc

Has the following ABI:

- */sys/bus/.../drivers/intel-m10-bmc/.../bmc_version*
- */sys/bus/.../drivers/intel-m10-bmc/.../bmcfw_version*
- */sys/bus/.../drivers/intel-m10-bmc/.../mac_address*
- */sys/bus/.../drivers/intel-m10-bmc/.../mac_count*

5.2.434 File testing/sysfs-driver-intel-m10-bmc-sec-update

Has the following ABI:

- */sys/bus/platform/drivers/intel-m10bmc-sec-update/.../security/sr_root_entry_hash*
- */sys/bus/platform/drivers/intel-m10bmc-sec-update/.../security/pr_root_entry_hash*
- */sys/bus/platform/drivers/intel-m10bmc-sec-update/.../security/bmc_root_entry_hash*
- */sys/bus/platform/drivers/intel-m10bmc-sec-update/.../security/sr_canceled_csks*
- */sys/bus/platform/drivers/intel-m10bmc-sec-update/.../security/pr_canceled_csks*
- */sys/bus/platform/drivers/intel-m10bmc-sec-update/.../security/bmc_canceled_csks*
- */sys/bus/platform/drivers/intel-m10bmc-sec-update/.../security/flash_count*

5.2.435 File testing/sysfs-driver-intel-rapid-start

Has the following ABI:

- */sys/bus/acpi/intel-rapid-start/wakeup_events*
- */sys/bus/acpi/intel-rapid-start/wakeup_time*

5.2.436 File testing/sysfs-driver-intel-xe-hwmon

Has the following ABI:

- */sys/bus/pci/drivers/xe/.../hwmon/hwmon<i>/power1_max*
- */sys/bus/pci/drivers/xe/.../hwmon/hwmon<i>/power1_rated_max*
- */sys/bus/pci/drivers/xe/.../hwmon/hwmon<i>/power1_crit*
- */sys/bus/pci/drivers/xe/.../hwmon/hwmon<i>/curr1_crit*
- */sys/bus/pci/drivers/xe/.../hwmon/hwmon<i>/in0_input*
- */sys/bus/pci/drivers/xe/.../hwmon/hwmon<i>/energy1_input*
- */sys/bus/pci/drivers/xe/.../hwmon/hwmon<i>/power1_max_interval*

5.2.437 File testing/sysfs-driver-intel_sdsi

Has the following ABI:

- */sys/bus/auxiliary/devices/intel_vsec.sdsi.X*
- */sys/bus/auxiliary/devices/intel_vsec.sdsi.X/guid*
- */sys/bus/auxiliary/devices/intel_vsec.sdsi.X/registers*
- */sys/bus/auxiliary/devices/intel_vsec.sdsi.X/provision_akc*
- */sys/bus/auxiliary/devices/intel_vsec.sdsi.X/provision_cap*
- */sys/bus/auxiliary/devices/intel_vsec.sdsi.X/meter_certificate*
- */sys/bus/auxiliary/devices/intel_vsec.sdsi.X/state_certificate*

5.2.438 File testing/sysfs-driver-jz4780-efuse

Has the following ABI:

- */sys/devices/*/<our-device>/nvmem*

5.2.439 File testing/sysfs-driver-pciback

Has the following ABI:

- */sys/bus/pci/drivers/pciback/quirks*
- */sys/bus/pci/drivers/pciback/allow_interrupt_control*

5.2.440 File testing/sysfs-driver-ppi

Has the following ABI:

- */sys/class/tpm/tpmX/ppi/*
- */sys/class/tpm/tpmX/ppi/version*
- */sys/class/tpm/tpmX/ppi/request*
- */sys/class/tpm/tpmX/ppi/response*
- */sys/class/tpm/tpmX/ppi/transition_action*
- */sys/class/tpm/tpmX/ppi/tcg_operations*
- */sys/class/tpm/tpmX/ppi/vs_operations*

5.2.441 File testing/sysfs-driver-qat

Has the following ABI:

- */sys/bus/pci/devices/<BDF>/qat/state*
- */sys/bus/pci/devices/<BDF>/qat/cfg_services*
- */sys/bus/pci/devices/<BDF>/qat/pm_idle_enabled*
- */sys/bus/pci/devices/<BDF>/qat/rp2srv*
- */sys/bus/pci/devices/<BDF>/qat/num_rps*

5.2.442 File testing/sysfs-driver-qat_ras

Has the following ABI:

- */sys/bus/pci/devices/<BDF>/qat_ras/errors_correctable*
- */sys/bus/pci/devices/<BDF>/qat_ras/errors_nonfatal*
- */sys/bus/pci/devices/<BDF>/qat_ras/errors_fatal*
- */sys/bus/pci/devices/<BDF>/qat_ras/reset_error_counters*

5.2.443 File testing/sysfs-driver-qat_rl

Has the following ABI:

- */sys/bus/pci/devices/<BDF>/qat_rl/sla_op*
- */sys/bus/pci/devices/<BDF>/qat_rl/rp*
- */sys/bus/pci/devices/<BDF>/qat_rl/id*
- */sys/bus/pci/devices/<BDF>/qat_rl/cir*
- */sys/bus/pci/devices/<BDF>/qat_rl/pir*
- */sys/bus/pci/devices/<BDF>/qat_rl/srv*
- */sys/bus/pci/devices/<BDF>/qat_rl/cap_rem*

5.2.444 File testing/sysfs-driver-samsung-laptop

Has the following ABI:

- */sys/devices/platform/samsung/performance_level*
- */sys/devices/platform/samsung/battery_life_extender*
- */sys/devices/platform/samsung/usb_charge*
- */sys/devices/platform/samsung/lid_handling*

5.2.445 File testing/sysfs-driver-st

Has the following ABI:

- */sys/bus/scsi/drivers/st/debug_flag*

5.2.446 File testing/sysfs-driver-tegra-fuse

Has the following ABI:

- */sys/devices/*/<our-device>/fuse*

5.2.447 File testing/sysfs-driver-toshiba_acpi

Has the following ABI:

- */sys/devices/LNXSYSTM:00/LNXSYBUS:00/TOS{1900,620{0,7,8}}:00/kbd_backlight_mode*
- */sys/devices/LNXSYSTM:00/LNXSYBUS:00/TOS{1900,620{0,7,8}}:00/kbd_backlight_timeout*
- */sys/devices/LNXSYSTM:00/LNXSYBUS:00/TOS{1900,620{0,7,8}}:00/position*
- */sys/devices/LNXSYSTM:00/LNXSYBUS:00/TOS{1900,620{0,7,8}}:00/touchpad*
- */sys/devices/LNXSYSTM:00/LNXSYBUS:00/TOS{1900,620{0,7,8}}:00/available_kbd_modes*
- */sys/devices/LNXSYSTM:00/LNXSYBUS:00/TOS{1900,620{0,7,8}}:00/kbd_type*
- */sys/devices/LNXSYSTM:00/LNXSYBUS:00/TOS{1900,620{0,7,8}}:00/usb_sleep_charge*
- */sys/devices/LNXSYSTM:00/LNXSYBUS:00/TOS{1900,620{0,7,8}}:00/sleep_functions_on_batte*
- */sys/devices/LNXSYSTM:00/LNXSYBUS:00/TOS{1900,620{0,7,8}}:00/usb_rapid_charge*
- */sys/devices/LNXSYSTM:00/LNXSYBUS:00/TOS{1900,620{0,7,8}}:00/usb_sleep_music*
- */sys/devices/LNXSYSTM:00/LNXSYBUS:00/TOS{1900,620{0,7,8}}:00/version*
- */sys/devices/LNXSYSTM:00/LNXSYBUS:00/TOS{1900,620{0,7,8}}:00/fan*
- */sys/devices/LNXSYSTM:00/LNXSYBUS:00/TOS{1900,620{0,7,8}}:00/kbd_function_keys*
- */sys/devices/LNXSYSTM:00/LNXSYBUS:00/TOS{1900,620{0,7,8}}:00/panel_power_on*
- */sys/devices/LNXSYSTM:00/LNXSYBUS:00/TOS{1900,620{0,7,8}}:00/usb_three*
- */sys/devices/LNXSYSTM:00/LNXSYBUS:00/TOS{1900,620{0,7,8}}:00/cooling_method*

5.2.448 File testing/sysfs-driver-toshiba_haps

Has the following ABI:

- */sys/devices/LNXSYSTM:00/LNXSYBUS:00/TOS620A:00/protection_level*
- */sys/devices/LNXSYSTM:00/LNXSYBUS:00/TOS620A:00/reset_protection*

5.2.449 File testing/sysfs-driver-typec-displayport

Has the following ABI:

- */sys/bus/typec/devices/.../displayport/configuration*
- */sys/bus/typec/devices/.../displayport/pin_assignment*
- */sys/bus/typec/devices/.../displayport/hpd*

5.2.450 File testing/sysfs-driver-uacce

Has the following ABI:

- */sys/class/uacce/<dev_name>/api*
- */sys/class/uacce/<dev_name>/flags*
- */sys/class/uacce/<dev_name>/available_instances*
- */sys/class/uacce/<dev_name>/isolate_strategy*
- */sys/class/uacce/<dev_name>/isolate*
- */sys/class/uacce/<dev_name>/algorithms*
- */sys/class/uacce/<dev_name>/region_mmio_size*
- */sys/class/uacce/<dev_name>/region_dus_size*

5.2.451 File testing/sysfs-driver-ucsi-ccg

Has the following ABI:

- */sys/bus/i2c/drivers/ucsi_ccg/.../do_flash*

5.2.452 File testing/sysfs-driver-ufs

Has the following ABI:

- */sys/bus/*/drivers/ufshcd/*/auto_hibern8*
- */sys/bus/platform/drivers/ufshcd/*/device_descriptor/device_type*
- */sys/bus/platform/devices/*.ufs/device_descriptor/device_type*

- */sys/bus/hid/devices/<bus>:<vid>:<pid>.<n>/wacom_remote/unpair_remote*
- */sys/bus/hid/devices/<bus>:<vid>:<pid>.<n>/wacom_remote/<serial_number>/remote_mode*

5.2.456 File testing/sysfs-driver-xdata

Has the following ABI:

- */sys/class/misc/drivers/dw-xdata-pcie.<device>/write*
- */sys/class/misc/dw-xdata-pcie.<device>/read*

5.2.457 File testing/sysfs-driver-xen-blkback

Has the following ABI:

- */sys/module/xen_blkback/parameters/max_buffer_pages*
- */sys/module/xen_blkback/parameters/max_persistent_grants*
- */sys/module/xen_blkback/parameters/persistent_grant_unused_seconds*
- */sys/module/xen_blkback/parameters/buffer_squeeze_duration_ms*
- */sys/module/xen_blkback/parameters/feature_persistent*

5.2.458 File testing/sysfs-driver-xen-blkfront

Has the following ABI:

- */sys/module/xen_blkfront/parameters/max_indirect_segments*
- */sys/module/xen_blkfront/parameters/feature_persistent*

5.2.459 File testing/sysfs-driver-xilinx-tmr-manager

Has the following ABI:

- */sys/devices/platform/amba_pl/<dev>/errcnt*
- */sys/devices/platform/amba_pl/<dev>/dis_block_break*

5.2.460 File testing/sysfs-driver-zynqmp-fpga

Has the following ABI:

- */sys/bus/platform/drivers/zynqmp_fpga_manager/firmware:zynqmp-firmware:pcap/status*

5.2.461 File testing/sysfs-firmware-acpi

Has the following ABI:

- */sys/firmware/acpi/fpdt/*
- */sys/firmware/acpi/bgrt/*
- */sys/firmware/acpi/hotplug/*
- */sys/firmware/acpi/interrupts/*

5.2.462 File testing/sysfs-firmware-dmi-entries

Has the following ABI:

- */sys/firmware/dmi/entries/*

5.2.463 File testing/sysfs-firmware-dmi-tables

Has the following ABI:

- */sys/firmware/dmi/tables/*

5.2.464 File testing/sysfs-firmware-efi

Has the following ABI:

- */sys/firmware/efi/fw_vendor*
- */sys/firmware/efi/runtime*
- */sys/firmware/efi/config_table*
- */sys/firmware/efi/systab*
- */sys/firmware/efi/tables/rci2*

5.2.465 File testing/sysfs-firmware-efi-esrt

Has the following ABI:

- */sys/firmware/efi/esrt/*
- */sys/firmware/efi/esrt/fw_resource_count*
- */sys/firmware/efi/esrt/fw_resource_count_max*
- */sys/firmware/efi/esrt/fw_resource_version*
- */sys/firmware/efi/esrt/entries/entry<N>/*
- */sys/firmware/efi/esrt/entries/entry<N>/fw_type*
- */sys/firmware/efi/esrt/entries/entry<N>/fw_class*
- */sys/firmware/efi/esrt/entries/entry<N>/fw_version*
- */sys/firmware/efi/esrt/entries/entry<N>/lowest_supported_fw_version*
- */sys/firmware/efi/esrt/entries/entry<N>/capsule_flags*
- */sys/firmware/efi/esrt/entries/entry<N>/last_attempt_version*
- */sys/firmware/efi/esrt/entries/entry<N>/last_attempt_status*

5.2.466 File testing/sysfs-firmware-efi-runtime-map

Has the following ABI:

- */sys/firmware/efi/runtime-map/*

5.2.467 File testing/sysfs-firmware-gsmi

Has the following ABI:

- */sys/firmware/gsmi*

5.2.468 File testing/sysfs-firmware-initrd

Has the following ABI:

- */sys/firmware/initrd*

5.2.469 File testing/sysfs-firmware-lefi-boardinfo

Has the following ABI:

- */sys/firmware/lefi/boardinfo*

5.2.470 File testing/sysfs-firmware-log

Has the following ABI:

- */sys/firmware/log*

5.2.471 File testing/sysfs-firmware-memmap

Has the following ABI:

- */sys/firmware/memmap/*

5.2.472 File testing/sysfs-firmware-ofw

Has the following ABI:

- */sys/firmware/devicetree/**
- */sys/firmware/fdt*

5.2.473 File testing/sysfs-firmware-opal-powercap

Has the following ABI:

- */sys/firmware/opal/powercap*
- */sys/firmware/opal/powercap/system-powercap*

5.2.474 File testing/sysfs-firmware-opal-psr

Has the following ABI:

- */sys/firmware/opal/psr*
- */sys/firmware/opal/psr/cpu_to_gpu_X*

5.2.475 File testing/sysfs-firmware-opal-sensor-groups

Has the following ABI:

- */sys/firmware/opal/sensor_groups*
- */sys/firmware/opal/sensor_groups/<sensor_group_name>/clear*

5.2.476 File testing/sysfs-firmware-papr-energy-scale-info

Has the following ABI:

- */sys/firmware/papr/energy_scale_info*
- */sys/firmware/papr/energy_scale_info/<id>*
- */sys/firmware/papr/energy_scale_info/<id>/desc*
- */sys/firmware/papr/energy_scale_info/<id>/value*
- */sys/firmware/papr/energy_scale_info/<id>/value_desc*

5.2.477 File testing/sysfs-firmware-qemu_fw_cfg

Has the following ABI:

- */sys/firmware/qemu_fw_cfg/*

5.2.478 File testing/sysfs-firmware-sgi_uv

Has the following ABI:

- */sys/firmware/sgi_uv/*

5.2.479 File testing/sysfs-firmware-turris-mox-rwtm

Has the following ABI:

- */sys/firmware/turris-mox-rwtm/board_version*
- */sys/firmware/turris-mox-rwtm/mac_address**
- */sys/firmware/turris-mox-rwtm/pubkey*
- */sys/firmware/turris-mox-rwtm/ram_size*
- */sys/firmware/turris-mox-rwtm/serial_number*

5.2.480 File testing/sysfs-fs-erofs

Has the following ABI:

- */sys/fs/erofs/features/*
- */sys/fs/erofs/<disk>/sync_decompress*

5.2.481 File testing/sysfs-fs-ext4

Has the following ABI:

- */sys/fs/ext4/<disk>/mb_stats*
- */sys/fs/ext4/<disk>/mb_group_prealloc*
- */sys/fs/ext4/<disk>/mb_max_to_scan*
- */sys/fs/ext4/<disk>/mb_min_to_scan*
- */sys/fs/ext4/<disk>/mb_order2_req*
- */sys/fs/ext4/<disk>/mb_stream_req*
- */sys/fs/ext4/<disk>/inode_readahead_blks*
- */sys/fs/ext4/<disk>/delayed_allocation_blocks*
- */sys/fs/ext4/<disk>/lifetime_write_kbytes*
- */sys/fs/ext4/<disk>/session_write_kbytes*
- */sys/fs/ext4/<disk>/inode_goal*
- */sys/fs/ext4/<disk>/max_writeback_mb_bump*
- */sys/fs/ext4/<disk>/extent_max_zeroout_kb*
- */sys/fs/ext4/<disk>/journal_task*

5.2.482 File testing/sysfs-fs-f2fs

Has the following ABI:

- */sys/fs/f2fs/<disk>/gc_max_sleep_time*
- */sys/fs/f2fs/<disk>/gc_min_sleep_time*
- */sys/fs/f2fs/<disk>/gc_no_gc_sleep_time*

5.2.484 File testing/sysfs-fs-ubifs

Has the following ABI:

- */sys/fs/ubifsX_Y/error_magic*
- */sys/fs/ubifsX_Y/error_node*
- */sys/fs/ubifsX_Y/error_crc*

5.2.485 File testing/sysfs-fs-xfs

Has the following ABI:

- */sys/fs/xfs/<disk>/log/log_head_lsn*
- */sys/fs/xfs/<disk>/log/log_tail_lsn*
- */sys/fs/xfs/<disk>/log/reserve_grant_head*
- */sys/fs/xfs/<disk>/log/write_grant_head*

5.2.486 File testing/sysfs-hypervisor-xen

Has the following ABI:

- */sys/hypervisor/guest_type*
- */sys/hypervisor/pmu/pmu_mode*
- */sys/hypervisor/pmu/pmu_features*
- */sys/hypervisor/properties/buildid*

5.2.487 File testing/sysfs-ibft

Has the following ABI:

- */sys/firmware/ibft/initiator*
- */sys/firmware/ibft/targetX*
- */sys/firmware/ibft/ethernetX*
- */sys/firmware/ibft/acpi_header*

5.2.488 File testing/sysfs-kernel-address_bits

Has the following ABI:

- */sys/kernel/address_bit*

5.2.489 File testing/sysfs-kernel-boot_params

Has the following ABI:

- */sys/kernel/boot_params*

5.2.490 File testing/sysfs-kernel-btf

Has the following ABI:

- */sys/kernel/btf*
- */sys/kernel/btf/vmlinux*
- */sys/kernel/btf/<module-name>*

5.2.491 File testing/sysfs-kernel-cpu_byteorder

Has the following ABI:

- */sys/kernel/cpu_byteorder*

5.2.492 File testing/sysfs-kernel-dmabuf-buffers

Has the following ABI:

- */sys/kernel/dmabuf/buffers*
- */sys/kernel/dmabuf/buffers/<inode_number>/exporter_name*
- */sys/kernel/dmabuf/buffers/<inode_number>/size*

5.2.493 File testing/sysfs-kernel-fadump

Has the following ABI:

- */sys/kernel/fadump/**
- */sys/kernel/fadump/enabled*
- */sys/kernel/fadump/registered*
- */sys/kernel/fadump/release_mem*
- */sys/kernel/fadump/mem_reserved*

5.2.494 File testing/sysfs-kernel-fscaps

Has the following ABI:

- */sys/kernel/fscaps*

5.2.495 File testing/sysfs-kernel-iommu_groups

Has the following ABI:

- */sys/kernel/iommu_groups/*
- */sys/kernel/iommu_groups/reserved_regions*
- */sys/kernel/iommu_groups/<grp_id>/type*

5.2.496 File testing/sysfs-kernel-irq

Has the following ABI:

- */sys/kernel/irq*
- */sys/kernel/irq/<irq>/actions*
- */sys/kernel/irq/<irq>/chip_name*
- */sys/kernel/irq/<irq>/hwirq*
- */sys/kernel/irq/<irq>/name*
- */sys/kernel/irq/<irq>/per_cpu_count*
- */sys/kernel/irq/<irq>/type*
- */sys/kernel/irq/<irq>/wakeup*

5.2.497 File testing/sysfs-kernel-livepatch

Has the following ABI:

- */sys/kernel/livepatch*
- */sys/kernel/livepatch/<patch>*
- */sys/kernel/livepatch/<patch>/enabled*
- */sys/kernel/livepatch/<patch>/transition*
- */sys/kernel/livepatch/<patch>/force*
- */sys/kernel/livepatch/<patch>/<object>*
- */sys/kernel/livepatch/<patch>/<object>/patched*
- */sys/kernel/livepatch/<patch>/<object>/<function,sympos>*

5.2.498 File testing/sysfs-kernel-mm

Has the following ABI:

- */sys/kernel/mm*

5.2.499 File testing/sysfs-kernel-mm-cma

Has the following ABI:

- */sys/kernel/mm/cma/*
- */sys/kernel/mm/cma/<cma-heap-name>/alloc_pages_success*
- */sys/kernel/mm/cma/<cma-heap-name>/alloc_pages_fail*

5.2.500 File testing/sysfs-kernel-mm-damon

Has the following ABI:

- */sys/kernel/mm/damon/*
- */sys/kernel/mm/damon/admin/*
- */sys/kernel/mm/damon/admin/kdamonds/nr_kdamonds*
- */sys/kernel/mm/damon/admin/kdamonds/<K>/state*

5.2.501 File testing/sysfs-kernel-mm-hugepages

Has the following ABI:

- /sys/kernel/mm/hugepages/

5.2.502 File testing/sysfs-kernel-mm-ksm

Has the following ABI:

- /sys/kernel/mm/ksm
- /sys/kernel/mm/ksm/full_scans
- /sys/kernel/mm/ksm/pages_shared
- /sys/kernel/mm/ksm/pages_sharing
- /sys/kernel/mm/ksm/pages_to_scan
- /sys/kernel/mm/ksm/pages_unshared
- /sys/kernel/mm/ksm/pages_volatile
- /sys/kernel/mm/ksm/run
- /sys/kernel/mm/ksm/sleep_millisecs
- /sys/kernel/mm/ksm/merge_across_nodes
- /sys/kernel/mm/ksm/general_profit

5.2.503 File testing/sysfs-kernel-mm-memory-tiers

Has the following ABI:

- */sys/devices/virtual/memory_tiering/*
- */sys/devices/virtual/memory_tiering/memory_tierN/*

5.2.504 File testing/sysfs-kernel-mm-numa

Has the following ABI:

- */sys/kernel/mm/numa/*
- */sys/kernel/mm/numa/demotion_enabled*

5.2.505 File testing/sysfs-kernel-mm-swap

Has the following ABI:

- */sys/kernel/mm/swap/*
- */sys/kernel/mm/swap/vma_ra_enabled*

5.2.506 File testing/sysfs-kernel-oops_count

Has the following ABI:

- */sys/kernel/oops_count*

5.2.507 File testing/sysfs-kernel-reboot

Has the following ABI:

- */sys/kernel/reboot*
- */sys/kernel/reboot/mode*
- */sys/kernel/reboot/type*
- */sys/kernel/reboot/cpu*
- */sys/kernel/reboot/force*

5.2.508 File testing/sysfs-kernel-slab

Has the following ABI:

- */sys/kernel/slab*
- */sys/kernel/slab/<cache>/aliases*
- */sys/kernel/slab/<cache>/align*
- */sys/kernel/slab/<cache>/alloc_calls*

- */sys/kernel/slab/<cache>/alloc_fastpath*

- */sys/kernel/slab/<cache>/slabs_cpu_partial*
- */sys/kernel/slab/<cache>/cpu_partial*

5.2.509 File testing/sysfs-kernel-vmcoreinfo

Has the following ABI:

- */sys/kernel/vmcoreinfo*

5.2.510 File testing/sysfs-kernel-warn_count

Has the following ABI:

- */sys/kernel/warn_count*

5.2.511 File testing/sysfs-mce

Has the following ABI:

- */sys/devices/system/machinecheck/machinecheckX/*
- */sys/devices/system/machinecheck/machinecheckX/bank<Y>*
- */sys/devices/system/machinecheck/machinecheckX/check_interval*
- */sys/devices/system/machinecheck/machinecheckX/trigger*
- */sys/devices/system/machinecheck/machinecheckX/monarch_timeout*
- */sys/devices/system/machinecheck/machinecheckX/ignore_ce*
- */sys/devices/system/machinecheck/machinecheckX/dont_log_ce*
- */sys/devices/system/machinecheck/machinecheckX/cmci_disabled*

5.2.512 File testing/sysfs-memory-page-offline

Has the following ABI:

- */sys/devices/system/memory/soft_offline_page*
- */sys/devices/system/memory/hard_offline_page*

5.2.513 File testing/sysfs-module

Has the following ABI:

- */sys/module/pch_phub/drivers/.../pch_mac*
- */sys/module/pch_phub/drivers/.../pch_firmware*
- */sys/module/ehci_hcd/drivers/.../uframe_periodic_max*
- */sys/module/*/{coresize,initsize}*
- */sys/module/*/initstate*
- */sys/module/*/taint*
- */sys/module/grant_table/parameters/free_per_iteration*

5.2.514 File testing/sysfs-nvmem-cells

Has the following ABI:

- */sys/bus/nvmem/devices/.../cells/<cell-name>*

5.2.515 File testing/sysfs-ocfs2

Has the following ABI:

- */sys/fs/ocfs2/*
- */sys/fs/ocfs2/max_locking_protocol*
- */sys/fs/ocfs2/loaded_cluster_plugins*
- */sys/fs/ocfs2/active_cluster_plugin*
- */sys/fs/ocfs2/cluster_stack*

5.2.516 File testing/sysfs-platform-asus-laptop

Has the following ABI:

- */sys/devices/platform/asus_laptop/display*
- */sys/devices/platform/asus_laptop/gps*
- */sys/devices/platform/asus_laptop/ledd*
- */sys/devices/platform/asus_laptop/bluetooth*
- */sys/devices/platform/asus_laptop/wlan*

- */sys/devices/platform/asus_laptop/wimax*
- */sys/devices/platform/asus_laptop/wwan*

5.2.517 File testing/sysfs-platform-asus-wmi

Has the following ABI:

- */sys/devices/platform/<platform>/cpufv*
- */sys/devices/platform/<platform>/camera*
- */sys/devices/platform/<platform>/cardr*
- */sys/devices/platform/<platform>/touchpad*
- */sys/devices/platform/<platform>/lid_resume*
- */sys/devices/platform/<platform>/fan_boost_mode*
- */sys/devices/platform/<platform>/throttle_thermal_policy*
- */sys/devices/platform/<platform>/gpu_mux_mode*
- */sys/devices/platform/<platform>/dgpu_disable*
- */sys/devices/platform/<platform>/egpu_enable*
- */sys/devices/platform/<platform>/panel_od*
- */sys/devices/platform/<platform>/charge_mode*
- */sys/devices/platform/<platform>/egpu_connected*
- */sys/devices/platform/<platform>/mini_led_mode*
- */sys/devices/platform/<platform>/ppt_pl1_spl*
- */sys/devices/platform/<platform>/ppt_pl2_sppt*
- */sys/devices/platform/<platform>/ppt_fppt*
- */sys/devices/platform/<platform>/ppt_apu_sppt*
- */sys/devices/platform/<platform>/ppt_platform_sppt*
- */sys/devices/platform/<platform>/nv_dynamic_boost*
- */sys/devices/platform/<platform>/nv_temp_target*

5.2.518 File testing/sysfs-platform-at91

Has the following ABI:

- */sys/devices/platform/at91_can/net/<iface>/mb0_id*

5.2.519 File testing/sysfs-platform-brcmstb-gisb-arb

Has the following ABI:

- */sys/devices/../../gisb_arb_timeout*

5.2.520 File testing/sysfs-platform-brcmstb-memc

Has the following ABI:

- */sys/bus/platform/devices/*/srpd*
- */sys/bus/platform/devices/*/frequency*

5.2.521 File testing/sysfs-platform-chipidea-usb-otg

Has the following ABI:

- */sys/bus/platform/devices/ci_hdrc.0/inputs/a_bus_req*
- */sys/bus/platform/devices/ci_hdrc.0/inputs/a_bus_drop*
- */sys/bus/platform/devices/ci_hdrc.0/inputs/b_bus_req*
- */sys/bus/platform/devices/ci_hdrc.0/inputs/a_clr_err*

5.2.522 File testing/sysfs-platform-chipidea-usb2

Has the following ABI:

- */sys/bus/platform/devices/ci_hdrc.0/role*

5.2.523 File testing/sysfs-platform-dell-laptop

Has the following ABI:

- */sys/class/leds/dell::kbd_backlight/als_enabled*
- */sys/class/leds/dell::kbd_backlight/als_setting*
- */sys/class/leds/dell::kbd_backlight/start_triggers*
- */sys/class/leds/dell::kbd_backlight/stop_timeout*

5.2.524 File testing/sysfs-platform-dell-privacy-wmi

Has the following ABI:

- */sys/bus/wmi/devices/6932965F-1671-4CEB-B988-D3AB0A901919/dell_privacy_supported_type*
- */sys/bus/wmi/devices/6932965F-1671-4CEB-B988-D3AB0A901919/dell_privacy_current_state*

5.2.525 File testing/sysfs-platform-dell-smbios

Has the following ABI:

- */sys/devices/platform/<platform>/tokens/**

5.2.526 File testing/sysfs-platform-dell-wmi-ddv

Has the following ABI:

- */sys/class/power_supply/<battery_name>/eppid*

5.2.527 File testing/sysfs-platform-dfl-fme

Has the following ABI:

- */sys/bus/platform/devices/dfl-fme.0/ports_num*
- */sys/bus/platform/devices/dfl-fme.0/bitstream_id*
- */sys/bus/platform/devices/dfl-fme.0/bitstream_metadata*
- */sys/bus/platform/devices/dfl-fme.0/cache_size*
- */sys/bus/platform/devices/dfl-fme.0/fabric_version*
- */sys/bus/platform/devices/dfl-fme.0/socket_id*
- */sys/bus/platform/devices/dfl-fme.0/errors/pcie0_errors*
- */sys/bus/platform/devices/dfl-fme.0/errors/pcie1_errors*
- */sys/bus/platform/devices/dfl-fme.0/errors/nonfatal_errors*
- */sys/bus/platform/devices/dfl-fme.0/errors/catfatal_errors*
- */sys/bus/platform/devices/dfl-fme.0/errors/inject_errors*
- */sys/bus/platform/devices/dfl-fme.0/errors/fme_errors*
- */sys/bus/platform/devices/dfl-fme.0/errors/first_error*
- */sys/bus/platform/devices/dfl-fme.0/errors/next_error*
- */sys/bus/platform/devices/dfl-fme.0/hwmon/hwmonX/name*
- */sys/bus/platform/devices/dfl-fme.0/hwmon/hwmonX/temp1_input*
- */sys/bus/platform/devices/dfl-fme.0/hwmon/hwmonX/temp1_max*
- */sys/bus/platform/devices/dfl-fme.0/hwmon/hwmonX/temp1_crit*
- */sys/bus/platform/devices/dfl-fme.0/hwmon/hwmonX/temp1_emergency*
- */sys/bus/platform/devices/dfl-fme.0/hwmon/hwmonX/temp1_max_alarm*
- */sys/bus/platform/devices/dfl-fme.0/hwmon/hwmonX/temp1_crit_alarm*
- */sys/bus/platform/devices/dfl-fme.0/hwmon/hwmonX/temp1_max_policy*
- */sys/bus/platform/devices/dfl-fme.0/hwmon/hwmonX/power1_input*
- */sys/bus/platform/devices/dfl-fme.0/hwmon/hwmonX/power1_max*

- */sys/bus/platform/devices/dfl-fme.0/hwmon/hwmonX/power1_crit*
- */sys/bus/platform/devices/dfl-fme.0/hwmon/hwmonX/power1_max_alarm*
- */sys/bus/platform/devices/dfl-fme.0/hwmon/hwmonX/power1_crit_alarm*
- */sys/bus/platform/devices/dfl-fme.0/hwmon/hwmonX/power1_xeon_limit*
- */sys/bus/platform/devices/dfl-fme.0/hwmon/hwmonX/power1_fpga_limit*
- */sys/bus/platform/devices/dfl-fme.0/hwmon/hwmonX/power1_ltr*

5.2.528 File testing/sysfs-platform-dfl-port

Has the following ABI:

- */sys/bus/platform/devices/dfl-port.0/id*
- */sys/bus/platform/devices/dfl-port.0/afu_id*
- */sys/bus/platform/devices/dfl-port.0/power_state*
- */sys/bus/platform/devices/dfl-port.0/ap1_event*
- */sys/bus/platform/devices/dfl-port.0/ap2_event*
- */sys/bus/platform/devices/dfl-port.0/ltr*
- */sys/bus/platform/devices/dfl-port.0/userclk_freqcmd*
- */sys/bus/platform/devices/dfl-port.0/userclk_freqsts*
- */sys/bus/platform/devices/dfl-port.0/userclk_freqcntrcmd*
- */sys/bus/platform/devices/dfl-port.0/userclk_freqcntrsts*
- */sys/bus/platform/devices/dfl-port.0/errors/errors*
- */sys/bus/platform/devices/dfl-port.0/errors/first_error*
- */sys/bus/platform/devices/dfl-port.0/errors/first_malformed_req*

5.2.529 File testing/sysfs-platform-dptf

Has the following ABI:

- */sys/bus/platform/devices/INT3407:00/dptf_power/charger_type*
- */sys/bus/platform/devices/INT3407:00/dptf_power/adapter_rating_mw*
- */sys/bus/platform/devices/INT3407:00/dptf_power/max_platform_power_mw*
- */sys/bus/platform/devices/INT3407:00/dptf_power/platform_power_source*
- */sys/bus/platform/devices/INT3407:00/dptf_power/battery_steady_power*
- */sys/bus/platform/devices/INT3407:00/dptf_power/rest_of_platform_power_mw*
- */sys/bus/platform/devices/INT3407:00/dptf_power/prochot_confirm*
- */sys/bus/platform/devices/INT3532:00/dptf_battery/max_platform_power_mw*
- */sys/bus/platform/devices/INT3532:00/dptf_battery/max_steady_state_power_mw*

- */sys/bus/platform/devices/INT3532:00/dptf_battery/high_freq_impedance_mohm*
- */sys/bus/platform/devices/INT3532:00/dptf_battery/no_load_voltage_mv*
- */sys/bus/platform/devices/INT3532:00/dptf_battery/current_discharge_capbility_ma*
- */sys/bus/platform/devices/INTC1045:00/pch_fivr_switch_frequency/freq_mhz_low_clock*
- */sys/bus/platform/devices/INTC1045:00/pch_fivr_switch_frequency/freq_mhz_high_clock*
- */sys/bus/platform/devices/INTC1045:00/pch_fivr_switch_frequency/fivr_switching_freq_mhz*
- */sys/bus/platform/devices/INTC1045:00/pch_fivr_switch_frequency/fivr_switching_fault_status*
- */sys/bus/platform/devices/INTC1045:00/pch_fivr_switch_frequency/ssc_clock_info*

5.2.530 File testing/sysfs-platform-eeepc-laptop

Has the following ABI:

- */sys/devices/platform/eeepc/disp*
- */sys/devices/platform/eeepc/camera*
- */sys/devices/platform/eeepc/cardr*
- */sys/devices/platform/eeepc/cpufv*
- */sys/devices/platform/eeepc/available_cpufv*

5.2.531 File testing/sysfs-platform-hidma

Has the following ABI:

- */sys/devices/platform/hidma-*/chid*

5.2.532 File testing/sysfs-platform-hidma-mgmt

Has the following ABI:

- */sys/devices/platform/hidma-mgmt*/chanops/chan*/priority*
- */sys/devices/platform/hidma-mgmt*/chanops/chan*/weight*
- */sys/devices/platform/hidma-mgmt*/chreset_timeout_cycles*
- */sys/devices/platform/hidma-mgmt*/dma_channels*
- */sys/devices/platform/hidma-mgmt*/hw_version_major*
- */sys/devices/platform/hidma-mgmt*/hw_version_minor*
- */sys/devices/platform/hidma-mgmt*/max_rd_xactions*
- */sys/devices/platform/hidma-mgmt*/max_read_request*
- */sys/devices/platform/hidma-mgmt*/max_wr_xactions*
- */sys/devices/platform/hidma-mgmt*/max_write_request*

5.2.533 File testing/sysfs-platform-i2c-demux-pinctrl

Has the following ABI:

- */sys/devices/platform/<i2c-demux-name>/available_masters*
- */sys/devices/platform/<i2c-demux-name>/current_master*

5.2.534 File testing/sysfs-platform-ideapad-laptop

Has the following ABI:

- */sys/bus/platform/devices/VPC2004:*/camera_power*
- */sys/bus/platform/devices/VPC2004:*/fan_mode*
- */sys/bus/platform/devices/VPC2004:*/touchpad*
- */sys/bus/platform/devices/VPC2004:*/conservation_mode*
- */sys/bus/platform/devices/VPC2004:*/fn_lock*
- */sys/bus/platform/devices/VPC2004:*/usb_charging*

5.2.535 File testing/sysfs-platform-intel-ifs

Device instance to test mapping intel_ifs_0 -> Scan Test intel_ifs_1 -> Array BIST test

Has the following ABI:

- */sys/devices/virtual/misc/intel_ifs_<N>/run_test*
- */sys/devices/virtual/misc/intel_ifs_<N>/status*
- */sys/devices/virtual/misc/intel_ifs_<N>/details*
- */sys/devices/virtual/misc/intel_ifs_<N>/image_version*
- */sys/devices/virtual/misc/intel_ifs_<N>/current_batch*

5.2.536 File testing/sysfs-platform-intel-pmc

Has the following ABI:

- */sys/devices/platform/<platform>/etr3*

5.2.537 File testing/sysfs-platform-intel-wmi-sbl-fw-update

Has the following ABI:

- */sys/bus/wmi/devices/44FADEB1-B204-40F2-8581-394BBDC1B651/firmware_update_request*

5.2.538 File testing/sysfs-platform-intel-wmi-thunderbolt

Has the following ABI:

- */sys/devices/platform/<platform>/force_power*

5.2.539 File testing/sysfs-platform-kim

Has the following ABI:

- */sys/devices/platform/kim/dev_name*
- */sys/devices/platform/kim/baud_rate*
- */sys/devices/platform/kim/flow_cntrl*
- */sys/devices/platform/kim/install*

5.2.540 File testing/sysfs-platform-lg-laptop

Has the following ABI:

- */sys/devices/platform/lg-laptop/reader_mode*
- */sys/devices/platform/lg-laptop/fn_lock*
- */sys/devices/platform/lg-laptop/battery_care_limit*
- */sys/devices/platform/lg-laptop/fan_mode*
- */sys/devices/platform/lg-laptop/usb_charge*

5.2.541 File testing/sysfs-platform-mellanox-bootctl

Has the following ABI:

- */sys/bus/platform/devices/MLNXBF04:00/lifecycle_state*
- */sys/bus/platform/devices/MLNXBF04:00/post_reset_wdog*
- */sys/bus/platform/devices/MLNXBF04:00/reset_action*
- */sys/bus/platform/devices/MLNXBF04:00/second_reset_action*
- */sys/bus/platform/devices/MLNXBF04:00/secure_boot_fuse_state*
- */sys/bus/platform/devices/MLNXBF04:00/bootfifo*
- */sys/bus/platform/devices/MLNXBF04:00/rsh_log*
- */sys/bus/platform/devices/MLNXBF04:00/oob_mac*
- */sys/bus/platform/devices/MLNXBF04:00/opn*
- */sys/bus/platform/devices/MLNXBF04:00/sku*
- */sys/bus/platform/devices/MLNXBF04:00/modl*
- */sys/bus/platform/devices/MLNXBF04:00/sn*
- */sys/bus/platform/devices/MLNXBF04:00/uuid*

- */sys/bus/platform/devices/MLNXBF04:00/rev*
- */sys/bus/platform/devices/MLNXBF04:00/mfg_lock*

5.2.542 File testing/sysfs-platform-msi-laptop

Has the following ABI:

- */sys/devices/platform/msi-laptop-pf/lcd_level*
- */sys/devices/platform/msi-laptop-pf/auto_brightness*
- */sys/devices/platform/msi-laptop-pf/wlan*
- */sys/devices/platform/msi-laptop-pf/bluetooth*
- */sys/devices/platform/msi-laptop-pf/touchpad*
- */sys/devices/platform/msi-laptop-pf/turbo_mode*
- */sys/devices/platform/msi-laptop-pf/eco_mode*
- */sys/devices/platform/msi-laptop-pf/turbo_cooldown*
- */sys/devices/platform/msi-laptop-pf/auto_fan*

5.2.543 File testing/sysfs-platform-phy-rcar-gen3-usb2

Has the following ABI:

- */sys/devices/platform/<phy-name>/role*

5.2.544 File testing/sysfs-platform-power-on-reason

Has the following ABI:

- */sys/devices/platform/.../power_on_reason*

5.2.545 File testing/sysfs-platform-renesas_usb3

Has the following ABI:

- */sys/devices/platform/<renesas_usb3's name>/role*

5.2.546 File testing/sysfs-platform-silicom

Has the following ABI:

- */sys/devices/platform/silicom-platform/uc_version*
- */sys/devices/platform/silicom-platform/power_cycle*
- */sys/devices/platform/silicom-platform/efuse_status*

5.2.547 File testing/sysfs-platform-sst-atom

Has the following ABI:

- */sys/devices/platform/8086<x>:00/firmware_version*

5.2.548 File testing/sysfs-platform-tahvo-usb

Has the following ABI:

- */sys/bus/platform/devices/tahvo-usb/otg_mode*
- */sys/bus/platform/devices/tahvo-usb/vbus*

5.2.549 File testing/sysfs-platform-ts5500

Has the following ABI:

- */sys/devices/platform/ts5500/adc*
- */sys/devices/platform/ts5500/ereset*
- */sys/devices/platform/ts5500/id*
- */sys/devices/platform/ts5500/jumpers*
- */sys/devices/platform/ts5500/name*
- */sys/devices/platform/ts5500/rs485*
- */sys/devices/platform/ts5500/sram*

5.2.550 File testing/sysfs-platform-twl4030-usb

Has the following ABI:

- */sys/bus/platform/devices/*twl4030-usb/vbus*

5.2.551 File testing/sysfs-platform-usbip-vudc

Has the following ABI:

- */sys/devices/platform/usbip-vudc.%d/dev_desc*
- */sys/devices/platform/usbip-vudc.%d/usbip_status*
- */sys/devices/platform/usbip-vudc.%d/usbip_sockfd*

5.2.552 File testing/sysfs-platform-wilco-ec

Has the following ABI:

- */sys/bus/platform/devices/GOOG000C\:00/boot_on_ac*
- */sys/bus/platform/devices/GOOG000C\:00/build_date*
- */sys/bus/platform/devices/GOOG000C\:00/build_revision*
- */sys/bus/platform/devices/GOOG000C\:00/model_number*
- */sys/bus/platform/devices/GOOG000C\:00/usb_charge*
- */sys/bus/platform/devices/GOOG000C\:00/version*

5.2.553 File testing/sysfs-platform_profile

Has the following ABI:

- */sys/firmware/acpi/platform_profile_choices*
- */sys/firmware/acpi/platform_profile*

5.2.554 File testing/sysfs-power

Has the following ABI:

- */sys/power/*
- */sys/power/state*
- */sys/power/mem_sleep*
- */sys/power/disk*
- */sys/power/image_size*
- */sys/power/pm_trace*
- */sys/power/pm_async*
- */sys/power/wakeup_count*
- */sys/power/reserved_size*
- */sys/power/autosleep*
- */sys/power/wake_lock*
- */sys/power/wake_unlock*
- */sys/power/pm_print_times*
- */sys/power/pm_wakeup_irq*
- */sys/power/pm_debug_messages*
- */sys/power/resume_offset*
- */sys/power/suspend_stats*
- */sys/power/suspend_stats/success*

- */sys/power/suspend_stats/fail*
- */sys/power/suspend_stats/failed_freeze*
- */sys/power/suspend_stats/failed_prepare*
- */sys/power/suspend_stats/failed_resume*
- */sys/power/suspend_stats/failed_resume_early*
- */sys/power/suspend_stats/failed_resume_noirq*
- */sys/power/suspend_stats/failed_suspend*
- */sys/power/suspend_stats/failed_suspend_late*
- */sys/power/suspend_stats/failed_suspend_noirq*
- */sys/power/suspend_stats/last_failed_dev*
- */sys/power/suspend_stats/last_failed_errno*
- */sys/power/suspend_stats/last_failed_step*
- */sys/power/suspend_stats/last_hw_sleep*
- */sys/power/suspend_stats/total_hw_sleep*
- */sys/power/suspend_stats/max_hw_sleep*
- */sys/power/sync_on_suspend*

5.2.555 File testing/sysfs-pps

Has the following ABI:

- */sys/class/pps/*
- */sys/class/pps/ppsX/*
- */sys/class/pps/ppsX/assert*
- */sys/class/pps/ppsX/clear*
- */sys/class/pps/ppsX/mode*
- */sys/class/pps/ppsX/echo*
- */sys/class/pps/ppsX/name*
- */sys/class/pps/ppsX/path*

5.2.556 File testing/sysfs-profiling

Has the following ABI:

- */sys/kernel/profiling*

5.2.557 File testing/sysfs-ptp

Has the following ABI:

- */sys/class/ptp/*
- */sys/class/ptp/ptp<N>/*
- */sys/class/ptp/ptp<N>/clock_name*
- */sys/class/ptp/ptp<N>/max_adjustment*
- */sys/class/ptp/ptp<N>/max_vclocks*
- */sys/class/ptp/ptp<N>/n_alarms*
- */sys/class/ptp/ptp<N>/n_external_timestamps*
- */sys/class/ptp/ptp<N>/n_periodic_outputs*
- */sys/class/ptp/ptp<N>/n_pins*
- */sys/class/ptp/ptp<N>/n_vclocks*
- */sys/class/ptp/ptp<N>/pins*
- */sys/class/ptp/ptp<N>/pps_available*
- */sys/class/ptp/ptp<N>/extts_enable*
- */sys/class/ptp/ptp<N>/fifo*
- */sys/class/ptp/ptp<N>/period*
- */sys/class/ptp/ptp<N>/pps_enable*

5.2.558 File testing/sysfs-secvar

Has the following ABI:

- */sys/firmware/secvar*
- */sys/firmware/secvar/vars*
- */sys/firmware/secvar/format*
- */sys/firmware/secvar/vars/<variable name>*
- */sys/firmware/secvar/vars/<variable_name>/size*
- */sys/firmware/secvar/vars/<variable_name>/data*
- */sys/firmware/secvar/vars/<variable_name>/update*
- */sys/firmware/secvar/config*
- */sys/firmware/secvar/config/version*
- */sys/firmware/secvar/config/max_object_size*
- */sys/firmware/secvar/config/total_size*
- */sys/firmware/secvar/config/used_space*
- */sys/firmware/secvar/config/supported_policies*

- */sys/firmware/secvar/config/signed_update_algorithms*

5.2.559 File testing/sysfs-timecard

Has the following ABI:

- */sys/class/timecard/*
- */sys/class/timecard/ocpN/*
- */sys/class/timecard/ocpN/available_clock_sources*
- */sys/class/timecard/ocpN/available_sma_inputs*
- */sys/class/timecard/ocpN/available_sma_outputs*
- */sys/class/timecard/ocpN/clock_source*
- */sys/class/timecard/ocpN/clock_status_drift*
- */sys/class/timecard/ocpN/clock_status_offset*
- */sys/class/timecard/ocpN/freqX*
- */sys/class/timecard/ocpN/freqX/frequency*
- */sys/class/timecard/ocpN/freqX/seconds*
- */sys/class/timecard/ocpN/genX*
- */sys/class/timecard/ocpN/genX/duty*
- */sys/class/timecard/ocpN/genX/period*
- */sys/class/timecard/ocpN/genX/phase*
- */sys/class/timecard/ocpN/genX/polarity*
- */sys/class/timecard/ocpN/genX/running*
- */sys/class/timecard/ocpN/genX/start*
- */sys/class/timecard/ocpN/genX/signal*
- */sys/class/timecard/ocpN/gnss_sync*
- */sys/class/timecard/ocpN/i2c*
- */sys/class/timecard/ocpN/irig_b_mode*
- */sys/class/timecard/ocpN/pps*
- */sys/class/timecard/ocpN/ptp*
- */sys/class/timecard/ocpN/serialnum*
- */sys/class/timecard/ocpN/sma1*
- */sys/class/timecard/ocpN/sma2*
- */sys/class/timecard/ocpN/sma3*
- */sys/class/timecard/ocpN/sma4*
- */sys/class/timecard/ocpN/tod_correction*

- */sys/class/timecard/ocpN/ts_window_adjust*
- */sys/class/timecard/ocpN/ttyGNSS*
- */sys/class/timecard/ocpN/ttyGNSS2*
- */sys/class/timecard/ocpN/ttyMAC*
- */sys/class/timecard/ocpN/ttyNMEA*
- */sys/class/timecard/ocpN/utc_tai_offset*

5.2.560 File testing/sysfs-tty

Has the following ABI:

- */sys/class/tty/console/active*
- */sys/class/tty/tty<x>/active*
- */sys/class/tty/ttyS<x>/uartclk*
- */sys/class/tty/ttyS<x>/type*
- */sys/class/tty/ttyS<x>/line*
- */sys/class/tty/ttyS<x>/port*
- */sys/class/tty/ttyS<x>/irq*
- */sys/class/tty/ttyS<x>/flags*
- */sys/class/tty/ttyS<x>/xmit_fifo_size*
- */sys/class/tty/ttyS<x>/close_delay*
- */sys/class/tty/ttyS<x>/closing_wait*
- */sys/class/tty/ttyS<x>/custom_divisor*
- */sys/class/tty/ttyS<x>/io_type*
- */sys/class/tty/ttyS<x>/iomem_base*
- */sys/class/tty/ttyS<x>/iomem_reg_shift*
- */sys/class/tty/ttyS<x>/rx_trig_bytes*
- */sys/class/tty/ttyS<x>/console*

5.2.561 File testing/sysfs-uevent

Has the following ABI:

- */sys/.../uevent*

5.2.562 File testing/usb-charger-uevent

Has the following ABI:

- *Raise a uevent when a USB charger is inserted or removed*

5.2.563 File testing/usb-uevent

Has the following ABI:

- *Raise a uevent when a USB Host Controller has died*

5.3 ABI obsolete symbols

Documents interfaces that are still remaining in the kernel, but are marked to be removed at some later point in time.

The description of the interface will document the reason why it is obsolete and when it can be expected to be removed.

5.3.1 Symbols under /proc/i8k

/proc/i8k

Defined on file *procfs-i8k*

Legacy interface for getting/setting sensor information like fan speed, temperature, serial number, hotkey status etc on Dell Laptops. Since the driver is now using the standard hwmon sysfs interface, the procfs interface is deprecated.

Users: https://github.com/vitorafsr/i8kutils

5.3.2 Symbols under /sys

/sys/.../iio:deviceX/scan_elements/in_pressure_type
/sys/.../iio:deviceX/scan_elements/in_rot_quaternion_type
/sys/.../iio:deviceX/scan_elements/in_proximity_type

Defined on file *sysfs-bus-iio*

Description of the scan element data storage within the buffer and hence the form in which it is read from user-space. Form is [be|le]:[s|u]bits/storagebits[>>shift]. be or le specifies big or little endian. s or u specifies if signed (2's complement) or unsigned. bits is the number of bits of data and storagebits is the space (after padding) that it occupies in the buffer. shift if specified, is the shift that needs to be applied prior to masking out unused bits. Some devices put their data in the middle of the transferred elements with additional information on both sides. Note that some devices will have additional information in the unused bits so to get a clean value, the bits value must be used to mask the buffer output value appropriately. The storagebits value also specifies the data alignment. So s48/64>>2 will be a signed 48 bit integer stored in a 64 bit location aligned to a 64 bit boundary. To obtain the clean value, shift right 2 and apply a mask to zero the top 16 bits of the result. For other storage combinations this attribute will be extended appropriately.

Since kernel 5.11 the scan_elements attributes are merged into the bufferY directory, to be configurable per buffer.

/sys/.../iio:deviceX/scan_elements/in_timestamp_index
/sys/.../iio:deviceX/scan_elements/in_pressureY_index
/sys/.../iio:deviceX/scan_elements/in_pressure_index
/sys/.../iio:deviceX/scan_elements/in_rot_quaternion_index
/sys/.../iio:deviceX/scan_elements/in_proximity_index

Defined on file *sysfs-bus-iio*

A single positive integer specifying the position of this scan element in the buffer. Note these are not dependent on what is enabled and may not be contiguous. Thus for user-space to establish the full layout these must be used in conjunction with all _en attributes to establish which channels are present, and the relevant _type attributes to establish the data storage format.

Since kernel 5.11 the scan_elements attributes are merged into the bufferY directory, to be configurable per buffer.

5.3.3 Symbols under /sys/bus

/sys/bus/iio/devices/iio:deviceX/buffer/data_available

Defined on file *sysfs-bus-iio*

A read-only value indicating the bytes of data available in the buffer. In the case of an output buffer, this indicates the amount of empty space available to write data to. In the case of an input buffer, this indicates the amount of data available for reading.

Since Kernel 5.11, multiple buffers are supported. so, it is better to use, instead:

/sys/bus/iio/devices/iio:deviceX/bufferY/data_available

/sys/bus/iio/devices/iio:deviceX/buffer/enable

Defined on file *sysfs-bus-iio*

Actually start the buffer capture up. Will start trigger if first device and appropriate.

Since Kernel 5.11, multiple buffers are supported. so, it is better to use, instead:

/sys/bus/iio/devices/iio:deviceX/bufferY/enable

/sys/bus/iio/devices/iio:deviceX/buffer/length

Defined on file *sysfs-bus-iio*

Number of scans contained by the buffer.

Since Kernel 5.11, multiple buffers are supported. so, it is better to use, instead:

/sys/bus/iio/devices/iio:deviceX/bufferY/length

/sys/bus/iio/devices/iio:deviceX/buffer/watermark

Defined on file *sysfs-bus-iio*

A single positive integer specifying the maximum number of scan elements to wait for.

Poll will block until the watermark is reached.

Blocking read will wait until the minimum between the requested read amount or the low water mark is available.

Non-blocking read will retrieve the available samples from the buffer even if there are less samples then watermark level. This allows the application to block on poll with a timeout and read the available samples after the timeout expires and thus have a maximum delay guarantee.

Since Kernel 5.11, multiple buffers are supported. so, it is better to use, instead:

/sys/bus/iio/devices/iio:deviceX/bufferY/watermark

/sys/bus/iio/devices/iio:deviceX/scan_elements

Defined on file *sysfs-bus-iio*

Directory containing interfaces for elements that will be captured for a single triggered sample set in the buffer.

Since kernel 5.11 the scan_elements attributes are merged into the bufferY directory, to be configurable per buffer.

/sys/bus/platform/devices/INT34D2:00/northpeak

Defined on file *sysfs-driver-intel_pmc_bxt*

This interface allows userspace to enable and disable Northpeak through the PMC/SCU.

Format: %u.

/sys/bus/platform/devices/INT34D2:00/simplecmd

Defined on file *sysfs-driver-intel_pmc_bxt*

This interface allows userspace to send an arbitrary IPC command to the PMC/SCU.

Format: %d %d where first number is command and second number is subcommand.

/sys/bus/usb/devices/.../power/level

Defined on file *sysfs-bus-usb*

Each USB device directory will contain a file named power/level. This file holds a power-level setting for the device, either "on" or "auto".

"on" means that the device is not allowed to autosuspend, although normal suspends for system sleep will still be honored. "auto" means the device will autosuspend and autoresume in the usual manner, according to the capabilities of its driver.

During normal use, devices should be left in the "auto" level. The "on" level is meant for administrative uses. If you want to suspend a device immediately but leave it free to wake up in response to I/O requests, you should write "0" to power/autosuspend.

Device not capable of proper suspend and resume should be left in the "on" level. Although the USB spec requires devices to support suspend/resume, many of them do not. In fact so many don't that by default, the USB core initializes all non-hub devices in the "on" level. Some drivers may change this setting when they are bound.

This file is deprecated and will be removed after 2010. Use the power/control file instead; it does exactly the same thing.

/sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/arvo/roccatarvo<minor>/actual_profile

Defined on file *sysfs-driver-hid-roccat-arvo*

The integer value of this attribute ranges from 1-5. When read, this attribute returns the number of the actual profile which is also the profile that's active on device startup. When written this attribute activates the selected profile immediately.

Users: http://roccat.sourceforge.net

/sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/arvo/roccatarvo<minor>/button

Defined on file *sysfs-driver-hid-roccat-arvo*

The keyboard can store short macros with consist of 1 button with several modifier keys internally. When written, this file lets one set the sequence for a specific button for a specific profile. Button and profile numbers are included in written data. The data has to be 24 bytes long. This file is writeonly.

Users: http://roccat.sourceforge.net

/sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/arvo/roccatarvo<minor>/info

Defined on file *sysfs-driver-hid-roccat-arvo*

When read, this file returns some info about the device like the installed firmware version. The size of the data is 8 bytes in size. This file is readonly.

Users: http://roccat.sourceforge.net

/sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/arvo/roccatarvo<minor>/key_mask

Defined on file *sysfs-driver-hid-roccat-arvo*

The keyboard lets the user deactivate 5 certain keys like the windows and application keys, to protect the user from the outcome of accidentally pressing them. The integer value of this attribute has bits 0-4 set depending on the state of the corresponding key. When read, this file returns the current state of the buttons. When written, the given buttons are activated/deactivated immediately.

Users: http://roccat.sourceforge.net

/sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/arvo/roccatarvo<minor>/mode_key

Defined on file *sysfs-driver-hid-roccat-arvo*

The keyboard has a condensed layout without num-lock key. Instead it uses a mode-key which activates a gaming mode where the assignment of the number block changes. The integer value of this attribute ranges from 0 (OFF) to 1 (ON). When read, this file returns the actual state of the key. When written, the key is activated/deactivated immediately.

Users: http://roccat.sourceforge.net

/sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/isku/roccatisku<minor>/actual_profile

Defined on file *sysfs-driver-hid-roccat-isku*

The integer value of this attribute ranges from 0-4. When read, this attribute returns the number of the actual profile. This value is persistent, so its equivalent to the profile that's active when the device is powered on next time. When written, this file sets the number of the startup profile and the device activates this profile immediately.

Users: http://roccat.sourceforge.net

/sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/isku/roccatisku<minor>/control

Defined on file *sysfs-driver-hid-roccat-isku*

When written, this file lets one select which data from which profile will be read next. The data has to be 3 bytes long. This file is writeonly.

Users: http://roccat.sourceforge.net

/sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/isku/roccatisku<minor>/info

Defined on file *sysfs-driver-hid-roccat-isku*

When read, this file returns general data like firmware version. The data is 6 bytes long. This file is readonly.

Users: http://roccat.sourceforge.net

/sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/isku/roccatisku<minor>/key_mask

Defined on file *sysfs-driver-hid-roccat-isku*

When written, this file lets one deactivate certain keys like windows and application keys, to prevent accidental presses. Profile number for which this settings occur is included in written data. The data has to be 6 bytes long. Before reading this file, control has to be written to select which profile to read.

Users: http://roccat.sourceforge.net

/sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/isku/roccatisku<minor>/keys_capslock

Defined on file *sysfs-driver-hid-roccat-isku*

When written, this file lets one set the function of the capslock key for a specific profile. Profile number is included in written data. The data has to be 6 bytes long. Before reading this file, control has to be written to select which profile to read.

Users: http://roccat.sourceforge.net

/sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/isku/roccatisku<minor>/keys_easyzone

Defined on file *sysfs-driver-hid-roccat-isku*

When written, this file lets one set the function of the easyzone keys for a specific profile. Profile number is included in written data. The data has to be 65 bytes long. Before reading this file, control has to be written to select which profile to read.

Users: http://roccat.sourceforge.net

/sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/isku/roccatisku<minor>/keys_function

Defined on file *sysfs-driver-hid-roccat-isku*

When written, this file lets one set the function of the function keys for a specific profile. Profile number is included in written data. The data has to be 41 bytes long. Before reading this file, control has to be written to select which profile to read.

Users: http://roccat.sourceforge.net

/sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/isku/roccatisku<minor>/keys_macro

Defined on file *sysfs-driver-hid-roccat-isku*

When written, this file lets one set the function of the macro keys for a specific profile. Profile number is included in written data. The data has to be 35 bytes long. Before reading this file, control has to be written to select which profile to read.

Users: http://roccat.sourceforge.net

/sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/isku/roccatisku<minor>/keys_media

Defined on file *sysfs-driver-hid-roccat-isku*

When written, this file lets one set the function of the media keys for a specific profile. Profile number is included in written data. The data has to be 29 bytes long. Before reading this file, control has to be written to select which profile to read.

Users: http://roccat.sourceforge.net

/sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/isku/roccatisku<minor>/keys_thumbster

Defined on file *sysfs-driver-hid-roccat-isku*

When written, this file lets one set the function of the thumbster keys for a specific profile. Profile number is included in written data. The data has to be 23 bytes long. Before reading this file, control has to be written to select which profile to read.

Users: http://roccat.sourceforge.net

/sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/isku/roccatisku<minor>/last_set

Defined on file *sysfs-driver-hid-roccat-isku*

When written, this file lets one set the time in secs since epoch in which the last configuration took place. The data has to be 20 bytes long.

Users: http://roccat.sourceforge.net

/sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/isku/roccatisku<minor>/light

Defined on file *sysfs-driver-hid-roccat-isku*

When written, this file lets one set the backlight intensity for a specific profile. Profile number is included in written data. The data has to be 10 bytes long for Isku, IskuFX needs 16 bytes of data. Before reading this file, control has to be written to select which profile to read.

Users: http://roccat.sourceforge.net

/sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/isku/roccatisku<minor>/macro

Defined on file *sysfs-driver-hid-roccat-isku*

When written, this file lets one store macros with max 500 keystrokes for a specific button for a specific profile. Button and profile numbers are included in written data. The data has to be 2083 bytes long. Before reading this file, control has to be written to select which profile and key to read.

Users: http://roccat.sourceforge.net

/sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/isku/roccatisku<minor>/reset

Defined on file *sysfs-driver-hid-roccat-isku*

When written, this file lets one reset the device. The data has to be 3 bytes long. This file is writeonly.

Users: http://roccat.sourceforge.net

/sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/isku/roccatisku<minor>/talk

Defined on file *sysfs-driver-hid-roccat-isku*

When written, this file lets one trigger easyshift functionality from the host. The data has to be 16 bytes long. This file is writeonly.

Users: http://roccat.sourceforge.net

/sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/isku/roccatisku<minor>/talkfx

Defined on file *sysfs-driver-hid-roccat-isku*

When written, this file lets one trigger temporary color schemes from the host. The data has to be 16 bytes long. This file is writeonly.

Users: http://roccat.sourceforge.net

/sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/koneplus/roccatkoneplus<minor>/actual_profile

Defined on file *sysfs-driver-hid-roccat-koneplus*

The integer value of this attribute ranges from 0-4. When read, this attribute returns the number of the actual profile. This value is persistent, so its equivalent to the profile that's active when the mouse is powered on next time. When written, this file sets the number of the startup profile and the mouse activates this profile immediately.

Users: http://roccat.sourceforge.net

/sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/koneplus/roccatkoneplus<minor>/firmware_versi

Defined on file *sysfs-driver-hid-roccat-koneplus*

When read, this file returns the raw integer version number of the firmware reported by the mouse. Using the integer value eases further usage in other programs. To receive the real version number the decimal point has to be shifted 2 positions to the left. E.g. a returned value of 121 means 1.21 This file is readonly. Please read binary attribute info which contains firmware version.

Users: http://roccat.sourceforge.net

/sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/koneplus/roccatkoneplus<minor>/info

Defined on file *sysfs-driver-hid-roccat-koneplus*

When read, this file returns general data like firmware version. When written, the device can be reset. The data is 8 bytes long.

Users: http://roccat.sourceforge.net

/sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/koneplus/roccatkoneplus<minor>/macro

Defined on file *sysfs-driver-hid-roccat-koneplus*

The mouse can store a macro with max 500 key/button strokes internally. When written, this file lets one set the sequence for a specific button for a specific profile. Button and profile numbers are included in written data. The data has to be 2082 bytes long. This file is writeonly.

Users: http://roccat.sourceforge.net

/sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/koneplus/roccatkoneplus<minor>/profile[1-5]_buttons

Defined on file *sysfs-driver-hid-roccat-koneplus*

The mouse can store 5 profiles which can be switched by the press of a button. A profile is split in settings and buttons. profile_buttons holds information about button layout. When read, these files return the respective profile buttons. The returned data is 77 bytes in size. This file is readonly. Write control to select profile and read profile_buttons instead.

Users: http://roccat.sourceforge.net

/sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/koneplus/roccatkoneplus<minor>/profile[1-5]_settings

Defined on file *sysfs-driver-hid-roccat-koneplus*

The mouse can store 5 profiles which can be switched by the press of a button. A profile is split in settings and buttons. profile_settings holds information like resolution, sensitivity and light effects. When read, these files return the respective profile settings. The returned data is 43 bytes in size. This file is readonly. Write control to select profile and read profile_settings instead.

Users: http://roccat.sourceforge.net

/sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/koneplus/roccatkoneplus<minor>/profile_buttons

Defined on file *sysfs-driver-hid-roccat-koneplus*

The mouse can store 5 profiles which can be switched by the press of a button. A profile is split in settings and buttons. profile_buttons holds information about button layout. When written, this file lets one write the respective profile buttons back to the mouse. The data has to be 77 bytes long. The mouse will reject invalid data. Which profile to write is determined by the profile number contained in the data. Before reading this file, control has to be written to select which profile to read.

Users: http://roccat.sourceforge.net

/sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/koneplus/roccatkoneplus<minor>/profile_settings

Defined on file *sysfs-driver-hid-roccat-koneplus*

The mouse can store 5 profiles which can be switched by the press of a button. A profile is split in settings and buttons. profile_settings holds information like resolution, sensitivity and light effects. When written, this file lets one write the respective profile settings back to the mouse. The data has to be 43 bytes long. The mouse will reject invalid data. Which profile to write is determined by the profile number contained in the data. Before reading this file, control has to be written to select which profile to read.

Users: http://roccat.sourceforge.net

/sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/koneplus/roccatkoneplus<minor>/sensor

Defined on file *sysfs-driver-hid-roccat-koneplus*

The mouse has a tracking- and a distance-control-unit. These can be activated/deactivated and the lift-off distance can be set. The data has to be 6 bytes long. This file is writeonly.

Users: http://roccat.sourceforge.net

/sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/koneplus/roccatkoneplus<minor>/startup_profile

Defined on file *sysfs-driver-hid-roccat-koneplus*

The integer value of this attribute ranges from 0-4. When read, this attribute returns the number of the actual profile. This value is persistent, so its equivalent to the profile that's active when the mouse is powered on next time. When written, this file sets the number of the startup profile and the mouse activates this profile immediately. Please use actual_profile, it does the same thing.

Users: http://roccat.sourceforge.net

/sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/koneplus/roccatkoneplus<minor>/talk

Defined on file *sysfs-driver-hid-roccat-koneplus*

Used to active some easy* functions of the mouse from outside. The data has to be 16 bytes long. This file is writeonly.

Users: http://roccat.sourceforge.net

/sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/koneplus/roccatkoneplus<minor>/tcu

Defined on file *sysfs-driver-hid-roccat-koneplus*

When written a calibration process for the tracking control unit can be initiated/cancelled. Also lets one read/write sensor registers. The data has to be 4 bytes long.

Users: http://roccat.sourceforge.net

/sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/koneplus/roccatkoneplus<minor>/tcu_image

Defined on file *sysfs-driver-hid-roccat-koneplus*

When read the mouse returns a 30x30 pixel image of the sampled underground. This works only in the course of a calibration process initiated with tcu. The returned data is 1028 bytes in size. This file is readonly.

Users: http://roccat.sourceforge.net

/sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/konepure/roccatkonepure<minor>/actual_profile

Defined on file *sysfs-driver-hid-roccat-konepure*

The mouse can store 5 profiles which can be switched by the press of a button. actual_profile holds number of actual profile. This value is persistent, so its value determines the profile that's active when the mouse is powered on next time. When written, the mouse activates the set profile immediately. The data has to be 3 bytes long. The mouse will reject invalid data.

Users: http://roccat.sourceforge.net

/sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/konepure/roccatkonepure<minor>/control

Defined on file *sysfs-driver-hid-roccat-konepure*

When written, this file lets one select which data from which profile will be read next. The data has to be 3 bytes long. This file is writeonly.

Users: http://roccat.sourceforge.net

/sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/konepure/roccatkonepure<minor>/info

Defined on file *sysfs-driver-hid-roccat-konepure*

When read, this file returns general data like firmware version. When written, the device can be reset. The data is 6 bytes long.

Users: http://roccat.sourceforge.net

/sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/konepure/roccatkonepure<minor>/macro

Defined on file *sysfs-driver-hid-roccat-konepure*

The mouse can store a macro with max 500 key/button strokes internally. When written, this file lets one set the sequence for a specific button for a specific profile. Button and profile numbers are included in written data. The data has to be 2082 bytes long. This file is writeonly.

Users: http://roccat.sourceforge.net

/sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/konepure/roccatkonepure<minor>/profile_button

Defined on file *sysfs-driver-hid-roccat-konepure*

The mouse can store 5 profiles which can be switched by the press of a button. A profile is split in settings and buttons. profile_buttons holds information about button layout. When written, this file lets one write the respective profile buttons back to the mouse. The data has to be 59 bytes long. The mouse will reject invalid data. Which profile to write is determined by the profile number contained in the data. Before reading this file, control has to be written to select which profile to read.

Users: http://roccat.sourceforge.net

/sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/konepure/roccatkonepure<minor>/profile_setting

Defined on file *sysfs-driver-hid-roccat-konepure*

The mouse can store 5 profiles which can be switched by the press of a button. A profile is split in settings and buttons. profile_settings holds information like resolution, sensitivity and light

effects. When written, this file lets one write the respective profile settings back to the mouse. The data has to be 31 bytes long. The mouse will reject invalid data. Which profile to write is determined by the profile number contained in the data. Before reading this file, control has to be written to select which profile to read.

Users: http://roccat.sourceforge.net

/sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/konepure/roccatkonepure<minor>/sensor

Defined on file *sysfs-driver-hid-roccat-konepure*

The mouse has a tracking- and a distance-control-unit. These can be activated/deactivated and the lift-off distance can be set. The data has to be 6 bytes long. This file is writeonly.

Users: http://roccat.sourceforge.net

/sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/konepure/roccatkonepure<minor>/talk

Defined on file *sysfs-driver-hid-roccat-konepure*

Used to active some easy* functions of the mouse from outside. The data has to be 16 bytes long. This file is writeonly.

Users: http://roccat.sourceforge.net

/sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/konepure/roccatkonepure<minor>/tcu

Defined on file *sysfs-driver-hid-roccat-konepure*

When written a calibration process for the tracking control unit can be initiated/cancelled. Also lets one read/write sensor registers. The data has to be 4 bytes long.

Users: http://roccat.sourceforge.net

/sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/konepure/roccatkonepure<minor>/tcu_image

Defined on file *sysfs-driver-hid-roccat-konepure*

When read the mouse returns a 30x30 pixel image of the sampled underground. This works only in the course of a calibration process initiated with tcu. The returned data is 1028 bytes in size. This file is readonly.

Users: http://roccat.sourceforge.net

/sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/kovaplus/roccatkovaplus<minor>/actual_cpi

Defined on file *sysfs-driver-hid-roccat-kovaplus*

The integer value of this attribute ranges from 1-4. When read, this attribute returns the number of the active cpi level. This file is readonly. Has never been used. If bookkeeping is done, it's done in userland tools.

Users: http://roccat.sourceforge.net

/sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/kovaplus/roccatkovaplus<minor>/actual_profile

Defined on file *sysfs-driver-hid-roccat-kovaplus*

The integer value of this attribute ranges from 0-4. When read, this attribute returns the number of the active profile. When written, the mouse activates this profile immediately. The profile that's active when powered down is the same that's active when the mouse is powered on.

Users: http://roccat.sourceforge.net

/sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/kovaplus/roccatkovaplus<minor>/actual_sensitivi

Defined on file *sysfs-driver-hid-roccat-kovaplus*

The integer value of this attribute ranges from 1-10. When read, this attribute returns the number of the actual sensitivity in x direction. This file is readonly. Has never been used. If bookkeeping is done, it's done in userland tools.

Users: http://roccat.sourceforge.net

/sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/kovaplus/roccatkovaplus<minor>/actual_sensitivi

Defined on file *sysfs-driver-hid-roccat-kovaplus*

The integer value of this attribute ranges from 1-10. When read, this attribute returns the number of the actual sensitivity in y direction. This file is readonly. Has never been used. If bookkeeping is done, it's done in userland tools.

Users: http://roccat.sourceforge.net

/sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/kovaplus/roccatkovaplus<minor>/firmware_versio

Defined on file *sysfs-driver-hid-roccat-kovaplus*

When read, this file returns the raw integer version number of the firmware reported by the mouse. Using the integer value eases further usage in other programs. To receive the real version number the decimal point has to be shifted 2 positions to the left. E.g. a returned value of 121 means 1.21 This file is readonly. Obsoleted by binary sysfs attribute ”info”.

Users: http://roccat.sourceforge.net

/sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/kovaplus/roccatkovaplus<minor>/info

Defined on file *sysfs-driver-hid-roccat-kovaplus*

When read, this file returns general data like firmware version. When written, the device can be reset. The data is 6 bytes long.

Users: http://roccat.sourceforge.net

/sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/kovaplus/roccatkovaplus<minor>/profile[1-5]_buttons

Defined on file *sysfs-driver-hid-roccat-kovaplus*

The mouse can store 5 profiles which can be switched by the press of a button. A profile is split in settings and buttons. profile_buttons holds information about button layout. When read, these files return the respective profile buttons. The returned data is 23 bytes in size. This file is readonly. Write control to select profile and read profile_buttons instead.

Users: http://roccat.sourceforge.net

/sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/kovaplus/roccatkovaplus<minor>/profile[1-5]_settings

Defined on file *sysfs-driver-hid-roccat-kovaplus*

The mouse can store 5 profiles which can be switched by the press of a button. A profile is split in settings and buttons. profile_settings holds information like resolution, sensitivity and light effects. When read, these files return the respective profile settings. The returned data is 16 bytes in size. This file is readonly. Write control to select profile and read profile_settings instead.

Users: http://roccat.sourceforge.net

/sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/kovaplus/roccatkovaplus<minor>/profile_buttons

Defined on file *sysfs-driver-hid-roccat-kovaplus*

The mouse can store 5 profiles which can be switched by the press of a button. A profile is split in settings and buttons. profile_buttons holds information about button layout. When written, this file lets one write the respective profile buttons back to the mouse. The data has to be 23 bytes long. The mouse will reject invalid data. Which profile to write is determined by the profile number contained in the data. Before reading this file, control has to be written to select which profile to read.

Users: http://roccat.sourceforge.net

/sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/kovaplus/roccatkovaplus<minor>/profile_settings

Defined on file *sysfs-driver-hid-roccat-kovaplus*

The mouse can store 5 profiles which can be switched by the press of a button. A profile is split in settings and buttons. profile_settings holds information like resolution, sensitivity and light effects. When written, this file lets one write the respective profile settings back to the mouse. The data has to be 16 bytes long. The mouse will reject invalid data. Which profile to write is determined by the profile number contained in the data. Before reading this file, control has to be written to select which profile to read.

Users: http://roccat.sourceforge.net

/sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/pyra/roccatpyra<minor>/actual_cpi

Defined on file *sysfs-driver-hid-roccat-pyra*

It is possible to switch the cpi setting of the mouse with the press of a button. When read, this file returns the raw number of the actual cpi setting reported by the mouse. This number has to be further processed to receive the real dpi value:

VALUE	DPI
1	400
2	800
4	1600

This file is readonly. Has never been used. If bookkeeping is done, it's done in userland tools.

Users: http://roccat.sourceforge.net

/sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/pyra/roccatpyra<minor>/actual_profile

Defined on file *sysfs-driver-hid-roccat-pyra*

When read, this file returns the number of the actual profile in range 0-4. This file is readonly. Please use binary attribute ”settings” which provides this information.

Users: http://roccat.sourceforge.net

/sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/pyra/roccatpyra<minor>/firmware_version

Defined on file *sysfs-driver-hid-roccat-pyra*

When read, this file returns the raw integer version number of the firmware reported by the mouse. Using the integer value eases further usage in other programs. To receive the real version number the decimal point has to be shifted 2 positions to the left. E.g. a returned value of 138 means 1.38 This file is readonly. Please use binary attribute ”info” which provides this information.

Users: http://roccat.sourceforge.net

/sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/pyra/roccatpyra<minor>/info

Defined on file *sysfs-driver-hid-roccat-pyra*

When read, this file returns general data like firmware version. When written, the device can be reset. The data is 6 bytes long.

Users: http://roccat.sourceforge.net

/sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/pyra/roccatpyra<minor>/profile[1-5]_buttons

Defined on file *sysfs-driver-hid-roccat-pyra*

The mouse can store 5 profiles which can be switched by the press of a button. A profile is split in settings and buttons. profile_buttons holds information about button layout. When read, these files return the respective profile buttons. The returned data is 19 bytes in size. This file is readonly. Write control to select profile and read profile_buttons instead.

Users: http://roccat.sourceforge.net

/sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/pyra/roccatpyra<minor>/profile[1-5]_settings

Defined on file *sysfs-driver-hid-roccat-pyra*

The mouse can store 5 profiles which can be switched by the press of a button. A profile is split in settings and buttons. profile_settings holds information like resolution, sensitivity and light effects. When read, these files return the respective profile settings. The returned data is 13 bytes in size. This file is readonly. Write control to select profile and read profile_settings instead.

Users: http://roccat.sourceforge.net

/sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/pyra/roccatpyra<minor>/profile_buttons

Defined on file *sysfs-driver-hid-roccat-pyra*

The mouse can store 5 profiles which can be switched by the press of a button. A profile is split in settings and buttons. profile_buttons holds information about button layout. When written, this file lets one write the respective profile buttons back to the mouse. The data has to be 19 bytes long. The mouse will reject invalid data. Which profile to write is determined by the profile number contained in the data. Before reading this file, control has to be written to select which profile to read.

/sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/pyra/roccatpyra<minor>/settings

Defined on file *sysfs-driver-hid-roccat-pyra*

When read, this file returns the settings stored in the mouse. The size of the data is 3 bytes and holds information on the startup_profile. When written, this file lets write settings back to the mouse. The data has to be 3 bytes long. The mouse will reject invalid data.

Users: http://roccat.sourceforge.net

/sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/pyra/roccatpyra<minor>/startup_profile

Defined on file *sysfs-driver-hid-roccat-pyra*

The integer value of this attribute ranges from 0-4. When read, this attribute returns the number of the profile that's active when the mouse is powered on. This file is readonly. Please use binary attribute ”settings” which provides this information.

Users: http://roccat.sourceforge.net

/sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/ryos/roccatryos<minor>/control

Defined on file *sysfs-driver-hid-roccat-ryos*

When written, this file lets one select which data from which profile will be read next. The data has to be 3 bytes long. This file is writeonly.

Users: http://roccat.sourceforge.net

/sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/ryos/roccatryos<minor>/custom_lights

Defined on file *sysfs-driver-hid-roccat-ryos*

When written, this file lets one set the actual per-key lighting. This attribute is only valid for the pro variant. The data has to be 20 bytes long. This file is writeonly.

Users: http://roccat.sourceforge.net

/sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/ryos/roccatryos<minor>/info

Defined on file *sysfs-driver-hid-roccat-ryos*

When read, this file returns general data like firmware version. The data is 8 bytes long. This file is readonly.

Users: http://roccat.sourceforge.net

/sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/ryos/roccatryos<minor>/key_mask

Defined on file *sysfs-driver-hid-roccat-ryos*

When written, this file lets one deactivate certain keys like windows and application keys, to prevent accidental presses. Profile index for which this settings occur is included in written data. The data has to be 6 bytes long. Before reading this file, control has to be written to select which profile to read.

Users: http://roccat.sourceforge.net

/sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/ryos/roccatryos<minor>/keys_easyzone

Defined on file *sysfs-driver-hid-roccat-ryos*

When written, this file lets one set the function of the easyzone keys for a specific profile. Profile index is included in written data. The data has to be 294 bytes long. Before reading this file, control has to be written to select which profile to read.

Users: http://roccat.sourceforge.net

/sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/ryos/roccatryos<minor>/keys_extra

Defined on file *sysfs-driver-hid-roccat-ryos*

When written, this file lets one set the function of the capslock and function keys for a specific profile. Profile index is included in written data. The data has to be 8 bytes long. Before reading this file, control has to be written to select which profile to read.

Users: http://roccat.sourceforge.net

/sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/ryos/roccatryos<minor>/keys_function

Defined on file *sysfs-driver-hid-roccat-ryos*

When written, this file lets one set the function of the function keys for a specific profile. Profile index is included in written data. The data has to be 95 bytes long. Before reading this file, control has to be written to select which profile to read.

Users: http://roccat.sourceforge.net

/sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/ryos/roccatryos<minor>/keys_macro

Defined on file *sysfs-driver-hid-roccat-ryos*

When written, this file lets one set the function of the macro keys for a specific profile. Profile index is included in written data. The data has to be 35 bytes long. Before reading this file, control has to be written to select which profile to read.

Users: http://roccat.sourceforge.net

/sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/ryos/roccatryos<minor>/keys_primary

Defined on file *sysfs-driver-hid-roccat-ryos*

When written, this file lets one set the default of all keys for a specific profile. Profile index is included in written data. The data has to be 125 bytes long. Before reading this file, control has to be written to select which profile to read.

Users: http://roccat.sourceforge.net

/sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/ryos/roccatryos<minor>/keys_thumbster

Defined on file *sysfs-driver-hid-roccat-ryos*

When written, this file lets one set the function of the thumbster keys for a specific profile. Profile index is included in written data. The data has to be 23 bytes long. Before reading this file, control has to be written to select which profile to read.

Users: http://roccat.sourceforge.net

/sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/ryos/roccatryos<minor>/light

Defined on file *sysfs-driver-hid-roccat-ryos*

When written, this file lets one set the backlight intensity for a specific profile. Profile index is included in written data. This attribute is only valid for the glow and pro variant. The data has to be 16 bytes long. Before reading this file, control has to be written to select which profile to read.

Users: http://roccat.sourceforge.net

/sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/ryos/roccatryos<minor>/light_control

Defined on file *sysfs-driver-hid-roccat-ryos*

When written, this file lets one switch between stored and custom light settings. This attribute is only valid for the pro variant. The data has to be 8 bytes long. This file is writeonly.

Users: http://roccat.sourceforge.net

/sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/ryos/roccatryos<minor>/light_macro

Defined on file *sysfs-driver-hid-roccat-ryos*

When written, this file lets one set a light macro that is looped whenever the device gets in dimness mode. This attribute is only valid for the pro variant. The data has to be 2002 bytes long. Before reading this file, control has to be written to select which profile to read.

Users: http://roccat.sourceforge.net

/sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/ryos/roccatryos<minor>/macro

Defined on file *sysfs-driver-hid-roccat-ryos*

When written, this file lets one store macros with max 480 keystrokes for a specific button for a specific profile. Button and profile indexes are included in written data. The data has to be 2002 bytes long. Before reading this file, control has to be written to select which profile and key to read.

Users: http://roccat.sourceforge.net

/sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/ryos/roccatryos<minor>/profile

Defined on file *sysfs-driver-hid-roccat-ryos*

The mouse can store 5 profiles which can be switched by the press of a button. profile holds index of actual profile. This value is persistent, so its value determines the profile that's active when the device is powered on next time. When written, the device activates the set profile immediately. The data has to be 3 bytes long. The device will reject invalid data.

Users: http://roccat.sourceforge.net

/sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/ryos/roccatryos<minor>/reset

Defined on file *sysfs-driver-hid-roccat-ryos*

When written, this file lets one reset the device. The data has to be 3 bytes long. This file is writeonly.

Users: http://roccat.sourceforge.net

/sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/ryos/roccatryos<minor>/stored_lights

Defined on file *sysfs-driver-hid-roccat-ryos*

When written, this file lets one set per-key lighting for different layers. This attribute is only valid for the pro variant. The data has to be 1382 bytes long. Before reading this file, control has to be written to select which profile to read.

Users: http://roccat.sourceforge.net

/sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/ryos/roccatryos<minor>/talk

Defined on file *sysfs-driver-hid-roccat-ryos*

When written, this file lets one trigger easyshift functionality from the host. The data has to be 16 bytes long. This file is writeonly.

Users: http://roccat.sourceforge.net

/sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/savu/roccatsavu<minor>/buttons

Defined on file *sysfs-driver-hid-roccat-savu*

The mouse can store 5 profiles which can be switched by the press of a button. A profile is split into general settings and button settings. The buttons variable holds information about button layout. When written, this file lets one write the respective profile buttons to the mouse. The data has to be 47 bytes long. The mouse will reject invalid data. Which profile to write is determined by the profile number contained in the data. Before reading this file, control has to be written to select which profile to read.

Users: http://roccat.sourceforge.net

/sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/savu/roccatsavu<minor>/control

Defined on file *sysfs-driver-hid-roccat-savu*

When written, this file lets one select which data from which profile will be read next. The data has to be 3 bytes long. This file is writeonly.

Users: http://roccat.sourceforge.net

/sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/savu/roccatsavu<minor>/general

Defined on file *sysfs-driver-hid-roccat-savu*

The mouse can store 5 profiles which can be switched by the press of a button. A profile is split into general settings and button settings. A profile holds information like resolution, sensitivity and light effects. When written, this file lets one write the respective profile settings back to the mouse. The data has to be 43 bytes long. The mouse will reject invalid data. Which profile to write is determined by the profile number contained in the data. This file is writeonly.

Users: http://roccat.sourceforge.net

/sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/savu/roccatsavu<minor>/info

Defined on file *sysfs-driver-hid-roccat-savu*

When read, this file returns general data like firmware version. When written, the device can be reset. The data is 8 bytes long.

Users: http://roccat.sourceforge.net

/sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/savu/roccatsavu<minor>/macro

Defined on file *sysfs-driver-hid-roccat-savu*

When written, this file lets one store macros with max 500 keystrokes for a specific button for a specific profile. Button and profile numbers are included in written data. The data has to be 2083 bytes long. Before reading this file, control has to be written to select which profile and key to read.

Users: http://roccat.sourceforge.net

/sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/savu/roccatsavu<minor>/profile

Defined on file *sysfs-driver-hid-roccat-savu*

The mouse can store 5 profiles which can be switched by the press of a button. profile holds number of actual profile. This value is persistent, so its value determines the profile that's active when the mouse is powered on next time. When written, the mouse activates the set profile immediately. The data has to be 3 bytes long. The mouse will reject invalid data.

Users: http://roccat.sourceforge.net

/sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/savu/roccatsavu<minor>/sensor

Defined on file *sysfs-driver-hid-roccat-savu*

The mouse has a Avago ADNS-3090 sensor. This file allows reading and writing of the mouse sensors registers. The data has to be 4 bytes long.

Users: http://roccat.sourceforge.net

/sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/control

Defined on file *sysfs-driver-hid-roccat-lua*

When written, cpi, button and light settings can be configured. When read, actual cpi setting and sensor data are returned. The data has to be 8 bytes long.

Users: http://roccat.sourceforge.net

5.3.4 Symbols under /sys/class

/sys/class/gpio/

Defined on file *sysfs-gpio*

As a Kconfig option, individual GPIO signals may be accessed from userspace. GPIOs are only made available to userspace by an explicit ”export” operation. If a given GPIO is not claimed

for use by kernel code, it may be exported by userspace (and unexported later). Kernel code may export it for complete or partial access.

GPIOs are identified as they are inside the kernel, using integers in the range 0..INT_MAX. See Documentation/admin-guide/gpio for more information.

```
/sys/class/gpio
    /export ... asks the kernel to export a GPIO to userspace
    /unexport ... to return a GPIO to the kernel
    /gpioN ... for each exported GPIO #N OR
    /<LINE-NAME> ... for a properly named GPIO line
        /value ... always readable, writes fail for input GPIOs
        /direction ... r/w as: in, out (default low); write: high, low
        /edge ... r/w as: none, falling, rising, both
    /gpiochipN ... for each gpiochip; #N is its first GPIO
        /base ... (r/o) same as N
        /label ... (r/o) descriptive, not necessarily unique
        /ngpio ... (r/o) number of GPIOs; numbered N to N + (ngpio - 1)
```

This ABI is deprecated and will be removed after 2020. It is replaced with the GPIO character device.

/sys/class/typec/<port|partner|cable>/<dev>/mode<index>/

Defined on file *sysfs-class-typec*

Every supported mode will have its own directory. The name of a mode will be "mode<index>" (for example mode1), where <index> is the actual index to the mode VDO returned by Discover Modes USB power delivery command.

/sys/class/typec/<port|partner|cable>/<dev>/mode<index>/active

Defined on file *sysfs-class-typec*

Shows if the mode is active or not. The attribute can be used for entering/exiting the mode with partners and cable plugs, and with the port alternate modes it can be used for disabling support for specific alternate modes. Entering/exiting modes is supported as synchronous operation so write(2) to the attribute does not return until the enter/exit mode operation has finished. The attribute is notified when the mode is entered/exited so poll(2) on the attribute wakes up. Entering/exiting a mode will also generate uevent KOBJ_CHANGE.

Valid values: yes, no

/sys/class/typec/<port|partner|cable>/<dev>/mode<index>/description

Defined on file *sysfs-class-typec*

Shows description of the mode. The description is optional for the drivers, just like with the Billboard Devices.

/sys/class/typec/<port|partner|cable>/<dev>/mode<index>/vdo

Defined on file *sysfs-class-typec*

Shows the VDO in hexadecimal returned by Discover Modes command for this mode.

/sys/class/typec/<port|partner|cable>/<dev>/svid

Defined on file *sysfs-class-typec*

The SVID (Standard or Vendor ID) assigned by USB-IF for this alternate mode.

5.3.5 Symbols under /sys/devices

/sys/devices/system/cpu/cpuidle/current_governor_ro

Defined on file *sysfs-cpuidle*

current_governor_ro shows current using cpuidle governor, but read only. with the update that cpuidle governor can be changed at runtime in default, both current_governor and current_governor_ro co-exist under /sys/devices/system/cpu/cpuidle/ file, it's duplicate so make current_governor_ro obsolete.

5.3.6 Symbols under /sys/firmware

/sys/firmware/acpi/hotplug/force_remove

Defined on file *sysfs-firmware-acpi*

Since the force_remove is inherently broken and dangerous to use for some hotplugable resources like memory (because ignoring the offline failure might lead to memory corruption and crashes) enabling this knob is not safe and thus unsupported.

5.3.7 Symbols under /sys/kernel

/sys/kernel/fadump_enabled

Defined on file *sysfs-kernel-fadump_enabled*

read only Primarily used to identify whether the FADump is enabled in the kernel or not. User: Kdump service

/sys/kernel/fadump_registered

Defined on file *sysfs-kernel-fadump_registered*

read/write Helps to control the dump collect feature from userspace. Setting 1 to this file enables the system to collect the dump and 0 to disable it. User: Kdump service

/sys/kernel/fadump_release_mem

Defined on file *sysfs-kernel-fadump_release_mem*

write only This is a special sysfs file and only available when the system is booted to capture the vmcore using FADump. It is used to release the memory reserved by FADump to save the crash dump.

5.3.8 Symbols under /sys/o2cb

/sys/o2cb

Defined on file *o2cb*

Ocfs2-tools looks at 'interface-revision' for versioning information. Each logmask/ file controls a set of debug prints and can be written into with the strings ”allow”, ”deny”, or ”off”. Reading the file returns the current state. Was renamed to /sys/fs/u2cb/

Users: ocfs2-tools. It's sufficient to mail proposed changes to ocfs2-devel@lists.linux.dev.

5.3.9 File obsolete/o2cb

Has the following ABI:

- */sys/o2cb*

5.3.10 File obsolete/procfs-i8k

Has the following ABI:

- */proc/i8k*

5.3.11 File obsolete/sysfs-bus-iio

Has the following ABI:

- */sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/savu/roccatsavu<minor>/macro*
- */sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/savu/roccatsavu<minor>/profile*

- */sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/savu/roccatsavu<minor>/sensor*

5.3.24 File obsolete/sysfs-driver-intel_pmc_bxt

These files allow sending arbitrary IPC commands to the PMC/SCU which may be dangerous. These will be removed eventually and should not be used in any new applications.

Has the following ABI:

- */sys/bus/platform/devices/INT34D2:00/simplecmd*
- */sys/bus/platform/devices/INT34D2:00/northpeak*

5.3.25 File obsolete/sysfs-firmware-acpi

Has the following ABI:

- */sys/firmware/acpi/hotplug/force_remove*

5.3.26 File obsolete/sysfs-gpio

Has the following ABI:

- */sys/class/gpio/*

5.3.27 File obsolete/sysfs-kernel-fadump_enabled

This ABI is renamed and moved to a new location /sys/kernel/fadump/enabled.

Has the following ABI:

- */sys/kernel/fadump_enabled*

5.3.28 File obsolete/sysfs-kernel-fadump_registered

This ABI is renamed and moved to a new location /sys/kernel/fadump/registered.

Has the following ABI:

- */sys/kernel/fadump_registered*

5.3.29 File obsolete/sysfs-kernel-fadump_release_mem

This ABI is renamed and moved to a new location /sys/kernel/fadump/release_mem.

Has the following ABI:

- */sys/kernel/fadump_release_mem*

5.4 ABI removed symbols

5.4.1 Symbols under /sys/bus

/sys/bus/nd/devices/regionX/nfit/ecc_unit_size

Defined on file *sysfs-bus-nfit*

(RO) Size of a write request to a DIMM that will not incur a read-modify-write cycle at the memory controller.

When the nfit driver initializes it runs an ARS (Address Range Scrub) operation across every pmem range. Part of that process involves determining the ARS capabilities of a given address range. One of the capabilities that is reported is the 'Clear Uncorrectable Error Range Length Unit Size' (see: ACPI 6.2 section 9.20.7.4 Function Index 1 - Query ARS Capabilities). This property indicates the boundary at which the NVDIMM may need to perform read-modify-write cycles to maintain ECC (Error Correcting Code) blocks.

5.4.2 Symbols under /sys/class

/sys/class/rfkill/rfkill[0-9]+/claim

Defined on file *sysfs-class-rfkill*

This file was deprecated because there no longer was a way to claim just control over a single rfkill instance. This file was scheduled to be removed in 2012, and was removed in 2016. Values: 0: Kernel handles events

5.4.3 Symbols under /sys/devices

/sys/devices/system/machinecheck/machinecheckX/tolerant

Defined on file *sysfs-mce*

Unused and obsolete after the advent of recoverable machine checks (see last sentence below) and those are present since 2010 (Nehalem).

Original description:

The entries appear for each CPU, but they are truly shared between all CPUs.

Tolerance level. When a machine check exception occurs for a non corrected machine check the kernel can take different actions.

Since machine check exceptions can happen any time it is sometimes risky for the kernel to kill a process because it defies normal kernel locking rules. The tolerance level configures how hard the kernel tries to recover even at some risk of deadlock. Higher tolerant values trade potentially better uptime with the risk of a crash or even corruption (for tolerant >= 3).

0	always panic on uncorrected errors, log corrected errors
1	panic or SIGBUS on uncorrected errors, log corrected errors
2	SIGBUS or log uncorrected errors, log corrected errors
3	never panic or SIGBUS, log all errors (for testing only)

Default: 1

Note this only makes a difference if the CPU allows recovery from a machine check exception. Current x86 CPUs generally do not.

5.4.4 Symbols under /sys/fs

/sys/fs/selinux/checkreqprot

Defined on file *sysfs-selinux-checkreqprot*

REMOVAL UPDATE: The SELinux checkreqprot functionality was removed in March 2023, the original deprecation notice is shown below.

The selinuxfs "checkreqprot" node allows SELinux to be configured to check the protection requested by userspace for mmap/mprotect calls instead of the actual protection applied by the kernel. This was a compatibility mechanism for legacy userspace and for the READ_IMPLIES_EXEC personality flag. However, if set to 1, it weakens security by allowing mappings to be made executable without authorization by policy. The default value of checkreqprot at boot was changed starting in Linux v4.4 to 0 (i.e. check the actual protection), and Android and Linux distributions have been explicitly writing a "0" to */sys/fs/selinux/checkreqprot* during initialization for some time. Support for setting checkreqprot to 1 will be removed no sooner than June 2021, at which point the kernel will always cease using checkreqprot internally and will always check the actual protections being applied upon mmap/mprotect calls. The checkreqprot selinuxfs node will remain for backward compatibility but will discard writes of the "0" value and will reject writes of the "1" value when this mechanism is removed.

/sys/fs/selinux/disable

Defined on file *sysfs-selinux-disable*

REMOVAL UPDATE: The SELinux runtime disable functionality was removed in March 2023, the original deprecation notice is shown below.

The selinuxfs "disable" node allows SELinux to be disabled at runtime prior to a policy being loaded into the kernel. If disabled via this mechanism, SELinux will remain disabled until the system is rebooted.

The preferred method of disabling SELinux is via the "selinux=0" boot parameter, but the selinuxfs "disable" node was created to make it easier for systems with primitive bootloaders that did not allow for easy modification of the kernel command line. Unfortunately, allowing for SELinux to be disabled at runtime makes it difficult to secure the kernel's LSM hooks using the "__ro_after_init" feature.

Thankfully, the need for the SELinux runtime disable appears to be gone, the default Kconfig configuration disables this selinuxfs node, and only one of the major distributions, Fedora, supports disabling SELinux at runtime. Fedora is in the process of removing the selinuxfs "disable"

node and once that is complete we will start the slow process of removing this code from the kernel.

More information on */sys/fs/selinux/disable* can be found under the CONFIG_SECURITY_SELINUX_DISABLE Kconfig option.

5.4.5 Symbols under /sys/kernel

/sys/kernel/fadump_release_opalcore

Defined on file *sysfs-kernel-fadump_release_opalcore*

write only The sysfs file is available when the system is booted to collect the dump on OPAL based machine. It used to release the memory used to collect the opalcore.

/sys/kernel/uids/<uid>/cpu_shares

Defined on file *sysfs-kernel-uids*

The */sys/kernel/uids/<uid>/cpu_shares* tunable is used to set the cpu bandwidth a user is allowed. This is a proportional value. What that means is that if there are two users logged in, each with an equal number of shares, then they will get equal CPU bandwidth. Another example would be, if User A has shares = 1024 and user B has shares = 2048, User B will get twice the CPU bandwidth user A will. For more details refer /scheduler/sched-design-CFS

5.4.6 Symbols under /sys/o2cb

/sys/o2cb symlink

Defined on file *o2cb*

This is a symlink: /sys/o2cb to /sys/fs/o2cb. The symlink is removed when new versions of ocfs2-tools which know to look in /sys/fs/o2cb are sufficiently prevalent. Don't code new software to look here, it should try /sys/fs/o2cb instead.

Users: ocfs2-tools. It's sufficient to mail proposed changes to ocfs2-devel@lists.linux.dev.

5.4.7 devfs

devfs

Defined on file *devfs*

devfs has been unmaintained for a number of years, has unfixable races, contains a naming policy within the kernel that is against the LSB, and can be replaced by using udev.

The files fs/devfs/*, include/linux/devfs_fs*.h were removed, along with the assorted devfs function calls throughout the kernel tree.

5.4.8 Symbols under dv1394

dv1394 (a.k.a. "OHCI-DV I/O support" for FireWire)

Defined on file *dv1394*

/dev/dv1394/* were character device files, one for each FireWire controller and for NTSC and PAL respectively, from which DV data could be received by read() or transmitted by write(). A few ioctl()s allowed limited control. This special-purpose interface has been superseded by libraw1394 + libiec61883 which are functionally equivalent, support HDV, and transparently work on top of the newer firewire kernel drivers.

Users:

ffmpeg/libavformat (if configured for DV1394)

5.4.9 ip_queue

ip_queue

Defined on file *ip_queue*

ip_queue has been replaced by nfnetlink_queue which provides more advanced queueing mechanism to user-space. The ip_queue module was already announced to become obsolete years ago.

5.4.10 Symbols under raw1394

raw1394 (a.k.a. "Raw IEEE1394 I/O support" for FireWire)

Defined on file *raw1394*

/dev/raw1394 was a character device file that allowed low-level access to FireWire buses. Its major drawbacks were its inability to implement sensible device security policies, and its low level of abstraction that required userspace clients to duplicate much of the kernel's ieee1394 core functionality.

Replaced by /dev/fw*, i.e. the <linux/firewire-cdev.h> ABI of firewire-core.

Users:

libraw1394 (works with firewire-cdev too, transparent to library ABI users)

5.4.11 tcp_dma_copybreak sysctl

tcp_dma_copybreak sysctl

Defined on file *net_dma*

Formerly the lower limit, in bytes, of the size of socket reads that will be offloaded to a DMA copy engine. Removed due to coherency issues of the cpu potentially touching the buffers while dma is in flight.

5.4.12 video1394 (a.k.a. "OHCI-1394 Video support" for FireWire)

video1394 (a.k.a. "OHCI-1394 Video support" for FireWire)

Defined on file *video1394*

/dev/video1394/* were character device files, one for each FireWire controller, which were used for isochronous I/O. It was added as an alternative to raw1394's isochronous I/O functionality which had performance issues in its first generation. Any video1394 user had to use raw1394 + libraw1394 too because video1394 did not provide asynchronous I/O for device discovery and configuration.

Replaced by /dev/fw*, i.e. the <linux/firewire-cdev.h> ABI of firewire-core.

Users:

libdc1394 (works with firewire-cdev too, transparent to library ABI users)

5.4.13 File removed/devfs

Has the following ABI:

- *devfs*

5.4.14 File removed/dv1394

Has the following ABI:

- *dv1394 (a.k.a. "OHCI-DV I/O support" for FireWire)*

5.4.15 File removed/ip_queue

Has the following ABI:

- *ip_queue*

5.4.16 File removed/net_dma

Has the following ABI:

- *tcp_dma_copybreak sysctl*

5.4.17 File removed/o2cb

Has the following ABI:

- */sys/o2cb symlink*

5.4.18 File removed/raw1394

Has the following ABI:

- *raw1394 (a.k.a. "Raw IEEE1394 I/O support" for FireWire)*

5.4.19 File removed/sysfs-bus-nfit

Has the following ABI:

- */sys/bus/nd/devices/regionX/nfit/ecc_unit_size*

5.4.20 File removed/sysfs-class-rfkill

rfkill - radio frequency (RF) connector kill switch support

For details to this subsystem look at /driver-api/rfkill.

Has the following ABI:

- */sys/class/rfkill/rfkill[0-9]+/claim*

5.4.21 File removed/sysfs-kernel-fadump_release_opalcore

This ABI is moved to /sys/firmware/opal/mpipl/release_core.

Has the following ABI:

- */sys/kernel/fadump_release_opalcore*

5.4.22 File removed/sysfs-kernel-uids

Has the following ABI:

- */sys/kernel/uids/<uid>/cpu_shares*

5.4.23 File removed/sysfs-mce

Has the following ABI:

- */sys/devices/system/machinecheck/machinecheckX/tolerant*

5.4.24 File removed/sysfs-selinux-checkreqprot

Has the following ABI:

- */sys/fs/selinux/checkreqprot*

5.4.25 File removed/sysfs-selinux-disable

Has the following ABI:

- */sys/fs/selinux/disable*

5.4.26 File removed/video1394

Has the following ABI:

- *video1394 (a.k.a. "OHCI-1394 Video support" for FireWire)*

CHAPTER

SIX

FEATURE STATUS ON ALL ARCHITECTURES

6.1 Subsystem: core

Feature	Kconfig / Description	Status per architecture
cBPF-JIT	`HAVE_CBPF_JIT` arch supports cBPF JIT optimizations	• **ok**: mips, powerpc sparc • **TODO**: alpha, arc, arm arm64, csky, hexagon loongarch, m68k, microblaze nios2, openrisc, parisc riscv, s390, sh, um, x86 xtensa
eBPF-JIT	`HAVE_EBPF_JIT` arch supports eBPF JIT optimizations	• **ok**: arm, arm64 loongarch, mips, powerpc riscv, s390, sparc, x86 • **TODO**: alpha, arc, csky hexagon, m68k, microblaze nios2, openrisc, parisc, sh um, xtensa
generic-idle-thread	`GENERIC_SMP_IDLE_THREAD` arch makes use of the generic SMP idle thread facility	• **ok**: alpha, arc, arm arm64, csky, hexagon loongarch, mips, openrisc parisc, powerpc, riscv s390, sh, sparc, x86 xtensa • **TODO**: m68k, microblaze nios2, um
jump-labels	`HAVE_ARCH_JUMP_LABEL` arch supports live patched, high efficiency branches	• **ok**: arc, arm, arm64 csky, loongarch, mips parisc, powerpc, riscv s390, sparc, x86, xtensa • **TODO**: alpha, hexagon m68k, microblaze, nios2 openrisc, sh, um
thread-info-in-task	`THREAD_INFO_IN_TASK` arch makes use of the core kernel facility to embed thread_info in task_struct	• **ok**: arm, arm64, parisc powerpc, riscv, s390, x86 • **TODO**

6.2 Subsystem: debug

Feature	Kconfig / Description	Status per architecture
debug-vm-pgtable	`ARCH_HAS_DEBUG_VM_PGTABLE` arch supports pgtable tests for semantics compliance	• **ok**: arc, arm64, parisc powerpc, riscv, s390, x86 xtensa • **TODO**: alpha, arm, csky hexagon, loongarch, m68k microblaze, mips, nios2 openrisc, sh, sparc, um
gcov-profile-all	`ARCH_HAS_GCOV_PROFILE_ALL` arch supports whole-kernel GCOV code coverage profiling	• **ok**: arm, arm64, csky microblaze, mips, powerpc riscv, s390, sh, um, x86 xtensa • **TODO**: alpha, arc hexagon, loongarch, m68k nios2, openrisc, parisc sparc
KASAN	`HAVE_ARCH_KASAN` arch supports the KASAN runtime memory checker	• **ok**: arm, arm64 loongarch, powerpc, riscv s390, um, x86, xtensa • **TODO**: alpha, arc, csky hexagon, m68k, microblaze mips, nios2, openrisc parisc, sh, sparc
kcov	`ARCH_HAS_KCOV` arch supports kcov for coverage-guided fuzzing	• **ok**: arm, arm64 loongarch, mips, powerpc riscv, s390, um, x86 xtensa • **TODO**: alpha, arc, csky hexagon, m68k, microblaze nios2, openrisc, parisc, sh sparc
kgdb	`HAVE_ARCH_KGDB` arch supports the kGDB kernel debugger	• **ok**: arc, arm, arm64 hexagon, loongarch microblaze, mips, nios2 parisc, powerpc, riscv, sh sparc, x86 • **TODO**: alpha, csky, m68k openrisc, s390, um, xtensa
kmemleak	`HAVE_DEBUG_KMEMLEAK` arch supports the kernel memory leak detector	• **ok**: arc, arm, arm64 csky, loongarch, microblaze mips, powerpc, riscv, s390 sh, sparc, um, x86, xtensa

6.3 Subsystem: io

Feature	Kconfig / Description	Status per architecture
dma-contiguous	`HAVE_DMA_CONTIGUOUS` arch supports the DMA CMA (continuous memory allocator)	• **ok**: arm, arm64, csky loongarch, microblaze, mips riscv, s390, x86, xtensa • **TODO**: alpha, arc hexagon, m68k, nios2 openrisc, parisc, powerpc sh, sparc, um

6.4 Subsystem: locking

Feature	Kconfig / Description	Status per architecture
cmpxchg-local	`HAVE_CMPXCHG_LOCAL` arch supports the this_cpu_cmpxchg() API	• **ok**: arm64, s390, x86 • **TODO**: alpha, arc, arm csky, hexagon, loongarch m68k, microblaze, mips nios2, openrisc, parisc powerpc, riscv, sh, sparc um, xtensa
lockdep	`LOCKDEP_SUPPORT` arch supports the runtime locking correctness debug facility	• **ok**: arc, arm, arm64 csky, hexagon, loongarch microblaze, mips, openrisc parisc, powerpc, riscv s390, sh, sparc, um, x86 xtensa • **TODO**: alpha, m68k nios2
queued-rwlocks	`ARCH_USE_QUEUED_RWLOCKS` arch supports queued rwlocks	• **ok**: arm64, csky loongarch, mips, openrisc powerpc, riscv, sparc, x86 xtensa • **TODO**: alpha, arc, arm hexagon, m68k, microblaze nios2, parisc, s390, sh, um
queued-spinlocks	`ARCH_USE_QUEUED_SPINLOCKS` arch supports queued spinlocks	• **ok**: arm64, csky loongarch, mips, openrisc powerpc, sparc, x86, xtensa • **TODO**: alpha, arc, arm hexagon, m68k, microblaze nios2, parisc, riscv, s390 sh, um

6.5 Subsystem: perf

Feature	Kconfig / Description	Status per architecture
kprobes-event	`HAVE_REGS_AND_STACK_ACCESS_API` arch supports kprobes with perf events	• **ok**: arc, arm, arm64 csky, hexagon, loongarch mips, parisc, powerpc riscv, s390, sh, sparc, x86 • **TODO**: alpha, m68k microblaze, nios2, openrisc um, xtensa
perf-regs	`HAVE_PERF_REGS` arch supports perf events register access	• **ok**: arm, arm64, csky loongarch, mips, powerpc riscv, s390, x86 • **TODO**: alpha, arc hexagon, m68k, microblaze nios2, openrisc, parisc, sh sparc, um, xtensa
perf-stackdump	`HAVE_PERF_USER_STACK_DUMP` arch supports perf events stack dumps	• **ok**: arm, arm64, csky loongarch, mips, powerpc riscv, s390, x86 • **TODO**: alpha, arc hexagon, m68k, microblaze nios2, openrisc, parisc, sh sparc, um, xtensa

6.6 Subsystem: sched

Feature	Kconfig / Description	Status per architecture
membarrier-sync-core	`ARCH_HAS_MEMBARRIER_SYNC_CORE` arch supports core serializing membarrier	• **ok**: arm, arm64, powerpc s390, x86 • **TODO**: alpha, arc, csky hexagon, loongarch, m68k microblaze, mips, nios2 openrisc, parisc, riscv, sh sparc, um, xtensa
numa-balancing	`ARCH_SUPPORTS_NUMA_BALANCING` arch supports NUMA balancing	• **ok**: arm64, loongarch powerpc, riscv, s390, x86 • **TODO**: alpha, mips sparc • **Not compatible**: arc arm, csky, hexagon, m68k microblaze, nios2, openrisc parisc, sh, um, xtensa

6.7 Subsystem: seccomp

Feature	Kconfig / Description	Status per architecture
seccomp-filter	`HAVE_ARCH_SECCOMP_FILTER` arch supports seccomp filters	• **ok**: arm, arm64, csky loongarch, m68k, mips parisc, powerpc, riscv s390, sh, um, x86, xtensa • **TODO**: alpha, arc hexagon, microblaze, nios2 openrisc, sparc

6.8 Subsystem: time

Feature	Kconfig / Description	Status per architecture
arch-tick-broadcast	`ARCH_HAS_TICK_BROADCAST` arch provides tick_broadcast()	• **ok**: arm, arm64 loongarch, mips, powerpc riscv, sh • **TODO**: alpha, arc, csky hexagon, m68k, microblaze nios2, openrisc, parisc s390, sparc, um, x86 xtensa
clockevents	`!LEGACY_TIMER_TICK` arch support generic clock events	• **ok**: alpha, arc, arm64 csky, hexagon, loongarch microblaze, mips, nios2 openrisc, powerpc, riscv s390, sh, sparc, um, x86 xtensa • **TODO**: arm, m68k, parisc
irq-time-acct	`HAVE_IRQ_TIME_ACCOUNTING` arch supports precise IRQ time accounting	• **ok**: arm, arm64 loongarch, mips, powerpc riscv, x86, xtensa • **TODO**: arc, csky hexagon, m68k, microblaze nios2, openrisc, sh, um • **Not compatible**: alpha parisc, s390, sparc
user-context-tracking	`HAVE_CONTEXT_TRACKING_USER` arch supports user context tracking for NO_HZ_FULL	• **ok**: arm, arm64, csky loongarch, mips, powerpc riscv, sparc, x86, xtensa • **TODO**: alpha, arc hexagon, m68k, microblaze nios2, openrisc, parisc s390, sh, um
virt-cpuacct	`HAVE_VIRT_CPU_ACCOUNTING` arch supports precise virtual CPU time accounting	• **ok**: alpha, arm, arm64 csky, loongarch, mips parisc, powerpc, s390 sparc, x86, xtensa • **TODO**: arc, hexagon m68k, microblaze, nios2 openrisc, riscv, sh, um

6.9 Subsystem: vm

Feature	Kconfig / Description	Status per architecture
batch-unmap-tlb-flush	`ARCH_WANT_BATCHED_UNMAP_TLB_FLUSH` arch supports deferral of TLB flush until multiple pages are unmapped	• **ok**: arm64, riscv, x86 • **TODO**: alpha, arc, arm csky, hexagon, loongarch mips, parisc, powerpc, s390 sh, sparc, xtensa • **Not compatible**: m68k microblaze, nios2, openrisc um
ELF-ASLR	`ARCH_WANT_DEFAULT_TOPDOWN_MMAP_LAYOUT` arch randomizes the stack, heap and binary images of ELF binaries	• **ok**: arm, arm64, csky loongarch, mips, parisc powerpc, riscv, s390, x86 • **TODO**: alpha, arc hexagon, m68k, microblaze nios2, openrisc, sh, sparc um, xtensa
huge-vmap	`HAVE_ARCH_HUGE_VMAP` arch supports the arch_vmap_pud_supported() and arch_vmap_pmd_supported() VM APIs	• **ok**: arm64, powerpc riscv, x86 • **TODO**: alpha, arc, arm csky, hexagon, loongarch m68k, microblaze, mips nios2, openrisc, parisc s390, sh, sparc, um, xtensa
ioremap_prot	`HAVE_IOREMAP_PROT` arch has ioremap_prot()	• **ok**: arc, arm64 loongarch, mips, powerpc s390, sh, x86 • **TODO**: alpha, arm, csky hexagon, m68k, microblaze nios2, openrisc, parisc riscv, sparc, um, xtensa
PG_uncached	`ARCH_USES_PG_UNCACHED` arch supports the PG_uncached page flag	• **ok**: x86 • **TODO**: alpha, arc, arm arm64, csky, hexagon loongarch, m68k, microblaze mips, nios2, openrisc parisc, powerpc, riscv s390, sh, sparc, um, xtensa
pte_special	`ARCH_HAS_PTE_SPECIAL` arch supports the pte_special()/pte_mkspecial() VM APIs	• **ok**: arc, arm, arm64 loongarch, mips, parisc powerpc, riscv, s390, sh

This section describes CPU vulnerabilities and their mitigations.

CHAPTER

SEVEN

HARDWARE VULNERABILITIES

This section describes CPU vulnerabilities and provides an overview of the possible mitigations along with guidance for selecting mitigations if they are configurable at compile, boot or run time.

7.1 Spectre Side Channels

Spectre is a class of side channel attacks that exploit branch prediction and speculative execution on modern CPUs to read memory, possibly bypassing access controls. Speculative execution side channel exploits do not modify memory but attempt to infer privileged data in the memory.

This document covers Spectre variant 1 and Spectre variant 2.

7.1.1 Affected processors

Speculative execution side channel methods affect a wide range of modern high performance processors, since most modern high speed processors use branch prediction and speculative execution.

The following CPUs are vulnerable:

- Intel Core, Atom, Pentium, and Xeon processors
- AMD Phenom, EPYC, and Zen processors
- IBM POWER and zSeries processors
- Higher end ARM processors
- Apple CPUs
- Higher end MIPS CPUs
- Likely most other high performance CPUs. Contact your CPU vendor for details.

Whether a processor is affected or not can be read out from the Spectre vulnerability files in sysfs. See *Spectre system information*.

7.1.2 Related CVEs

The following CVE entries describe Spectre variants:

CVE-2017-5753	Bounds check bypass	Spectre variant 1
CVE-2017-5715	Branch target injection	Spectre variant 2
CVE-2019-1125	Spectre v1 swapgs	Spectre variant 1 (swapgs)

7.1.3 Problem

CPUs use speculative operations to improve performance. That may leave traces of memory accesses or computations in the processor's caches, buffers, and branch predictors. Malicious software may be able to influence the speculative execution paths, and then use the side effects of the speculative execution in the CPUs' caches and buffers to infer privileged data touched during the speculative execution.

Spectre variant 1 attacks take advantage of speculative execution of conditional branches, while Spectre variant 2 attacks use speculative execution of indirect branches to leak privileged memory. See *[1] [5] [6] [7] [10] [11]*.

7.1.4 Spectre variant 1 (Bounds Check Bypass)

The bounds check bypass attack *[2]* takes advantage of speculative execution that bypasses conditional branch instructions used for memory access bounds check (e.g. checking if the index of an array results in memory access within a valid range). This results in memory accesses to invalid memory (with out-of-bound index) that are done speculatively before validation checks resolve. Such speculative memory accesses can leave side effects, creating side channels which leak information to the attacker.

There are some extensions of Spectre variant 1 attacks for reading data over the network, see *[12]*. However such attacks are difficult, low bandwidth, fragile, and are considered low risk.

Note that, despite ”Bounds Check Bypass” name, Spectre variant 1 is not only about user-controlled array bounds checks. It can affect any conditional checks. The kernel entry code interrupt, exception, and NMI handlers all have conditional swapgs checks. Those may be problematic in the context of Spectre v1, as kernel code can speculatively run with a user GS.

7.1.5 Spectre variant 2 (Branch Target Injection)

The branch target injection attack takes advantage of speculative execution of indirect branches *[3]*. The indirect branch predictors inside the processor used to guess the target of indirect branches can be influenced by an attacker, causing gadget code to be speculatively executed, thus exposing sensitive data touched by the victim. The side effects left in the CPU's caches during speculative execution can be measured to infer data values.

In Spectre variant 2 attacks, the attacker can steer speculative indirect branches in the victim to gadget code by poisoning the branch target buffer of a CPU used for predicting indirect branch addresses. Such poisoning could be done by indirect branching into existing code, with the address offset of the indirect branch under the attacker's control. Since the branch prediction on impacted hardware does not fully disambiguate branch address and uses the

offset for prediction, this could cause privileged code's indirect branch to jump to a gadget code with the same offset.

The most useful gadgets take an attacker-controlled input parameter (such as a register value) so that the memory read can be controlled. Gadgets without input parameters might be possible, but the attacker would have very little control over what memory can be read, reducing the risk of the attack revealing useful data.

One other variant 2 attack vector is for the attacker to poison the return stack buffer (RSB) *[13]* to cause speculative subroutine return instruction execution to go to a gadget. An attacker's imbalanced subroutine call instructions might ”poison” entries in the return stack buffer which are later consumed by a victim's subroutine return instructions. This attack can be mitigated by flushing the return stack buffer on context switch, or virtual machine (VM) exit.

On systems with simultaneous multi-threading (SMT), attacks are possible from the sibling thread, as level 1 cache and branch target buffer (BTB) may be shared between hardware threads in a CPU core. A malicious program running on the sibling thread may influence its peer's BTB to steer its indirect branch speculations to gadget code, and measure the speculative execution's side effects left in level 1 cache to infer the victim's data.

Yet another variant 2 attack vector is for the attacker to poison the Branch History Buffer (BHB) to speculatively steer an indirect branch to a specific Branch Target Buffer (BTB) entry, even if the entry isn't associated with the source address of the indirect branch. Specifically, the BHB might be shared across privilege levels even in the presence of Enhanced IBRS.

Currently the only known real-world BHB attack vector is via unprivileged eBPF. Therefore, it's highly recommended to not enable unprivileged eBPF, especially when eIBRS is used (without retpolines). For a full mitigation against BHB attacks, it's recommended to use retpolines (or eIBRS combined with retpolines).

7.1.6 Attack scenarios

The following list of attack scenarios have been anticipated, but may not cover all possible attack vectors.

1. A user process attacking the kernel

Spectre variant 1

> The attacker passes a parameter to the kernel via a register or via a known address in memory during a syscall. Such parameter may be used later by the kernel as an index to an array or to derive a pointer for a Spectre variant 1 attack. The index or pointer is invalid, but bound checks are bypassed in the code branch taken for speculative execution. This could cause privileged memory to be accessed and leaked.
>
> For kernel code that has been identified where data pointers could potentially be influenced for Spectre attacks, new ”nospec” accessor macros are used to prevent speculative loading of data.

Spectre variant 1 (swapgs)

An attacker can train the branch predictor to speculatively skip the swapgs path for an interrupt or exception. If they initialize the GS register to a user-space value, if the swapgs is speculatively skipped, subsequent GS-related percpu accesses in the speculation window will be done with the attacker-controlled GS value. This could cause privileged memory to be accessed and leaked.

For example:

```
if (coming from user space)
    swapgs
mov %gs:<percpu_offset>, %reg
mov (%reg), %reg1
```

When coming from user space, the CPU can speculatively skip the swapgs, and then do a speculative percpu load using the user GS value. So the user can speculatively force a read of any kernel value. If a gadget exists which uses the percpu value as an address in another load/store, then the contents of the kernel value may become visible via an L1 side channel attack.

A similar attack exists when coming from kernel space. The CPU can speculatively do the swapgs, causing the user GS to get used for the rest of the speculative window.

Spectre variant 2

A spectre variant 2 attacker can *poison* the branch target buffer (BTB) before issuing syscall to launch an attack. After entering the kernel, the kernel could use the poisoned branch target buffer on indirect jump and jump to gadget code in speculative execution.

If an attacker tries to control the memory addresses leaked during speculative execution, he would also need to pass a parameter to the gadget, either through a register or a known address in memory. After the gadget has executed, he can measure the side effect.

The kernel can protect itself against consuming poisoned branch target buffer entries by using return trampolines (also known as ”retpoline”) *[3] [9]* for all indirect branches. Return trampolines trap speculative execution paths to prevent jumping to gadget code during speculative execution. x86 CPUs with Enhanced Indirect Branch Restricted Speculation (Enhanced IBRS) available in hardware should use the feature to mitigate Spectre variant 2 instead of retpoline. Enhanced IBRS is more efficient than retpoline.

There may be gadget code in firmware which could be exploited with Spectre variant 2 attack by a rogue user process. To mitigate such attacks on x86, Indirect Branch Restricted Speculation (IBRS) feature is turned on before the kernel invokes any firmware code.

2. A user process attacking another user process

A malicious user process can try to attack another user process, either via a context switch on the same hardware thread, or from the sibling hyperthread sharing a physical processor core on simultaneous multi-threading (SMT) system.

Spectre variant 1 attacks generally require passing parameters between the processes, which needs a data passing relationship, such as remote procedure calls (RPC). Those parameters are used in gadget code to derive invalid data pointers accessing privileged memory in the attacked process.

Spectre variant 2 attacks can be launched from a rogue process by *poisoning* the branch target buffer. This can influence the indirect branch targets for a victim process that either runs later on the same hardware thread, or running concurrently on a sibling hardware thread sharing the same physical core.

A user process can protect itself against Spectre variant 2 attacks by using the prctl() syscall to disable indirect branch speculation for itself. An administrator can also cordon off an unsafe process from polluting the branch target buffer by disabling the process's indirect branch speculation. This comes with a performance cost from not using indirect branch speculation and clearing the branch target buffer. When SMT is enabled on x86, for a process that has indirect branch speculation disabled, Single Threaded Indirect Branch Predictors (STIBP) *[4]* are turned on to prevent the sibling thread from controlling branch target buffer. In addition, the Indirect Branch Prediction Barrier (IBPB) is issued to clear the branch target buffer when context switching to and from such process.

On x86, the return stack buffer is stuffed on context switch. This prevents the branch target buffer from being used for branch prediction when the return stack buffer underflows while switching to a deeper call stack. Any poisoned entries in the return stack buffer left by the previous process will also be cleared.

User programs should use address space randomization to make attacks more difficult (Set /proc/sys/kernel/randomize_va_space = 1 or 2).

3. A virtualized guest attacking the host

The attack mechanism is similar to how user processes attack the kernel. The kernel is entered via hyper-calls or other virtualization exit paths.

For Spectre variant 1 attacks, rogue guests can pass parameters (e.g. in registers) via hyper-calls to derive invalid pointers to speculate into privileged memory after entering the kernel. For places where such kernel code has been identified, nospec accessor macros are used to stop speculative memory access.

For Spectre variant 2 attacks, rogue guests can *poison* the branch target buffer or return stack buffer, causing the kernel to jump to gadget code in the speculative execution paths.

To mitigate variant 2, the host kernel can use return trampolines for indirect branches to bypass the poisoned branch target buffer, and flushing the return stack buffer on VM exit. This prevents rogue guests from affecting indirect branching in the host kernel.

To protect host processes from rogue guests, host processes can have indirect branch speculation disabled via prctl(). The branch target buffer is cleared before context switching to such processes.

4. A virtualized guest attacking other guest

A rogue guest may attack another guest to get data accessible by the other guest.

Spectre variant 1 attacks are possible if parameters can be passed between guests. This may be done via mechanisms such as shared memory or message passing. Such parameters could be used to derive data pointers to privileged data in guest. The privileged data could be accessed by gadget code in the victim's speculation paths.

Spectre variant 2 attacks can be launched from a rogue guest by *poisoning* the branch target buffer or the return stack buffer. Such poisoned entries could be used to influence speculation execution paths in the victim guest.

Linux kernel mitigates attacks to other guests running in the same CPU hardware thread by flushing the return stack buffer on VM exit, and clearing the branch target buffer before switching to a new guest.

If SMT is used, Spectre variant 2 attacks from an untrusted guest in the sibling hyperthread can be mitigated by the administrator, by turning off the unsafe guest's indirect branch speculation via prctl(). A guest can also protect itself by turning on microcode based mitigations (such as IBPB or STIBP on x86) within the guest.

7.1.7 Spectre system information

The Linux kernel provides a sysfs interface to enumerate the current mitigation status of the system for Spectre: whether the system is vulnerable, and which mitigations are active.

The sysfs file showing Spectre variant 1 mitigation status is:

/sys/devices/system/cpu/vulnerabilities/spectre_v1

The possible values in this file are:

'Not affected'	The processor is not vulnerable.
'Vulnerable: __user pointer sanitization and usercopy barriers only; no swapgs barriers'	The swapgs protections are disabled; otherwise it has protection in the kernel on a case by case base with explicit pointer sanitation and usercopy LFENCE barriers.
'Mitigation: usercopy/swapgs barriers and __user pointer sanitization'	Protection in the kernel on a case by case base with explicit pointer sanitation, usercopy LFENCE barriers, and swapgs LFENCE barriers.

However, the protections are put in place on a case by case basis, and there is no guarantee that all possible attack vectors for Spectre variant 1 are covered.

The spectre_v2 kernel file reports if the kernel has been compiled with retpoline mitigation or if the CPU has hardware mitigation, and if the CPU has support for additional process-specific mitigation.

This file also reports CPU features enabled by microcode to mitigate attack between user processes:

1. Indirect Branch Prediction Barrier (IBPB) to add additional isolation between processes of different users.
2. Single Thread Indirect Branch Predictors (STIBP) to add additional isolation between CPU threads running on the same core.

These CPU features may impact performance when used and can be enabled per process on a case-by-case base.

The sysfs file showing Spectre variant 2 mitigation status is:

/sys/devices/system/cpu/vulnerabilities/spectre_v2

The possible values in this file are:

- Kernel status:

'Not affected'	The processor is not vulnerable
'Mitigation: None'	Vulnerable, no mitigation
'Mitigation: Retpolines'	Use Retpoline thunks
'Mitigation: LFENCE'	Use LFENCE instructions
'Mitigation: Enhanced IBRS'	Hardware-focused mitigation
'Mitigation: Enhanced IBRS + Retpolines'	Hardware-focused + Retpolines
'Mitigation: Enhanced IBRS + LFENCE'	Hardware-focused + LFENCE

- Firmware status: Show if Indirect Branch Restricted Speculation (IBRS) is used to protect against Spectre variant 2 attacks when calling firmware (x86 only).

'IBRS_FW'	Protection against user program attacks when calling firmware

- Indirect branch prediction barrier (IBPB) status for protection between processes of different users. This feature can be controlled through prctl() per process, or through kernel command line options. This is an x86 only feature. For more details see below.

'IBPB: disabled'	IBPB unused
'IBPB: always-on'	Use IBPB on all tasks
'IBPB: conditional'	Use IBPB on SECCOMP or indirect branch restricted tasks

- Single threaded indirect branch prediction (STIBP) status for protection between different hyper threads. This feature can be controlled through prctl per process, or through kernel command line options. This is x86 only feature. For more details see below.

'STIBP: disabled'	STIBP unused
'STIBP: forced'	Use STIBP on all tasks
'STIBP: conditional'	Use STIBP on SECCOMP or indirect branch restricted tasks

- Return stack buffer (RSB) protection status:

'RSB filling'	Protection of RSB on context switch enabled

- EIBRS Post-barrier Return Stack Buffer (PBRSB) protection status:

'PBRSB-eIBRS: SW sequence'	CPU is affected and protection of RSB on VMEXIT enabled
'PBRSB-eIBRS: Vulnerable'	CPU is vulnerable
'PBRSB-eIBRS: Not affected'	CPU is not affected by PBRSB

Full mitigation might require a microcode update from the CPU vendor. When the necessary microcode is not available, the kernel will report vulnerability.

7.1.8 Turning on mitigation for Spectre variant 1 and Spectre variant 2

1. Kernel mitigation

Spectre variant 1

For the Spectre variant 1, vulnerable kernel code (as determined by code audit or scanning tools) is annotated on a case by case basis to use nospec accessor macros for bounds clipping *[2]* to avoid any usable disclosure gadgets. However, it may not cover all attack vectors for Spectre variant 1.

Copy-from-user code has an LFENCE barrier to prevent the access_ok() check from being mis-speculated. The barrier is done by the barrier_nospec() macro.

For the swapgs variant of Spectre variant 1, LFENCE barriers are added to interrupt, exception and NMI entry where needed. These barriers are done by the FENCE_SWAPGS_KERNEL_ENTRY and FENCE_SWAPGS_USER_ENTRY macros.

Spectre variant 2

For Spectre variant 2 mitigation, the compiler turns indirect calls or jumps in the kernel into equivalent return trampolines (retpolines) *[3] [9]* to go to the target addresses. Speculative execution paths under retpolines are trapped in an infinite loop to prevent any speculative execution jumping to a gadget.

To turn on retpoline mitigation on a vulnerable CPU, the kernel needs to be compiled with a gcc compiler that supports the -mindirect-branch=thunk-extern -mindirect-branch-register options. If the kernel is compiled with a Clang compiler, the compiler needs to support -mretpoline-external-thunk option. The kernel config CONFIG_RETPOLINE needs to be turned on, and the CPU needs to run with the latest updated microcode.

On Intel Skylake-era systems the mitigation covers most, but not all, cases. See *[3]* for more details.

On CPUs with hardware mitigation for Spectre variant 2 (e.g. IBRS or enhanced IBRS on x86), retpoline is automatically disabled at run time.

Systems which support enhanced IBRS (eIBRS) enable IBRS protection once at boot, by setting the IBRS bit, and they're automatically protected against Spectre v2 variant attacks.

On Intel's enhanced IBRS systems, this includes cross-thread branch target injections on SMT systems (STIBP). In other words, Intel eIBRS enables STIBP, too.

AMD Automatic IBRS does not protect userspace, and Legacy IBRS systems clear the IBRS bit on exit to userspace, therefore both explicitly enable STIBP.

The retpoline mitigation is turned on by default on vulnerable CPUs. It can be forced on or off by the administrator via the kernel command line and sysfs control files. See *Mitigation control on the kernel command line*.

On x86, indirect branch restricted speculation is turned on by default before invoking any firmware code to prevent Spectre variant 2 exploits using the firmware.

Using kernel address space randomization (CONFIG_RANDOMIZE_BASE=y and CONFIG_SLAB_FREELIST_RANDOM=y in the kernel configuration) makes attacks on the kernel generally more difficult.

2. User program mitigation

User programs can mitigate Spectre variant 1 using LFENCE or "bounds clipping". For more details see *[2]*.

For Spectre variant 2 mitigation, individual user programs can be compiled with return trampolines for indirect branches. This protects them from consuming poisoned entries in the branch target buffer left by malicious software.

On legacy IBRS systems, at return to userspace, implicit STIBP is disabled because the kernel clears the IBRS bit. In this case, the userspace programs can disable indirect branch speculation via prctl() (See Documentation/userspace-api/spec_ctrl.rst). On x86, this will turn on STIBP to guard against attacks from the sibling thread when the user program is running, and use IBPB to flush the branch target buffer when switching to/from the program.

Restricting indirect branch speculation on a user program will also prevent the program from launching a variant 2 attack on x86. Administrators can change that behavior via the kernel command line and sysfs control files. See *Mitigation control on the kernel command line*.

Programs that disable their indirect branch speculation will have more overhead and run slower.

User programs should use address space randomization (/proc/sys/kernel/randomize_va_space = 1 or 2) to make attacks more difficult.

3. VM mitigation

Within the kernel, Spectre variant 1 attacks from rogue guests are mitigated on a case by case basis in VM exit paths. Vulnerable code uses nospec accessor macros for "bounds clipping", to avoid any usable disclosure gadgets. However, this may not cover all variant 1 attack vectors.

For Spectre variant 2 attacks from rogue guests to the kernel, the Linux kernel uses retpoline or Enhanced IBRS to prevent consumption of poisoned entries in branch target buffer left by rogue guests. It also flushes the return stack buffer on every VM

exit to prevent a return stack buffer underflow so poisoned branch target buffer could be used, or attacker guests leaving poisoned entries in the return stack buffer.

To mitigate guest-to-guest attacks in the same CPU hardware thread, the branch target buffer is sanitized by flushing before switching to a new guest on a CPU.

The above mitigations are turned on by default on vulnerable CPUs.

To mitigate guest-to-guest attacks from sibling thread when SMT is in use, an untrusted guest running in the sibling thread can have its indirect branch speculation disabled by administrator via prctl().

The kernel also allows guests to use any microcode based mitigation they choose to use (such as IBPB or STIBP on x86) to protect themselves.

7.1.9 Mitigation control on the kernel command line

Spectre variant 2 mitigation can be disabled or force enabled at the kernel command line.

nospectre_v1

[X86,PPC] Disable mitigations for Spectre Variant 1 (bounds check bypass). With this option data leaks are possible in the system.

nospectre_v2

[X86] Disable all mitigations for the Spectre variant 2 (indirect branch prediction) vulnerability. System may allow data leaks with this option, which is equivalent to spectre_v2=off.

spectre_v2=

[X86] Control mitigation of Spectre variant 2 (indirect branch speculation) vulnerability. The default operation protects the kernel from user space attacks.

on
unconditionally enable, implies spectre_v2_user=on

off
unconditionally disable, implies spectre_v2_user=off

auto
kernel detects whether your CPU model is vulnerable

Selecting 'on' will, and 'auto' may, choose a mitigation method at run time according to the CPU, the available microcode, the setting of the CONFIG_RETPOLINE configuration option, and the compiler with which the kernel was built.

Selecting 'on' will also enable the mitigation against user space to user space task attacks.

Selecting 'off' will disable both the kernel and the user space protections.

Specific mitigations can also be selected manually:

retpoline auto pick between generic,lfence retpoline,generic Retpolines retpoline,lfence LFENCE; indirect branch retpoline,amd alias for retpoline,lfence eibrs Enhanced/Auto IBRS eibrs,retpoline Enhanced/Auto IBRS

+ Retpolines eibrs,lfence Enhanced/Auto IBRS + LFENCE ibrs use IBRS to protect kernel

Not specifying this option is equivalent to spectre_v2=auto.

In general the kernel by default selects reasonable mitigations for the current CPU. To disable Spectre variant 2 mitigations, boot with spectre_v2=off. Spectre variant 1 mitigations cannot be disabled.

For spectre_v2_user see *The kernel's command-line parameters*

7.1.10 Mitigation selection guide

1. Trusted userspace

If all userspace applications are from trusted sources and do not execute externally supplied untrusted code, then the mitigations can be disabled.

2. Protect sensitive programs

For security-sensitive programs that have secrets (e.g. crypto keys), protection against Spectre variant 2 can be put in place by disabling indirect branch speculation when the program is running (See Documentation/userspace-api/spec_ctrl.rst).

3. Sandbox untrusted programs

Untrusted programs that could be a source of attacks can be cordoned off by disabling their indirect branch speculation when they are run (See Documentation/userspace-api/spec_ctrl.rst). This prevents untrusted programs from polluting the branch target buffer. This behavior can be changed via the kernel command line and sysfs control files. See *Mitigation control on the kernel command line*.

3. High security mode

All Spectre variant 2 mitigations can be forced on at boot time for all programs (See the ”on” option in *Mitigation control on the kernel command line*). This will add overhead as indirect branch speculations for all programs will be restricted.

On x86, branch target buffer will be flushed with IBPB when switching to a new program. STIBP is left on all the time to protect programs against variant 2 attacks originating from programs running on sibling threads.

Alternatively, STIBP can be used only when running programs whose indirect branch speculation is explicitly disabled, while IBPB is still used all the time when switching to a new program to clear the branch target buffer (See ”ibpb” option in *Mitigation control on the kernel command line*). This ”ibpb” option has less performance cost than the ”on” option, which leaves STIBP on all the time.

7.2 L1TF - L1 Terminal Fault

L1 Terminal Fault is a hardware vulnerability which allows unprivileged speculative access to data which is available in the Level 1 Data Cache when the page table entry controlling the virtual address, which is used for the access, has the Present bit cleared or other reserved bits set.

7.2.1 Affected processors

This vulnerability affects a wide range of Intel processors. The vulnerability is not present on:

- Processors from AMD, Centaur and other non Intel vendors
- Older processor models, where the CPU family is < 6
- A range of Intel ATOM processors (Cedarview, Cloverview, Lincroft, Penwell, Pineview, Silvermont, Airmont, Merrifield)
- The Intel XEON PHI family

- Intel processors which have the ARCH_CAP_RDCL_NO bit set in the IA32_ARCH_CAPABILITIES MSR. If the bit is set the CPU is not affected by the Meltdown vulnerability either. These CPUs should become available by end of 2018.

Whether a processor is affected or not can be read out from the L1TF vulnerability file in sysfs. See *L1TF system information*.

7.2.2 Related CVEs

The following CVE entries are related to the L1TF vulnerability:

CVE-2018-3615	L1 Terminal Fault	SGX related aspects
CVE-2018-3620	L1 Terminal Fault	OS, SMM related aspects
CVE-2018-3646	L1 Terminal Fault	Virtualization related aspects

7.2.3 Problem

If an instruction accesses a virtual address for which the relevant page table entry (PTE) has the Present bit cleared or other reserved bits set, then speculative execution ignores the invalid PTE and loads the referenced data if it is present in the Level 1 Data Cache, as if the page referenced by the address bits in the PTE was still present and accessible.

While this is a purely speculative mechanism and the instruction will raise a page fault when it is retired eventually, the pure act of loading the data and making it available to other speculative instructions opens up the opportunity for side channel attacks to unprivileged malicious code, similar to the Meltdown attack.

While Meltdown breaks the user space to kernel space protection, L1TF allows to attack any physical memory address in the system and the attack works across all protection domains. It allows an attack of SGX and also works from inside virtual machines because the speculation bypasses the extended page table (EPT) protection mechanism.

7.2.4 Attack scenarios

1. Malicious user space

Operating Systems store arbitrary information in the address bits of a PTE which is marked non present. This allows a malicious user space application to attack the physical memory to which these PTEs resolve. In some cases user-space can maliciously influence the information encoded in the address bits of the PTE, thus making attacks more deterministic and more practical.

The Linux kernel contains a mitigation for this attack vector, PTE inversion, which is permanently enabled and has no performance impact. The kernel ensures that the address bits of PTEs, which are not marked present, never point to cacheable physical memory space.

A system with an up to date kernel is protected against attacks from malicious user space applications.

2. Malicious guest in a virtual machine

The fact that L1TF breaks all domain protections allows malicious guest OSes, which can control the PTEs directly, and malicious guest user space applications, which run on an unprotected guest kernel lacking the PTE inversion mitigation for L1TF, to attack physical host memory.

A special aspect of L1TF in the context of virtualization is symmetric multi threading (SMT). The Intel implementation of SMT is called HyperThreading. The fact that Hyperthreads on the affected processors share the L1 Data Cache (L1D) is important for this. As the flaw allows only to attack data which is present in L1D, a malicious guest running on one Hyperthread can attack the data which is brought into the L1D by the context which runs on the sibling Hyperthread of the same physical core. This context can be host OS, host user space or a different guest.

If the processor does not support Extended Page Tables, the attack is only possible, when the hypervisor does not sanitize the content of the effective (shadow) page tables.

While solutions exist to mitigate these attack vectors fully, these mitigations are not enabled by default in the Linux kernel because they can affect performance significantly. The kernel provides several mechanisms which can be utilized to address the problem depending on the deployment scenario. The mitigations, their protection scope and impact are described in the next sections.

The default mitigations and the rationale for choosing them are explained at the end of this document. See *Default mitigations*.

7.2.5 L1TF system information

The Linux kernel provides a sysfs interface to enumerate the current L1TF status of the system: whether the system is vulnerable, and which mitigations are active. The relevant sysfs file is:

/sys/devices/system/cpu/vulnerabilities/l1tf

The possible values in this file are:

'Not affected'	The processor is not vulnerable
'Mitigation: PTE Inversion'	The host protection is active

If KVM/VMX is enabled and the processor is vulnerable then the following information is appended to the 'Mitigation: PTE Inversion' part:

- SMT status:

'VMX: SMT vulnerable'	SMT is enabled
'VMX: SMT disabled'	SMT is disabled

- L1D Flush mode:

'L1D vulnerable'	L1D flushing is disabled
'L1D conditional cache flushes'	L1D flush is conditionally enabled
'L1D cache flushes'	L1D flush is unconditionally enabled

The resulting grade of protection is discussed in the following sections.

7.2.6 Host mitigation mechanism

The kernel is unconditionally protected against L1TF attacks from malicious user space running on the host.

7.2.7 Guest mitigation mechanisms

1. L1D flush on VMENTER

To make sure that a guest cannot attack data which is present in the L1D the hypervisor flushes the L1D before entering the guest.

Flushing the L1D evicts not only the data which should not be accessed by a potentially malicious guest, it also flushes the guest data. Flushing the L1D has a performance impact as the processor has to bring the flushed guest data back into the L1D. Depending on the frequency of VMEXIT/VMENTER and the type of computations in the guest performance degradation in the range of 1% to 50% has been observed. For scenarios where guest VMEXIT/VMENTER are rare the performance impact is minimal. Virtio and mechanisms like posted interrupts are designed to confine the VMEXITs to a bare minimum, but specific configurations and application scenarios might still suffer from a high VMEXIT rate.

The kernel provides two L1D flush modes:

- conditional ('cond')
- unconditional ('always')

The conditional mode avoids L1D flushing after VMEXITs which execute only audited code paths before the corresponding VMENTER. These code paths have been verified that they cannot expose secrets or other interesting data to an attacker, but they can leak information about the address space layout of the hypervisor.

Unconditional mode flushes L1D on all VMENTER invocations and provides maximum protection. It has a higher overhead than the conditional mode. The overhead cannot be quantified correctly as it depends on the workload scenario and the resulting number of VMEXITs.

The general recommendation is to enable L1D flush on VMENTER. The kernel defaults to conditional mode on affected processors.

Note, that L1D flush does not prevent the SMT problem because the sibling thread will also bring back its data into the L1D which makes it attackable again.

L1D flush can be controlled by the administrator via the kernel command line and sysfs control files. See *Mitigation control on the kernel command line* and *Mitigation control for KVM - module parameter*.

2. Guest VCPU confinement to dedicated physical cores

To address the SMT problem, it is possible to make a guest or a group of guests affine to one or more physical cores. The proper mechanism for that is to utilize exclusive cpusets to ensure that no other guest or host tasks can run on these cores.

If only a single guest or related guests run on sibling SMT threads on the same physical core then they can only attack their own memory and restricted parts of the host memory.

Host memory is attackable, when one of the sibling SMT threads runs in host OS (hypervisor) context and the other in guest context. The amount of valuable information from the host OS context depends on the context which the host OS executes, i.e. interrupts, soft interrupts and kernel threads. The amount of valuable data from these contexts cannot be declared as non-interesting for an attacker without deep inspection of the code.

Note, that assigning guests to a fixed set of physical cores affects the ability of the scheduler to do load balancing and might have negative effects on CPU utilization depending on the hosting scenario. Disabling SMT might be a viable alternative for particular scenarios.

For further information about confining guests to a single or to a group of cores consult the cpusets documentation:

https://www.kernel.org/doc/Documentation/admin-guide/cgroup-v1/cpusets.rst

3. Interrupt affinity

Interrupts can be made affine to logical CPUs. This is not universally true because there are types of interrupts which are truly per CPU interrupts, e.g. the local timer interrupt. Aside of that multi queue devices affine their interrupts to single CPUs or groups of CPUs per queue without allowing the administrator to control the affinities.

Moving the interrupts, which can be affinity controlled, away from CPUs which run untrusted guests, reduces the attack vector space.

Whether the interrupts with are affine to CPUs, which run untrusted guests, provide interesting data for an attacker depends on the system configuration and the scenarios which run on the system. While for some of the interrupts it can be assumed that they won't expose interesting information beyond exposing hints about the host OS memory layout, there is no way to make general assumptions.

Interrupt affinity can be controlled by the administrator via the /proc/irq/$NR/smp_affinity[_list] files. Limited documentation is available at:

https://www.kernel.org/doc/Documentation/core-api/irq/irq-affinity.rst

4. SMT control

To prevent the SMT issues of L1TF it might be necessary to disable SMT completely. Disabling SMT can have a significant performance impact, but the impact depends on the hosting scenario and the type of workloads. The impact of disabling SMT needs also to be weighted against the impact of other mitigation solutions like confining guests to dedicated cores.

The kernel provides a sysfs interface to retrieve the status of SMT and to control it. It also provides a kernel command line interface to control SMT.

The kernel command line interface consists of the following options:

nosmt	Affects the bring up of the secondary CPUs during boot. The kernel tries to bring all present CPUs online during the boot process. "nosmt" makes sure that from each physical core only one - the so called primary (hyper) thread is activated. Due to a design flaw of Intel processors related to Machine Check Exceptions the non primary siblings have to be brought up at least partially and are then shut down again. "nosmt" can be undone via the sysfs interface.
nosmt=force	Has the same effect as "nosmt" but it does not allow to undo the SMT disable via the sysfs interface.

The sysfs interface provides two files:

- /sys/devices/system/cpu/smt/control
- /sys/devices/system/cpu/smt/active

/sys/devices/system/cpu/smt/control:

This file allows to read out the SMT control state and provides the ability to disable or (re)enable SMT. The possible states are:

on	SMT is supported by the CPU and enabled. All logical CPUs can be onlined and offlined without restrictions.
off	SMT is supported by the CPU and disabled. Only the so called primary SMT threads can be onlined and offlined without restrictions. An attempt to online a non-primary sibling is rejected
forceoff	Same as 'off' but the state cannot be controlled. Attempts to write to the control file are rejected.
notsupported	The processor does not support SMT. It's therefore not affected by the SMT implications of L1TF. Attempts to write to the control file are rejected.

The possible states which can be written into this file to control SMT state are:

- on

- off
- forceoff

/sys/devices/system/cpu/smt/active:

This file reports whether SMT is enabled and active, i.e. if on any physical core two or more sibling threads are online.

SMT control is also possible at boot time via the l1tf kernel command line parameter in combination with L1D flush control. See *Mitigation control on the kernel command line*.

5. Disabling EPT

Disabling EPT for virtual machines provides full mitigation for L1TF even with SMT enabled, because the effective page tables for guests are managed and sanitized by the hypervisor. Though disabling EPT has a significant performance impact especially when the Meltdown mitigation KPTI is enabled.

EPT can be disabled in the hypervisor via the 'kvm-intel.ept' parameter.

There is ongoing research and development for new mitigation mechanisms to address the performance impact of disabling SMT or EPT.

7.2.8 Mitigation control on the kernel command line

The kernel command line allows to control the L1TF mitigations at boot time with the option ”l1tf=”. The valid arguments for this option are:

full	Provides all available mitigations for the L1TF vulnerability. Disables SMT and enables all mitigations in the hypervisors, i.e. unconditional L1D flushing SMT control and L1D flush control via the sysfs interface is still possible after boot. Hypervisors will issue a warning when the first VM is started in a potentially insecure configuration, i.e. SMT enabled or L1D flush disabled.
full,force	Same as 'full', but disables SMT and L1D flush runtime control. Implies the 'nosmt=force' command line option. (i.e. sysfs control of SMT is disabled.)
flush	Leaves SMT enabled and enables the default hypervisor mitigation, i.e. conditional L1D flushing SMT control and L1D flush control via the sysfs interface is still possible after boot. Hypervisors will issue a warning when the first VM is started in a potentially insecure configuration, i.e. SMT enabled or L1D flush disabled.
flush,nosmt	Disables SMT and enables the default hypervisor mitigation, i.e. conditional L1D flushing. SMT control and L1D flush control via the sysfs interface is still possible after boot. Hypervisors will issue a warning when the first VM is started in a potentially insecure configuration, i.e. SMT enabled or L1D flush disabled.
flush,nowarn	Same as 'flush', but hypervisors will not warn when a VM is started in a potentially insecure configuration.
off	Disables hypervisor mitigations and doesn't emit any warnings. It also drops the swap size and available RAM limit restrictions on both hypervisor and bare metal.

The default is 'flush'. For details about L1D flushing see *1. L1D flush on VMENTER*.

7.2.9 Mitigation control for KVM - module parameter

The KVM hypervisor mitigation mechanism, flushing the L1D cache when entering a guest, can be controlled with a module parameter.

The option/parameter is "kvm-intel.vmentry_l1d_flush=". It takes the following arguments:

always	L1D cache flush on every VMENTER.
cond	Flush L1D on VMENTER only when the code between VMEXIT and VMENTER can leak host memory which is considered interesting for an attacker. This still can leak host memory which allows e.g. to determine the hosts address space layout.
never	Disables the mitigation

The parameter can be provided on the kernel command line, as a module parameter when loading the modules and at runtime modified via the sysfs file:

/sys/module/kvm_intel/parameters/vmentry_l1d_flush

The default is 'cond'. If 'l1tf=full,force' is given on the kernel command line, then 'always' is enforced and the kvm-intel.vmentry_l1d_flush module parameter is ignored and writes to the sysfs file are rejected.

7.2.10 Mitigation selection guide

1. No virtualization in use

The system is protected by the kernel unconditionally and no further action is required.

2. Virtualization with trusted guests

If the guest comes from a trusted source and the guest OS kernel is guaranteed to have the L1TF mitigations in place the system is fully protected against L1TF and no further action is required.

To avoid the overhead of the default L1D flushing on VMENTER the administrator can disable the flushing via the kernel command line and sysfs control files. See *Mitigation control on the kernel command line* and *Mitigation control for KVM - module parameter*.

3. Virtualization with untrusted guests

3.1. SMT not supported or disabled

If SMT is not supported by the processor or disabled in the BIOS or by the kernel, it's only required to enforce L1D flushing on VMENTER.

Conditional L1D flushing is the default behaviour and can be tuned. See *Mitigation control on the kernel command line* and *Mitigation control for KVM - module parameter*.

3.2. EPT not supported or disabled

If EPT is not supported by the processor or disabled in the hypervisor, the system is fully protected. SMT can stay enabled and L1D flushing on VMENTER is not required.

EPT can be disabled in the hypervisor via the 'kvm-intel.ept' parameter.

3.3. SMT and EPT supported and active

If SMT and EPT are supported and active then various degrees of mitigations can be employed:

- L1D flushing on VMENTER:

  L1D flushing on VMENTER is the minimal protection requirement, but it is only potent in combination with other mitigation methods.

  Conditional L1D flushing is the default behaviour and can be tuned. See *Mitigation control on the kernel command line* and *Mitigation control for KVM - module parameter*.

- Guest confinement:

  Confinement of guests to a single or a group of physical cores which are not running any other processes, can reduce the attack surface significantly, but interrupts, soft interrupts and kernel threads can still expose valuable data to a potential attacker. See *2. Guest VCPU confinement to dedicated physical cores*.

- Interrupt isolation:

  Isolating the guest CPUs from interrupts can reduce the attack surface further, but still allows a malicious guest to explore a limited amount of host physical memory. This can at least be used to gain knowledge about the host address space layout. The interrupts which have a fixed affinity to the CPUs which run the untrusted guests can depending on the scenario still trigger soft interrupts and schedule kernel threads which might expose valuable information. See *3. Interrupt affinity*.

The above three mitigation methods combined can provide protection to a certain degree, but the risk of the remaining attack surface has to be carefully analyzed. For full protection the following methods are available:

- Disabling SMT:

  Disabling SMT and enforcing the L1D flushing provides the maximum amount of protection. This mitigation is not depending on any of the above mitigation methods.

  SMT control and L1D flushing can be tuned by the command line parameters 'nosmt', 'l1tf', 'kvm-intel.vmentry_l1d_flush' and at run time with the matching sysfs control files. See *4. SMT control*, *Mitigation control on the kernel command line* and *Mitigation control for KVM - module parameter*.

- Disabling EPT:

  Disabling EPT provides the maximum amount of protection as well. It is not depending on any of the above mitigation methods. SMT can stay enabled and L1D flushing is not required, but the performance impact is significant.

  EPT can be disabled in the hypervisor via the 'kvm-intel.ept' parameter.

3.4. Nested virtual machines

When nested virtualization is in use, three operating systems are involved: the bare metal hypervisor, the nested hypervisor and the nested virtual machine. VMENTER operations from the nested hypervisor into the nested guest will always be processed by the bare metal hypervisor. If KVM is the bare metal hypervisor it will:

- Flush the L1D cache on every switch from the nested hypervisor to the nested virtual machine, so that the nested hypervisor's secrets are not exposed to the nested virtual machine;
- Flush the L1D cache on every switch from the nested virtual machine to the nested hypervisor; this is a complex operation, and flushing the L1D cache avoids that the bare metal hypervisor's secrets are exposed to the nested virtual machine;
- Instruct the nested hypervisor to not perform any L1D cache flush. This is an optimization to avoid double L1D flushing.

7.2.11 Default mitigations

The kernel default mitigations for vulnerable processors are:

- PTE inversion to protect against malicious user space. This is done unconditionally and cannot be controlled. The swap storage is limited to ~16TB.
- L1D conditional flushing on VMENTER when EPT is enabled for a guest.

The kernel does not by default enforce the disabling of SMT, which leaves SMT systems vulnerable when running untrusted guests with EPT enabled.

The rationale for this choice is:

- Force disabling SMT can break existing setups, especially with unattended updates.
- If regular users run untrusted guests on their machine, then L1TF is just an add on to other malware which might be embedded in an untrusted guest, e.g. spambots or attacks on the local network.

  There is no technical way to prevent a user from running untrusted code on their machines blindly.
- It's technically extremely unlikely and from today's knowledge even impossible that L1TF can be exploited via the most popular attack mechanisms like JavaScript because these mechanisms have no way to control PTEs. If this would be possible and not other mitigation would be possible, then the default might be different.
- The administrators of cloud and hosting setups have to carefully analyze the risk for their scenarios and make the appropriate mitigation choices, which might even vary across their deployed machines and also result in other changes of their overall setup. There is no way for the kernel to provide a sensible default for this kind of scenarios.

7.3 MDS - Microarchitectural Data Sampling

Microarchitectural Data Sampling is a hardware vulnerability which allows unprivileged speculative access to data which is available in various CPU internal buffers.

7.3.1 Affected processors

This vulnerability affects a wide range of Intel processors. The vulnerability is not present on:

- Processors from AMD, Centaur and other non Intel vendors
- Older processor models, where the CPU family is < 6
- Some Atoms (Bonnell, Saltwell, Goldmont, GoldmontPlus)
- Intel processors which have the ARCH_CAP_MDS_NO bit set in the IA32_ARCH_CAPABILITIES MSR.

Whether a processor is affected or not can be read out from the MDS vulnerability file in sysfs. See *MDS system information*.

Not all processors are affected by all variants of MDS, but the mitigation is identical for all of them so the kernel treats them as a single vulnerability.

7.3.2 Related CVEs

The following CVE entries are related to the MDS vulnerability:

CVE-2018-12126	MSBDS	Microarchitectural Store Buffer Data Sampling
CVE-2018-12130	MFBDS	Microarchitectural Fill Buffer Data Sampling
CVE-2018-12127	MLPDS	Microarchitectural Load Port Data Sampling
CVE-2019-11091	MDSUM	Microarchitectural Data Sampling Uncacheable Memory

7.3.3 Problem

When performing store, load, L1 refill operations, processors write data into temporary microarchitectural structures (buffers). The data in the buffer can be forwarded to load operations as an optimization.

Under certain conditions, usually a fault/assist caused by a load operation, data unrelated to the load memory address can be speculatively forwarded from the buffers. Because the load operation causes a fault or assist and its result will be discarded, the forwarded data will not cause incorrect program execution or state changes. But a malicious operation may be able to forward this speculative data to a disclosure gadget which allows in turn to infer the value via a cache side channel attack.

Because the buffers are potentially shared between Hyper-Threads cross Hyper-Thread attacks are possible.

Deeper technical information is available in the MDS specific x86 architecture section: Documentation/arch/x86/mds.rst.

7.3.4 Attack scenarios

Attacks against the MDS vulnerabilities can be mounted from malicious non- privileged user space applications running on hosts or guest. Malicious guest OSes can obviously mount attacks as well.

Contrary to other speculation based vulnerabilities the MDS vulnerability does not allow the attacker to control the memory target address. As a consequence the attacks are purely sampling based, but as demonstrated with the TLBleed attack samples can be postprocessed successfully.

Web-Browsers

> It's unclear whether attacks through Web-Browsers are possible at all. The exploitation through Java-Script is considered very unlikely, but other widely used web technologies like Webassembly could possibly be abused.

7.3.5 MDS system information

The Linux kernel provides a sysfs interface to enumerate the current MDS status of the system: whether the system is vulnerable, and which mitigations are active. The relevant sysfs file is:

/sys/devices/system/cpu/vulnerabilities/mds

The possible values in this file are:

'Not affected'	The processor is not vulnerable
'Vulnerable'	The processor is vulnerable, but no mitigation enabled
'Vulnerable: Clear CPU buffers attempted, no microcode'	The processor is vulnerable but microcode is not updated. The mitigation is enabled on a best effort basis. If the processor is vulnerable but the availability of the microcode based mitigation mechanism is not advertised via CPUID, the kernel selects a best effort mitigation mode. This mode invokes the mitigation instructions without a guarantee that they clear the CPU buffers. This is done to address virtualization scenarios where the host has the microcode update applied, but the hypervisor is not yet updated to expose the CPUID to the guest. If the host has updated microcode the protection takes effect; otherwise a few CPU cycles are wasted pointlessly.
'Mitigation: Clear CPU buffers'	The processor is vulnerable and the CPU buffer clearing mitigation is enabled.

If the processor is vulnerable then the following information is appended to the above information:

'SMT vulnerable'	SMT is enabled
'SMT mitigated'	SMT is enabled and mitigated
'SMT disabled'	SMT is disabled
'SMT Host state unknown'	Kernel runs in a VM, Host SMT state unknown

7.3.6 Mitigation mechanism

The kernel detects the affected CPUs and the presence of the microcode which is required.

If a CPU is affected and the microcode is available, then the kernel enables the mitigation by default. The mitigation can be controlled at boot time via a kernel command line option. See *Mitigation control on the kernel command line*.

CPU buffer clearing

The mitigation for MDS clears the affected CPU buffers on return to user space and when entering a guest.

If SMT is enabled it also clears the buffers on idle entry when the CPU is only affected by MSBDS and not any other MDS variant, because the other variants cannot be protected against cross Hyper-Thread attacks.

For CPUs which are only affected by MSBDS the user space, guest and idle transition mitigations are sufficient and SMT is not affected.

Virtualization mitigation

The protection for host to guest transition depends on the L1TF vulnerability of the CPU:

- CPU is affected by L1TF:

  If the L1D flush mitigation is enabled and up to date microcode is available, the L1D flush mitigation is automatically protecting the guest transition.

  If the L1D flush mitigation is disabled then the MDS mitigation is invoked explicit when the host MDS mitigation is enabled.

  For details on L1TF and virtualization see: *Documentation/admin-guide/hw-vuln//l1tf.rst*.

- CPU is not affected by L1TF:

  CPU buffers are flushed before entering the guest when the host MDS mitigation is enabled.

The resulting MDS protection matrix for the host to guest transition:

L1TF	MDS	VMX-L1FLUSH	Host MDS	MDS-State
Don't care	No	Don't care	N/A	Not affected
Yes	Yes	Disabled	Off	Vulnerable
Yes	Yes	Disabled	Full	Mitigated
Yes	Yes	Enabled	Don't care	Mitigated
No	Yes	N/A	Off	Vulnerable
No	Yes	N/A	Full	Mitigated

This only covers the host to guest transition, i.e. prevents leakage from host to guest, but does not protect the guest internally. Guests need to have their own protections.

XEON PHI specific considerations

The XEON PHI processor family is affected by MSBDS which can be exploited cross Hyper-Threads when entering idle states. Some XEON PHI variants allow to use MWAIT in user space (Ring 3) which opens an potential attack vector for malicious user space. The exposure can be disabled on the kernel command line with the 'ring3mwait=disable' command line option.

XEON PHI is not affected by the other MDS variants and MSBDS is mitigated before the CPU enters a idle state. As XEON PHI is not affected by L1TF either disabling SMT is not required for full protection.

SMT control

All MDS variants except MSBDS can be attacked cross Hyper-Threads. That means on CPUs which are affected by MFBDS or MLPDS it is necessary to disable SMT for full protection. These are most of the affected CPUs; the exception is XEON PHI, see *XEON PHI specific considerations*.

Disabling SMT can have a significant performance impact, but the impact depends on the type of workloads.

See the relevant chapter in the L1TF mitigation documentation for details: *Documentation/admin-guide/hw-vuln/l1tf.rst*.

7.3.7 Mitigation control on the kernel command line

The kernel command line allows to control the MDS mitigations at boot time with the option ”mds=”. The valid arguments for this option are:

full	If the CPU is vulnerable, enable all available mitigations for the MDS vulnerability, CPU buffer clearing on exit to userspace and when entering a VM. Idle transitions are protected as well if SMT is enabled. It does not automatically disable SMT.
full,nosmt	The same as mds=full, with SMT disabled on vulnerable CPUs. This is the complete mitigation.
off	Disables MDS mitigations completely.

Not specifying this option is equivalent to "mds=full". For processors that are affected by both TAA (TSX Asynchronous Abort) and MDS, specifying just "mds=off" without an accompanying "tsx_async_abort=off" will have no effect as the same mitigation is used for both vulnerabilities.

7.3.8 Mitigation selection guide

1. Trusted userspace

If all userspace applications are from a trusted source and do not execute untrusted code which is supplied externally, then the mitigation can be disabled.

2. Virtualization with trusted guests

The same considerations as above versus trusted user space apply.

3. Virtualization with untrusted guests

The protection depends on the state of the L1TF mitigations. See *Virtualization mitigation*.

If the MDS mitigation is enabled and SMT is disabled, guest to host and guest to guest attacks are prevented.

7.3.9 Default mitigations

The kernel default mitigations for vulnerable processors are:

- Enable CPU buffer clearing

The kernel does not by default enforce the disabling of SMT, which leaves SMT systems vulnerable when running untrusted code. The same rationale as for L1TF applies. See *Documentation/admin-guide/hw-vuln//l1tf.rst*.

7.4 TAA - TSX Asynchronous Abort

TAA is a hardware vulnerability that allows unprivileged speculative access to data which is available in various CPU internal buffers by using asynchronous aborts within an Intel TSX transactional region.

7.4.1 Affected processors

This vulnerability only affects Intel processors that support Intel Transactional Synchronization Extensions (TSX) when the TAA_NO bit (bit 8) is 0 in the IA32_ARCH_CAPABILITIES MSR. On processors where the MDS_NO bit (bit 5) is 0 in the IA32_ARCH_CAPABILITIES MSR, the existing MDS mitigations also mitigate against TAA.

Whether a processor is affected or not can be read out from the TAA vulnerability file in sysfs. See *TAA system information*.

7.4.2 Related CVEs

The following CVE entry is related to this TAA issue:

CVE-2019-11135	TAA	TSX Asynchronous Abort (TAA) condition on some microprocessors utilizing speculative execution may allow an authenticated user to potentially enable information disclosure via a side channel with local access.

7.4.3 Problem

When performing store, load or L1 refill operations, processors write data into temporary microarchitectural structures (buffers). The data in those buffers can be forwarded to load operations as an optimization.

Intel TSX is an extension to the x86 instruction set architecture that adds hardware transactional memory support to improve performance of multi-threaded software. TSX lets the processor expose and exploit concurrency hidden in an application due to dynamically avoiding unnecessary synchronization.

TSX supports atomic memory transactions that are either committed (success) or aborted. During an abort, operations that happened within the transactional region are rolled back. An asynchronous abort takes place, among other options, when a different thread accesses a cache line that is also used within the transactional region when that access might lead to a data race.

Immediately after an uncompleted asynchronous abort, certain speculatively executed loads may read data from those internal buffers and pass it to dependent operations. This can be then used to infer the value via a cache side channel attack.

Because the buffers are potentially shared between Hyper-Threads cross Hyper-Thread attacks are possible.

The victim of a malicious actor does not need to make use of TSX. Only the attacker needs to begin a TSX transaction and raise an asynchronous abort which in turn potentially leaks data stored in the buffers.

More detailed technical information is available in the TAA specific x86 architecture section: Documentation/arch/x86/tsx_async_abort.rst.

7.4.4 Attack scenarios

Attacks against the TAA vulnerability can be implemented from unprivileged applications running on hosts or guests.

As for MDS, the attacker has no control over the memory addresses that can be leaked. Only the victim is responsible for bringing data to the CPU. As a result, the malicious actor has to sample as much data as possible and then postprocess it to try to infer any useful information from it.

A potential attacker only has read access to the data. Also, there is no direct privilege escalation by using this technique.

7.4.5 TAA system information

The Linux kernel provides a sysfs interface to enumerate the current TAA status of mitigated systems. The relevant sysfs file is:

/sys/devices/system/cpu/vulnerabilities/tsx_async_abort

The possible values in this file are:

'Vulnerable'	The CPU is affected by this vulnerability and the microcode and kernel mitigation are not applied.
'Vulnerable: Clear CPU buffers attempted, no microcode'	The processor is vulnerable but microcode is not updated. The mitigation is enabled on a best effort basis. If the processor is vulnerable but the availability of the microcode based mitigation mechanism is not advertised via CPUID, the kernel selects a best effort mitigation mode. This mode invokes the mitigation instructions without a guarantee that they clear the CPU buffers. This is done to address virtualization scenarios where the host has the microcode update applied, but the hypervisor is not yet updated to expose the CPUID to the guest. If the host has updated microcode the protection takes effect; otherwise a few CPU cycles are wasted pointlessly.
'Mitigation: Clear CPU buffers'	The microcode has been updated to clear the buffers. TSX is still enabled.
'Mitigation: TSX disabled'	TSX is disabled.
'Not affected'	The CPU is not affected by this issue.

7.4.6 Mitigation mechanism

The kernel detects the affected CPUs and the presence of the microcode which is required. If a CPU is affected and the microcode is available, then the kernel enables the mitigation by default.

The mitigation can be controlled at boot time via a kernel command line option. See *Mitigation control on the kernel command line*.

Virtualization mitigation

Affected systems where the host has TAA microcode and TAA is mitigated by having disabled TSX previously, are not vulnerable regardless of the status of the VMs.

In all other cases, if the host either does not have the TAA microcode or the kernel is not mitigated, the system might be vulnerable.

7.4.7 Mitigation control on the kernel command line

The kernel command line allows to control the TAA mitigations at boot time with the option "tsx_async_abort=". The valid arguments for this option are:

off	This option disables the TAA mitigation on affected platforms. If the system has TSX enabled (see next parameter) and the CPU is affected, the system is vulnerable.
full	TAA mitigation is enabled. If TSX is enabled, on an affected system it will clear CPU buffers on ring transitions. On systems which are MDS-affected and deploy MDS mitigation, TAA is also mitigated. Specifying this option on those systems will have no effect.
full,nosmt	The same as tsx_async_abort=full, with SMT disabled on vulnerable CPUs that have TSX enabled. This is the complete mitigation. When TSX is disabled, SMT is not disabled because CPU is not vulnerable to cross-thread TAA attacks.

Not specifying this option is equivalent to "tsx_async_abort=full". For processors that are affected by both TAA and MDS, specifying just "tsx_async_abort=off" without an accompanying "mds=off" will have no effect as the same mitigation is used for both vulnerabilities.

The kernel command line also allows to control the TSX feature using the parameter "tsx=" on CPUs which support TSX control. MSR_IA32_TSX_CTRL is used to control the TSX feature and the enumeration of the TSX feature bits (RTM and HLE) in CPUID.

The valid options are:

off	Disables TSX on the system. Note that this option takes effect only on newer CPUs which are not vulnerable to MDS, i.e., have MSR_IA32_ARCH_CAPABILITIES.MDS_NO=1 and which get the new IA32_TSX_CTRL MSR through a microcode update. This new MSR allows for the reliable deactivation of the TSX functionality.
on	Enables TSX. Although there are mitigations for all known security vulnerabilities, TSX has been known to be an accelerator for several previous speculation-related CVEs, and so there may be unknown security risks associated with leaving it enabled.
auto	Disables TSX if X86_BUG_TAA is present, otherwise enables TSX on the system.

Not specifying this option is equivalent to "tsx=off".

The following combinations of the "tsx_async_abort" and "tsx" are possible. For affected platforms tsx=auto is equivalent to tsx=off and the result will be:

tsx=on	tsx_async_abort=full	The system will use VERW to clear CPU buffers. Cross-thread attacks are still possible on SMT machines.
tsx=on	tsx_async_abort=full,nosmt	As above, cross-thread attacks on SMT mitigated.
tsx=on	tsx_async_abort=off	The system is vulnerable.
tsx=off	tsx_async_abort=full	TSX might be disabled if microcode provides a TSX control MSR. If so, system is not vulnerable.
tsx=off	tsx_async_abort=full,nosmt	Ditto
tsx=off	tsx_async_abort=off	ditto

For unaffected platforms "tsx=on" and "tsx_async_abort=full" does not clear CPU buffers. For platforms without TSX control (MSR_IA32_ARCH_CAPABILITIES.MDS_NO=0) "tsx" command line argument has no effect.

For the affected platforms below table indicates the mitigation status for the combinations of CPUID bit MD_CLEAR and IA32_ARCH_CAPABILITIES MSR bits MDS_NO and TSX_CTRL_MSR.

MDS_NO	MD_CLEAR	TSX_CTRL_MSR	Status
0	0	0	Vulnerable (needs microcode)
0	1	0	MDS and TAA mitigated via VERW
1	1	0	MDS fixed, TAA vulnerable if TSX enabled because MD_CLEAR has no meaning and VERW is not guaranteed to clear buffers
1	X	1	MDS fixed, TAA can be mitigated by VERW or TSX_CTRL_MSR

7.4.8 Mitigation selection guide

1. Trusted userspace and guests

If all user space applications are from a trusted source and do not execute untrusted code which is supplied externally, then the mitigation can be disabled. The same applies to virtualized environments with trusted guests.

2. Untrusted userspace and guests

If there are untrusted applications or guests on the system, enabling TSX might allow a malicious actor to leak data from the host or from other processes running on the same physical core.

If the microcode is available and the TSX is disabled on the host, attacks are prevented in a virtualized environment as well, even if the VMs do not explicitly enable the mitigation.

7.4.9 Default mitigations

The kernel's default action for vulnerable processors is:

- Deploy TSX disable mitigation (tsx_async_abort=full tsx=off).

7.5 iTLB multihit

iTLB multihit is an erratum where some processors may incur a machine check error, possibly resulting in an unrecoverable CPU lockup, when an instruction fetch hits multiple entries in the instruction TLB. This can occur when the page size is changed along with either the physical address or cache type. A malicious guest running on a virtualized system can exploit this erratum to perform a denial of service attack.

7.5.1 Affected processors

Variations of this erratum are present on most Intel Core and Xeon processor models. The erratum is not present on:

- non-Intel processors
- Some Atoms (Airmont, Bonnell, Goldmont, GoldmontPlus, Saltwell, Silvermont)
- Intel processors that have the PSCHANGE_MC_NO bit set in the IA32_ARCH_CAPABILITIES MSR.

7.5.2 Related CVEs

The following CVE entry is related to this issue:

CVE-2018-12207	Machine Check Error Avoidance on Page Size Change

7.5.3 Problem

Privileged software, including OS and virtual machine managers (VMM), are in charge of memory management. A key component in memory management is the control of the page tables. Modern processors use virtual memory, a technique that creates the illusion of a very large memory for processors. This virtual space is split into pages of a given size. Page tables translate virtual addresses to physical addresses.

To reduce latency when performing a virtual to physical address translation, processors include a structure, called TLB, that caches recent translations. There are separate TLBs for instruction (iTLB) and data (dTLB).

Under this errata, instructions are fetched from a linear address translated using a 4 KB translation cached in the iTLB. Privileged software modifies the paging structure so that the same linear address using large page size (2 MB, 4 MB, 1 GB) with a different physical address or memory type. After the page structure modification but before the software invalidates any iTLB entries for the linear address, a code fetch that happens on the same linear address may cause a machine-check error which can result in a system hang or shutdown.

7.5.4 Attack scenarios

Attacks against the iTLB multihit erratum can be mounted from malicious guests in a virtualized system.

7.5.5 iTLB multihit system information

The Linux kernel provides a sysfs interface to enumerate the current iTLB multihit status of the system:whether the system is vulnerable and which mitigations are active. The relevant sysfs file is:

/sys/devices/system/cpu/vulnerabilities/itlb_multihit

The possible values in this file are:

Not affected	The processor is not vulnerable.
KVM: Mitigation: Split huge pages	Software changes mitigate this issue.
KVM: Mitigation: VMX unsupported	KVM is not vulnerable because Virtual Machine Extensions (VMX) is not supported.
KVM: Mitigation: VMX disabled	KVM is not vulnerable because Virtual Machine Extensions (VMX) is disabled.
KVM: Vulnerable	The processor is vulnerable, but no mitigation enabled

7.5.6 Enumeration of the erratum

A new bit has been allocated in the IA32_ARCH_CAPABILITIES (PSCHANGE_MC_NO) msr and will be set on CPU's which are mitigated against this issue.

IA32_ARCH_CAPABILITIES MSR	Not present	Possibly vulnerable,check model
IA32_ARCH_CAPABILITIES[PSCHANGE_MC_NO]	0	Likely vulnerable,check model
IA32_ARCH_CAPABILITIES[PSCHANGE_MC_NO]	1	Not vulnerable

7.5.7 Mitigation mechanism

This erratum can be mitigated by restricting the use of large page sizes to non-executable pages. This forces all iTLB entries to be 4K, and removes the possibility of multiple hits.

In order to mitigate the vulnerability, KVM initially marks all huge pages as non-executable. If the guest attempts to execute in one of those pages, the page is broken down into 4K pages, which are then marked executable.

If EPT is disabled or not available on the host, KVM is in control of TLB flushes and the problematic situation cannot happen. However, the shadow EPT paging mechanism used by nested virtualization is vulnerable, because the nested guest can trigger multiple iTLB hits by modifying its own (non-nested) page tables. For simplicity, KVM will make large pages non-executable in all shadow paging modes.

7.5.8 Mitigation control on the kernel command line and KVM - module parameter

The KVM hypervisor mitigation mechanism for marking huge pages as non-executable can be controlled with a module parameter ”nx_huge_pages=”. The kernel command line allows to control the iTLB multihit mitigations at boot time with the option ”kvm.nx_huge_pages=”.

The valid arguments for these options are:

force	Mitigation is enabled. In this case, the mitigation implements non-executable huge pages in Linux kernel KVM module. All huge pages in the EPT are marked as non-executable. If a guest attempts to execute in one of those pages, the page is broken down into 4K pages, which are then marked executable.
off	Mitigation is disabled.
auto	Enable mitigation only if the platform is affected and the kernel was not booted with the ”mitigations=off” command line parameter. This is the default option.

7.5.9 Mitigation selection guide

1. No virtualization in use

The system is protected by the kernel unconditionally and no further action is required.

2. Virtualization with trusted guests

If the guest comes from a trusted source, you may assume that the guest will not attempt to maliciously exploit these errata and no further action is required.

3. Virtualization with untrusted guests

If the guest comes from an untrusted source, the guest host kernel will need to apply iTLB multihit mitigation via the kernel command line or kvm module parameter.

7.6 SRBDS - Special Register Buffer Data Sampling

SRBDS is a hardware vulnerability that allows MDS *MDS - Microarchitectural Data Sampling* techniques to infer values returned from special register accesses. Special register accesses are accesses to off core registers. According to Intel's evaluation, the special register reads that have a security expectation of privacy are RDRAND, RDSEED and SGX EGETKEY.

When RDRAND, RDSEED and EGETKEY instructions are used, the data is moved to the core through the special register mechanism that is susceptible to MDS attacks.

7.6.1 Affected processors

Core models (desktop, mobile, Xeon-E3) that implement RDRAND and/or RDSEED may be affected.

A processor is affected by SRBDS if its Family_Model and stepping is in the following list, with the exception of the listed processors exporting MDS_NO while Intel TSX is available yet not enabled. The latter class of processors are only affected when Intel TSX is enabled by software using TSX_CTRL_MSR otherwise they are not affected.

common name	Family_Model	Stepping
IvyBridge	06_3AH	All
Haswell	06_3CH	All
Haswell_L	06_45H	All
Haswell_G	06_46H	All
Broadwell_G	06_47H	All
Broadwell	06_3DH	All
Skylake_L	06_4EH	All
Skylake	06_5EH	All
Kabylake_L	06_8EH	<= 0xC
Kabylake	06_9EH	<= 0xD

7.6.2 Related CVEs

The following CVE entry is related to this SRBDS issue:

CVE-2020-0543	SRBDS	Special Register Buffer Data Sampling

7.6.3 Attack scenarios

An unprivileged user can extract values returned from RDRAND and RDSEED executed on another core or sibling thread using MDS techniques.

7.6.4 Mitigation mechanism

Intel will release microcode updates that modify the RDRAND, RDSEED, and EGETKEY instructions to overwrite secret special register data in the shared staging buffer before the secret data can be accessed by another logical processor.

During execution of the RDRAND, RDSEED, or EGETKEY instructions, off-core accesses from other logical processors will be delayed until the special register read is complete and the secret data in the shared staging buffer is overwritten.

This has three effects on performance:

1. RDRAND, RDSEED, or EGETKEY instructions have higher latency.
2. Executing RDRAND at the same time on multiple logical processors will be serialized, resulting in an overall reduction in the maximum RDRAND bandwidth.
3. Executing RDRAND, RDSEED or EGETKEY will delay memory accesses from other logical processors that miss their core caches, with an impact similar to legacy locked cache-line-split accesses.

The microcode updates provide an opt-out mechanism (RNGDS_MITG_DIS) to disable the mitigation for RDRAND and RDSEED instructions executed outside of Intel Software Guard Extensions (Intel SGX) enclaves. On logical processors that disable the mitigation using this opt-out mechanism, RDRAND and RDSEED do not take longer to execute and do not impact performance of sibling logical processors memory accesses. The opt-out mechanism does not affect Intel SGX enclaves (including execution of RDRAND or RDSEED inside an enclave, as well as EGETKEY execution).

7.6.5 IA32_MCU_OPT_CTRL MSR Definition

Along with the mitigation for this issue, Intel added a new thread-scope IA32_MCU_OPT_CTRL MSR, (address 0x123). The presence of this MSR and RNGDS_MITG_DIS (bit 0) is enumerated by CPUID.(EAX=07H,ECX=0).EDX[SRBDS_CTRL = 9]==1. This MSR is introduced through the microcode update.

Setting IA32_MCU_OPT_CTRL[0] (RNGDS_MITG_DIS) to 1 for a logical processor disables the mitigation for RDRAND and RDSEED executed outside of an Intel SGX enclave on that logical processor. Opting out of the mitigation for a particular logical processor does not affect the RDRAND and RDSEED mitigations for other logical processors.

Note that inside of an Intel SGX enclave, the mitigation is applied regardless of the value of RNGDS_MITG_DS.

7.6.6 Mitigation control on the kernel command line

The kernel command line allows control over the SRBDS mitigation at boot time with the option "srbds=". The option for this is:

off	This option disables SRBDS mitigation for RDRAND and RDSEED on affected platforms.

7.6.7 SRBDS System Information

The Linux kernel provides vulnerability status information through sysfs. For SRBDS this can be accessed by the following sysfs file: /sys/devices/system/cpu/vulnerabilities/srbds

The possible values contained in this file are:

Not affected	Processor not vulnerable
Vulnerable	Processor vulnerable and mitigation disabled
Vulnerable: No microcode	Processor vulnerable and microcode is missing mitigation
Mitigation: Microcode	Processor is vulnerable and mitigation is in effect.
Mitigation: TSX disabled	Processor is only vulnerable when TSX is enabled while this system was booted with TSX disabled.
Unknown: Dependent on	
hypervisor status	Running on virtual guest processor that is affected but with no way to know if host processor is mitigated or vulnerable.

7.6.8 SRBDS Default mitigation

This new microcode serializes processor access during execution of RDRAND, RDSEED ensures that the shared buffer is overwritten before it is released for reuse. Use the "srbds=off" kernel command line to disable the mitigation for RDRAND and RDSEED.

7.7 Core Scheduling

Core scheduling support allows userspace to define groups of tasks that can share a core. These groups can be specified either for security usecases (one group of tasks don't trust another), or for performance usecases (some workloads may benefit from running on the same core as they don't need the same hardware resources of the shared core, or may prefer different cores if they do share hardware resource needs). This document only describes the security usecase.

7.7.1 Security usecase

A cross-HT attack involves the attacker and victim running on different Hyper Threads of the same core. MDS and L1TF are examples of such attacks. The only full mitigation of cross-HT attacks is to disable Hyper Threading (HT). Core scheduling is a scheduler feature that can mitigate some (not all) cross-HT attacks. It allows HT to be turned on safely by ensuring that only tasks in a user-designated trusted group can share a core. This increase in core sharing can also improve performance, however it is not guaranteed that performance will always improve, though that is seen to be the case with a number of real world workloads. In theory, core scheduling aims to perform at least as good as when Hyper Threading is disabled. In practice, this is mostly the case though not always: as synchronizing scheduling decisions across 2 or more CPUs in a core involves additional overhead - especially when the system is lightly loaded. When `total_threads <= N_CPUS/2`, the extra overhead may cause core scheduling to perform more poorly compared to SMT-disabled, where N_CPUS is the total number of CPUs. Please measure the performance of your workloads always.

7.7.2 Usage

Core scheduling support is enabled via the `CONFIG_SCHED_CORE` config option. Using this feature, userspace defines groups of tasks that can be co-scheduled on the same core. The core scheduler uses this information to make sure that tasks that are not in the same group never run simultaneously on a core, while doing its best to satisfy the system's scheduling requirements.

Core scheduling can be enabled via the `PR_SCHED_CORE` prctl interface. This interface provides support for the creation of core scheduling groups, as well as admission and removal of tasks from created groups:

```
#include <sys/prctl.h>

int prctl(int option, unsigned long arg2, unsigned long arg3,
        unsigned long arg4, unsigned long arg5);
```

option:
`PR_SCHED_CORE`

arg2:
Command for operation, must be one off:

- `PR_SCHED_CORE_GET` -- get core_sched cookie of `pid`.
- `PR_SCHED_CORE_CREATE` -- create a new unique cookie for `pid`.
- `PR_SCHED_CORE_SHARE_TO` -- push core_sched cookie to `pid`.
- `PR_SCHED_CORE_SHARE_FROM` -- pull core_sched cookie from `pid`.

arg3:
`pid` of the task for which the operation applies.

arg4:
`pid_type` for which the operation applies. It is one of `PR_SCHED_CORE_SCOPE_`-prefixed macro constants. For example, if arg4 is `PR_SCHED_CORE_SCOPE_THREAD_GROUP`, then the operation of this command will be performed for all tasks in the task group of `pid`.

arg5:
userspace pointer to an unsigned long for storing the cookie returned by `PR_SCHED_CORE_GET` command. Should be 0 for all other commands.

In order for a process to push a cookie to, or pull a cookie from a process, it is required to have the ptrace access mode: *PTRACE_MODE_READ_REALCREDS* to the process.

Building hierarchies of tasks

The simplest way to build hierarchies of threads/processes which share a cookie and thus a core is to rely on the fact that the core-sched cookie is inherited across forks/clones and execs, thus setting a cookie for the 'initial' script/executable/daemon will place every spawned child in the same core-sched group.

Cookie Transferral

Transferring a cookie between the current and other tasks is possible using PR_SCHED_CORE_SHARE_FROM and PR_SCHED_CORE_SHARE_TO to inherit a cookie from a specified task or a share a cookie with a task. In combination this allows a simple helper program to pull a cookie from a task in an existing core scheduling group and share it with already running tasks.

7.7.3 Design/Implementation

Each task that is tagged is assigned a cookie internally in the kernel. As mentioned in *Usage*, tasks with the same cookie value are assumed to trust each other and share a core.

The basic idea is that, every schedule event tries to select tasks for all the siblings of a core such that all the selected tasks running on a core are trusted (same cookie) at any point in time. Kernel threads are assumed trusted. The idle task is considered special, as it trusts everything and everything trusts it.

During a schedule() event on any sibling of a core, the highest priority task on the sibling's core is picked and assigned to the sibling calling schedule(), if the sibling has the task enqueued. For rest of the siblings in the core, highest priority task with the same cookie is selected if there is one runnable in their individual run queues. If a task with same cookie is not available, the idle task is selected. Idle task is globally trusted.

Once a task has been selected for all the siblings in the core, an IPI is sent to siblings for whom a new task was selected. Siblings on receiving the IPI will switch to the new task immediately. If an idle task is selected for a sibling, then the sibling is considered to be in a *forced idle* state. I.e., it may have tasks on its on runqueue to run, however it will still have to run idle. More on this in the next section.

Forced-idling of hyperthreads

The scheduler tries its best to find tasks that trust each other such that all tasks selected to be scheduled are of the highest priority in a core. However, it is possible that some runqueues had tasks that were incompatible with the highest priority ones in the core. Favoring security over fairness, one or more siblings could be forced to select a lower priority task if the highest priority task is not trusted with respect to the core wide highest priority task. If a sibling does not have a trusted task to run, it will be forced idle by the scheduler (idle thread is scheduled to run).

When the highest priority task is selected to run, a reschedule-IPI is sent to the sibling to force it into idle. This results in 4 cases which need to be considered depending on whether a VM or a regular usermode process was running on either HT:

```
       HT1 (attack)            HT2 (victim)
A      idle -> user space      user space -> idle
B      idle -> user space      guest -> idle
C      idle -> guest           user space -> idle
D      idle -> guest           guest -> idle
```

Note that for better performance, we do not wait for the destination CPU (victim) to enter idle mode. This is because the sending of the IPI would bring the destination CPU immediately into kernel mode from user space, or VMEXIT in the case of guests. At best, this would only leak some scheduler metadata which may not be worth protecting. It is also possible that the IPI is received too late on some architectures, but this has not been observed in the case of x86.

Trust model

Core scheduling maintains trust relationships amongst groups of tasks by assigning them a tag that is the same cookie value. When a system with core scheduling boots, all tasks are considered to trust each other. This is because the core scheduler does not have information about trust relationships until userspace uses the above mentioned interfaces, to communicate them. In other words, all tasks have a default cookie value of 0. and are considered system-wide trusted. The forced-idling of siblings running cookie-0 tasks is also avoided.

Once userspace uses the above mentioned interfaces to group sets of tasks, tasks within such groups are considered to trust each other, but do not trust those outside. Tasks outside the group also don't trust tasks within.

7.7.4 Limitations of core-scheduling

Core scheduling tries to guarantee that only trusted tasks run concurrently on a core. But there could be small window of time during which untrusted tasks run concurrently or kernel could be running concurrently with a task not trusted by kernel.

IPI processing delays

Core scheduling selects only trusted tasks to run together. IPI is used to notify the siblings to switch to the new task. But there could be hardware delays in receiving of the IPI on some arch (on x86, this has not been observed). This may cause an attacker task to start running on a CPU before its siblings receive the IPI. Even though cache is flushed on entry to user mode, victim tasks on siblings may populate data in the cache and micro architectural buffers after the attacker starts to run and this is a possibility for data leak.

7.7.5 Open cross-HT issues that core scheduling does not solve

1. For MDS

Core scheduling cannot protect against MDS attacks between the siblings running in user mode and the others running in kernel mode. Even though all siblings run tasks which trust each other, when the kernel is executing code on behalf of a task, it cannot trust the code running in the sibling. Such attacks are possible for any combination of sibling CPU modes (host or guest mode).

2. For L1TF

Core scheduling cannot protect against an L1TF guest attacker exploiting a guest or host victim. This is because the guest attacker can craft invalid PTEs which are not inverted due to a vulnerable guest kernel. The only solution is to disable EPT (Extended Page Tables).

For both MDS and L1TF, if the guest vCPU is configured to not trust each other (by tagging separately), then the guest to guest attacks would go away. Or it could be a system admin policy which considers guest to guest attacks as a guest problem.

Another approach to resolve these would be to make every untrusted task on the system to not trust every other untrusted task. While this could reduce parallelism of the untrusted tasks, it would still solve the above issues while allowing system processes (trusted tasks) to share a core.

3. Protecting the kernel (IRQ, syscall, VMEXIT)

Unfortunately, core scheduling does not protect kernel contexts running on sibling hyperthreads from one another. Prototypes of mitigations have been posted to LKML to solve this, but it is debatable whether such windows are practically exploitable, and whether the performance overhead of the prototypes are worth it (not to mention, the added code complexity).

7.7.6 Other Use cases

The main use case for Core scheduling is mitigating the cross-HT vulnerabilities with SMT enabled. There are other use cases where this feature could be used:

- Isolating tasks that needs a whole core: Examples include realtime tasks, tasks that uses SIMD instructions etc.
- Gang scheduling: Requirements for a group of tasks that needs to be scheduled together could also be realized using core scheduling. One example is vCPUs of a VM.

7.8 L1D Flushing

With an increasing number of vulnerabilities being reported around data leaks from the Level 1 Data cache (L1D) the kernel provides an opt-in mechanism to flush the L1D cache on context switch.

This mechanism can be used to address e.g. CVE-2020-0550. For applications the mechanism keeps them safe from vulnerabilities, related to leaks (snooping of) from the L1D cache.

7.8.1 Related CVEs

The following CVEs can be addressed by this mechanism

CVE-2020-0550	Improper Data Forwarding	OS related aspects

7.8.2 Usage Guidelines

Please see document: Documentation/userspace-api/spec_ctrl.rst for details.

NOTE: The feature is disabled by default, applications need to specifically opt into the feature to enable it.

7.8.3 Mitigation

When PR_SET_L1D_FLUSH is enabled for a task a flush of the L1D cache is performed when the task is scheduled out and the incoming task belongs to a different process and therefore to a different address space.

If the underlying CPU supports L1D flushing in hardware, the hardware mechanism is used, software fallback for the mitigation, is not supported.

7.8.4 Mitigation control on the kernel command line

The kernel command line allows to control the L1D flush mitigations at boot time with the option "l1d_flush=". The valid arguments for this option are:

on	Enables the prctl interface, applications trying to use the prctl() will fail with an error if l1d_flush is not enabled

By default the mechanism is disabled.

7.8.5 Limitations

The mechanism does not mitigate L1D data leaks between tasks belonging to different processes which are concurrently executing on sibling threads of a physical CPU core when SMT is enabled on the system.

This can be addressed by controlled placement of processes on physical CPU cores or by disabling SMT. See the relevant chapter in the L1TF mitigation document: *Documentation/admin-guide/hw-vuln/l1tf.rst*.

NOTE : The opt-in of a task for L1D flushing works only when the task's affinity is limited to cores running in non-SMT mode. If a task which requested L1D flushing is scheduled on a SMT-enabled core the kernel sends a SIGBUS to the task.

7.9 Processor MMIO Stale Data Vulnerabilities

Processor MMIO Stale Data Vulnerabilities are a class of memory-mapped I/O (MMIO) vulnerabilities that can expose data. The sequences of operations for exposing data range from simple to very complex. Because most of the vulnerabilities require the attacker to have access to MMIO, many environments are not affected. System environments using virtualization where MMIO access is provided to untrusted guests may need mitigation. These vulnerabilities are not transient execution attacks. However, these vulnerabilities may propagate stale data into core fill buffers where the data can subsequently be inferred by an unmitigated transient execution attack. Mitigation for these vulnerabilities includes a combination of microcode update and software changes, depending on the platform and usage model. Some of these mitigations are similar to those used to mitigate Microarchitectural Data Sampling (MDS) or those used to mitigate Special Register Buffer Data Sampling (SRBDS).

7.9.1 Data Propagators

Propagators are operations that result in stale data being copied or moved from one microarchitectural buffer or register to another. Processor MMIO Stale Data Vulnerabilities are operations that may result in stale data being directly read into an architectural, software-visible state or sampled from a buffer or register.

Fill Buffer Stale Data Propagator (FBSDP)

Stale data may propagate from fill buffers (FB) into the non-coherent portion of the uncore on some non-coherent writes. Fill buffer propagation by itself does not make stale data architecturally visible. Stale data must be propagated to a location where it is subject to reading or sampling.

Sideband Stale Data Propagator (SSDP)

The sideband stale data propagator (SSDP) is limited to the client (including Intel Xeon server E3) uncore implementation. The sideband response buffer is shared by all client cores. For non-coherent reads that go to sideband destinations, the uncore logic returns 64 bytes of data to the core, including both requested data and unrequested stale data, from a transaction buffer and the sideband response buffer. As a result, stale data from the sideband response and transaction buffers may now reside in a core fill buffer.

Primary Stale Data Propagator (PSDP)

The primary stale data propagator (PSDP) is limited to the client (including Intel Xeon server E3) uncore implementation. Similar to the sideband response buffer, the primary response buffer is shared by all client cores. For some processors, MMIO primary reads will return 64 bytes of data to the core fill buffer including both requested data and unrequested stale data. This is similar to the sideband stale data propagator.

7.9.2 Vulnerabilities

Device Register Partial Write (DRPW) (CVE-2022-21166)

Some endpoint MMIO registers incorrectly handle writes that are smaller than the register size. Instead of aborting the write or only copying the correct subset of bytes (for example, 2 bytes for a 2-byte write), more bytes than specified by the write transaction may be written to the register. On processors affected by FBSDP, this may expose stale data from the fill buffers of the core that created the write transaction.

Shared Buffers Data Sampling (SBDS) (CVE-2022-21125)

After propagators may have moved data around the uncore and copied stale data into client core fill buffers, processors affected by MFBDS can leak data from the fill buffer. It is limited to the client (including Intel Xeon server E3) uncore implementation.

Shared Buffers Data Read (SBDR) (CVE-2022-21123)

It is similar to Shared Buffer Data Sampling (SBDS) except that the data is directly read into the architectural software-visible state. It is limited to the client (including Intel Xeon server E3) uncore implementation.

7.9.3 Affected Processors

Not all the CPUs are affected by all the variants. For instance, most processors for the server market (excluding Intel Xeon E3 processors) are impacted by only Device Register Partial Write (DRPW).

Below is the list of affected Intel processors[1]:

Common name	Family_Model	Steppings
HASWELL_X	06_3FH	2,4
SKYLAKE_L	06_4EH	3
BROADWELL_X	06_4FH	All
SKYLAKE_X	06_55H	3,4,6,7,11
BROADWELL_D	06_56H	3,4,5
SKYLAKE	06_5EH	3
ICELAKE_X	06_6AH	4,5,6
ICELAKE_D	06_6CH	1
ICELAKE_L	06_7EH	5
ATOM_TREMONT_D	06_86H	All
LAKEFIELD	06_8AH	1
KABYLAKE_L	06_8EH	9 to 12
ATOM_TREMONT	06_96H	1
ATOM_TREMONT_L	06_9CH	0
KABYLAKE	06_9EH	9 to 13
COMETLAKE	06_A5H	2,3,5
COMETLAKE_L	06_A6H	0,1
ROCKETLAKE	06_A7H	1

If a CPU is in the affected processor list, but not affected by a variant, it is indicated by new bits in MSR IA32_ARCH_CAPABILITIES. As described in a later section, mitigation largely remains the same for all the variants, i.e. to clear the CPU fill buffers via VERW instruction.

7.9.4 New bits in MSRs

Newer processors and microcode update on existing affected processors added new bits to IA32_ARCH_CAPABILITIES MSR. These bits can be used to enumerate specific variants of Processor MMIO Stale Data vulnerabilities and mitigation capability.

[1] Affected Processors https://www.intel.com/content/www/us/en/developer/topic-technology/software-security-guidance/processors-affected-consolidated-product-cpu-model.html

MSR IA32_ARCH_CAPABILITIES

Bit 13 - SBDR_SSDP_NO - When set, processor is not affected by either the
Shared Buffers Data Read (SBDR) vulnerability or the sideband stale data propagator (SSDP).

Bit 14 - FBSDP_NO - When set, processor is not affected by the Fill Buffer
Stale Data Propagator (FBSDP).

Bit 15 - PSDP_NO - When set, processor is not affected by Primary Stale Data
Propagator (PSDP).

Bit 17 - FB_CLEAR - When set, VERW instruction will overwrite CPU fill buffer
values as part of MD_CLEAR operations. Processors that do not enumerate MDS_NO (meaning they are affected by MDS) but that do enumerate support for both L1D_FLUSH and MD_CLEAR implicitly enumerate FB_CLEAR as part of their MD_CLEAR support.

Bit 18 - FB_CLEAR_CTRL - Processor supports read and write to MSR
IA32_MCU_OPT_CTRL[FB_CLEAR_DIS]. On such processors, the FB_CLEAR_DIS bit can be set to cause the VERW instruction to not perform the FB_CLEAR action. Not all processors that support FB_CLEAR will support FB_CLEAR_CTRL.

MSR IA32_MCU_OPT_CTRL

Bit 3 - FB_CLEAR_DIS - When set, VERW instruction does not perform the FB_CLEAR action. This may be useful to reduce the performance impact of FB_CLEAR in cases where system software deems it warranted (for example, when performance is more critical, or the untrusted software has no MMIO access). Note that FB_CLEAR_DIS has no impact on enumeration (for example, it does not change FB_CLEAR or MD_CLEAR enumeration) and it may not be supported on all processors that enumerate FB_CLEAR.

7.9.5 Mitigation

Like MDS, all variants of Processor MMIO Stale Data vulnerabilities have the same mitigation strategy to force the CPU to clear the affected buffers before an attacker can extract the secrets.

This is achieved by using the otherwise unused and obsolete VERW instruction in combination with a microcode update. The microcode clears the affected CPU buffers when the VERW instruction is executed.

Kernel reuses the MDS function to invoke the buffer clearing:

```
mds_clear_cpu_buffers()
```

On MDS affected CPUs, the kernel already invokes CPU buffer clear on kernel/userspace, hypervisor/guest and C-state (idle) transitions. No additional mitigation is needed on such CPUs.

For CPUs not affected by MDS or TAA, mitigation is needed only for the attacker with MMIO capability. Therefore, VERW is not required for kernel/userspace. For virtualization case, VERW is only needed at VMENTER for a guest with MMIO capability.

Mitigation points

Return to user space

Same mitigation as MDS when affected by MDS/TAA, otherwise no mitigation needed.

C-State transition

Control register writes by CPU during C-state transition can propagate data from fill buffer to uncore buffers. Execute VERW before C-state transition to clear CPU fill buffers.

Guest entry point

Same mitigation as MDS when processor is also affected by MDS/TAA, otherwise execute VERW at VMENTER only for MMIO capable guests. On CPUs not affected by MDS/TAA, guest without MMIO access cannot extract secrets using Processor MMIO Stale Data vulnerabilities, so there is no need to execute VERW for such guests.

Mitigation control on the kernel command line

The kernel command line allows to control the Processor MMIO Stale Data mitigations at boot time with the option "mmio_stale_data=". The valid arguments for this option are:

full	If the CPU is vulnerable, enable mitigation; CPU buffer clearing on exit to userspace and when entering a VM. Idle transitions are protected as well. It does not automatically disable SMT.
full,nosmt	Same as full, with SMT disabled on vulnerable CPUs. This is the complete mitigation.
off	Disables mitigation completely.

If the CPU is affected and mmio_stale_data=off is not supplied on the kernel command line, then the kernel selects the appropriate mitigation.

Mitigation status information

The Linux kernel provides a sysfs interface to enumerate the current vulnerability status of the system: whether the system is vulnerable, and which mitigations are active. The relevant sysfs file is:

/sys/devices/system/cpu/vulnerabilities/mmio_stale_data

The possible values in this file are:

'Not affected'	The processor is not vulnerable
'Vulnerable'	The processor is vulnerable, but no mitigation enabled
'Vulnerable: Clear CPU buffers attempted, no microcode'	The processor is vulnerable but microcode is not updated. The mitigation is enabled on a best effort basis. If the processor is vulnerable but the availability of the microcode based mitigation mechanism is not advertised via CPUID, the kernel selects a best effort mitigation mode. This mode invokes the mitigation instructions without a guarantee that they clear the CPU buffers. This is done to address virtualization scenarios where the host has the microcode update applied, but the hypervisor is not yet updated to expose the CPUID to the guest. If the host has updated microcode the protection takes effect; otherwise a few CPU cycles are wasted pointlessly.
'Mitigation: Clear CPU buffers'	The processor is vulnerable and the CPU buffer clearing mitigation is enabled.
'Unknown: No mitigations'	The processor vulnerability status is unknown because it is out of Servicing period. Mitigation is not attempted.

Definitions:

Servicing period: The process of providing functional and security updates to Intel processors or platforms, utilizing the Intel Platform Update (IPU) process or other similar mechanisms.

End of Servicing Updates (ESU): ESU is the date at which Intel will no longer provide Servicing, such as through IPU or other similar update processes. ESU dates will typically be aligned to end of quarter.

If the processor is vulnerable then the following information is appended to the above information:

'SMT vulnerable'	SMT is enabled
'SMT disabled'	SMT is disabled
'SMT Host state unknown'	Kernel runs in a VM, Host SMT state unknown

References

7.10 Cross-Thread Return Address Predictions

Certain AMD and Hygon processors are subject to a cross-thread return address predictions vulnerability. When running in SMT mode and one sibling thread transitions out of C0 state, the other sibling thread could use return target predictions from the sibling thread that transitioned out of C0.

The Spectre v2 mitigations protect the Linux kernel, as it fills the return address prediction entries with safe targets when context switching to the idle thread. However, KVM does allow a VMM to prevent exiting guest mode when transitioning out of C0. This could result in a guest-controlled return target being consumed by the sibling thread.

7.10.1 Affected processors

The following CPUs are vulnerable:

- AMD Family 17h processors
- Hygon Family 18h processors

7.10.2 Related CVEs

The following CVE entry is related to this issue:

CVE-2022-27672	Cross-Thread Return Address Predictions

7.10.3 Problem

Affected SMT-capable processors support 1T and 2T modes of execution when SMT is enabled. In 2T mode, both threads in a core are executing code. For the processor core to enter 1T mode, it is required that one of the threads requests to transition out of the C0 state. This can be communicated with the HLT instruction or with an MWAIT instruction that requests non-C0. When the thread re-enters the C0 state, the processor transitions back to 2T mode, assuming the other thread is also still in C0 state.

In affected processors, the return address predictor (RAP) is partitioned depending on the SMT mode. For instance, in 2T mode each thread uses a private 16-entry RAP, but in 1T mode, the active thread uses a 32-entry RAP. Upon transition between 1T/2T mode, the RAP contents are not modified but the RAP pointers (which control the next return target to use for predictions) may change. This behavior may result in return targets from one SMT thread being used by RET predictions in the sibling thread following a 1T/2T switch. In particular, a RET instruction executed immediately after a transition to 1T may use a return target from the thread that just became idle. In theory, this could lead to information disclosure if the return targets used do not come from trustworthy code.

7.10.4 Attack scenarios

An attack can be mounted on affected processors by performing a series of CALL instructions with targeted return locations and then transitioning out of C0 state.

7.10.5 Mitigation mechanism

Before entering idle state, the kernel context switches to the idle thread. The context switch fills the RAP entries (referred to as the RSB in Linux) with safe targets by performing a sequence of CALL instructions.

Prevent a guest VM from directly putting the processor into an idle state by intercepting HLT and MWAIT instructions.

Both mitigations are required to fully address this issue.

7.10.6 Mitigation control on the kernel command line

Use existing Spectre v2 mitigations that will fill the RSB on context switch.

7.10.7 Mitigation control for KVM - module parameter

By default, the KVM hypervisor mitigates this issue by intercepting guest attempts to transition out of C0. A VMM can use the KVM_CAP_X86_DISABLE_EXITS capability to override those interceptions, but since this is not common, the mitigation that covers this path is not enabled by default.

The mitigation for the KVM_CAP_X86_DISABLE_EXITS capability can be turned on using the boolean module parameter mitigate_smt_rsb, e.g. `kvm.mitigate_smt_rsb=1`.

7.11 Speculative Return Stack Overflow (SRSO)

This is a mitigation for the speculative return stack overflow (SRSO) vulnerability found on AMD processors. The mechanism is by now the well known scenario of poisoning CPU functional units - the Branch Target Buffer (BTB) and Return Address Predictor (RAP) in this case - and then tricking the elevated privilege domain (the kernel) into leaking sensitive data.

AMD CPUs predict RET instructions using a Return Address Predictor (aka Return Address Stack/Return Stack Buffer). In some cases, a non-architectural CALL instruction (i.e., an instruction predicted to be a CALL but is not actually a CALL) can create an entry in the RAP which may be used to predict the target of a subsequent RET instruction.

The specific circumstances that lead to this varies by microarchitecture but the concern is that an attacker can mis-train the CPU BTB to predict non-architectural CALL instructions in kernel space and use this to control the speculative target of a subsequent kernel RET, potentially leading to information disclosure via a speculative side-channel.

The issue is tracked under CVE-2023-20569.

7.11.1 Affected processors

AMD Zen, generations 1-4. That is, all families 0x17 and 0x19. Older processors have not been investigated.

7.11.2 System information and options

First of all, it is required that the latest microcode be loaded for mitigations to be effective.

The sysfs file showing SRSO mitigation status is:

/sys/devices/system/cpu/vulnerabilities/spec_rstack_overflow

The possible values in this file are:

- 'Not affected':

  The processor is not vulnerable

- 'Vulnerable':

  The processor is vulnerable and no mitigations have been applied.

  - 'Vulnerable: No microcode':

    The processor is vulnerable, no microcode extending IBPB functionality to address the vulnerability has been applied.

  - 'Vulnerable: Safe RET, no microcode':

    The "Safe RET" mitigation (see below) has been applied to protect the kernel, but the IBPB-extending microcode has not been applied. User space tasks may still be vulnerable.

  - 'Vulnerable: Microcode, no safe RET':

    Extended IBPB functionality microcode patch has been applied. It does not address User->Kernel and Guest->Host transitions protection but it does address User->User and VM->VM attack vectors.

    Note that User->User mitigation is controlled by how the IBPB aspect in the Spectre v2 mitigation is selected:

    - conditional IBPB:

      where each process can select whether it needs an IBPB issued around it PR_SPEC_DISABLE/_ENABLE etc, see *Spectre Side Channels*

    - strict:

      i.e., always on - by supplying spectre_v2_user=on on the kernel command line

    (spec_rstack_overflow=microcode)

  - 'Mitigation: Safe RET':

    Combined microcode/software mitigation. It complements the extended IBPB microcode patch functionality by addressing User->Kernel and Guest->Host transitions protection.

    Selected by default or by spec_rstack_overflow=safe-ret

- 'Mitigation: IBPB':

  Similar protection as "safe RET" above but employs an IBPB barrier on privilege domain crossings (User->Kernel, Guest->Host).

  (spec_rstack_overflow=ibpb)

- 'Mitigation: IBPB on VMEXIT':

  Mitigation addressing the cloud provider scenario - the Guest->Host transitions only.

  (spec_rstack_overflow=ibpb-vmexit)

In order to exploit vulnerability, an attacker needs to:

- gain local access on the machine
- break kASLR
- find gadgets in the running kernel in order to use them in the exploit
- potentially create and pin an additional workload on the sibling thread, depending on the microarchitecture (not necessary on fam 0x19)
- run the exploit

Considering the performance implications of each mitigation type, the default one is 'Mitigation: safe RET' which should take care of most attack vectors, including the local User->Kernel one.

As always, the user is advised to keep her/his system up-to-date by applying software updates regularly.

The default setting will be reevaluated when needed and especially when new attack vectors appear.

As one can surmise, 'Mitigation: safe RET' does come at the cost of some performance depending on the workload. If one trusts her/his userspace and does not want to suffer the performance impact, one can always disable the mitigation with spec_rstack_overflow=off.

Similarly, 'Mitigation: IBPB' is another full mitigation type employing an indrect branch prediction barrier after having applied the required microcode patch for one's system. This mitigation comes also at a performance cost.

7.11.3 Mitigation: Safe RET

The mitigation works by ensuring all RET instructions speculate to a controlled location, similar to how speculation is controlled in the retpoline sequence. To accomplish this, the __x86_return_thunk forces the CPU to mispredict every function return using a 'safe return' sequence.

To ensure the safety of this mitigation, the kernel must ensure that the safe return sequence is itself free from attacker interference. In Zen3 and Zen4, this is accomplished by creating a BTB alias between the untraining function srso_alias_untrain_ret() and the safe return function srso_alias_safe_ret() which results in evicting a potentially poisoned BTB entry and using that safe one for all function returns.

In older Zen1 and Zen2, this is accomplished using a reinterpretation technique similar to Retbleed one: srso_untrain_ret() and srso_safe_ret().

7.12 GDS - Gather Data Sampling

Gather Data Sampling is a hardware vulnerability which allows unprivileged speculative access to data which was previously stored in vector registers.

7.12.1 Problem

When a gather instruction performs loads from memory, different data elements are merged into the destination vector register. However, when a gather instruction that is transiently executed encounters a fault, stale data from architectural or internal vector registers may get transiently forwarded to the destination vector register instead. This will allow a malicious attacker to infer stale data using typical side channel techniques like cache timing attacks. GDS is a purely sampling-based attack.

The attacker uses gather instructions to infer the stale vector register data. The victim does not need to do anything special other than use the vector registers. The victim does not need to use gather instructions to be vulnerable.

Because the buffers are shared between Hyper-Threads cross Hyper-Thread attacks are possible.

7.12.2 Attack scenarios

Without mitigation, GDS can infer stale data across virtually all permission boundaries:

> Non-enclaves can infer SGX enclave data Userspace can infer kernel data Guests can infer data from hosts Guest can infer guest from other guests Users can infer data from other users

Because of this, it is important to ensure that the mitigation stays enabled in lower-privilege contexts like guests and when running outside SGX enclaves.

The hardware enforces the mitigation for SGX. Likewise, VMMs should ensure that guests are not allowed to disable the GDS mitigation. If a host erred and allowed this, a guest could theoretically disable GDS mitigation, mount an attack, and re-enable it.

7.12.3 Mitigation mechanism

This issue is mitigated in microcode. The microcode defines the following new bits:

IA32_ARCH_CAPABILITIES[GDS_CTRL]	RO	Enumerates GDS vulnerability and mitigation support.
IA32_ARCH_CAPABILITIES[GDS_NO]	RO	Processor is not vulnerable.
IA32_MCU_OPT_CTRL[GDS_MITG_DIS]	RW	Disables the mitigation 0 by default.
IA32_MCU_OPT_CTRL[GDS_MITG_LOCK]	RW	GDS_MITG_DIS=0. Writes to GDS_MITG_DIS are ignored Can't be cleared once set.

GDS can also be mitigated on systems that don't have updated microcode by disabling AVX. This can be done by setting gather_data_sampling="force" or "clearcpuid=avx" on the kernel command-line.

If used, these options will disable AVX use by turning off XSAVE YMM support. However, the processor will still enumerate AVX support. Userspace that does not follow proper AVX enumeration to check both AVX *and* XSAVE YMM support will break.

7.12.4 Mitigation control on the kernel command line

The mitigation can be disabled by setting "gather_data_sampling=off" or "mitigations=off" on the kernel command line. Not specifying either will default to the mitigation being enabled. Specifying "gather_data_sampling=force" will use the microcode mitigation when available or disable AVX on affected systems where the microcode hasn't been updated to include the mitigation.

7.12.5 GDS System Information

The kernel provides vulnerability status information through sysfs. For GDS this can be accessed by the following sysfs file:

/sys/devices/system/cpu/vulnerabilities/gather_data_sampling

The possible values contained in this file are:

Not affected	Processor not vulnerable.
Vulnerable	Processor vulnerable and mitigation disabled.
Vulnerable: No microcode	Processor vulnerable and microcode is missing mitigation.
Mitigation: AVX disabled,	
no microcode	Processor is vulnerable and microcode is missing mitigation. AVX disabled as mitigation.
Mitigation: Microcode	Processor is vulnerable and mitigation is in effect.
Mitigation: Microcode (locked)	Processor is vulnerable and mitigation is in effect and cannot be disabled.
Unknown: Dependent on	
hypervisor status	Running on a virtual guest processor that is affected but with no way to know if host processor is mitigated or vulnerable.

7.12.6 GDS Default mitigation

The updated microcode will enable the mitigation by default. The kernel's default action is to leave the mitigation enabled.

Here is a set of documents aimed at users who are trying to track down problems and bugs in particular.

CHAPTER

EIGHT

REPORTING ISSUES

8.1 The short guide (aka TL;DR)

Are you facing a regression with vanilla kernels from the same stable or longterm series? One still supported? Then search the LKML and the Linux stable mailing list archives for matching reports to join. If you don't find any, install the latest release from that series. If it still shows the issue, report it to the stable mailing list (stable@vger.kernel.org) and CC the regressions list (regressions@lists.linux.dev); ideally also CC the maintainer and the mailing list for the subsystem in question.

In all other cases try your best guess which kernel part might be causing the issue. Check the MAINTAINERS file for how its developers expect to be told about problems, which most of the time will be by email with a mailing list in CC. Check the destination's archives for matching reports; search the LKML and the web, too. If you don't find any to join, install the latest mainline kernel. If the issue is present there, send a report.

The issue was fixed there, but you would like to see it resolved in a still supported stable or longterm series as well? Then install its latest release. If it shows the problem, search for the change that fixed it in mainline and check if backporting is in the works or was discarded; if it's neither, ask those who handled the change for it.

General remarks: When installing and testing a kernel as outlined above, ensure it's vanilla (IOW: not patched and not using add-on modules). Also make sure it's built and running in a healthy environment and not already tainted before the issue occurs.

If you are facing multiple issues with the Linux kernel at once, report each separately. While writing your report, include all information relevant to the issue, like the kernel and the distro used. In case of a regression, CC the regressions mailing list (regressions@lists.linux.dev) to your report. Also try to pin-point the culprit with a bisection; if you succeed, include its commit-id and CC everyone in the sign-off-by chain.

Once the report is out, answer any questions that come up and help where you can. That includes keeping the ball rolling by occasionally retesting with newer releases and sending a status update afterwards.

8.2 Step-by-step guide how to report issues to the kernel maintainers

The above TL;DR outlines roughly how to report issues to the Linux kernel developers. It might be all that's needed for people already familiar with reporting issues to Free/Libre & Open Source Software (FLOSS) projects. For everyone else there is this section. It is more detailed and uses a step-by-step approach. It still tries to be brief for readability and leaves out a lot of details; those are described below the step-by-step guide in a reference section, which explains each of the steps in more detail.

Note: this section covers a few more aspects than the TL;DR and does things in a slightly different order. That's in your interest, to make sure you notice early if an issue that looks like a Linux kernel problem is actually caused by something else. These steps thus help to ensure the time you invest in this process won't feel wasted in the end:

- Are you facing an issue with a Linux kernel a hardware or software vendor provided? Then in almost all cases you are better off to stop reading this document and reporting the issue to your vendor instead, unless you are willing to install the latest Linux version yourself. Be aware the latter will often be needed anyway to hunt down and fix issues.
- Perform a rough search for existing reports with your favorite internet search engine; additionally, check the archives of the Linux Kernel Mailing List (LKML). If you find matching reports, join the discussion instead of sending a new one.
- See if the issue you are dealing with qualifies as regression, security issue, or a really severe problem: those are 'issues of high priority' that need special handling in some steps that are about to follow.
- Make sure it's not the kernel's surroundings that are causing the issue you face.
- Create a fresh backup and put system repair and restore tools at hand.
- Ensure your system does not enhance its kernels by building additional kernel modules on-the-fly, which solutions like DKMS might be doing locally without your knowledge.
- Check if your kernel was 'tainted' when the issue occurred, as the event that made the kernel set this flag might be causing the issue you face.
- Write down coarsely how to reproduce the issue. If you deal with multiple issues at once, create separate notes for each of them and make sure they work independently on a freshly booted system. That's needed, as each issue needs to get reported to the kernel developers separately, unless they are strongly entangled.
- If you are facing a regression within a stable or longterm version line (say something broke when updating from 5.10.4 to 5.10.5), scroll down to 'Dealing with regressions within a stable and longterm kernel line'.
- Locate the driver or kernel subsystem that seems to be causing the issue. Find out how and where its developers expect reports. Note: most of the time this won't be bugzilla.kernel.org, as issues typically need to be sent by mail to a maintainer and a public mailing list.
- Search the archives of the bug tracker or mailing list in question thoroughly for reports that might match your issue. If you find anything, join the discussion instead of sending a new report.

After these preparations you'll now enter the main part:

- Unless you are already running the latest 'mainline' Linux kernel, better go and install it for the reporting process. Testing and reporting with the latest 'stable' Linux can be an acceptable alternative in some situations; during the merge window that actually might be even the best approach, but in that development phase it can be an even better idea to suspend your efforts for a few days anyway. Whatever version you choose, ideally use a 'vanilla' build. Ignoring these advices will dramatically increase the risk your report will be rejected or ignored.
- Ensure the kernel you just installed does not 'taint' itself when running.
- Reproduce the issue with the kernel you just installed. If it doesn't show up there, scroll down to the instructions for issues only happening with stable and longterm kernels.
- Optimize your notes: try to find and write the most straightforward way to reproduce your issue. Make sure the end result has all the important details, and at the same time is easy to read and understand for others that hear about it for the first time. And if you learned something in this process, consider searching again for existing reports about the issue.
- If your failure involves a 'panic', 'Oops', 'warning', or 'BUG', consider decoding the kernel log to find the line of code that triggered the error.
- If your problem is a regression, try to narrow down when the issue was introduced as much as possible.
- Start to compile the report by writing a detailed description about the issue. Always mention a few things: the latest kernel version you installed for reproducing, the Linux Distribution used, and your notes on how to reproduce the issue. Ideally, make the kernel's build configuration (.config) and the output from `dmesg` available somewhere on the net and link to it. Include or upload all other information that might be relevant, like the output/screenshot of an Oops or the output from `lspci`. Once you wrote this main part, insert a normal length paragraph on top of it outlining the issue and the impact quickly. On top of this add one sentence that briefly describes the problem and gets people to read on. Now give the thing a descriptive title or subject that yet again is shorter. Then you're ready to send or file the report like the MAINTAINERS file told you, unless you are dealing with one of those 'issues of high priority': they need special care which is explained in 'Special handling for high priority issues' below.
- Wait for reactions and keep the thing rolling until you can accept the outcome in one way or the other. Thus react publicly and in a timely manner to any inquiries. Test proposed fixes. Do proactive testing: retest with at least every first release candidate (RC) of a new mainline version and report your results. Send friendly reminders if things stall. And try to help yourself, if you don't get any help or if it's unsatisfying.

8.2.1 Reporting regressions within a stable and longterm kernel line

This subsection is for you, if you followed above process and got sent here at the point about regression within a stable or longterm kernel version line. You face one of those if something breaks when updating from 5.10.4 to 5.10.5 (a switch from 5.9.15 to 5.10.5 does not qualify). The developers want to fix such regressions as quickly as possible, hence there is a streamlined process to report them:

- Check if the kernel developers still maintain the Linux kernel version line you care about: go to the front page of kernel.org and make sure it mentions the latest release of the particular version line without an '[EOL]' tag.

- Check the archives of the Linux stable mailing list for existing reports.
- Install the latest release from the particular version line as a vanilla kernel. Ensure this kernel is not tainted and still shows the problem, as the issue might have already been fixed there. If you first noticed the problem with a vendor kernel, check a vanilla build of the last version known to work performs fine as well.
- Send a short problem report to the Linux stable mailing list (stable@vger.kernel.org) and CC the Linux regressions mailing list (regressions@lists.linux.dev); if you suspect the cause in a particular subsystem, CC its maintainer and its mailing list. Roughly describe the issue and ideally explain how to reproduce it. Mention the first version that shows the problem and the last version that's working fine. Then wait for further instructions.

The reference section below explains each of these steps in more detail.

8.2.2 Reporting issues only occurring in older kernel version lines

This subsection is for you, if you tried the latest mainline kernel as outlined above, but failed to reproduce your issue there; at the same time you want to see the issue fixed in a still supported stable or longterm series or vendor kernels regularly rebased on those. If that the case, follow these steps:

- Prepare yourself for the possibility that going through the next few steps might not get the issue solved in older releases: the fix might be too big or risky to get backported there.
- Perform the first three steps in the section ”Dealing with regressions within a stable and longterm kernel line” above.
- Search the Linux kernel version control system for the change that fixed the issue in mainline, as its commit message might tell you if the fix is scheduled for backporting already. If you don't find anything that way, search the appropriate mailing lists for posts that discuss such an issue or peer-review possible fixes; then check the discussions if the fix was deemed unsuitable for backporting. If backporting was not considered at all, join the newest discussion, asking if it's in the cards.
- One of the former steps should lead to a solution. If that doesn't work out, ask the maintainers for the subsystem that seems to be causing the issue for advice; CC the mailing list for the particular subsystem as well as the stable mailing list.

The reference section below explains each of these steps in more detail.

8.3 Reference section: Reporting issues to the kernel maintainers

The detailed guides above outline all the major steps in brief fashion, which should be enough for most people. But sometimes there are situations where even experienced users might wonder how to actually do one of those steps. That's what this section is for, as it will provide a lot more details on each of the above steps. Consider this as reference documentation: it's possible to read it from top to bottom. But it's mainly meant to skim over and a place to look up details how to actually perform those steps.

A few words of general advice before digging into the details:

- The Linux kernel developers are well aware this process is complicated and demands more than other FLOSS projects. We'd love to make it simpler. But that would require work in various places as well as some infrastructure, which would need constant maintenance; nobody has stepped up to do that work, so that's just how things are for now.
- A warranty or support contract with some vendor doesn't entitle you to request fixes from developers in the upstream Linux kernel community: such contracts are completely outside the scope of the Linux kernel, its development community, and this document. That's why you can't demand anything such a contract guarantees in this context, not even if the developer handling the issue works for the vendor in question. If you want to claim your rights, use the vendor's support channel instead. When doing so, you might want to mention you'd like to see the issue fixed in the upstream Linux kernel; motivate them by saying it's the only way to ensure the fix in the end will get incorporated in all Linux distributions.
- If you never reported an issue to a FLOSS project before you should consider reading How to Report Bugs Effectively, How To Ask Questions The Smart Way, and How to ask good questions.

With that off the table, find below the details on how to properly report issues to the Linux kernel developers.

8.3.1 Make sure you're using the upstream Linux kernel

> *Are you facing an issue with a Linux kernel a hardware or software vendor provided? Then in almost all cases you are better off to stop reading this document and reporting the issue to your vendor instead, unless you are willing to install the latest Linux version yourself. Be aware the latter will often be needed anyway to hunt down and fix issues.*

Like most programmers, Linux kernel developers don't like to spend time dealing with reports for issues that don't even happen with their current code. It's just a waste everybody's time, especially yours. Unfortunately such situations easily happen when it comes to the kernel and often leads to frustration on both sides. That's because almost all Linux-based kernels preinstalled on devices (Computers, Laptops, Smartphones, Routers, ...) and most shipped by Linux distributors are quite distant from the official Linux kernel as distributed by kernel.org: these kernels from these vendors are often ancient from the point of Linux development or heavily modified, often both.

Most of these vendor kernels are quite unsuitable for reporting issues to the Linux kernel developers: an issue you face with one of them might have been fixed by the Linux kernel developers months or years ago already; additionally, the modifications and enhancements by the vendor might be causing the issue you face, even if they look small or totally unrelated. That's why you should report issues with these kernels to the vendor. Its developers should look into the report and, in case it turns out to be an upstream issue, fix it directly upstream or forward the report there. In practice that often does not work out or might not what you want. You thus might want to consider circumventing the vendor by installing the very latest Linux kernel core yourself. If that's an option for you move ahead in this process, as a later step in this guide will explain how to do that once it rules out other potential causes for your issue.

Note, the previous paragraph is starting with the word 'most', as sometimes developers in fact are willing to handle reports about issues occurring with vendor kernels. If they do in the end highly depends on the developers and the issue in question. Your chances are quite good if the distributor applied only small modifications to a kernel based on a recent Linux version; that for example often holds true for the mainline kernels shipped by Debian GNU/Linux Sid or Fedora

Rawhide. Some developers will also accept reports about issues with kernels from distributions shipping the latest stable kernel, as long as its only slightly modified; that for example is often the case for Arch Linux, regular Fedora releases, and openSUSE Tumbleweed. But keep in mind, you better want to use a mainline Linux and avoid using a stable kernel for this process, as outlined in the section 'Install a fresh kernel for testing' in more detail.

Obviously you are free to ignore all this advice and report problems with an old or heavily modified vendor kernel to the upstream Linux developers. But note, those often get rejected or ignored, so consider yourself warned. But it's still better than not reporting the issue at all: sometimes such reports directly or indirectly will help to get the issue fixed over time.

8.3.2 Search for existing reports, first run

> *Perform a rough search for existing reports with your favorite internet search engine; additionally, check the archives of the Linux Kernel Mailing List (LKML). If you find matching reports, join the discussion instead of sending a new one.*

Reporting an issue that someone else already brought forward is often a waste of time for everyone involved, especially you as the reporter. So it's in your own interest to thoroughly check if somebody reported the issue already. At this step of the process it's okay to just perform a rough search: a later step will tell you to perform a more detailed search once you know where your issue needs to be reported to. Nevertheless, do not hurry with this step of the reporting process, it can save you time and trouble.

Simply search the internet with your favorite search engine first. Afterwards, search the Linux Kernel Mailing List (LKML) archives.

If you get flooded with results consider telling your search engine to limit search timeframe to the past month or year. And wherever you search, make sure to use good search terms; vary them a few times, too. While doing so try to look at the issue from the perspective of someone else: that will help you to come up with other words to use as search terms. Also make sure not to use too many search terms at once. Remember to search with and without information like the name of the kernel driver or the name of the affected hardware component. But its exact brand name (say 'ASUS Red Devil Radeon RX 5700 XT Gaming OC') often is not much helpful, as it is too specific. Instead try search terms like the model line (Radeon 5700 or Radeon 5000) and the code name of the main chip ('Navi' or 'Navi10') with and without its manufacturer ('AMD').

In case you find an existing report about your issue, join the discussion, as you might be able to provide valuable additional information. That can be important even when a fix is prepared or in its final stages already, as developers might look for people that can provide additional information or test a proposed fix. Jump to the section 'Duties after the report went out' for details on how to get properly involved.

Note, searching bugzilla.kernel.org might also be a good idea, as that might provide valuable insights or turn up matching reports. If you find the latter, just keep in mind: most subsystems expect reports in different places, as described below in the section ”Check where you need to report your issue”. The developers that should take care of the issue thus might not even be aware of the bugzilla ticket. Hence, check the ticket if the issue already got reported as outlined in this document and if not consider doing so.

8.3.3 Issue of high priority?

See if the issue you are dealing with qualifies as regression, security issue, or a really severe problem: those are 'issues of high priority' that need special handling in some steps that are about to follow.

Linus Torvalds and the leading Linux kernel developers want to see some issues fixed as soon as possible, hence there are 'issues of high priority' that get handled slightly differently in the reporting process. Three type of cases qualify: regressions, security issues, and really severe problems.

You deal with a regression if some application or practical use case running fine with one Linux kernel works worse or not at all with a newer version compiled using a similar configuration. The document *Reporting regressions* explains this in more detail. It also provides a good deal of other information about regressions you might want to be aware of; it for example explains how to add your issue to the list of tracked regressions, to ensure it won't fall through the cracks.

What qualifies as security issue is left to your judgment. Consider reading Documentation/process/security-bugs.rst before proceeding, as it provides additional details how to best handle security issues.

An issue is a 'really severe problem' when something totally unacceptably bad happens. That's for example the case when a Linux kernel corrupts the data it's handling or damages hardware it's running on. You're also dealing with a severe issue when the kernel suddenly stops working with an error message ('kernel panic') or without any farewell note at all. Note: do not confuse a 'panic' (a fatal error where the kernel stop itself) with a 'Oops' (a recoverable error), as the kernel remains running after the latter.

8.3.4 Ensure a healthy environment

Make sure it's not the kernel's surroundings that are causing the issue you face.

Problems that look a lot like a kernel issue are sometimes caused by build or runtime environment. It's hard to rule out that problem completely, but you should minimize it:

- Use proven tools when building your kernel, as bugs in the compiler or the binutils can cause the resulting kernel to misbehave.
- Ensure your computer components run within their design specifications; that's especially important for the main processor, the main memory, and the motherboard. Therefore, stop undervolting or overclocking when facing a potential kernel issue.
- Try to make sure it's not faulty hardware that is causing your issue. Bad main memory for example can result in a multitude of issues that will manifest itself in problems looking like kernel issues.
- If you're dealing with a filesystem issue, you might want to check the file system in question with `fsck`, as it might be damaged in a way that leads to unexpected kernel behavior.
- When dealing with a regression, make sure it's not something else that changed in parallel to updating the kernel. The problem for example might be caused by other software that was updated at the same time. It can also happen that a hardware component coincidentally just broke when you rebooted into a new kernel for the first time. Updating the systems BIOS or changing something in the BIOS Setup can also lead to problems that on look a lot like a kernel regression.

8.3.5 Prepare for emergencies

Create a fresh backup and put system repair and restore tools at hand.

Reminder, you are dealing with computers, which sometimes do unexpected things, especially if you fiddle with crucial parts like the kernel of its operating system. That's what you are about to do in this process. Thus, make sure to create a fresh backup; also ensure you have all tools at hand to repair or reinstall the operating system as well as everything you need to restore the backup.

8.3.6 Make sure your kernel doesn't get enhanced

Ensure your system does not enhance its kernels by building additional kernel modules on-the-fly, which solutions like DKMS might be doing locally without your knowledge.

The risk your issue report gets ignored or rejected dramatically increases if your kernel gets enhanced in any way. That's why you should remove or disable mechanisms like akmods and DKMS: those build add-on kernel modules automatically, for example when you install a new Linux kernel or boot it for the first time. Also remove any modules they might have installed. Then reboot before proceeding.

Note, you might not be aware that your system is using one of these solutions: they often get set up silently when you install Nvidia's proprietary graphics driver, VirtualBox, or other software that requires a some support from a module not part of the Linux kernel. That why your might need to uninstall the packages with such software to get rid of any 3rd party kernel module.

8.3.7 Check 'taint' flag

Check if your kernel was 'tainted' when the issue occurred, as the event that made the kernel set this flag might be causing the issue you face.

The kernel marks itself with a 'taint' flag when something happens that might lead to follow-up errors that look totally unrelated. The issue you face might be such an error if your kernel is tainted. That's why it's in your interest to rule this out early before investing more time into this process. This is the only reason why this step is here, as this process later will tell you to install the latest mainline kernel; you will need to check the taint flag again then, as that's when it matters because it's the kernel the report will focus on.

On a running system is easy to check if the kernel tainted itself: if `cat /proc/sys/kernel/tainted` returns '0' then the kernel is not tainted and everything is fine. Checking that file is impossible in some situations; that's why the kernel also mentions the taint status when it reports an internal problem (a 'kernel bug'), a recoverable error (a 'kernel Oops') or a non-recoverable error before halting operation (a 'kernel panic'). Look near the top of the error messages printed when one of these occurs and search for a line starting with 'CPU:'. It should end with 'Not tainted' if the kernel was not tainted when it noticed the problem; it was tainted if you see 'Tainted:' followed by a few spaces and some letters.

If your kernel is tainted, study *Tainted kernels* to find out why. Try to eliminate the reason. Often it's caused by one these three things:

1. A recoverable error (a 'kernel Oops') occurred and the kernel tainted itself, as the kernel knows it might misbehave in strange ways after that point. In that case check your kernel

or system log and look for a section that starts with this:

```
Oops: 0000 [#1] SMP
```

That's the first Oops since boot-up, as the '#1' between the brackets shows. Every Oops and any other problem that happens after that point might be a follow-up problem to that first Oops, even if both look totally unrelated. Rule this out by getting rid of the cause for the first Oops and reproducing the issue afterwards. Sometimes simply restarting will be enough, sometimes a change to the configuration followed by a reboot can eliminate the Oops. But don't invest too much time into this at this point of the process, as the cause for the Oops might already be fixed in the newer Linux kernel version you are going to install later in this process.

2. Your system uses a software that installs its own kernel modules, for example Nvidia's proprietary graphics driver or VirtualBox. The kernel taints itself when it loads such module from external sources (even if they are Open Source): they sometimes cause errors in unrelated kernel areas and thus might be causing the issue you face. You therefore have to prevent those modules from loading when you want to report an issue to the Linux kernel developers. Most of the time the easiest way to do that is: temporarily uninstall such software including any modules they might have installed. Afterwards reboot.

3. The kernel also taints itself when it's loading a module that resides in the staging tree of the Linux kernel source. That's a special area for code (mostly drivers) that does not yet fulfill the normal Linux kernel quality standards. When you report an issue with such a module it's obviously okay if the kernel is tainted; just make sure the module in question is the only reason for the taint. If the issue happens in an unrelated area reboot and temporarily block the module from being loaded by specifying `foo.blacklist=1` as kernel parameter (replace 'foo' with the name of the module in question).

8.3.8 Document how to reproduce issue

Write down coarsely how to reproduce the issue. If you deal with multiple issues at once, create separate notes for each of them and make sure they work independently on a freshly booted system. That's needed, as each issue needs to get reported to the kernel developers separately, unless they are strongly entangled.

If you deal with multiple issues at once, you'll have to report each of them separately, as they might be handled by different developers. Describing various issues in one report also makes it quite difficult for others to tear it apart. Hence, only combine issues in one report if they are very strongly entangled.

Additionally, during the reporting process you will have to test if the issue happens with other kernel versions. Therefore, it will make your work easier if you know exactly how to reproduce an issue quickly on a freshly booted system.

Note: it's often fruitless to report issues that only happened once, as they might be caused by a bit flip due to cosmic radiation. That's why you should try to rule that out by reproducing the issue before going further. Feel free to ignore this advice if you are experienced enough to tell a one-time error due to faulty hardware apart from a kernel issue that rarely happens and thus is hard to reproduce.

8.3.9 Regression in stable or longterm kernel?

> *If you are facing a regression within a stable or longterm version line (say something broke when updating from 5.10.4 to 5.10.5), scroll down to 'Dealing with regressions within a stable and longterm kernel line'.*

Regression within a stable and longterm kernel version line are something the Linux developers want to fix badly, as such issues are even more unwanted than regression in the main development branch, as they can quickly affect a lot of people. The developers thus want to learn about such issues as quickly as possible, hence there is a streamlined process to report them. Note, regressions with newer kernel version line (say something broke when switching from 5.9.15 to 5.10.5) do not qualify.

8.3.10 Check where you need to report your issue

> *Locate the driver or kernel subsystem that seems to be causing the issue. Find out how and where its developers expect reports. Note: most of the time this won't be bugzilla.kernel.org, as issues typically need to be sent by mail to a maintainer and a public mailing list.*

It's crucial to send your report to the right people, as the Linux kernel is a big project and most of its developers are only familiar with a small subset of it. Quite a few programmers for example only care for just one driver, for example one for a WiFi chip; its developer likely will only have small or no knowledge about the internals of remote or unrelated ”subsystems”, like the TCP stack, the PCIe/PCI subsystem, memory management or file systems.

Problem is: the Linux kernel lacks a central bug tracker where you can simply file your issue and make it reach the developers that need to know about it. That's why you have to find the right place and way to report issues yourself. You can do that with the help of a script (see below), but it mainly targets kernel developers and experts. For everybody else the MAINTAINERS file is the better place.

How to read the MAINTAINERS file

To illustrate how to use the MAINTAINERS file, lets assume the WiFi in your Laptop suddenly misbehaves after updating the kernel. In that case it's likely an issue in the WiFi driver. Obviously it could also be some code it builds upon, but unless you suspect something like that stick to the driver. If it's really something else, the driver's developers will get the right people involved.

Sadly, there is no way to check which code is driving a particular hardware component that is both universal and easy.

In case of a problem with the WiFi driver you for example might want to look at the output of `lspci -k`, as it lists devices on the PCI/PCIe bus and the kernel module driving it:

```
[user@something ~]$ lspci -k
[...]
3a:00.0 Network controller: Qualcomm Atheros QCA6174 802.11ac Wireless Network␣
↪Adapter (rev 32)
  Subsystem: Bigfoot Networks, Inc. Device 1535
  Kernel driver in use: ath10k_pci
```

```
  Kernel modules: ath10k_pci
[...]
```

But this approach won't work if your WiFi chip is connected over USB or some other internal bus. In those cases you might want to check your WiFi manager or the output of `ip link`. Look for the name of the problematic network interface, which might be something like 'wlp58s0'. This name can be used like this to find the module driving it:

```
[user@something ~]$ realpath --relative-to=/sys/module/ /sys/class/net/wlp58s0/
↪device/driver/module
ath10k_pci
```

In case tricks like these don't bring you any further, try to search the internet on how to narrow down the driver or subsystem in question. And if you are unsure which it is: just try your best guess, somebody will help you if you guessed poorly.

Once you know the driver or subsystem, you want to search for it in the MAINTAINERS file. In the case of 'ath10k_pci' you won't find anything, as the name is too specific. Sometimes you will need to search on the net for help; but before doing so, try a somewhat shorted or modified name when searching the MAINTAINERS file, as then you might find something like this:

```
QUALCOMM ATHEROS ATH10K WIRELESS DRIVER
Mail:           A. Some Human <shuman@example.com>
Mailing list:   ath10k@lists.infradead.org
Status:         Supported
Web-page:       https://wireless.wiki.kernel.org/en/users/Drivers/ath10k
SCM:            git git://git.kernel.org/pub/scm/linux/kernel/git/kvalo/ath.git
Files:          drivers/net/wireless/ath/ath10k/
```

Note: the line description will be abbreviations, if you read the plain MAINTAINERS file found in the root of the Linux source tree. 'Mail:' for example will be 'M:', 'Mailing list:' will be 'L', and 'Status:' will be 'S:'. A section near the top of the file explains these and other abbreviations.

First look at the line 'Status'. Ideally it should be 'Supported' or 'Maintained'. If it states 'Obsolete' then you are using some outdated approach that was replaced by a newer solution you need to switch to. Sometimes the code only has someone who provides 'Odd Fixes' when feeling motivated. And with 'Orphan' you are totally out of luck, as nobody takes care of the code anymore. That only leaves these options: arrange yourself to live with the issue, fix it yourself, or find a programmer somewhere willing to fix it.

After checking the status, look for a line starting with 'bugs:': it will tell you where to find a subsystem specific bug tracker to file your issue. The example above does not have such a line. That is the case for most sections, as Linux kernel development is completely driven by mail. Very few subsystems use a bug tracker, and only some of those rely on bugzilla.kernel.org.

In this and many other cases you thus have to look for lines starting with 'Mail:' instead. Those mention the name and the email addresses for the maintainers of the particular code. Also look for a line starting with 'Mailing list:', which tells you the public mailing list where the code is developed. Your report later needs to go by mail to those addresses. Additionally, for all issue reports sent by email, make sure to add the Linux Kernel Mailing List (LKML) <linux-kernel@vger.kernel.org> to CC. Don't omit either of the mailing lists when sending your issue report by mail later! Maintainers are busy people and might leave some work for other developers on the subsystem specific list; and LKML is important to have one place where all

issue reports can be found.

Finding the maintainers with the help of a script

For people that have the Linux sources at hand there is a second option to find the proper place to report: the script 'scripts/get_maintainer.pl' which tries to find all people to contact. It queries the MAINTAINERS file and needs to be called with a path to the source code in question. For drivers compiled as module if often can be found with a command like this:

```
$ modinfo ath10k_pci | grep filename | sed 's!/lib/modules/.*/kernel/!!; s!
↪filename:!!; s!\.ko\(\|\.xz\)!!'
drivers/net/wireless/ath/ath10k/ath10k_pci.ko
```

Pass parts of this to the script:

```
$ ./scripts/get_maintainer.pl -f drivers/net/wireless/ath/ath10k*
Some Human <shuman@example.com> (supporter:QUALCOMM ATHEROS ATH10K WIRELESS␣
↪DRIVER)
Another S. Human <asomehuman@example.com> (maintainer:NETWORKING DRIVERS)
ath10k@lists.infradead.org (open list:QUALCOMM ATHEROS ATH10K WIRELESS DRIVER)
linux-wireless@vger.kernel.org (open list:NETWORKING DRIVERS (WIRELESS))
netdev@vger.kernel.org (open list:NETWORKING DRIVERS)
linux-kernel@vger.kernel.org (open list)
```

Don't sent your report to all of them. Send it to the maintainers, which the script calls ”supporter:”; additionally CC the most specific mailing list for the code as well as the Linux Kernel Mailing List (LKML). In this case you thus would need to send the report to 'Some Human <shuman@example.com>' with 'ath10k@lists.infradead.org' and 'linux-kernel@vger.kernel.org' in CC.

Note: in case you cloned the Linux sources with git you might want to call `get_maintainer.pl` a second time with `--git`. The script then will look at the commit history to find which people recently worked on the code in question, as they might be able to help. But use these results with care, as it can easily send you in a wrong direction. That for example happens quickly in areas rarely changed (like old or unmaintained drivers): sometimes such code is modified during tree-wide cleanups by developers that do not care about the particular driver at all.

8.3.11 Search for existing reports, second run

> *Search the archives of the bug tracker or mailing list in question thoroughly for reports that might match your issue. If you find anything, join the discussion instead of sending a new report.*

As mentioned earlier already: reporting an issue that someone else already brought forward is often a waste of time for everyone involved, especially you as the reporter. That's why you should search for existing report again, now that you know where they need to be reported to. If it's mailing list, you will often find its archives on lore.kernel.org.

But some list are hosted in different places. That for example is the case for the ath10k WiFi driver used as example in the previous step. But you'll often find the archives for these lists easily on the net. Searching for 'archive ath10k@lists.infradead.org' for example will lead you to the Info page for the ath10k mailing list, which at the top links to its list archives. Sadly

this and quite a few other lists miss a way to search the archives. In those cases use a regular internet search engine and add something like 'site:lists.infradead.org/pipermail/ath10k/' to your search terms, which limits the results to the archives at that URL.

It's also wise to check the internet, LKML and maybe bugzilla.kernel.org again at this point. If your report needs to be filed in a bug tracker, you may want to check the mailing list archives for the subsystem as well, as someone might have reported it only there.

For details how to search and what to do if you find matching reports see ”Search for existing reports, first run” above.

Do not hurry with this step of the reporting process: spending 30 to 60 minutes or even more time can save you and others quite a lot of time and trouble.

8.3.12 Install a fresh kernel for testing

> *Unless you are already running the latest 'mainline' Linux kernel, better go and install it for the reporting process. Testing and reporting with the latest 'stable' Linux can be an acceptable alternative in some situations; during the merge window that actually might be even the best approach, but in that development phase it can be an even better idea to suspend your efforts for a few days anyway. Whatever version you choose, ideally use a 'vanilla' built. Ignoring these advices will dramatically increase the risk your report will be rejected or ignored.*

As mentioned in the detailed explanation for the first step already: Like most programmers, Linux kernel developers don't like to spend time dealing with reports for issues that don't even happen with the current code. It's just a waste everybody's time, especially yours. That's why it's in everybody's interest that you confirm the issue still exists with the latest upstream code before reporting it. You are free to ignore this advice, but as outlined earlier: doing so dramatically increases the risk that your issue report might get rejected or simply ignored.

In the scope of the kernel ”latest upstream” normally means:

- Install a mainline kernel; the latest stable kernel can be an option, but most of the time is better avoided. Longterm kernels (sometimes called 'LTS kernels') are unsuitable at this point of the process. The next subsection explains all of this in more detail.
- The over next subsection describes way to obtain and install such a kernel. It also outlines that using a pre-compiled kernel are fine, but better are vanilla, which means: it was built using Linux sources taken straight from kernel.org and not modified or enhanced in any way.

Choosing the right version for testing

Head over to kernel.org to find out which version you want to use for testing. Ignore the big yellow button that says 'Latest release' and look a little lower at the table. At its top you'll see a line starting with mainline, which most of the time will point to a pre-release with a version number like '5.8-rc2'. If that's the case, you'll want to use this mainline kernel for testing, as that where all fixes have to be applied first. Do not let that 'rc' scare you, these 'development kernels' are pretty reliable — and you made a backup, as you were instructed above, didn't you?

In about two out of every nine to ten weeks, mainline might point you to a proper release with a version number like '5.7'. If that happens, consider suspending the reporting process until the first pre-release of the next version (5.8-rc1) shows up on kernel.org. That's because the Linux

development cycle then is in its two-week long 'merge window'. The bulk of the changes and all intrusive ones get merged for the next release during this time. It's a bit more risky to use mainline during this period. Kernel developers are also often quite busy then and might have no spare time to deal with issue reports. It's also quite possible that one of the many changes applied during the merge window fixes the issue you face; that's why you soon would have to retest with a newer kernel version anyway, as outlined below in the section 'Duties after the report went out'.

That's why it might make sense to wait till the merge window is over. But don't to that if you're dealing with something that shouldn't wait. In that case consider obtaining the latest mainline kernel via git (see below) or use the latest stable version offered on kernel.org. Using that is also acceptable in case mainline for some reason does currently not work for you. An in general: using it for reproducing the issue is also better than not reporting it issue at all.

Better avoid using the latest stable kernel outside merge windows, as all fixes must be applied to mainline first. That's why checking the latest mainline kernel is so important: any issue you want to see fixed in older version lines needs to be fixed in mainline first before it can get backported, which can take a few days or weeks. Another reason: the fix you hope for might be too hard or risky for backporting; reporting the issue again hence is unlikely to change anything.

These aspects are also why longterm kernels (sometimes called ”LTS kernels”) are unsuitable for this part of the reporting process: they are to distant from the current code. Hence go and test mainline first and follow the process further: if the issue doesn't occur with mainline it will guide you how to get it fixed in older version lines, if that's in the cards for the fix in question.

How to obtain a fresh Linux kernel

Using a pre-compiled kernel: This is often the quickest, easiest, and safest way for testing — especially is you are unfamiliar with the Linux kernel. The problem: most of those shipped by distributors or add-on repositories are build from modified Linux sources. They are thus not vanilla and therefore often unsuitable for testing and issue reporting: the changes might cause the issue you face or influence it somehow.

But you are in luck if you are using a popular Linux distribution: for quite a few of them you'll find repositories on the net that contain packages with the latest mainline or stable Linux built as vanilla kernel. It's totally okay to use these, just make sure from the repository's description they are vanilla or at least close to it. Additionally ensure the packages contain the latest versions as offered on kernel.org. The packages are likely unsuitable if they are older than a week, as new mainline and stable kernels typically get released at least once a week.

Please note that you might need to build your own kernel manually later: that's sometimes needed for debugging or testing fixes, as described later in this document. Also be aware that pre-compiled kernels might lack debug symbols that are needed to decode messages the kernel prints when a panic, Oops, warning, or BUG occurs; if you plan to decode those, you might be better off compiling a kernel yourself (see the end of this subsection and the section titled 'Decode failure messages' for details).

Using git: Developers and experienced Linux users familiar with git are often best served by obtaining the latest Linux kernel sources straight from the official development repository on kernel.org. Those are likely a bit ahead of the latest mainline pre-release. Don't worry about it: they are as reliable as a proper pre-release, unless the kernel's development cycle is currently in the middle of a merge window. But even then they are quite reliable.

Conventional: People unfamiliar with git are often best served by downloading the sources as tarball from kernel.org.

How to actually build a kernel is not described here, as many websites explain the necessary steps already. If you are new to it, consider following one of those how-to's that suggest to use `make localmodconfig`, as that tries to pick up the configuration of your current kernel and then tries to adjust it somewhat for your system. That does not make the resulting kernel any better, but quicker to compile.

Note: If you are dealing with a panic, Oops, warning, or BUG from the kernel, please try to enable CONFIG_KALLSYMS when configuring your kernel. Additionally, enable CONFIG_DEBUG_KERNEL and CONFIG_DEBUG_INFO, too; the latter is the relevant one of those two, but can only be reached if you enable the former. Be aware CONFIG_DEBUG_INFO increases the storage space required to build a kernel by quite a bit. But that's worth it, as these options will allow you later to pinpoint the exact line of code that triggers your issue. The section 'Decode failure messages' below explains this in more detail.

But keep in mind: Always keep a record of the issue encountered in case it is hard to reproduce. Sending an undecoded report is better than not reporting the issue at all.

8.3.13 Check 'taint' flag

> *Ensure the kernel you just installed does not 'taint' itself when running.*

As outlined above in more detail already: the kernel sets a 'taint' flag when something happens that can lead to follow-up errors that look totally unrelated. That's why you need to check if the kernel you just installed does not set this flag. And if it does, you in almost all the cases needs to eliminate the reason for it before you reporting issues that occur with it. See the section above for details how to do that.

8.3.14 Reproduce issue with the fresh kernel

> *Reproduce the issue with the kernel you just installed. If it doesn't show up there, scroll down to the instructions for issues only happening with stable and longterm kernels.*

Check if the issue occurs with the fresh Linux kernel version you just installed. If it was fixed there already, consider sticking with this version line and abandoning your plan to report the issue. But keep in mind that other users might still be plagued by it, as long as it's not fixed in either stable and longterm version from kernel.org (and thus vendor kernels derived from those). If you prefer to use one of those or just want to help their users, head over to the section ”Details about reporting issues only occurring in older kernel version lines” below.

8.3.15 Optimize description to reproduce issue

> *Optimize your notes: try to find and write the most straightforward way to reproduce your issue. Make sure the end result has all the important details, and at the same time is easy to read and understand for others that hear about it for the first time. And if you learned something in this process, consider searching again for existing reports about the issue.*

An unnecessarily complex report will make it hard for others to understand your report. Thus try to find a reproducer that's straight forward to describe and thus easy to understand in written form. Include all important details, but at the same time try to keep it as short as possible.

In this in the previous steps you likely have learned a thing or two about the issue you face. Use this knowledge and search again for existing reports instead you can join.

8.3.16 Decode failure messages

> *If your failure involves a 'panic', 'Oops', 'warning', or 'BUG', consider decoding the kernel log to find the line of code that triggered the error.*

When the kernel detects an internal problem, it will log some information about the executed code. This makes it possible to pinpoint the exact line in the source code that triggered the issue and shows how it was called. But that only works if you enabled CONFIG_DEBUG_INFO and CONFIG_KALLSYMS when configuring your kernel. If you did so, consider to decode the information from the kernel's log. That will make it a lot easier to understand what lead to the 'panic', 'Oops', 'warning', or 'BUG', which increases the chances that someone can provide a fix.

Decoding can be done with a script you find in the Linux source tree. If you are running a kernel you compiled yourself earlier, call it like this:

```
[user@something ~]$ sudo dmesg | ./linux-5.10.5/scripts/decode_stacktrace.sh ./
↪linux-5.10.5/vmlinux
```

If you are running a packaged vanilla kernel, you will likely have to install the corresponding packages with debug symbols. Then call the script (which you might need to get from the Linux sources if your distro does not package it) like this:

```
[user@something ~]$ sudo dmesg | ./linux-5.10.5/scripts/decode_stacktrace.sh \
 /usr/lib/debug/lib/modules/5.10.10-4.1.x86_64/vmlinux /usr/src/kernels/5.10.
↪10-4.1.x86_64/
```

The script will work on log lines like the following, which show the address of the code the kernel was executing when the error occurred:

```
[   68.387301] RIP: 0010:test_module_init+0x5/0xffa [test_module]
```

Once decoded, these lines will look like this:

```
[   68.387301] RIP: 0010:test_module_init (/home/username/linux-5.10.5/test-
↪module/test-module.c:16) test_module
```

In this case the executed code was built from the file '~/linux-5.10.5/test-module/test-module.c' and the error occurred by the instructions found in line '16'.

The script will similarly decode the addresses mentioned in the section starting with 'Call trace', which show the path to the function where the problem occurred. Additionally, the script will show the assembler output for the code section the kernel was executing.

Note, if you can't get this to work, simply skip this step and mention the reason for it in the report. If you're lucky, it might not be needed. And if it is, someone might help you to get things going. Also be aware this is just one of several ways to decode kernel stack traces. Sometimes different steps will be required to retrieve the relevant details. Don't worry about that, if that's needed in your case, developers will tell you what to do.

8.3.17 Special care for regressions

> *If your problem is a regression, try to narrow down when the issue was introduced as much as possible.*

Linux lead developer Linus Torvalds insists that the Linux kernel never worsens, that's why he deems regressions as unacceptable and wants to see them fixed quickly. That's why changes that introduced a regression are often promptly reverted if the issue they cause can't get solved quickly any other way. Reporting a regression is thus a bit like playing a kind of trump card to get something quickly fixed. But for that to happen the change that's causing the regression needs to be known. Normally it's up to the reporter to track down the culprit, as maintainers often won't have the time or setup at hand to reproduce it themselves.

To find the change there is a process called 'bisection' which the document *Bisecting a bug* describes in detail. That process will often require you to build about ten to twenty kernel images, trying to reproduce the issue with each of them before building the next. Yes, that takes some time, but don't worry, it works a lot quicker than most people assume. Thanks to a 'binary search' this will lead you to the one commit in the source code management system that's causing the regression. Once you find it, search the net for the subject of the change, its commit id and the shortened commit id (the first 12 characters of the commit id). This will lead you to existing reports about it, if there are any.

Note, a bisection needs a bit of know-how, which not everyone has, and quite a bit of effort, which not everyone is willing to invest. Nevertheless, it's highly recommended performing a bisection yourself. If you really can't or don't want to go down that route at least find out which mainline kernel introduced the regression. If something for example breaks when switching from 5.5.15 to 5.8.4, then try at least all the mainline releases in that area (5.6, 5.7 and 5.8) to check when it first showed up. Unless you're trying to find a regression in a stable or longterm kernel, avoid testing versions which number has three sections (5.6.12, 5.7.8), as that makes the outcome hard to interpret, which might render your testing useless. Once you found the major version which introduced the regression, feel free to move on in the reporting process. But keep in mind: it depends on the issue at hand if the developers will be able to help without knowing the culprit. Sometimes they might recognize from the report want went wrong and can fix it; other times they will be unable to help unless you perform a bisection.

When dealing with regressions make sure the issue you face is really caused by the kernel and not by something else, as outlined above already.

In the whole process keep in mind: an issue only qualifies as regression if the older and the newer kernel got built with a similar configuration. This can be achieved by using `make olddefconfig`, as explained in more detail by *Reporting regressions*; that document also provides a good deal of other information about regressions you might want to be aware of.

8.3.18 Write and send the report

> *Start to compile the report by writing a detailed description about the issue. Always mention a few things: the latest kernel version you installed for reproducing, the Linux Distribution used, and your notes on how to reproduce the issue. Ideally, make the kernel's build configuration (.config) and the output from ``dmesg`` available somewhere on the net and link to it. Include or upload all other information that might be relevant, like the output/screenshot of an Oops or the output from ``lspci``. Once you wrote this main part, insert a normal length paragraph on top of it outlining the issue and the impact quickly. On top of this add one sentence that briefly describes the problem and gets people to read on. Now give the thing a descriptive title or subject that yet again is shorter. Then you're ready to send or file the report like the MAINTAINERS file told you, unless you are dealing with one of those 'issues of high priority': they need special care which is explained in 'Special handling for high priority issues' below.*

Now that you have prepared everything it's time to write your report. How to do that is partly explained by the three documents linked to in the preface above. That's why this text will only mention a few of the essentials as well as things specific to the Linux kernel.

There is one thing that fits both categories: the most crucial parts of your report are the title/subject, the first sentence, and the first paragraph. Developers often get quite a lot of mail. They thus often just take a few seconds to skim a mail before deciding to move on or look closer. Thus: the better the top section of your report, the higher are the chances that someone will look into it and help you. And that is why you should ignore them for now and write the detailed report first. ;-)

Things each report should mention

Describe in detail how your issue happens with the fresh vanilla kernel you installed. Try to include the step-by-step instructions you wrote and optimized earlier that outline how you and ideally others can reproduce the issue; in those rare cases where that's impossible try to describe what you did to trigger it.

Also include all the relevant information others might need to understand the issue and its environment. What's actually needed depends a lot on the issue, but there are some things you should include always:

- the output from `cat /proc/version`, which contains the Linux kernel version number and the compiler it was built with.
- the Linux distribution the machine is running (`hostnamectl | grep "Operating System"`)
- the architecture of the CPU and the operating system (`uname -mi`)
- if you are dealing with a regression and performed a bisection, mention the subject and the commit-id of the change that is causing it.

In a lot of cases it's also wise to make two more things available to those that read your report:

- the configuration used for building your Linux kernel (the '.config' file)
- the kernel's messages that you get from `dmesg` written to a file. Make sure that it starts with a line like 'Linux version 5.8-1 (foobar@example.com) (gcc (GCC) 10.2.1, GNU ld

version 2.34) #1 SMP Mon Aug 3 14:54:37 UTC 2020' If it's missing, then important messages from the first boot phase already got discarded. In this case instead consider using `journalctl -b 0 -k`; alternatively you can also reboot, reproduce the issue and call `dmesg` right afterwards.

These two files are big, that's why it's a bad idea to put them directly into your report. If you are filing the issue in a bug tracker then attach them to the ticket. If you report the issue by mail do not attach them, as that makes the mail too large; instead do one of these things:

- Upload the files somewhere public (your website, a public file paste service, a ticket created just for this purpose on bugzilla.kernel.org, ...) and include a link to them in your report. Ideally use something where the files stay available for years, as they could be useful to someone many years from now; this for example can happen if five or ten years from now a developer works on some code that was changed just to fix your issue.
- Put the files aside and mention you will send them later in individual replies to your own mail. Just remember to actually do that once the report went out. ;-)

Things that might be wise to provide

Depending on the issue you might need to add more background data. Here are a few suggestions what often is good to provide:

- If you are dealing with a 'warning', an 'OOPS' or a 'panic' from the kernel, include it. If you can't copy'n'paste it, try to capture a netconsole trace or at least take a picture of the screen.
- If the issue might be related to your computer hardware, mention what kind of system you use. If you for example have problems with your graphics card, mention its manufacturer, the card's model, and what chip is uses. If it's a laptop mention its name, but try to make sure it's meaningful. 'Dell XPS 13' for example is not, because it might be the one from 2012; that one looks not that different from the one sold today, but apart from that the two have nothing in common. Hence, in such cases add the exact model number, which for example are '9380' or '7390' for XPS 13 models introduced during 2019. Names like 'Lenovo Thinkpad T590' are also somewhat ambiguous: there are variants of this laptop with and without a dedicated graphics chip, so try to find the exact model name or specify the main components.
- Mention the relevant software in use. If you have problems with loading modules, you want to mention the versions of kmod, systemd, and udev in use. If one of the DRM drivers misbehaves, you want to state the versions of libdrm and Mesa; also specify your Wayland compositor or the X-Server and its driver. If you have a filesystem issue, mention the version of corresponding filesystem utilities (e2fsprogs, btrfs-progs, xfsprogs, ...).
- Gather additional information from the kernel that might be of interest. The output from `lspci -nn` will for example help others to identify what hardware you use. If you have a problem with hardware you even might want to make the output from `sudo lspci -vvv` available, as that provides insights how the components were configured. For some issues it might be good to include the contents of files like `/proc/cpuinfo`, `/proc/ioports`, `/proc/iomem`, `/proc/modules`, or `/proc/scsi/scsi`. Some subsystem also offer tools to collect relevant information. One such tool is `alsa-info.sh` which the audio/sound subsystem developers provide.

Those examples should give your some ideas of what data might be wise to attach, but you have to think yourself what will be helpful for others to know. Don't worry too much about forget-

ting something, as developers will ask for additional details they need. But making everything important available from the start increases the chance someone will take a closer look.

The important part: the head of your report

Now that you have the detailed part of the report prepared let's get to the most important section: the first few sentences. Thus go to the top, add something like 'The detailed description:' before the part you just wrote and insert two newlines at the top. Now write one normal length paragraph that describes the issue roughly. Leave out all boring details and focus on the crucial parts readers need to know to understand what this is all about; if you think this bug affects a lot of users, mention this to get people interested.

Once you did that insert two more lines at the top and write a one sentence summary that explains quickly what the report is about. After that you have to get even more abstract and write an even shorter subject/title for the report.

Now that you have written this part take some time to optimize it, as it is the most important parts of your report: a lot of people will only read this before they decide if reading the rest is time well spent.

Now send or file the report like the MAINTAINERS file told you, unless it's one of those 'issues of high priority' outlined earlier: in that case please read the next subsection first before sending the report on its way.

Special handling for high priority issues

Reports for high priority issues need special handling.

Severe issues: make sure the subject or ticket title as well as the first paragraph makes the severeness obvious.

Regressions: make the report's subject start with '[REGRESSION]'.

In case you performed a successful bisection, use the title of the change that introduced the regression as the second part of your subject. Make the report also mention the commit id of the culprit. In case of an unsuccessful bisection, make your report mention the latest tested version that's working fine (say 5.7) and the oldest where the issue occurs (say 5.8-rc1).

When sending the report by mail, CC the Linux regressions mailing list (regressions@lists.linux.dev). In case the report needs to be filed to some web tracker, proceed to do so. Once filed, forward the report by mail to the regressions list; CC the maintainer and the mailing list for the subsystem in question. Make sure to inline the forwarded report, hence do not attach it. Also add a short note at the top where you mention the URL to the ticket.

When mailing or forwarding the report, in case of a successful bisection add the author of the culprit to the recipients; also CC everyone in the signed-off-by chain, which you find at the end of its commit message.

Security issues: for these issues your will have to evaluate if a short-term risk to other users would arise if details were publicly disclosed. If that's not the case simply proceed with reporting the issue as described. For issues that bear such a risk you will need to adjust the reporting process slightly:

- If the MAINTAINERS file instructed you to report the issue by mail, do not CC any public mailing lists.

- If you were supposed to file the issue in a bug tracker make sure to mark the ticket as 'private' or 'security issue'. If the bug tracker does not offer a way to keep reports private, forget about it and send your report as a private mail to the maintainers instead.

In both cases make sure to also mail your report to the addresses the MAINTAINERS file lists in the section 'security contact'. Ideally directly CC them when sending the report by mail. If you filed it in a bug tracker, forward the report's text to these addresses; but on top of it put a small note where you mention that you filed it with a link to the ticket.

See Documentation/process/security-bugs.rst for more information.

8.3.19 Duties after the report went out

> *Wait for reactions and keep the thing rolling until you can accept the outcome in one way or the other. Thus react publicly and in a timely manner to any inquiries. Test proposed fixes. Do proactive testing: retest with at least every first release candidate (RC) of a new mainline version and report your results. Send friendly reminders if things stall. And try to help yourself, if you don't get any help or if it's unsatisfying.*

If your report was good and you are really lucky then one of the developers might immediately spot what's causing the issue; they then might write a patch to fix it, test it, and send it straight for integration in mainline while tagging it for later backport to stable and longterm kernels that need it. Then all you need to do is reply with a 'Thank you very much' and switch to a version with the fix once it gets released.

But this ideal scenario rarely happens. That's why the job is only starting once you got the report out. What you'll have to do depends on the situations, but often it will be the things listed below. But before digging into the details, here are a few important things you need to keep in mind for this part of the process.

General advice for further interactions

Always reply in public: When you filed the issue in a bug tracker, always reply there and do not contact any of the developers privately about it. For mailed reports always use the 'Reply-all' function when replying to any mails you receive. That includes mails with any additional data you might want to add to your report: go to your mail applications 'Sent' folder and use 'reply-all' on your mail with the report. This approach will make sure the public mailing list(s) and everyone else that gets involved over time stays in the loop; it also keeps the mail thread intact, which among others is really important for mailing lists to group all related mails together.

There are just two situations where a comment in a bug tracker or a 'Reply-all' is unsuitable:

- Someone tells you to send something privately.
- You were told to send something, but noticed it contains sensitive information that needs to be kept private. In that case it's okay to send it in private to the developer that asked for it. But note in the ticket or a mail that you did that, so everyone else knows you honored the request.

Do research before asking for clarifications or help: In this part of the process someone might tell you to do something that requires a skill you might not have mastered yet. For example, you might be asked to use some test tools you never have heard of yet; or you might be asked to apply a patch to the Linux kernel sources to test if it helps. In some cases it will be fine sending a reply asking for instructions how to do that. But before going that route try to

find the answer own your own by searching the internet; alternatively consider asking in other places for advice. For example ask a friend or post about it to a chatroom or forum you normally hang out.

Be patient: If you are really lucky you might get a reply to your report within a few hours. But most of the time it will take longer, as maintainers are scattered around the globe and thus might be in a different time zone – one where they already enjoy their night away from keyboard.

In general, kernel developers will take one to five business days to respond to reports. Sometimes it will take longer, as they might be busy with the merge windows, other work, visiting developer conferences, or simply enjoying a long summer holiday.

The 'issues of high priority' (see above for an explanation) are an exception here: maintainers should address them as soon as possible; that's why you should wait a week at maximum (or just two days if it's something urgent) before sending a friendly reminder.

Sometimes the maintainer might not be responding in a timely manner; other times there might be disagreements, for example if an issue qualifies as regression or not. In such cases raise your concerns on the mailing list and ask others for public or private replies how to move on. If that fails, it might be appropriate to get a higher authority involved. In case of a WiFi driver that would be the wireless maintainers; if there are no higher level maintainers or all else fails, it might be one of those rare situations where it's okay to get Linus Torvalds involved.

Proactive testing: Every time the first pre-release (the 'rc1') of a new mainline kernel version gets released, go and check if the issue is fixed there or if anything of importance changed. Mention the outcome in the ticket or in a mail you sent as reply to your report (make sure it has all those in the CC that up to that point participated in the discussion). This will show your commitment and that you are willing to help. It also tells developers if the issue persists and makes sure they do not forget about it. A few other occasional retests (for example with rc3, rc5 and the final) are also a good idea, but only report your results if something relevant changed or if you are writing something anyway.

With all these general things off the table let's get into the details of how to help to get issues resolved once they were reported.

Inquires and testing request

Here are your duties in case you got replies to your report:

Check who you deal with: Most of the time it will be the maintainer or a developer of the particular code area that will respond to your report. But as issues are normally reported in public it could be anyone that's replying — including people that want to help, but in the end might guide you totally off track with their questions or requests. That rarely happens, but it's one of many reasons why it's wise to quickly run an internet search to see who you're interacting with. By doing this you also get aware if your report was heard by the right people, as a reminder to the maintainer (see below) might be in order later if discussion fades out without leading to a satisfying solution for the issue.

Inquiries for data: Often you will be asked to test something or provide additional details. Try to provide the requested information soon, as you have the attention of someone that might help and risk losing it the longer you wait; that outcome is even likely if you do not provide the information within a few business days.

Requests for testing: When you are asked to test a diagnostic patch or a possible fix, try to test it in timely manner, too. But do it properly and make sure to not rush it: mixing things up can happen easily and can lead to a lot of confusion for everyone involved. A common mistake for example is thinking a proposed patch with a fix was applied, but in fact wasn't. Things like that happen even to experienced testers occasionally, but they most of the time will notice when the kernel with the fix behaves just as one without it.

What to do when nothing of substance happens

Some reports will not get any reaction from the responsible Linux kernel developers; or a discussion around the issue evolved, but faded out with nothing of substance coming out of it.

In these cases wait two (better: three) weeks before sending a friendly reminder: maybe the maintainer was just away from keyboard for a while when your report arrived or had something more important to take care of. When writing the reminder, kindly ask if anything else from your side is needed to get the ball running somehow. If the report got out by mail, do that in the first lines of a mail that is a reply to your initial mail (see above) which includes a full quote of the original report below: that's on of those few situations where such a 'TOFU' (Text Over, Fullquote Under) is the right approach, as then all the recipients will have the details at hand immediately in the proper order.

After the reminder wait three more weeks for replies. If you still don't get a proper reaction, you first should reconsider your approach. Did you maybe try to reach out to the wrong people? Was the report maybe offensive or so confusing that people decided to completely stay away from it? The best way to rule out such factors: show the report to one or two people familiar with FLOSS issue reporting and ask for their opinion. Also ask them for their advice how to move forward. That might mean: prepare a better report and make those people review it before you send it out. Such an approach is totally fine; just mention that this is the second and improved report on the issue and include a link to the first report.

If the report was proper you can send a second reminder; in it ask for advice why the report did not get any replies. A good moment for this second reminder mail is shortly after the first pre-release (the 'rc1') of a new Linux kernel version got published, as you should retest and provide a status update at that point anyway (see above).

If the second reminder again results in no reaction within a week, try to contact a higher-level maintainer asking for advice: even busy maintainers by then should at least have sent some kind of acknowledgment.

Remember to prepare yourself for a disappointment: maintainers ideally should react somehow to every issue report, but they are only obliged to fix those 'issues of high priority' outlined earlier. So don't be too devastating if you get a reply along the lines of 'thanks for the report, I have more important issues to deal with currently and won't have time to look into this for the foreseeable future'.

It's also possible that after some discussion in the bug tracker or on a list nothing happens anymore and reminders don't help to motivate anyone to work out a fix. Such situations can be devastating, but is within the cards when it comes to Linux kernel development. This and several other reasons for not getting help are explained in 'Why some issues won't get any reaction or remain unfixed after being reported' near the end of this document.

Don't get devastated if you don't find any help or if the issue in the end does not get solved: the Linux kernel is FLOSS and thus you can still help yourself. You for example could try to find others that are affected and team up with them to get the issue resolved. Such a team could

prepare a fresh report together that mentions how many you are and why this is something that in your option should get fixed. Maybe together you can also narrow down the root cause or the change that introduced a regression, which often makes developing a fix easier. And with a bit of luck there might be someone in the team that knows a bit about programming and might be able to write a fix.

8.3.20 Reference for "Reporting regressions within a stable and longterm kernel line"

This subsection provides details for the steps you need to perform if you face a regression within a stable and longterm kernel line.

Make sure the particular version line still gets support

> *Check if the kernel developers still maintain the Linux kernel version line you care about: go to the front page of kernel.org and make sure it mentions the latest release of the particular version line without an '[EOL]' tag.*

Most kernel version lines only get supported for about three months, as maintaining them longer is quite a lot of work. Hence, only one per year is chosen and gets supported for at least two years (often six). That's why you need to check if the kernel developers still support the version line you care for.

Note, if kernel.org lists two stable version lines on the front page, you should consider switching to the newer one and forget about the older one: support for it is likely to be abandoned soon. Then it will get a "end-of-life" (EOL) stamp. Version lines that reached that point still get mentioned on the kernel.org front page for a week or two, but are unsuitable for testing and reporting.

Search stable mailing list

> *Check the archives of the Linux stable mailing list for existing reports.*

Maybe the issue you face is already known and was fixed or is about to. Hence, search the archives of the Linux stable mailing list for reports about an issue like yours. If you find any matches, consider joining the discussion, unless the fix is already finished and scheduled to get applied soon.

Reproduce issue with the newest release

> *Install the latest release from the particular version line as a vanilla kernel. Ensure this kernel is not tainted and still shows the problem, as the issue might have already been fixed there. If you first noticed the problem with a vendor kernel, check a vanilla build of the last version known to work performs fine as well.*

Before investing any more time in this process you want to check if the issue was already fixed in the latest release of version line you're interested in. This kernel needs to be vanilla and shouldn't be tainted before the issue happens, as detailed outlined already above in the section "Install a fresh kernel for testing".

Did you first notice the regression with a vendor kernel? Then changes the vendor applied might be interfering. You need to rule that out by performing a recheck. Say something broke when you updated from 5.10.4-vendor.42 to 5.10.5-vendor.43. Then after testing the latest 5.10 release as outlined in the previous paragraph check if a vanilla build of Linux 5.10.4 works fine as well. If things are broken there, the issue does not qualify as upstream regression and you need switch back to the main step-by-step guide to report the issue.

Report the regression

> *Send a short problem report to the Linux stable mailing list (stable@vger.kernel.org) and CC the Linux regressions mailing list (regressions@lists.linux.dev); if you suspect the cause in a particular subsystem, CC its maintainer and its mailing list. Roughly describe the issue and ideally explain how to reproduce it. Mention the first version that shows the problem and the last version that's working fine. Then wait for further instructions.*

When reporting a regression that happens within a stable or longterm kernel line (say when updating from 5.10.4 to 5.10.5) a brief report is enough for the start to get the issue reported quickly. Hence a rough description to the stable and regressions mailing list is all it takes; but in case you suspect the cause in a particular subsystem, CC its maintainers and its mailing list as well, because that will speed things up.

And note, it helps developers a great deal if you can specify the exact version that introduced the problem. Hence if possible within a reasonable time frame, try to find that version using vanilla kernels. Lets assume something broke when your distributor released a update from Linux kernel 5.10.5 to 5.10.8. Then as instructed above go and check the latest kernel from that version line, say 5.10.9. If it shows the problem, try a vanilla 5.10.5 to ensure that no patches the distributor applied interfere. If the issue doesn't manifest itself there, try 5.10.7 and then (depending on the outcome) 5.10.8 or 5.10.6 to find the first version where things broke. Mention it in the report and state that 5.10.9 is still broken.

What the previous paragraph outlines is basically a rough manual 'bisection'. Once your report is out your might get asked to do a proper one, as it allows to pinpoint the exact change that causes the issue (which then can easily get reverted to fix the issue quickly). Hence consider to do a proper bisection right away if time permits. See the section 'Special care for regressions' and the document *Bisecting a bug* for details how to perform one. In case of a successful bisection add the author of the culprit to the recipients; also CC everyone in the signed-off-by chain, which you find at the end of its commit message.

8.3.21 Reference for ”Reporting issues only occurring in older kernel version lines”

This section provides details for the steps you need to take if you could not reproduce your issue with a mainline kernel, but want to see it fixed in older version lines (aka stable and longterm kernels).

Some fixes are too complex

> *Prepare yourself for the possibility that going through the next few steps might not get the issue solved in older releases: the fix might be too big or risky to get backported there.*

Even small and seemingly obvious code-changes sometimes introduce new and totally unexpected problems. The maintainers of the stable and longterm kernels are very aware of that and thus only apply changes to these kernels that are within rules outlined in Documentation/process/stable-kernel-rules.rst.

Complex or risky changes for example do not qualify and thus only get applied to mainline. Other fixes are easy to get backported to the newest stable and longterm kernels, but too risky to integrate into older ones. So be aware the fix you are hoping for might be one of those that won't be backported to the version line your care about. In that case you'll have no other choice then to live with the issue or switch to a newer Linux version, unless you want to patch the fix into your kernels yourself.

Common preparations

> *Perform the first three steps in the section "Reporting issues only occurring in older kernel version lines" above.*

You need to carry out a few steps already described in another section of this guide. Those steps will let you:

- Check if the kernel developers still maintain the Linux kernel version line you care about.
- Search the Linux stable mailing list for exiting reports.
- Check with the latest release.

Check code history and search for existing discussions

> *Search the Linux kernel version control system for the change that fixed the issue in mainline, as its commit message might tell you if the fix is scheduled for backporting already. If you don't find anything that way, search the appropriate mailing lists for posts that discuss such an issue or peer-review possible fixes; then check the discussions if the fix was deemed unsuitable for backporting. If backporting was not considered at all, join the newest discussion, asking if it's in the cards.*

In a lot of cases the issue you deal with will have happened with mainline, but got fixed there. The commit that fixed it would need to get backported as well to get the issue solved. That's why you want to search for it or any discussions abound it.

- First try to find the fix in the Git repository that holds the Linux kernel sources. You can do this with the web interfaces on kernel.org or its mirror on GitHub; if you have a local clone you alternatively can search on the command line with `git log --grep=<pattern>`.

  If you find the fix, look if the commit message near the end contains a 'stable tag' that looks like this:

  > Cc: <stable@vger.kernel.org> # 5.4+

If that's case the developer marked the fix safe for backporting to version line 5.4 and later. Most of the time it's getting applied there within two weeks, but sometimes it takes a bit longer.

- If the commit doesn't tell you anything or if you can't find the fix, look again for discussions about the issue. Search the net with your favorite internet search engine as well as the archives for the Linux kernel developers mailing list. Also read the section *Locate kernel area that causes the issue* above and follow the instructions to find the subsystem in question: its bug tracker or mailing list archive might have the answer you are looking for.
- If you see a proposed fix, search for it in the version control system as outlined above, as the commit might tell you if a backport can be expected.
  - Check the discussions for any indicators the fix might be too risky to get backported to the version line you care about. If that's the case you have to live with the issue or switch to the kernel version line where the fix got applied.
  - If the fix doesn't contain a stable tag and backporting was not discussed, join the discussion: mention the version where you face the issue and that you would like to see it fixed, if suitable.

Ask for advice

One of the former steps should lead to a solution. If that doesn't work out, ask the maintainers for the subsystem that seems to be causing the issue for advice; CC the mailing list for the particular subsystem as well as the stable mailing list.

If the previous three steps didn't get you closer to a solution there is only one option left: ask for advice. Do that in a mail you sent to the maintainers for the subsystem where the issue seems to have its roots; CC the mailing list for the subsystem as well as the stable mailing list (stable@vger.kernel.org).

8.4 Why some issues won't get any reaction or remain unfixed after being reported

When reporting a problem to the Linux developers, be aware only 'issues of high priority' (regressions, security issues, severe problems) are definitely going to get resolved. The maintainers or if all else fails Linus Torvalds himself will make sure of that. They and the other kernel developers will fix a lot of other issues as well. But be aware that sometimes they can't or won't help; and sometimes there isn't even anyone to send a report to.

This is best explained with kernel developers that contribute to the Linux kernel in their spare time. Quite a few of the drivers in the kernel were written by such programmers, often because they simply wanted to make their hardware usable on their favorite operating system.

These programmers most of the time will happily fix problems other people report. But nobody can force them to do, as they are contributing voluntarily.

Then there are situations where such developers really want to fix an issue, but can't: sometimes they lack hardware programming documentation to do so. This often happens when the publicly available docs are superficial or the driver was written with the help of reverse engineering.

Sooner or later spare time developers will also stop caring for the driver. Maybe their test hardware broke, got replaced by something more fancy, or is so old that it's something you don't find much outside of computer museums anymore. Sometimes developer stops caring for their code and Linux at all, as something different in their life became way more important. In some cases nobody is willing to take over the job as maintainer – and nobody can be forced to, as contributing to the Linux kernel is done on a voluntary basis. Abandoned drivers nevertheless remain in the kernel: they are still useful for people and removing would be a regression.

The situation is not that different with developers that are paid for their work on the Linux kernel. Those contribute most changes these days. But their employers sooner or later also stop caring for their code or make its programmer focus on other things. Hardware vendors for example earn their money mainly by selling new hardware; quite a few of them hence are not investing much time and energy in maintaining a Linux kernel driver for something they stopped selling years ago. Enterprise Linux distributors often care for a longer time period, but in new versions often leave support for old and rare hardware aside to limit the scope. Often spare time contributors take over once a company orphans some code, but as mentioned above: sooner or later they will leave the code behind, too.

Priorities are another reason why some issues are not fixed, as maintainers quite often are forced to set those, as time to work on Linux is limited. That's true for spare time or the time employers grant their developers to spend on maintenance work on the upstream kernel. Sometimes maintainers also get overwhelmed with reports, even if a driver is working nearly perfectly. To not get completely stuck, the programmer thus might have no other choice than to prioritize issue reports and reject some of them.

But don't worry too much about all of this, a lot of drivers have active maintainers who are quite interested in fixing as many issues as possible.

8.5 Closing words

Compared with other Free/Libre & Open Source Software it's hard to report issues to the Linux kernel developers: the length and complexity of this document and the implications between the lines illustrate that. But that's how it is for now. The main author of this text hopes documenting the state of the art will lay some groundwork to improve the situation over time.

CHAPTER

NINE

REPORTING REGRESSIONS

”*We don't cause regressions*” is the first rule of Linux kernel development; Linux founder and lead developer Linus Torvalds established it himself and ensures it's obeyed.

This document describes what the rule means for users and how the Linux kernel's development model ensures to address all reported regressions; aspects relevant for kernel developers are left to Documentation/process/handling-regressions.rst.

9.1 The important bits (aka ”TL;DR”)

1. It's a regression if something running fine with one Linux kernel works worse or not at all with a newer version. Note, the newer kernel has to be compiled using a similar configuration; the detailed explanations below describes this and other fine print in more detail.
2. Report your issue as outlined in *Reporting issues*, it already covers all aspects important for regressions and repeated below for convenience. Two of them are important: start your report's subject with ”[REGRESSION]” and CC or forward it to the regression mailing list (regressions@lists.linux.dev).
3. Optional, but recommended: when sending or forwarding your report, make the Linux kernel regression tracking bot ”regzbot” track the issue by specifying when the regression started like this:

```
#regzbot introduced v5.13..v5.14-rc1
```

9.2 All the details on Linux kernel regressions relevant for users

9.2.1 The important basics

What is a ”regression” and what is the ”no regressions rule”?

It's a regression if some application or practical use case running fine with one Linux kernel works worse or not at all with a newer version compiled using a similar configuration. The ”no regressions rule” forbids this to take place; if it happens by accident, developers that caused it are expected to quickly fix the issue.

It thus is a regression when a WiFi driver from Linux 5.13 works fine, but with 5.14 doesn't work at all, works significantly slower, or misbehaves somehow. It's also a regression if a perfectly working application suddenly shows erratic behavior with a newer kernel version; such issues

can be caused by changes in procfs, sysfs, or one of the many other interfaces Linux provides to userland software. But keep in mind, as mentioned earlier: 5.14 in this example needs to be built from a configuration similar to the one from 5.13. This can be achieved using `make olddefconfig`, as explained in more detail below.

Note the "practical use case" in the first sentence of this section: developers despite the "no regressions" rule are free to change any aspect of the kernel and even APIs or ABIs to userland, as long as no existing application or use case breaks.

Also be aware the "no regressions" rule covers only interfaces the kernel provides to the userland. It thus does not apply to kernel-internal interfaces like the module API, which some externally developed drivers use to hook into the kernel.

How do I report a regression?

Just report the issue as outlined in *Reporting issues*, it already describes the important points. The following aspects outlined there are especially relevant for regressions:

- When checking for existing reports to join, also search the archives of the Linux regressions mailing list and regzbot's web-interface.
- Start your report's subject with "[REGRESSION]".
- In your report, clearly mention the last kernel version that worked fine and the first broken one. Ideally try to find the exact change causing the regression using a bisection, as explained below in more detail.
- Remember to let the Linux regressions mailing list (regressions@lists.linux.dev) know about your report:
  - If you report the regression by mail, CC the regressions list.
  - If you report your regression to some bug tracker, forward the submitted report by mail to the regressions list while CCing the maintainer and the mailing list for the subsystem in question.

  If it's a regression within a stable or longterm series (e.g. v5.15.3..v5.15.5), remember to CC the Linux stable mailing list (stable@vger.kernel.org).

  In case you performed a successful bisection, add everyone to the CC the culprit's commit message mentions in lines starting with "Signed-off-by:".

When CCing for forwarding your report to the list, consider directly telling the aforementioned Linux kernel regression tracking bot about your report. To do that, include a paragraph like this in your mail:

```
#regzbot introduced: v5.13..v5.14-rc1
```

Regzbot will then consider your mail a report for a regression introduced in the specified version range. In above case Linux v5.13 still worked fine and Linux v5.14-rc1 was the first version where you encountered the issue. If you performed a bisection to find the commit that caused the regression, specify the culprit's commit-id instead:

```
#regzbot introduced: 1f2e3d4c5d
```

Placing such a "regzbot command" is in your interest, as it will ensure the report won't fall through the cracks unnoticed. If you omit this, the Linux kernel's regressions tracker will take

care of telling regzbot about your regression, as long as you send a copy to the regressions mailing lists. But the regression tracker is just one human which sometimes has to rest or occasionally might even enjoy some time away from computers (as crazy as that might sound). Relying on this person thus will result in an unnecessary delay before the regressions becomes mentioned on the list of tracked and unresolved Linux kernel regressions and the weekly regression reports sent by regzbot. Such delays can result in Linus Torvalds being unaware of important regressions when deciding between ”continue development or call this finished and release the final?”.

Are really all regressions fixed?

Nearly all of them are, as long as the change causing the regression (the ”culprit commit”) is reliably identified. Some regressions can be fixed without this, but often it's required.

Who needs to find the root cause of a regression?

Developers of the affected code area should try to locate the culprit on their own. But for them that's often impossible to do with reasonable effort, as quite a lot of issues only occur in a particular environment outside the developer's reach -- for example, a specific hardware platform, firmware, Linux distro, system's configuration, or application. That's why in the end it's often up to the reporter to locate the culprit commit; sometimes users might even need to run additional tests afterwards to pinpoint the exact root cause. Developers should offer advice and reasonably help where they can, to make this process relatively easy and achievable for typical users.

How can I find the culprit?

Perform a bisection, as roughly outlined in *Reporting issues* and described in more detail by *Bisecting a bug*. It might sound like a lot of work, but in many cases finds the culprit relatively quickly. If it's hard or time-consuming to reliably reproduce the issue, consider teaming up with other affected users to narrow down the search range together.

Who can I ask for advice when it comes to regressions?

Send a mail to the regressions mailing list (regressions@lists.linux.dev) while CCing the Linux kernel's regression tracker (regressions@leemhuis.info); if the issue might better be dealt with in private, feel free to omit the list.

9.2.2 Additional details about regressions

What is the goal of the ”no regressions rule”?

Users should feel safe when updating kernel versions and not have to worry something might break. This is in the interest of the kernel developers to make updating attractive: they don't want users to stay on stable or longterm Linux series that are either abandoned or more than one and a half years old. That's in everybody's interest, as those series might have known bugs, security issues, or other problematic aspects already fixed in later versions. Additionally, the kernel developers want to make it simple and appealing for users to test the latest pre-release

or regular release. That's also in everybody's interest, as it's a lot easier to track down and fix problems, if they are reported shortly after being introduced.

Is the ”no regressions” rule really adhered in practice?

It's taken really seriously, as can be seen by many mailing list posts from Linux creator and lead developer Linus Torvalds, some of which are quoted in Documentation/process/handling-regressions.rst.

Exceptions to this rule are extremely rare; in the past developers almost always turned out to be wrong when they assumed a particular situation was warranting an exception.

Who ensures the ”no regressions” is actually followed?

The subsystem maintainers should take care of that, which are watched and supported by the tree maintainers -- e.g. Linus Torvalds for mainline and Greg Kroah-Hartman et al. for various stable/longterm series.

All of them are helped by people trying to ensure no regression report falls through the cracks. One of them is Thorsten Leemhuis, who's currently acting as the Linux kernel's ”regressions tracker”; to facilitate this work he relies on regzbot, the Linux kernel regression tracking bot. That's why you want to bring your report on the radar of these people by CCing or forwarding each report to the regressions mailing list, ideally with a ”regzbot command” in your mail to get it tracked immediately.

How quickly are regressions normally fixed?

Developers should fix any reported regression as quickly as possible, to provide affected users with a solution in a timely manner and prevent more users from running into the issue; nevertheless developers need to take enough time and care to ensure regression fixes do not cause additional damage.

The answer thus depends on various factors like the impact of a regression, its age, or the Linux series in which it occurs. In the end though, most regressions should be fixed within two weeks.

Is it a regression, if the issue can be avoided by updating some software?

Almost always: yes. If a developer tells you otherwise, ask the regression tracker for advice as outlined above.

Is it a regression, if a newer kernel works slower or consumes more energy?

Yes, but the difference has to be significant. A five percent slow-down in a micro-benchmark thus is unlikely to qualify as regression, unless it also influences the results of a broad benchmark by more than one percent. If in doubt, ask for advice.

Is it a regression, if an external kernel module breaks when updating Linux?

No, as the ”no regression” rule is about interfaces and services the Linux kernel provides to the userland. It thus does not cover building or running externally developed kernel modules, as they run in kernel-space and hook into the kernel using internal interfaces occasionally changed.

How are regressions handled that are caused by security fixes?

In extremely rare situations security issues can't be fixed without causing regressions; those fixes are given way, as they are the lesser evil in the end. Luckily this middling almost always can be avoided, as key developers for the affected area and often Linus Torvalds himself try very hard to fix security issues without causing regressions.

If you nevertheless face such a case, check the mailing list archives if people tried their best to avoid the regression. If not, report it; if in doubt, ask for advice as outlined above.

What happens if fixing a regression is impossible without causing another?

Sadly these things happen, but luckily not very often; if they occur, expert developers of the affected code area should look into the issue to find a fix that avoids regressions or at least their impact. If you run into such a situation, do what was outlined already for regressions caused by security fixes: check earlier discussions if people already tried their best and ask for advice if in doubt.

A quick note while at it: these situations could be avoided, if people would regularly give mainline pre-releases (say v5.15-rc1 or -rc3) from each development cycle a test run. This is best explained by imagining a change integrated between Linux v5.14 and v5.15-rc1 which causes a regression, but at the same time is a hard requirement for some other improvement applied for 5.15-rc1. All these changes often can simply be reverted and the regression thus solved, if someone finds and reports it before 5.15 is released. A few days or weeks later this solution can become impossible, as some software might have started to rely on aspects introduced by one of the follow-up changes: reverting all changes would then cause a regression for users of said software and thus is out of the question.

Is it a regression, if some feature I relied on was removed months ago?

It is, but often it's hard to fix such regressions due to the aspects outlined in the previous section. It hence needs to be dealt with on a case-by-case basis. This is another reason why it's in everybody's interest to regularly test mainline pre-releases.

Does the ”no regression” rule apply if I seem to be the only affected person?

It does, but only for practical usage: the Linux developers want to be free to remove support for hardware only to be found in attics and museums anymore.

Note, sometimes regressions can't be avoided to make progress -- and the latter is needed to prevent Linux from stagnation. Hence, if only very few users seem to be affected by a regression, it for the greater good might be in their and everyone else's interest to lettings things pass. Especially if there is an easy way to circumvent the regression somehow, for example by updating some software or using a kernel parameter created just for this purpose.

Does the regression rule apply for code in the staging tree as well?

Not according to the help text for the configuration option covering all staging code, which since its early days states:

```
Please note that these drivers are under heavy development, may or
may not work, and may contain userspace interfaces that most likely
will be changed in the near future.
```

The staging developers nevertheless often adhere to the ”no regressions” rule, but sometimes bend it to make progress. That's for example why some users had to deal with (often negligible) regressions when a WiFi driver from the staging tree was replaced by a totally different one written from scratch.

Why do later versions have to be ”compiled with a similar configuration”?

Because the Linux kernel developers sometimes integrate changes known to cause regressions, but make them optional and disable them in the kernel's default configuration. This trick allows progress, as the ”no regressions” rule otherwise would lead to stagnation.

Consider for example a new security feature blocking access to some kernel interfaces often abused by malware, which at the same time are required to run a few rarely used applications. The outlined approach makes both camps happy: people using these applications can leave the new security feature off, while everyone else can enable it without running into trouble.

How to create a configuration similar to the one of an older kernel?

Start your machine with a known-good kernel and configure the newer Linux version with `make olddefconfig`. This makes the kernel's build scripts pick up the configuration file (the ”.config” file) from the running kernel as base for the new one you are about to compile; afterwards they set all new configuration options to their default value, which should disable new features that might cause regressions.

Can I report a regression I found with pre-compiled vanilla kernels?

You need to ensure the newer kernel was compiled with a similar configuration file as the older one (see above), as those that built them might have enabled some known-to-be incompatible feature for the newer kernel. If in doubt, report the matter to the kernel's provider and ask for advice.

9.2.3 More about regression tracking with ”regzbot”

What is regression tracking and why should I care about it?

Rules like ”no regressions” need someone to ensure they are followed, otherwise they are broken either accidentally or on purpose. History has shown this to be true for Linux kernel development as well. That's why Thorsten Leemhuis, the Linux Kernel's regression tracker, and some people try to ensure all regression are fixed by keeping an eye on them until they are resolved. Neither of them are paid for this, that's why the work is done on a best effort basis.

Why and how are Linux kernel regressions tracked using a bot?

Tracking regressions completely manually has proven to be quite hard due to the distributed and loosely structured nature of Linux kernel development process. That's why the Linux kernel's regression tracker developed regzbot to facilitate the work, with the long term goal to automate regression tracking as much as possible for everyone involved.

Regzbot works by watching for replies to reports of tracked regressions. Additionally, it's looking out for posted or committed patches referencing such reports with ”Link:” tags; replies to such patch postings are tracked as well. Combined this data provides good insights into the current state of the fixing process.

How to see which regressions regzbot tracks currently?

Check out regzbot's web-interface.

What kind of issues are supposed to be tracked by regzbot?

The bot is meant to track regressions, hence please don't involve regzbot for regular issues. But it's okay for the Linux kernel's regression tracker if you involve regzbot to track severe issues, like reports about hangs, corrupted data, or internal errors (Panic, Oops, BUG(), warning, ...).

How to change aspects of a tracked regression?

By using a 'regzbot command' in a direct or indirect reply to the mail with the report. The easiest way to do that: find the report in your ”Sent” folder or the mailing list archive and reply to it using your mailer's ”Reply-all” function. In that mail, use one of the following commands in a stand-alone paragraph (IOW: use blank lines to separate one or multiple of these commands from the rest of the mail's text).

- Update when the regression started to happen, for example after performing a bisection:

```
#regzbot introduced: 1f2e3d4c5d
```

- Set or update the title:

```
#regzbot title: foo
```

- Monitor a discussion or bugzilla.kernel.org ticket where additions aspects of the issue or a fix are discussed::

```
#regzbot monitor: https://lore.kernel.org/r/30th.anniversary.repost@klaava.
↪Helsinki.FI/
#regzbot monitor: https://bugzilla.kernel.org/show_bug.cgi?id=123456789
```

- Point to a place with further details of interest, like a mailing list post or a ticket in a bug tracker that are slightly related, but about a different topic:

```
#regzbot link: https://bugzilla.kernel.org/show_bug.cgi?id=123456789
```

- Mark a regression as invalid:

```
#regzbot invalid: wasn't a regression, problem has always existed
```

Regzbot supports a few other commands primarily used by developers or people tracking regressions. They and more details about the aforementioned regzbot commands can be found in the getting started guide and the reference documentation for regzbot.

CHAPTER

TEN

HOW TO QUICKLY BUILD A TRIMMED LINUX KERNEL

This guide explains how to swiftly build Linux kernels that are ideal for testing purposes, but perfectly fine for day-to-day use, too.

10.1 The essence of the process (aka 'TL;DR')

[If you are new to compiling Linux, ignore this TLDR and head over to the next section below: it contains a step-by-step guide, which is more detailed, but still brief and easy to follow; that guide and its accompanying reference section also mention alternatives, pitfalls, and additional aspects, all of which might be relevant for you.]

If your system uses techniques like Secure Boot, prepare it to permit starting self-compiled Linux kernels; install compilers and everything else needed for building Linux; make sure to have 12 Gigabyte free space in your home directory. Now run the following commands to download fresh Linux mainline sources, which you then use to configure, build and install your own kernel:

```
git clone --depth 1 -b master \
  https://git.kernel.org/pub/scm/linux/kernel/git/stable/linux.git ~/linux/
cd ~/linux/
# Hint: if you want to apply patches, do it at this point. See below for␣
↪details.
# Hint: it's recommended to tag your build at this point. See below for␣
↪details.
yes "" | make localmodconfig
# Hint: at this point you might want to adjust the build configuration; you'll
#   have to, if you are running Debian. See below for details.
make -j $(nproc --all)
# Note: on many commodity distributions the next command suffices, but on Arch
#   Linux, its derivatives, and some others it does not. See below for details.
command -v installkernel && sudo make modules_install install
reboot
```

If you later want to build a newer mainline snapshot, use these commands:

```
cd ~/linux/
git fetch --depth 1 origin
# Note: the next command will discard any changes you did to the code:
git checkout --force --detach origin/master
# Reminder: if you want to (re)apply patches, do it at this point.
```

```
# Reminder: you might want to add or modify a build tag at this point.
make olddefconfig
make -j $(nproc --all)
# Reminder: the next command on some distributions does not suffice.
command -v installkernel && sudo make modules_install install
reboot
```

10.2 Step-by-step guide

Compiling your own Linux kernel is easy in principle. There are various ways to do it. Which of them actually work and is the best depends on the circumstances.

This guide describes a way perfectly suited for those who want to quickly install Linux from sources without being bothered by complicated details; the goal is to cover everything typically needed on mainstream Linux distributions running on commodity PC or server hardware.

The described approach is great for testing purposes, for example to try a proposed fix or to check if a problem was already fixed in the latest codebase. Nonetheless, kernels built this way are also totally fine for day-to-day use while at the same time being easy to keep up to date.

The following steps describe the important aspects of the process; a comprehensive reference section later explains each of them in more detail. It sometimes also describes alternative approaches, pitfalls, as well as errors that might occur at a particular point -- and how to then get things rolling again.

- Create a fresh backup and put system repair and restore tools at hand, just to be prepared for the unlikely case of something going sideways.

  [*details*]

- On platforms with 'Secure Boot' or similar techniques, prepare everything to ensure the system will permit your self-compiled kernel to boot later. The quickest and easiest way to achieve this on commodity x86 systems is to disable such techniques in the BIOS setup utility; alternatively, remove their restrictions through a process initiated by `mokutil --disable-validation`.

  [*details*]

- Install all software required to build a Linux kernel. Often you will need: 'bc', 'binutils' ('ld' et al.), 'bison', 'flex', 'gcc', 'git', 'openssl', 'pahole', 'perl', and the development headers for 'libelf' and 'openssl'. The reference section shows how to quickly install those on various popular Linux distributions.

  [*details*]

- Ensure to have enough free space for building and installing Linux. For the latter 150 Megabyte in /lib/ and 100 in /boot/ are a safe bet. For storing sources and build artifacts 12 Gigabyte in your home directory should typically suffice. If you have less available, be sure to check the reference section for the step that explains adjusting your kernels build configuration: it mentions a trick that reduce the amount of required space in /home/ to around 4 Gigabyte.

  [*details*]

- Retrieve the sources of the Linux version you intend to build; then change into the directory holding them, as all further commands in this guide are meant to be executed from there.

  [Note: the following paragraphs describe how to retrieve the sources by partially cloning the Linux stable git repository. This is called a shallow clone. The reference section explains two alternatives: packaged archives and a full git clone ; prefer the latter, if downloading a lot of data does not bother you, as that will avoid some peculiar characteristics of shallow clones the reference section explains .]

  First, execute the following command to retrieve a fresh mainline codebase:

  ```
  git clone --no-checkout --depth 1 -b master \
    https://git.kernel.org/pub/scm/linux/kernel/git/stable/linux.git ~/linux/
  cd ~/linux/
  ```

  If you want to access recent mainline releases and pre-releases, deepen you clone's history to the oldest mainline version you are interested in:

  ```
  git fetch --shallow-exclude=v6.0 origin
  ```

  In case you want to access a stable/longterm release (say v6.1.5), simply add the branch holding that series; afterwards fetch the history at least up to the mainline version that started the series (v6.1):

  ```
  git remote set-branches --add origin linux-6.1.y
  git fetch --shallow-exclude=v6.0 origin
  ```

  Now checkout the code you are interested in. If you just performed the initial clone, you will be able to check out a fresh mainline codebase, which is ideal for checking whether developers already fixed an issue:

  ```
  git checkout --detach origin/master
  ```

  If you deepened your clone, you instead of `origin/master` can specify the version you deepened to (`v6.0` above); later releases like `v6.1` and pre-release like `v6.2-rc1` will work, too. Stable or longterm versions like `v6.1.5` work just the same, if you added the appropriate stable/longterm branch as described.

  [*details*]

- In case you want to apply a kernel patch, do so now. Often a command like this will do the trick:

  ```
  patch -p1 < ../proposed-fix.patch
  ```

  If the `-p1` is actually needed, depends on how the patch was created; in case it does not apply thus try without it.

  If you cloned the sources with git and anything goes sideways, run `git reset --hard` to undo any changes to the sources.

  [*details*]

  - If you patched your kernel or have one of the same version installed already, better add a unique tag to the one you are about to build:

```
echo "-proposed_fix" > localversion
```

Running `uname -r` under your kernel later will then print something like '6.1-rc4-proposed_fix'.

[*details*]

- Create the build configuration for your kernel based on an existing configuration.

  If you already prepared such a '.config' file yourself, copy it to ~/linux/ and run `make olddefconfig`.

  Use the same command, if your distribution or somebody else already tailored your running kernel to your or your hardware's needs: the make target 'olddefconfig' will then try to use that kernel's .config as base.

  Using this make target is fine for everybody else, too -- but you often can save a lot of time by using this command instead:

```
yes "" | make localmodconfig
```

  This will try to pick your distribution's kernel as base, but then disable modules for any features apparently superfluous for your setup. This will reduce the compile time enormously, especially if you are running an universal kernel from a commodity Linux distribution.

  There is a catch: 'localmodconfig' is likely to disable kernel features you did not use since you booted your Linux -- like drivers for currently disconnected peripherals or a virtualization software not haven't used yet. You can reduce or nearly eliminate that risk with tricks the reference section outlines; but when building a kernel just for quick testing purposes it is often negligible if such features are missing. But you should keep that aspect in mind when using a kernel built with this make target, as it might be the reason why something you only use occasionally stopped working.

  [*details*]

- Check if you might want to or have to adjust some kernel configuration options:
- Evaluate how you want to handle debug symbols. Enable them, if you later might need to decode a stack trace found for example in a 'panic', 'Oops', 'warning', or 'BUG'; on the other hand disable them, if you are short on storage space or prefer a smaller kernel binary. See the reference section for details on how to do either. If neither applies, it will likely be fine to simply not bother with this. [*details*]
- Are you running Debian? Then to avoid known problems by performing additional adjustments explained in the reference section. [*details*].
- If you want to influence the other aspects of the configuration, do so now by using make targets like 'menuconfig' or 'xconfig'. [*details*].

- Build the image and the modules of your kernel:

```
make -j $(nproc --all)
```

  If you want your kernel packaged up as deb, rpm, or tar file, see the reference section for alternatives.

[*details*]

- Now install your kernel:

```
command -v installkernel && sudo make modules_install install
```

Often all left for you to do afterwards is a `reboot`, as many commodity Linux distributions will then create an initramfs (also known as initrd) and an entry for your kernel in your bootloader's configuration; but on some distributions you have to take care of these two steps manually for reasons the reference section explains.

On a few distributions like Arch Linux and its derivatives the above command does nothing at all; in that case you have to manually install your kernel, as outlined in the reference section.

If you are running a immutable Linux distribution, check its documentation and the web to find out how to install your own kernel there.

[*details*]

- To later build another kernel you need similar steps, but sometimes slightly different commands.

First, switch back into the sources tree:

```
cd ~/linux/
```

In case you want to build a version from a stable/longterm series you have not used yet (say 6.2.y), tell git to track it:

```
git remote set-branches --add origin linux-6.2.y
```

Now fetch the latest upstream changes; you again need to specify the earliest version you care about, as git otherwise might retrieve the entire commit history:

```
git fetch --shallow-exclude=v6.0 origin
```

Now switch to the version you are interested in -- but be aware the command used here will discard any modifications you performed, as they would conflict with the sources you want to checkout:

```
git checkout --force --detach origin/master
```

At this point you might want to patch the sources again or set/modify a build tag, as explained earlier. Afterwards adjust the build configuration to the new codebase using olddefconfig, which will now adjust the configuration file you prepared earlier using localmodconfig (~/linux/.config) for your next kernel:

```
# reminder: if you want to apply patches, do it at this point
# reminder: you might want to update your build tag at this point
make olddefconfig
```

Now build your kernel:

```
make -j $(nproc --all)
```

Afterwards install the kernel as outlined above:

```
command -v installkernel && sudo make modules_install install
```

[*details*]

- Your kernel is easy to remove later, as its parts are only stored in two places and clearly identifiable by the kernel's release name. Just ensure to not delete the kernel you are running, as that might render your system unbootable.

  Start by deleting the directory holding your kernel's modules, which is named after its release name -- '6.0.1-foobar' in the following example:

  ```
  sudo rm -rf /lib/modules/6.0.1-foobar
  ```

  Now try the following command, which on some distributions will delete all other kernel files installed while also removing the kernel's entry from the bootloader configuration:

  ```
  command -v kernel-install && sudo kernel-install -v remove 6.0.1-foobar
  ```

  If that command does not output anything or fails, see the reference section; do the same if any files named '*6.0.1-foobar*' remain in /boot/.

  [*details*]

Did you run into trouble following any of the above steps that is not cleared up by the reference section below? Or do you have ideas how to improve the text? Then please take a moment of your time and let the maintainer of this document know by email (Thorsten Leemhuis <linux@leemhuis.info>), ideally while CCing the Linux docs mailing list (linux-doc@vger.kernel.org). Such feedback is vital to improve this document further, which is in everybody's interest, as it will enable more people to master the task described here.

10.3 Reference section for the step-by-step guide

This section holds additional information for each of the steps in the above guide.

10.3.1 Prepare for emergencies

Create a fresh backup and put system repair and restore tools at hand [...]

Remember, you are dealing with computers, which sometimes do unexpected things -- especially if you fiddle with crucial parts like the kernel of an operating system. That's what you are about to do in this process. Hence, better prepare for something going sideways, even if that should not happen.

[*back to step-by-step guide*]

10.3.2 Dealing with techniques like Secure Boot

> *On platforms with 'Secure Boot' or similar techniques, prepare everything to ensure the system will permit your self-compiled kernel to boot later.* [...]

Many modern systems allow only certain operating systems to start; they thus by default will reject booting self-compiled kernels.

You ideally deal with this by making your platform trust your self-built kernels with the help of a certificate and signing. How to do that is not described here, as it requires various steps that would take the text too far away from its purpose; '*Kernel module signing facility*' and various web sides already explain this in more detail.

Temporarily disabling solutions like Secure Boot is another way to make your own Linux boot. On commodity x86 systems it is possible to do this in the BIOS Setup utility; the steps to do so are not described here, as they greatly vary between machines.

On mainstream x86 Linux distributions there is a third and universal option: disable all Secure Boot restrictions for your Linux environment. You can initiate this process by running `mokutil --disable-validation`; this will tell you to create a one-time password, which is safe to write down. Now restart; right after your BIOS performed all self-tests the bootloader Shim will show a blue box with a message 'Press any key to perform MOK management'. Hit some key before the countdown exposes. This will open a menu and choose 'Change Secure Boot state' there. Shim's 'MokManager' will now ask you to enter three randomly chosen characters from the one-time password specified earlier. Once you provided them, confirm that you really want to disable the validation. Afterwards, permit MokManager to reboot the machine.

[*back to step-by-step guide*]

10.3.3 Install build requirements

> *Install all software required to build a Linux kernel.* [...]

The kernel is pretty stand-alone, but besides tools like the compiler you will sometimes need a few libraries to build one. How to install everything needed depends on your Linux distribution and the configuration of the kernel you are about to build.

Here are a few examples what you typically need on some mainstream distributions:

- Debian, Ubuntu, and derivatives:

```
sudo apt install bc binutils bison dwarves flex gcc git make openssl \
  pahole perl-base libssl-dev libelf-dev
```

- Fedora and derivatives:

```
sudo dnf install binutils /usr/include/{libelf.h,openssl/pkcs7.h} \
  /usr/bin/{bc,bison,flex,gcc,git,openssl,make,perl,pahole}
```

- openSUSE and derivatives:

```
sudo zypper install bc binutils bison dwarves flex gcc git make perl-base \
  openssl openssl-devel libelf-dev
```

In case you wonder why these lists include openssl and its development headers: they are needed for the Secure Boot support, which many distributions enable in their kernel configuration for x86 machines.

Sometimes you will need tools for compression formats like bzip2, gzip, lz4, lzma, lzo, xz, or zstd as well.

You might need additional libraries and their development headers in case you perform tasks not covered in this guide. For example, zlib will be needed when building kernel tools from the tools/ directory; adjusting the build configuration with make targets like 'menuconfig' or 'xconfig' will require development headers for ncurses or Qt5.

[*back to step-by-step guide*]

10.3.4 Space requirements

> *Ensure to have enough free space for building and installing Linux.* [...]

The numbers mentioned are rough estimates with a big extra charge to be on the safe side, so often you will need less.

If you have space constraints, remember to read the reference section when you reach the *section about configuration adjustments*', as ensuring debug symbols are disabled will reduce the consumed disk space by quite a few gigabytes.

[*back to step-by-step guide*]

10.3.5 Download the sources

> *Retrieve the sources of the Linux version you intend to build.* [...]

The step-by-step guide outlines how to retrieve Linux' sources using a shallow git clone. There is *more to tell about this method* and two alternate ways worth describing: *packaged archives* and *a full git clone*. And the aspects '*wouldn't it be wiser to use a proper pre-release than the latest mainline code*' and '*how to get an even fresher mainline codebase*' need elaboration, too.

Note, to keep things simple the commands used in this guide store the build artifacts in the source tree. If you prefer to separate them, simply add something like `O=~/linux-builddir/` to all make calls; also adjust the path in all commands that add files or modify any generated (like your '.config').

[*back to step-by-step guide*]

Noteworthy characteristics of shallow clones

The step-by-step guide uses a shallow clone, as it is the best solution for most of this document's target audience. There are a few aspects of this approach worth mentioning:

- This document in most places uses `git fetch` with `--shallow-exclude=` to specify the earliest version you care about (or to be precise: its git tag). You alternatively can use the parameter `--shallow-since=` to specify an absolute (say `'2023-07-15'`) or relative (`'12 months'`) date to define the depth of the history you want to download. As a second alternative, you can also specify a certain depth explicitly with a parameter like `--depth=1`, unless you add branches for stable/longterm kernels.

- When running `git fetch`, remember to always specify the oldest version, the time you care about, or an explicit depth as shown in the step-by-step guide. Otherwise you will risk downloading nearly the entire git history, which will consume quite a bit of time and bandwidth while also stressing the servers.

  Note, you do not have to use the same version or date all the time. But when you change it over time, git will deepen or flatten the history to the specified point. That allows you to retrieve versions you initially thought you did not need -- or it will discard the sources of older versions, for example in case you want to free up some disk space. The latter will happen automatically when using `--shallow-since=` or `--depth=`.

- Be warned, when deepening your clone you might encounter an error like 'fatal: error in object: unshallow cafecaca0c0dacafecaca0c0dacafecaca0c0da'. In that case run `git repack -d` and try again``

- In case you want to revert changes from a certain version (say Linux 6.3) or perform a bisection (v6.2..v6.3), better tell `git fetch` to retrieve objects up to three versions earlier (e.g. 6.0): `git describe` will then be able to describe most commits just like it would in a full git clone.

[*back to step-by-step guide*] [*back to section intro*]

Downloading the sources using a packages archive

People new to compiling Linux often assume downloading an archive via the front-page of https://kernel.org is the best approach to retrieve Linux' sources. It actually can be, if you are certain to build just one particular kernel version without changing any code. Thing is: you might be sure this will be the case, but in practice it often will turn out to be a wrong assumption.

That's because when reporting or debugging an issue developers will often ask to give another version a try. They also might suggest temporarily undoing a commit with `git revert` or might provide various patches to try. Sometimes reporters will also be asked to use `git bisect` to find the change causing a problem. These things rely on git or are a lot easier and quicker to handle with it.

A shallow clone also does not add any significant overhead. For example, when you use `git clone --depth=1` to create a shallow clone of the latest mainline codebase git will only retrieve a little more data than downloading the latest mainline pre-release (aka 'rc') via the front-page of kernel.org would.

A shallow clone therefore is often the better choice. If you nevertheless want to use a packaged source archive, download one via kernel.org; afterwards extract its content to some directory and change to the subdirectory created during extraction. The rest of the step-by-step guide will work just fine, apart from things that rely on git -- but this mainly concerns the section on successive builds of other versions.

[*back to step-by-step guide*] [*back to section intro*]

Downloading the sources using a full git clone

If downloading and storing a lot of data (~4,4 Gigabyte as of early 2023) is nothing that bothers you, instead of a shallow clone perform a full git clone instead. You then will avoid the specialties mentioned above and will have all versions and individual commits at hand at any time:

```
curl -L \
  https://git.kernel.org/pub/scm/linux/kernel/git/stable/linux.git/clone.
↪bundle \
  -o linux-stable.git.bundle
git clone linux-stable.git.bundle ~/linux/
rm linux-stable.git.bundle
cd ~/linux/
git remote set-url origin \
  https://git.kernel.org/pub/scm/linux/kernel/git/stable/linux.git
git fetch origin
git checkout --detach origin/master
```

[*back to step-by-step guide*] [*back to section intro*]

Proper pre-releases (RCs) vs. latest mainline

When cloning the sources using git and checking out origin/master, you often will retrieve a codebase that is somewhere between the latest and the next release or pre-release. This almost always is the code you want when giving mainline a shot: pre-releases like v6.1-rc5 are in no way special, as they do not get any significant extra testing before being published.

There is one exception: you might want to stick to the latest mainline release (say v6.1) before its successor's first pre-release (v6.2-rc1) is out. That is because compiler errors and other problems are more likely to occur during this time, as mainline then is in its 'merge window': a usually two week long phase, in which the bulk of the changes for the next release is merged.

[*back to step-by-step guide*] [*back to section intro*]

Avoiding the mainline lag

The explanations for both the shallow clone and the full clone both retrieve the code from the Linux stable git repository. That makes things simpler for this document's audience, as it allows easy access to both mainline and stable/longterm releases. This approach has just one downside:

Changes merged into the mainline repository are only synced to the master branch of the Linux stable repository every few hours. This lag most of the time is not something to worry about; but in case you really need the latest code, just add the mainline repo as additional remote and checkout the code from there:

```
git remote add mainline \
  https://git.kernel.org/pub/scm/linux/kernel/git/torvalds/linux.git
git fetch mainline
git checkout --detach mainline/master
```

When doing this with a shallow clone, remember to call `git fetch` with one of the parameters described earlier to limit the depth.

[*back to step-by-step guide*] [*back to section intro*]

10.3.6 Patch the sources (optional)

> *In case you want to apply a kernel patch, do so now.* [...]

This is the point where you might want to patch your kernel -- for example when a developer proposed a fix and asked you to check if it helps. The step-by-step guide already explains everything crucial here.

[*back to step-by-step guide*]

10.3.7 Tagging this kernel build (optional, often wise)

> *If you patched your kernel or already have that kernel version installed, better tag your kernel by extending its release name:* [...]

Tagging your kernel will help avoid confusion later, especially when you patched your kernel. Adding an individual tag will also ensure the kernel's image and its modules are installed in parallel to any existing kernels.

There are various ways to add such a tag. The step-by-step guide realizes one by creating a 'localversion' file in your build directory from which the kernel build scripts will automatically pick up the tag. You can later change that file to use a different tag in subsequent builds or simply remove that file to dump the tag.

[*back to step-by-step guide*]

10.3.8 Define the build configuration for your kernel

> *Create the build configuration for your kernel based on an existing configuration.* [...]

There are various aspects for this steps that require a more careful explanation:

Pitfalls when using another configuration file as base

Make targets like localmodconfig and olddefconfig share a few common snares you want to be aware of:

- These targets will reuse a kernel build configuration in your build directory (e.g. '~/linux/.config'), if one exists. In case you want to start from scratch you thus need to delete it.
- The make targets try to find the configuration for your running kernel automatically, but might choose poorly. A line like '# using defaults found in /boot/config-6.0.7-250.fc36.x86_64' or 'using config: '/boot/config-6.0.7-250.fc36.x86_64' tells you which file they picked. If that is not the intended one, simply store it as '~/linux/.config' before using these make targets.

- Unexpected things might happen if you try to use a config file prepared for one kernel (say v6.0) on an older generation (say v5.15). In that case you might want to use a configuration as base which your distribution utilized when they used that or an slightly older kernel version.

Influencing the configuration

The make target olddefconfig and the `yes "" |` used when utilizing localmodconfig will set any undefined build options to their default value. This among others will disable many kernel features that were introduced after your base kernel was released.

If you want to set these configurations options manually, use `oldconfig` instead of `olddefconfig` or omit the `yes "" |` when utilizing localmodconfig. Then for each undefined configuration option you will be asked how to proceed. In case you are unsure what to answer, simply hit 'enter' to apply the default value.

Big pitfall when using localmodconfig

As explained briefly in the step-by-step guide already: with localmodconfig it can easily happen that your self-built kernel will lack modules for tasks you did not perform before utilizing this make target. That's because those tasks require kernel modules that are normally autoloaded when you perform that task for the first time; if you didn't perform that task at least once before using localmodonfig, the latter will thus assume these modules are superfluous and disable them.

You can try to avoid this by performing typical tasks that often will autoload additional kernel modules: start a VM, establish VPN connections, loop-mount a CD/DVD ISO, mount network shares (CIFS, NFS, ...), and connect all external devices (2FA keys, headsets, webcams, ...) as well as storage devices with file systems you otherwise do not utilize (btrfs, ext4, FAT, NTFS, XFS, ...). But it is hard to think of everything that might be needed -- even kernel developers often forget one thing or another at this point.

Do not let that risk bother you, especially when compiling a kernel only for testing purposes: everything typically crucial will be there. And if you forget something important you can turn on a missing feature later and quickly run the commands to compile and install a better kernel.

But if you plan to build and use self-built kernels regularly, you might want to reduce the risk by recording which modules your system loads over the course of a few weeks. You can automate this with modprobed-db. Afterwards use `LSMOD=<path>` to point localmodconfig to the list of modules modprobed-db noticed being used:

```
yes "" | make LSMOD="${HOME}"/.config/modprobed.db localmodconfig
```

Remote building with localmodconfig

If you want to use localmodconfig to build a kernel for another machine, run `lsmod > lsmod_foo-machine` on it and transfer that file to your build host. Now point the build scripts to the file like this: `yes "" | make LSMOD=~/lsmod_foo-machine localmodconfig`. Note, in this case you likely want to copy a base kernel configuration from the other machine over as well and place it as .config in your build directory.

[*back to step-by-step guide*]

10.3.9 Adjust build configuration

Check if you might want to or have to adjust some kernel configuration options:

Depending on your needs you at this point might want or have to adjust some kernel configuration options.

Debug symbols

Evaluate how you want to handle debug symbols. [...]

Most users do not need to care about this, it's often fine to leave everything as it is; but you should take a closer look at this, if you might need to decode a stack trace or want to reduce space consumption.

Having debug symbols available can be important when your kernel throws a 'panic', 'Oops', 'warning', or 'BUG' later when running, as then you will be able to find the exact place where the problem occurred in the code. But collecting and embedding the needed debug information takes time and consumes quite a bit of space: in late 2022 the build artifacts for a typical x86 kernel configured with localmodconfig consumed around 5 Gigabyte of space with debug symbols, but less than 1 when they were disabled. The resulting kernel image and the modules are bigger as well, which increases load times.

Hence, if you want a small kernel and are unlikely to decode a stack trace later, you might want to disable debug symbols to avoid above downsides:

```
./scripts/config --file .config -d DEBUG_INFO \
  -d DEBUG_INFO_DWARF_TOOLCHAIN_DEFAULT -d DEBUG_INFO_DWARF4 \
  -d DEBUG_INFO_DWARF5 -e CONFIG_DEBUG_INFO_NONE
make olddefconfig
```

You on the other hand definitely want to enable them, if there is a decent chance that you need to decode a stack trace later (as explained by 'Decode failure messages' in *Tainted kernels* in more detail):

```
./scripts/config --file .config -d DEBUG_INFO_NONE -e DEBUG_KERNEL
  -e DEBUG_INFO -e DEBUG_INFO_DWARF_TOOLCHAIN_DEFAULT -e KALLSYMS -e KALLSYMS_
↪ALL
make olddefconfig
```

Note, many mainstream distributions enable debug symbols in their kernel configurations -- make targets like localmodconfig and olddefconfig thus will often pick that setting up.

[*back to step-by-step guide*]

Distro specific adjustments

Are you running [...]

The following sections help you to avoid build problems that are known to occur when following this guide on a few commodity distributions.

Debian:

- Remove a stale reference to a certificate file that would cause your build to fail:

```
./scripts/config --file .config --set-str SYSTEM_TRUSTED_KEYS ''
```

  Alternatively, download the needed certificate and make that configuration option point to it, as the Debian handbook explains in more detail -- or generate your own, as explained in *Kernel module signing facility*.

[*back to step-by-step guide*]

Individual adjustments

If you want to influence the other aspects of the configuration, do so now [...]

You at this point can use a command like `make menuconfig` to enable or disable certain features using a text-based user interface; to use a graphical configuration utilize, use the make target `xconfig` or `gconfig` instead. All of them require development libraries from toolkits they are based on (ncurses, Qt5, Gtk2); an error message will tell you if something required is missing.

[*back to step-by-step guide*]

10.3.10 Build your kernel

Build the image and the modules of your kernel [...]

A lot can go wrong at this stage, but the instructions below will help you help yourself. Another subsection explains how to directly package your kernel up as deb, rpm or tar file.

Dealing with build errors

When a build error occurs, it might be caused by some aspect of your machine's setup that often can be fixed quickly; other times though the problem lies in the code and can only be fixed by a developer. A close examination of the failure messages coupled with some research on the internet will often tell you which of the two it is. To perform such a investigation, restart the build process like this:

```
make V=1
```

The `V=1` activates verbose output, which might be needed to see the actual error. To make it easier to spot, this command also omits the `-j $(nproc --all)` used earlier to utilize every CPU core in the system for the job -- but this parallelism also results in some clutter when failures occur.

After a few seconds the build process should run into the error again. Now try to find the most crucial line describing the problem. Then search the internet for the most important and non-generic section of that line (say 4 to 8 words); avoid or remove anything that looks remotely system-specific, like your username or local path names like `/home/username/linux/`. First try your regular internet search engine with that string, afterwards search Linux kernel mailing lists via lore.kernel.org/all/.

This most of the time will find something that will explain what is wrong; quite often one of the hits will provide a solution for your problem, too. If you do not find anything that matches your problem, try again from a different angle by modifying your search terms or using another line from the error messages.

In the end, most trouble you are to run into has likely been encountered and reported by others already. That includes issues where the cause is not your system, but lies the code. If you run into one of those, you might thus find a solution (e.g. a patch) or workaround for your problem, too.

Package your kernel up

The step-by-step guide uses the default make targets (e.g. 'bzImage' and 'modules' on x86) to build the image and the modules of your kernel, which later steps of the guide then install. You instead can also directly build everything and directly package it up by using one of the following targets:

- `make -j $(nproc --all) bindeb-pkg` to generate a deb package
- `make -j $(nproc --all) binrpm-pkg` to generate a rpm package
- `make -j $(nproc --all) tarbz2-pkg` to generate a bz2 compressed tarball

This is just a selection of available make targets for this purpose, see `make help` for others. You can also use these targets after running `make -j $(nproc --all)`, as they will pick up everything already built.

If you employ the targets to generate deb or rpm packages, ignore the step-by-step guide's instructions on installing and removing your kernel; instead install and remove the packages using the package utility for the format (e.g. dpkg and rpm) or a package management utility build on top of them (apt, aptitude, dnf/yum, zypper, ...). Be aware that the packages generated using these two make targets are designed to work on various distributions utilizing those formats, they thus will sometimes behave differently than your distribution's kernel packages.

[*back to step-by-step guide*]

10.3.11 Install your kernel

> *Now install your kernel* [...]

What you need to do after executing the command in the step-by-step guide depends on the existence and the implementation of an `installkernel` executable. Many commodity Linux distributions ship such a kernel installer in `/sbin/` that does everything needed, hence there is nothing left for you except rebooting. But some distributions contain an installkernel that does only part of the job -- and a few lack it completely and leave all the work to you.

If `installkernel` is found, the kernel's build system will delegate the actual installation of your kernel's image and related files to this executable. On almost all Linux distributions it will

store the image as '/boot/vmlinuz- <your kernel's release name>' and put a 'System.map-<your kernel's release name>' alongside it. Your kernel will thus be installed in parallel to any existing ones, unless you already have one with exactly the same release name.

Installkernel on many distributions will afterwards generate an 'initramfs' (often also called 'initrd'), which commodity distributions rely on for booting; hence be sure to keep the order of the two make targets used in the step-by-step guide, as things will go sideways if you install your kernel's image before its modules. Often installkernel will then add your kernel to the bootloader configuration, too. You have to take care of one or both of these tasks yourself, if your distributions installkernel doesn't handle them.

A few distributions like Arch Linux and its derivatives totally lack an installkernel executable. On those just install the modules using the kernel's build system and then install the image and the System.map file manually:

```
sudo make modules_install
sudo install -m 0600 $(make -s image_name) /boot/vmlinuz-$(make -s␣
↪kernelrelease)
sudo install -m 0600 System.map /boot/System.map-$(make -s kernelrelease)
```

If your distribution boots with the help of an initramfs, now generate one for your kernel using the tools your distribution provides for this process. Afterwards add your kernel to your bootloader configuration and reboot.

[*back to step-by-step guide*]

10.3.12 Another round later

> *To later build another kernel you need similar, but sometimes slightly different commands* [...]

The process to build later kernels is similar, but at some points slightly different. You for example do not want to use 'localmodconfig' for succeeding kernel builds, as you already created a trimmed down configuration you want to use from now on. Hence instead just use `oldconfig` or `olddefconfig` to adjust your build configurations to the needs of the kernel version you are about to build.

If you created a shallow-clone with git, remember what the *section that explained the setup described in more detail*: you need to use a slightly different `git fetch` command and when switching to another series need to add an additional remote branch.

[*back to step-by-step guide*]

10.3.13 Uninstall the kernel later

> *All parts of your installed kernel are identifiable by its release name and thus easy to remove later.* [...]

Do not worry installing your kernel manually and thus bypassing your distribution's packaging system will totally mess up your machine: all parts of your kernel are easy to remove later, as files are stored in two places only and normally identifiable by the kernel's release name.

One of the two places is a directory in /lib/modules/, which holds the modules for each installed kernel. This directory is named after the kernel's release name; hence, to remove all modules

for one of your kernels, simply remove its modules directory in /lib/modules/.

The other place is /boot/, where typically one to five files will be placed during installation of a kernel. All of them usually contain the release name in their file name, but how many files and their name depends somewhat on your distribution's installkernel executable (*see above*) and its initramfs generator. On some distributions the `kernel-install` command mentioned in the step-by-step guide will remove all of these files for you -- and the entry for your kernel in the bootloader configuration at the same time, too. On others you have to take care of these steps yourself. The following command should interactively remove the two main files of a kernel with the release name '6.0.1-foobar':

```
rm -i /boot/{System.map,vmlinuz}-6.0.1-foobar
```

Now remove the belonging initramfs, which often will be called something like `/boot/initramfs-6.0.1-foobar.img` or `/boot/initrd.img-6.0.1-foobar`. Afterwards check for other files in /boot/ that have '6.0.1-foobar' in their name and delete them as well. Now remove the kernel from your bootloader's configuration.

Note, be very careful with wildcards like '*' when deleting files or directories for kernels manually: you might accidentally remove files of a 6.0.11 kernel when all you want is to remove 6.0 or 6.0.1.

[*back to step-by-step guide*]

10.4 FAQ

10.4.1 Why does this 'how-to' not work on my system?

As initially stated, this guide is 'designed to cover everything typically needed [to build a kernel] on mainstream Linux distributions running on commodity PC or server hardware'. The outlined approach despite this should work on many other setups as well. But trying to cover every possible use-case in one guide would defeat its purpose, as without such a focus you would need dozens or hundreds of constructs along the lines of 'in case you are having <insert machine or distro>, you at this point have to do <this and that> <instead|additionally>'. Each of which would make the text longer, more complicated, and harder to follow.

That being said: this of course is a balancing act. Hence, if you think an additional use-case is worth describing, suggest it to the maintainers of this document, as *described above*.

CHAPTER

ELEVEN

BUG HUNTING

Kernel bug reports often come with a stack dump like the one below:

```

---[ end trace 6ebc60ef3981792f ]---
```

Such stack traces provide enough information to identify the line inside the Kernel's source code where the bug happened. Depending on the severity of the issue, it may also contain the

word **Oops**, as on this one:

```
BUG: unable to handle kernel NULL pointer dereference at   (null)
IP: [<c06969d4>] iret_exc+0x7d0/0xa59
*pdpt = 000000002258a001 *pde = 0000000000000000
Oops: 0002 [#1] PREEMPT SMP
...
```

Despite being an **Oops** or some other sort of stack trace, the offended line is usually required to identify and handle the bug. Along this chapter, we'll refer to ”Oops” for all kinds of stack traces that need to be analyzed.

If the kernel is compiled with `CONFIG_DEBUG_INFO`, you can enhance the quality of the stack trace by using file:*scripts/decode_stacktrace.sh*.

11.1 Modules linked in

Modules that are tainted or are being loaded or unloaded are marked with ”(...)”, where the taint flags are described in file:Tainted kernels, ”being loaded” is annotated with ”+”, and ”being unloaded” is annotated with ”-”.

11.2 Where is the Oops message is located?

Normally the Oops text is read from the kernel buffers by klogd and handed to `syslogd` which writes it to a syslog file, typically `/var/log/messages` (depends on `/etc/syslog.conf`). On systems with systemd, it may also be stored by the `journald` daemon, and accessed by running `journalctl` command.

Sometimes `klogd` dies, in which case you can run `dmesg > file` to read the data from the kernel buffers and save it. Or you can `cat /proc/kmsg > file`, however you have to break in to stop the transfer, since `kmsg` is a ”never ending file”.

If the machine has crashed so badly that you cannot enter commands or the disk is not available then you have three options:

(1) Hand copy the text from the screen and type it in after the machine has restarted. Messy but it is the only option if you have not planned for a crash. Alternatively, you can take a picture of the screen with a digital camera - not nice, but better than nothing. If the messages scroll off the top of the console, you may find that booting with a higher resolution (e.g., `vga=791`) will allow you to read more of the text. (Caveat: This needs `vesafb`, so won't help for 'early' oopses.)

(2) Boot with a serial console (see *Documentation/admin-guide/serial-console.rst*), run a null modem to a second machine and capture the output there using your favourite communication program. Minicom works well.

(3) Use Kdump (see *Documentation for Kdump - The kexec-based Crash Dumping Solution*), extract the kernel ring buffer from old memory with using dmesg gdbmacro in Documentation/admin-guide/kdump/gdbmacros.txt.

11.3 Finding the bug's location

Reporting a bug works best if you point the location of the bug at the Kernel source file. There are two methods for doing that. Usually, using `gdb` is easier, but the Kernel should be pre-compiled with debug info.

11.3.1 gdb

The GNU debugger (`gdb`) is the best way to figure out the exact file and line number of the OOPS from the `vmlinux` file.

The usage of gdb works best on a kernel compiled with `CONFIG_DEBUG_INFO`. This can be set by running:

```
$ ./scripts/config -d COMPILE_TEST -e DEBUG_KERNEL -e DEBUG_INFO
```

On a kernel compiled with `CONFIG_DEBUG_INFO`, you can simply copy the EIP value from the OOPS:

```
EIP:    0060:[<c021e50e>]    Not tainted VLI
```

And use GDB to translate that to human-readable form:

```
$ gdb vmlinux
(gdb) l *0xc021e50e
```

If you don't have `CONFIG_DEBUG_INFO` enabled, you use the function offset from the OOPS:

```
EIP is at vt_ioctl+0xda8/0x1482
```

And recompile the kernel with `CONFIG_DEBUG_INFO` enabled:

```
$ ./scripts/config -d COMPILE_TEST -e DEBUG_KERNEL -e DEBUG_INFO
$ make vmlinux
$ gdb vmlinux
(gdb) l *vt_ioctl+0xda8
0x1888 is in vt_ioctl (drivers/tty/vt/vt_ioctl.c:293).
288   {
289           struct vc_data *vc = NULL;
290           int ret = 0;
291
292           console_lock();
293           if (VT_BUSY(vc_num))
294                   ret = -EBUSY;
295           else if (vc_num)
296                   vc = vc_deallocate(vc_num);
297           console_unlock();
```

or, if you want to be more verbose:

```
(gdb) p vt_ioctl
$1 = {int (struct tty_struct *, unsigned int, unsigned long)} 0xae0 <vt_ioctl>
(gdb) l *0xae0+0xda8
```

You could, instead, use the object file:

```
$ make drivers/tty/
$ gdb drivers/tty/vt/vt_ioctl.o
(gdb) l *vt_ioctl+0xda8
```

If you have a call trace, such as:

```
Call Trace:
 [<ffffffff8802c8e9>] :jbd:log_wait_commit+0xa3/0xf5
 [<ffffffff810482d9>] autoremove_wake_function+0x0/0x2e
 [<ffffffff8802770b>] :jbd:journal_stop+0x1be/0x1ee
 ...
```

this shows the problem likely is in the :jbd: module. You can load that module in gdb and list the relevant code:

```
$ gdb fs/jbd/jbd.ko
(gdb) l *log_wait_commit+0xa3
```

Note: You can also do the same for any function call at the stack trace, like this one:

```
[<f80bc9ca>] ? dvb_usb_adapter_frontend_exit+0x3a/0x70 [dvb_usb]
```

The position where the above call happened can be seen with:

```
$ gdb drivers/media/usb/dvb-usb/dvb-usb.o
(gdb) l *dvb_usb_adapter_frontend_exit+0x3a
```

11.3.2 objdump

To debug a kernel, use objdump and look for the hex offset from the crash output to find the valid line of code/assembler. Without debug symbols, you will see the assembler code for the routine shown, but if your kernel has debug symbols the C code will also be available. (Debug symbols can be enabled in the kernel hacking menu of the menu configuration.) For example:

```
$ objdump -r -S -l --disassemble net/dccp/ipv4.o
```

Note: You need to be at the top level of the kernel tree for this to pick up your C files.

If you don't have access to the source code you can still debug some crash dumps using the following method (example crash dump output as shown by Dave Miller):

```
EIP is at  +0x14/0x4c0
 ...
Code: 44 24 04 e8 6f 05 00 00 e9 e8 fe ff ff 8d 76 00 8d bc 27 00 00
00 00 55 57  56 53 81 ec bc 00 00 00 8b ac 24 d0 00 00 00 8b 5d 08
<8b> 83 3c 01 00 00 89 44  24 14 8b 45 28 85 c0 89 44 24 18 0f 85

Put the bytes into a "foo.s" file like this:

       .text
       .globl foo
foo:
       .byte  .... /* bytes from Code: part of OOPS dump */

Compile it with "gcc -c -o foo.o foo.s" then look at the output of
"objdump --disassemble foo.o".

Output:

ip_queue_xmit:
    push       %ebp
    push       %edi
    push       %esi
    push       %ebx
    sub        $0xbc, %esp
    mov        0xd0(%esp), %ebp        ! %ebp = arg0 (skb)
    mov        0x8(%ebp), %ebx         ! %ebx = skb->sk
    mov        0x13c(%ebx), %eax       ! %eax = inet_sk(sk)->opt
```

file:*scripts/decodecode* can be used to automate most of this, depending on what CPU architecture is being debugged.

11.4 Reporting the bug

Once you find where the bug happened, by inspecting its location, you could either try to fix it yourself or report it upstream.

In order to report it upstream, you should identify the mailing list used for the development of the affected code. This can be done by using the `get_maintainer.pl` script.

For example, if you find a bug at the gspca's sonixj.c file, you can get its maintainers with:

```
$ ./scripts/get_maintainer.pl -f drivers/media/usb/gspca/sonixj.c
Hans Verkuil <hverkuil@xs4all.nl> (odd fixer:GSPCA USB WEBCAM DRIVER,commit_
↪signer:1/1=100%)
Mauro Carvalho Chehab <mchehab@kernel.org> (maintainer:MEDIA INPUT␣
↪INFRASTRUCTURE (V4L/DVB),commit_signer:1/1=100%)
Tejun Heo <tj@kernel.org> (commit_signer:1/1=100%)
Bhaktipriya Shridhar <bhaktipriya96@gmail.com> (commit_signer:1/1=100%,
↪authored:1/1=100%,added_lines:4/4=100%,removed_lines:9/9=100%)
linux-media@vger.kernel.org (open list:GSPCA USB WEBCAM DRIVER)
```

```
linux-kernel@vger.kernel.org (open list)
```

Please notice that it will point to:

- The last developers that touched the source code (if this is done inside a git tree). On the above example, Tejun and Bhaktipriya (in this specific case, none really involved on the development of this file);
- The driver maintainer (Hans Verkuil);
- The subsystem maintainer (Mauro Carvalho Chehab);
- The driver and/or subsystem mailing list (linux-media@vger.kernel.org);
- the Linux Kernel mailing list (linux-kernel@vger.kernel.org).

Usually, the fastest way to have your bug fixed is to report it to mailing list used for the development of the code (linux-media ML) copying the driver maintainer (Hans).

If you are totally stumped as to whom to send the report, and `get_maintainer.pl` didn't provide you anything useful, send it to linux-kernel@vger.kernel.org.

Thanks for your help in making Linux as stable as humanly possible.

11.5 Fixing the bug

If you know programming, you could help us by not only reporting the bug, but also providing us with a solution. After all, open source is about sharing what you do and don't you want to be recognised for your genius?

If you decide to take this way, once you have worked out a fix please submit it upstream.

Please do read Documentation/process/submitting-patches.rst though to help your code get accepted.

11.6 Notes on Oops tracing with `klogd`

In order to help Linus and the other kernel developers there has been substantial support incorporated into `klogd` for processing protection faults. In order to have full support for address resolution at least version 1.3-pl3 of the `sysklogd` package should be used.

When a protection fault occurs the `klogd` daemon automatically translates important addresses in the kernel log messages to their symbolic equivalents. This translated kernel message is then forwarded through whatever reporting mechanism `klogd` is using. The protection fault message can be simply cut out of the message files and forwarded to the kernel developers.

Two types of address resolution are performed by `klogd`. The first is static translation and the second is dynamic translation. Static translation uses the System.map file. In order to do static translation the `klogd` daemon must be able to find a system map file at daemon initialization time. See the klogd man page for information on how `klogd` searches for map files.

Dynamic address translation is important when kernel loadable modules are being used. Since memory for kernel modules is allocated from the kernel's dynamic memory pools there are no fixed locations for either the start of the module or for functions and symbols in the module.

The kernel supports system calls which allow a program to determine which modules are loaded and their location in memory. Using these system calls the klogd daemon builds a symbol table which can be used to debug a protection fault which occurs in a loadable kernel module.

At the very minimum klogd will provide the name of the module which generated the protection fault. There may be additional symbolic information available if the developer of the loadable module chose to export symbol information from the module.

Since the kernel module environment can be dynamic there must be a mechanism for notifying the `klogd` daemon when a change in module environment occurs. There are command line options available which allow klogd to signal the currently executing daemon that symbol information should be refreshed. See the `klogd` manual page for more information.

A patch is included with the sysklogd distribution which modifies the `modules-2.0.0` package to automatically signal klogd whenever a module is loaded or unloaded. Applying this patch provides essentially seamless support for debugging protection faults which occur with kernel loadable modules.

The following is an example of a protection fault in a loadable module processed by `klogd`:

```

CHAPTER

TWELVE

BISECTING A BUG

Last updated: 28 October 2016

12.1 Introduction

Always try the latest kernel from kernel.org and build from source. If you are not confident in doing that please report the bug to your distribution vendor instead of to a kernel developer.

Finding bugs is not always easy. Have a go though. If you can't find it don't give up. Report as much as you have found to the relevant maintainer. See MAINTAINERS for who that is for the subsystem you have worked on.

Before you submit a bug report read '*Reporting issues*'.

12.2 Devices not appearing

Often this is caused by udev/systemd. Check that first before blaming it on the kernel.

12.3 Finding patch that caused a bug

Using the provided tools with `git` makes finding bugs easy provided the bug is reproducible.

Steps to do it:

- build the Kernel from its git source
- start bisect with[1]:

```
$ git bisect start
```

- mark the broken changeset with:

```
$ git bisect bad [commit]
```

- mark a changeset where the code is known to work with:

```
$ git bisect good [commit]
```

[1] You can, optionally, provide both good and bad arguments at git start with `git bisect start [BAD] [GOOD]`

- rebuild the Kernel and test
- interact with git bisect by using either:

```
$ git bisect good
```

  or:

```
$ git bisect bad
```

  depending if the bug happened on the changeset you're testing
- After some interactions, git bisect will give you the changeset that likely caused the bug.
- For example, if you know that the current version is bad, and version 4.8 is good, you could do:

```
$ git bisect start
$ git bisect bad                 # Current version is bad
$ git bisect good v4.8
```

For further references, please read:

- The man page for `git-bisect`
- Fighting regressions with git bisect
- Fully automated bisecting with "git bisect run"
- Using Git bisect to figure out when brokenness was introduced

CHAPTER

THIRTEEN

TAINTED KERNELS

The kernel will mark itself as 'tainted' when something occurs that might be relevant later when investigating problems. Don't worry too much about this, most of the time it's not a problem to run a tainted kernel; the information is mainly of interest once someone wants to investigate some problem, as its real cause might be the event that got the kernel tainted. That's why bug reports from tainted kernels will often be ignored by developers, hence try to reproduce problems with an untainted kernel.

Note the kernel will remain tainted even after you undo what caused the taint (i.e. unload a proprietary kernel module), to indicate the kernel remains not trustworthy. That's also why the kernel will print the tainted state when it notices an internal problem (a 'kernel bug'), a recoverable error ('kernel oops') or a non-recoverable error ('kernel panic') and writes debug information about this to the logs `dmesg` outputs. It's also possible to check the tainted state at runtime through a file in `/proc/`.

13.1 Tainted flag in bugs, oops or panics messages

You find the tainted state near the top in a line starting with 'CPU:'; if or why the kernel was tainted is shown after the Process ID ('PID:') and a shortened name of the command ('Comm:') that triggered the event:

```
BUG: unable to handle kernel NULL pointer dereference at 0000000000000000
Oops: 0002 [#1] SMP PTI
CPU: 0 PID: 4424 Comm: insmod Tainted: P        W  O      4.20.0-0.rc6.fc30 #1
Hardware name: Red Hat KVM, BIOS 0.5.1 01/01/2011
RIP: 0010:my_oops_init+0x13/0x1000 [kpanic]
[...]
```

You'll find a 'Not tainted: ' there if the kernel was not tainted at the time of the event; if it was, then it will print 'Tainted: ' and characters either letters or blanks. In above example it looks like this:

```
Tainted: P        W  O
```

The meaning of those characters is explained in the table below. In this case the kernel got tainted earlier because a proprietary Module (`P`) was loaded, a warning occurred (`W`), and an externally-built module was loaded (`O`). To decode other letters use the table below.

13.2 Decoding tainted state at runtime

At runtime, you can query the tainted state by reading `cat /proc/sys/kernel/tainted`. If that returns `0`, the kernel is not tainted; any other number indicates the reasons why it is. The easiest way to decode that number is the script `tools/debugging/kernel-chktaint`, which your distribution might ship as part of a package called `linux-tools` or `kernel-tools`; if it doesn't you can download the script from git.kernel.org and execute it with `sh kernel-chktaint`, which would print something like this on the machine that had the statements in the logs that were quoted earlier:

```
Kernel is Tainted for following reasons:
 * Proprietary module was loaded (#0)
 * Kernel issued warning (#9)
 * Externally-built ('out-of-tree') module was loaded  (#12)
See Documentation/admin-guide/tainted-kernels.rst in the Linux kernel or
 https://www.kernel.org/doc/html/latest/admin-guide/tainted-kernels.html for
 a more details explanation of the various taint flags.
Raw taint value as int/string: 4609/'P       W  O     '
```

You can try to decode the number yourself. That's easy if there was only one reason that got your kernel tainted, as in this case you can find the number with the table below. If there were multiple reasons you need to decode the number, as it is a bitfield, where each bit indicates the absence or presence of a particular type of taint. It's best to leave that to the aforementioned script, but if you need something quick you can use this shell command to check which bits are set:

```
$ for i in $(seq 18); do echo $(($i-1)) $(($(cat /proc/sys/kernel/tainted)>>(
↪$i-1)&1));done
```

13.3 Table for decoding tainted state

Bit	Log	Number	Reason that got the kernel tainted
0	G/P	1	proprietary module was loaded
1	_/F	2	module was force loaded
2	_/S	4	kernel running on an out of specification system
3	_/R	8	module was force unloaded
4	_/M	16	processor reported a Machine Check Exception (MCE)
5	_/B	32	bad page referenced or some unexpected page flags
6	_/U	64	taint requested by userspace application
7	_/D	128	kernel died recently, i.e. there was an OOPS or BUG
8	_/A	256	ACPI table overridden by user
9	_/W	512	kernel issued warning
10	_/C	1024	staging driver was loaded
11	_/I	2048	workaround for bug in platform firmware applied
12	_/O	4096	externally-built (”out-of-tree”) module was loaded
13	_/E	8192	unsigned module was loaded
14	_/L	16384	soft lockup occurred
15	_/K	32768	kernel has been live patched
16	_/X	65536	auxiliary taint, defined for and used by distros
17	_/T	131072	kernel was built with the struct randomization plugin
18	_/N	262144	an in-kernel test has been run

Note: The character _ is representing a blank in this table to make reading easier.

13.4 More detailed explanation for tainting

0) `G` if all modules loaded have a GPL or compatible license, `P` if any proprietary module has been loaded. Modules without a MODULE_LICENSE or with a MODULE_LICENSE that is not recognised by insmod as GPL compatible are assumed to be proprietary.

1) `F` if any module was force loaded by `insmod -f`, `' '` if all modules were loaded normally.

2) `S` if the kernel is running on a processor or system that is out of specification: hardware has been put into an unsupported configuration, therefore proper execution cannot be guaranteed. Kernel will be tainted if, for example:

   - on x86: PAE is forced through forcepae on intel CPUs (such as Pentium M) which do not report PAE but may have a functional implementation, an SMP kernel is running on non officially capable SMP Athlon CPUs, MSRs are being poked at from userspace.
   - on arm: kernel running on certain CPUs (such as Keystone 2) without having certain kernel features enabled.
   - on arm64: there are mismatched hardware features between CPUs, the bootloader has booted CPUs in different modes.
   - certain drivers are being used on non supported architectures (such as scsi/snic on something else than x86_64, scsi/ips on non x86/x86_64/itanium, have broken firmware settings for the irqchip/irq-gic on arm64 ...).

- x86/x86_64: Microcode late loading is dangerous and will result in tainting the kernel. It requires that all CPUs rendezvous to make sure the update happens when the system is as quiescent as possible. However, a higher priority MCE/SMI/NMI can move control flow away from that rendezvous and interrupt the update, which can be detrimental to the machine.

3) `R` if a module was force unloaded by `rmmod -f`, `' '` if all modules were unloaded normally.
4) `M` if any processor has reported a Machine Check Exception, `' '` if no Machine Check Exceptions have occurred.
5) `B` If a page-release function has found a bad page reference or some unexpected page flags. This indicates a hardware problem or a kernel bug; there should be other information in the log indicating why this tainting occurred.
6) `U` if a user or user application specifically requested that the Tainted flag be set, `' '` otherwise.
7) `D` if the kernel has died recently, i.e. there was an OOPS or BUG.
8) `A` if an ACPI table has been overridden.
9) `W` if a warning has previously been issued by the kernel. (Though some warnings may set more specific taint flags.)
10) `C` if a staging driver has been loaded.
11) `I` if the kernel is working around a severe bug in the platform firmware (BIOS or similar).
12) `O` if an externally-built (”out-of-tree”) module has been loaded.
13) `E` if an unsigned module has been loaded in a kernel supporting module signature.
14) `L` if a soft lockup has previously occurred on the system.
15) `K` if the kernel has been live patched.
16) `X` Auxiliary taint, defined for and used by Linux distributors.
17) `T` Kernel was build with the randstruct plugin, which can intentionally produce extremely unusual kernel structure layouts (even performance pathological ones), which is important to know when debugging. Set at build time.

CHAPTER

FOURTEEN

RAMOOPS OOPS/PANIC LOGGER

Sergiu Iordache <sergiu@chromium.org>

Updated: 10 Feb 2021

14.1 Introduction

Ramoops is an oops/panic logger that writes its logs to RAM before the system crashes. It works by logging oopses and panics in a circular buffer. Ramoops needs a system with persistent RAM so that the content of that area can survive after a restart.

14.2 Ramoops concepts

Ramoops uses a predefined memory area to store the dump. The start and size and type of the memory area are set using three variables:

- `mem_address` for the start
- `mem_size` for the size. The memory size will be rounded down to a power of two.
- `mem_type` to specify if the memory type (default is pgprot_writecombine).

Typically the default value of `mem_type=0` should be used as that sets the pstore mapping to pgprot_writecombine. Setting `mem_type=1` attempts to use `pgprot_noncached`, which only works on some platforms. This is because pstore depends on atomic operations. At least on ARM, pgprot_noncached causes the memory to be mapped strongly ordered, and atomic operations on strongly ordered memory are implementation defined, and won't work on many ARMs such as omaps. Setting `mem_type=2` attempts to treat the memory region as normal memory, which enables full cache on it. This can improve the performance.

The memory area is divided into `record_size` chunks (also rounded down to power of two) and each kmesg dump writes a `record_size` chunk of information.

Limiting which kinds of kmsg dumps are stored can be controlled via the `max_reason` value, as defined in include/linux/kmsg_dump.h's `enum kmsg_dump_reason`. For example, to store both Oopses and Panics, `max_reason` should be set to 2 (KMSG_DUMP_OOPS), to store only Panics `max_reason` should be set to 1 (KMSG_DUMP_PANIC). Setting this to 0 (KMSG_DUMP_UNDEF), means the reason filtering will be controlled by the `printk.always_kmsg_dump` boot param: if unset, it'll be KMSG_DUMP_OOPS, otherwise KMSG_DUMP_MAX.

The module uses a counter to record multiple dumps but the counter gets reset on restart (i.e. new dumps after the restart will overwrite old ones).

Ramoops also supports software ECC protection of persistent memory regions. This might be useful when a hardware reset was used to bring the machine back to life (i.e. a watchdog triggered). In such cases, RAM may be somewhat corrupt, but usually it is restorable.

14.3 Setting the parameters

Setting the ramoops parameters can be done in several different manners:

A. Use the module parameters (which have the names of the variables described as before). For quick debugging, you can also reserve parts of memory during boot and then use the reserved memory for ramoops. For example, assuming a machine with > 128 MB of memory, the following kernel command line will tell the kernel to use only the first 128 MB of memory, and place ECC-protected ramoops region at 128 MB boundary:

```
mem=128M ramoops.mem_address=0x8000000 ramoops.ecc=1
```

B. Use Device Tree bindings, as described in `Documentation/devicetree/bindings/reserved-memory/ramoops.yaml`. For example:

```
reserved-memory {
        #address-cells = <2>;
        #size-cells = <2>;
        ranges;

        ramoops@8f000000 {
                compatible = "ramoops";
                reg = <0 0x8f000000 0 0x100000>;
                record-size = <0x4000>;
                console-size = <0x4000>;
        };
};
```

C. Use a platform device and set the platform data. The parameters can then be set through that platform data. An example of doing that is:

```
#include <linux/pstore_ram.h>
[...]

static struct ramoops_platform_data ramoops_data = {
      .mem_size               = <...>,
      .mem_address            = <...>,
      .mem_type               = <...>,
      .record_size            = <...>,
      .max_reason             = <...>,
      .ecc                    = <...>,
};
```

```
static struct platform_device ramoops_dev = {
      .name = "ramoops",
      .dev = {
              .platform_data = &ramoops_data,
      },
};

[... inside a function ...]
int ret;

ret = platform_device_register(&ramoops_dev);
if (ret) {
      printk(KERN_ERR "unable to register platform device\n");
      return ret;
}
```

You can specify either RAM memory or peripheral devices' memory. However, when specifying RAM, be sure to reserve the memory by issuing memblock_reserve() very early in the architecture code, e.g.:

```
#include <linux/memblock.h>

memblock_reserve(ramoops_data.mem_address, ramoops_data.mem_size);
```

14.4 Dump format

The data dump begins with a header, currently defined as ==== followed by a timestamp and a new line. The dump then continues with the actual data.

14.5 Reading the data

The dump data can be read from the pstore filesystem. The format for these files is `dmesg-ramoops-N`, where N is the record number in memory. To delete a stored record from RAM, simply unlink the respective pstore file.

14.6 Persistent function tracing

Persistent function tracing might be useful for debugging software or hardware related hangs. The functions call chain log is stored in a `ftrace-ramoops` file. Here is an example of usage:

```
# mount -t debugfs debugfs /sys/kernel/debug/
# echo 1 > /sys/kernel/debug/pstore/record_ftrace
# reboot -f
[...]
# mount -t pstore pstore /mnt/
# tail /mnt/ftrace-ramoops
```

```
0 ffffffff8101ea64  ffffffff8101bcda  native_apic_mem_read <- disconnect_bsp_
↪APIC+0x6a/0xc0
0 ffffffff8101ea44  ffffffff8101bcf6  native_apic_mem_write <- disconnect_bsp_

```

CHAPTER

FIFTEEN

DYNAMIC DEBUG

15.1 Introduction

Dynamic debug allows you to dynamically enable/disable kernel debug-print code to obtain additional kernel information.

If `/proc/dynamic_debug/control` exists, your kernel has dynamic debug. You'll need root access (sudo su) to use this.

Dynamic debug provides:

- a Catalog of all *prdbgs* in your kernel. `cat /proc/dynamic_debug/control` to see them.
- a Simple query/command language to alter *prdbgs* by selecting on any combination of 0 or 1 of:
  - source filename
  - function name
  - line number (including ranges of line numbers)
  - module name
  - format string
  - class name (as known/declared by each module)

15.2 Viewing Dynamic Debug Behaviour

You can view the currently configured behaviour in the *prdbg* catalog:

```
:#> head -n7 /proc/dynamic_debug/control
# filename:lineno [module]function flags format
init/main.c:1179 [main]initcall_blacklist =_ "blacklisting initcall %s\012
init/main.c:1218 [main]initcall_blacklisted =_ "initcall %s blacklisted\012"
init/main.c:1424 [main]run_init_process =_ "  with arguments:\012"
init/main.c:1426 [main]run_init_process =_ "    %s\012"
init/main.c:1427 [main]run_init_process =_ "  with environment:\012"
init/main.c:1429 [main]run_init_process =_ "    %s\012"
```

The 3rd space-delimited column shows the current flags, preceded by a = for easy use with grep/cut. `=p` shows enabled callsites.

15.3 Controlling dynamic debug Behaviour

The behaviour of *prdbg* sites are controlled by writing query/commands to the control file. Example:

```
# grease the interface
:#> alias ddcmd='echo $* > /proc/dynamic_debug/control'

:#> ddcmd '-p; module main func run* +p'
:#> grep =p /proc/dynamic_debug/control
init/main.c:1424 [main]run_init_process =p "  with arguments:\012"
init/main.c:1426 [main]run_init_process =p "    %s\012"
init/main.c:1427 [main]run_init_process =p "  with environment:\012"
init/main.c:1429 [main]run_init_process =p "    %s\012"
```

Error messages go to console/syslog:

```
:#> ddcmd mode foo +p
dyndbg: unknown keyword "mode"
dyndbg: query parse failed
bash: echo: write error: Invalid argument
```

If debugfs is also enabled and mounted, `dynamic_debug/control` is also under the mount-dir, typically `/sys/kernel/debug/`.

15.4 Command Language Reference

At the basic lexical level, a command is a sequence of words separated by spaces or tabs. So these are all equivalent:

```
:#> ddcmd file svcsock.c line 1603 +p
:#> ddcmd "file svcsock.c line 1603 +p"
:#> ddcmd '  file   svcsock.c     line  1603 +p  '
```

Command submissions are bounded by a write() system call. Multiple commands can be written together, separated by `;` or `\n`:

```
:#> ddcmd "func pnpacpi_get_resources +p; func pnp_assign_mem +p"
:#> ddcmd <<"EOC"
func pnpacpi_get_resources +p
func pnp_assign_mem +p
EOC
:#> cat query-batch-file > /proc/dynamic_debug/control
```

You can also use wildcards in each query term. The match rule supports * (matches zero or more characters) and ? (matches exactly one character). For example, you can match all usb drivers:

```
:#> ddcmd file "drivers/usb/*" +p     # "" to suppress shell expansion
```

Syntactically, a command is pairs of keyword values, followed by a flags change or setting:

```
command ::= match-spec* flags-spec
```

The match-spec's select *prdbgs* from the catalog, upon which to apply the flags-spec, all constraints are ANDed together. An absent keyword is the same as keyword "*".

A match specification is a keyword, which selects the attribute of the callsite to be compared, and a value to compare against. Possible keywords are::

```
match-spec ::= 'func' string |
               'file' string |
               'module' string |
               'format' string |
               'class' string |
               'line' line-range

line-range ::= lineno |
               '-'lineno |
               lineno'-' |
               lineno'-'lineno

lineno ::= unsigned-int
```

Note: `line-range` cannot contain space, e.g. "1-30" is valid range but "1 - 30" is not.

The meanings of each keyword are:

func
The given string is compared against the function name of each callsite. Example:

```
func svc_tcp_accept
func *recv*             # in rfcomm, bluetooth, ping, tcp
```

file
The given string is compared against either the src-root relative pathname, or the basename of the source file of each callsite. Examples:

```
file svcsock.c
file kernel/freezer.c   # ie column 1 of control file
file drivers/usb/*      # all callsites under it
file inode.c:start_*    # parse :tail as a func (above)
file inode.c:1-100      # parse :tail as a line-range (above)
```

module
The given string is compared against the module name of each callsite. The module name is the string as seen in `lsmod`, i.e. without the directory or the `.ko` suffix and with `-` changed to `_`. Examples:

```
module sunrpc
module nfsd
module drm*     # both drm, drm_kms_helper
```

format

The given string is searched for in the dynamic debug format string. Note that the string does not need to match the entire format, only some part. Whitespace and other special characters can be escaped using C octal character escape `\ooo` notation, e.g. the space character is `\040`. Alternatively, the string can be enclosed in double quote characters (`"`) or single quote characters (`'`). Examples:

```
format svcrdma:         // many of the NFS/RDMA server pr_debugs
format readahead        // some pr_debugs in the readahead cache
format nfsd:\040SETATTR // one way to match a format with whitespace
format "nfsd: SETATTR"  // a neater way to match a format with whitespace
format 'nfsd: SETATTR'  // yet another way to match a format with␣
↪whitespace
```

class

The given class_name is validated against each module, which may have declared a list of known class_names. If the class_name is found for a module, callsite & class matching and adjustment proceeds. Examples:

```
class DRM_UT_KMS        # a DRM.debug category
class JUNK              # silent non-match
// class TLD_*          # NOTICE: no wildcard in class names
```

line

The given line number or range of line numbers is compared against the line number of each `pr_debug()` callsite. A single line number matches the callsite line number exactly. A range of line numbers matches any callsite between the first and last line number inclusive. An empty first number means the first line in the file, an empty last line number means the last line number in the file. Examples:

```
line 1603           // exactly line 1603
line 1600-1605      // the six lines from line 1600 to line 1605
line -1605          // the 1605 lines from line 1 to line 1605
line 1600-          // all lines from line 1600 to the end of the file
```

The flags specification comprises a change operation followed by one or more flag characters. The change operation is one of the characters:

```
-    remove the given flags
+    add the given flags
=    set the flags to the given flags
```

The flags are:

```
p    enables the pr_debug() callsite.
_    enables no flags.

Decorator flags add to the message-prefix, in order:
t    Include thread ID, or <intr>
m    Include module name
f    Include the function name
s    Include the source file name
```

```
l    Include line number
```

For `print_hex_dump_debug()` and `print_hex_dump_bytes()`, only the `p` flag has meaning, other flags are ignored.

Note the regexp `^[-+=][fslmpt_]+$` matches a flags specification. To clear all flags at once, use `=_` or `-fslmpt`.

15.5 Debug messages during Boot Process

To activate debug messages for core code and built-in modules during the boot process, even before userspace and debugfs exists, use `dyndbg="QUERY"` or `module.dyndbg="QUERY"`. QUERY follows the syntax described above, but must not exceed 1023 characters. Your bootloader may impose lower limits.

These `dyndbg` params are processed just after the ddebug tables are processed, as part of the early_initcall. Thus you can enable debug messages in all code run after this early_initcall via this boot parameter.

On an x86 system for example ACPI enablement is a subsys_initcall and:

```
dyndbg="file ec.c +p"
```

will show early Embedded Controller transactions during ACPI setup if your machine (typically a laptop) has an Embedded Controller. PCI (or other devices) initialization also is a hot candidate for using this boot parameter for debugging purposes.

If `foo` module is not built-in, `foo.dyndbg` will still be processed at boot time, without effect, but will be reprocessed when module is loaded later. Bare `dyndbg=` is only processed at boot.

15.6 Debug Messages at Module Initialization Time

When `modprobe foo` is called, modprobe scans `/proc/cmdline` for `foo.params`, strips `foo.`, and passes them to the kernel along with params given in modprobe args or `/etc/modprobe.d/*.conf` files, in the following order:

1. parameters given via `/etc/modprobe.d/*.conf`:

   ```
   options foo dyndbg=+pt
   options foo dyndbg # defaults to +p
   ```

2. `foo.dyndbg` as given in boot args, `foo.` is stripped and passed:

   ```
   foo.dyndbg=" func bar +p; func buz +mp"
   ```

3. args to modprobe:

   ```
   modprobe foo dyndbg==pmf # override previous settings
   ```

These `dyndbg` queries are applied in order, with last having final say. This allows boot args to override or modify those from `/etc/modprobe.d` (sensible, since 1 is system wide, 2 is kernel or boot specific), and modprobe args to override both.

In the `foo.dyndbg="QUERY"` form, the query must exclude `module foo`. `foo` is extracted from the param-name, and applied to each query in `QUERY`, and only 1 match-spec of each type is allowed.

The `dyndbg` option is a "fake" module parameter, which means:

- modules do not need to define it explicitly
- every module gets it tacitly, whether they use pr_debug or not
- it doesn't appear in `/sys/module/$module/parameters/` To see it, grep the control file, or inspect `/proc/cmdline`.

For `CONFIG_DYNAMIC_DEBUG` kernels, any settings given at boot-time (or enabled by `-DDEBUG` flag during compilation) can be disabled later via the debugfs interface if the debug messages are no longer needed:

```
echo "module module_name -p" > /proc/dynamic_debug/control
```

15.7 Examples

```
// enable the message at line 1603 of file svcsock.c
:#> ddcmd 'file svcsock.c line 1603 +p'

// enable all the messages in file svcsock.c
:#> ddcmd 'file svcsock.c +p'

// enable all the messages in the NFS server module
:#> ddcmd 'module nfsd +p'

// enable all 12 messages in the function svc_process()
:#> ddcmd 'func svc_process +p'

// disable all 12 messages in the function svc_process()
:#> ddcmd 'func svc_process -p'

// enable messages for NFS calls READ, READLINK, READDIR and READDIR+.
:#> ddcmd 'format "nfsd: READ" +p'

// enable messages in files of which the paths include string "usb"
:#> ddcmd 'file *usb* +p'

// enable all messages
:#> ddcmd '+p'

// add module, function to all enabled messages
:#> ddcmd '+mf'

// boot-args example, with newlines and comments for readability
Kernel command line: ...
  // see what's going on in dyndbg=value processing
  dynamic_debug.verbose=3
```

```
  // enable pr_debugs in the btrfs module (can be builtin or loadable)
  btrfs.dyndbg="+p"
  // enable pr_debugs in all files under init/
  // and the function parse_one, #cmt is stripped
  dyndbg="file init/* +p #cmt ; func parse_one +p"
  // enable pr_debugs in 2 functions in a module loaded later
  pc87360.dyndbg="func pc87360_init_device +p; func pc87360_find +p"
```

15.8 Kernel Configuration

Dynamic Debug is enabled via kernel config items:

```
CONFIG_DYNAMIC_DEBUG=y        # build catalog, enables CORE
CONFIG_DYNAMIC_DEBUG_CORE=y   # enable mechanics only, skip catalog
```

If you do not want to enable dynamic debug globally (i.e. in some embedded system), you may set `CONFIG_DYNAMIC_DEBUG_CORE` as basic support of dynamic debug and add `ccflags := -DDYNAMIC_DEBUG_MODULE` into the Makefile of any modules which you'd like to dynamically debug later.

15.9 Kernel *prdbg* API

The following functions are cataloged and controllable when dynamic debug is enabled:

```
pr_debug()
dev_dbg()
print_hex_dump_debug()
print_hex_dump_bytes()
```

Otherwise, they are off by default; `ccflags += -DDEBUG` or `#define DEBUG` in a source file will enable them appropriately.

If `CONFIG_DYNAMIC_DEBUG` is not set, `print_hex_dump_debug()` is just a shortcut for `print_hex_dump(KERN_DEBUG)`.

For `print_hex_dump_debug()`/`print_hex_dump_bytes()`, format string is its `prefix_str` argument, if it is constant string; or `hexdump` in case `prefix_str` is built dynamically.

CHAPTER

EXPLAINING THE ”NO WORKING INIT FOUND.” BOOT HANG MESSAGE

Authors
Andreas Mohr <andi at lisas period de> Cristian Souza <cristianmsbr at gmail period com>

This document provides some high-level reasons for failure (listed roughly in order of execution) to load the init binary.

1) **Unable to mount root FS**: Set ”debug” kernel parameter (in bootloader config file or CONFIG_CMDLINE) to get more detailed kernel messages.

2) **init binary doesn't exist on rootfs**: Make sure you have the correct root FS type (and `root=` kernel parameter points to the correct partition), required drivers such as storage hardware (such as SCSI or USB!) and filesystem (ext3, jffs2, etc.) are builtin (alternatively as modules, to be pre-loaded by an initrd).

3) **Broken console device**: Possibly a conflict in `console= setup` --> initial console unavailable. E.g. some serial consoles are unreliable due to serial IRQ issues (e.g. missing interrupt-based configuration). Try using a different `console= device` or e.g. `netconsole=`.

4) **Binary exists but dependencies not available**: E.g. required library dependencies of the init binary such as `/lib/ld-linux.so.2` missing or broken. Use `readelf -d <INIT>|grep NEEDED` to find out which libraries are required.

5) **Binary cannot be loaded**: Make sure the binary's architecture matches your hardware. E.g. i386 vs. x86_64 mismatch, or trying to load x86 on ARM hardware. In case you tried loading a non-binary file here (shell script?), you should make sure that the script specifies an interpreter in its shebang header line (`#!/...`) that is fully working (including its library dependencies). And before tackling scripts, better first test a simple non-script binary such as `/bin/sh` and confirm its successful execution. To find out more, add code `to init/main.c` to display kernel_execve()s return values.

Please extend this explanation whenever you find new failure causes (after all loading the init binary is a CRITICAL and hard transition step which needs to be made as painless as possible), then submit a patch to LKML. Further TODOs:

- Implement the various `run_init_process()` invocations via a struct array which can then store the `kernel_execve()` result value and on failure log it all by iterating over **all** results (very important usability fix).
- Try to make the implementation itself more helpful in general, e.g. by providing additional error messages at affected places.

CHAPTER

SEVENTEEN

DOCUMENTATION FOR KDUMP - THE KEXEC-BASED CRASH DUMPING SOLUTION

This document includes overview, setup and installation, and analysis information.

17.1 Documentation for Kdump - The kexec-based Crash Dumping Solution

This document includes overview, setup, installation, and analysis information.

17.1.1 Overview

Kdump uses kexec to quickly boot to a dump-capture kernel whenever a dump of the system kernel's memory needs to be taken (for example, when the system panics). The system kernel's memory image is preserved across the reboot and is accessible to the dump-capture kernel.

You can use common commands, such as cp, scp or makedumpfile to copy the memory image to a dump file on the local disk, or across the network to a remote system.

Kdump and kexec are currently supported on the x86, x86_64, ppc64, s390x, arm and arm64 architectures.

When the system kernel boots, it reserves a small section of memory for the dump-capture kernel. This ensures that ongoing Direct Memory Access (DMA) from the system kernel does not corrupt the dump-capture kernel. The kexec -p command loads the dump-capture kernel into this reserved memory.

On x86 machines, the first 640 KB of physical memory is needed for boot, regardless of where the kernel loads. For simpler handling, the whole low 1M is reserved to avoid any later kernel or device driver writing data into this area. Like this, the low 1M can be reused as system RAM by kdump kernel without extra handling.

On PPC64 machines first 32KB of physical memory is needed for booting regardless of where the kernel is loaded and to support 64K page size kexec backs up the first 64KB memory.

For s390x, when kdump is triggered, the crashkernel region is exchanged with the region [0, crashkernel region size] and then the kdump kernel runs in [0, crashkernel region size]. Therefore no relocatable kernel is needed for s390x.

All of the necessary information about the system kernel's core image is encoded in the ELF format, and stored in a reserved area of memory before a crash. The physical address of the start of the ELF header is passed to the dump-capture kernel through the elfcorehdr= boot

parameter. Optionally the size of the ELF header can also be passed when using the elfcorehdr=[size[KMG]@]offset[KMG] syntax.

With the dump-capture kernel, you can access the memory image through /proc/vmcore. This exports the dump as an ELF-format file that you can write out using file copy commands such as cp or scp. You can also use makedumpfile utility to analyze and write out filtered contents with options, e.g with '-d 31' it will only write out kernel data. Further, you can use analysis tools such as the GNU Debugger (GDB) and the Crash tool to debug the dump file. This method ensures that the dump pages are correctly ordered.

17.1.2 Setup and Installation

Install kexec-tools

1) Login as the root user.
2) Download the kexec-tools user-space package from the following URL:

http://kernel.org/pub/linux/utils/kernel/kexec/kexec-tools.tar.gz

This is a symlink to the latest version.

The latest kexec-tools git tree is available at:

- git://git.kernel.org/pub/scm/utils/kernel/kexec/kexec-tools.git
- http://www.kernel.org/pub/scm/utils/kernel/kexec/kexec-tools.git

There is also a gitweb interface available at http://www.kernel.org/git/?p=utils/kernel/kexec/kexec-tools.git

More information about kexec-tools can be found at http://horms.net/projects/kexec/

3) Unpack the tarball with the tar command, as follows:

```
tar xvpzf kexec-tools.tar.gz
```

4) Change to the kexec-tools directory, as follows:

```
cd kexec-tools-VERSION
```

5) Configure the package, as follows:

```
./configure
```

6) Compile the package, as follows:

```
make
```

7) Install the package, as follows:

```
make install
```

Build the system and dump-capture kernels

There are two possible methods of using Kdump.

1) Build a separate custom dump-capture kernel for capturing the kernel core dump.
2) Or use the system kernel binary itself as dump-capture kernel and there is no need to build a separate dump-capture kernel. This is possible only with the architectures which support a relocatable kernel. As of today, i386, x86_64, ppc64, arm and arm64 architectures support relocatable kernel.

Building a relocatable kernel is advantageous from the point of view that one does not have to build a second kernel for capturing the dump. But at the same time one might want to build a custom dump capture kernel suitable to his needs.

Following are the configuration setting required for system and dump-capture kernels for enabling kdump support.

System kernel config options

1) Enable ”kexec system call” or ”kexec file based system call” in ”Processor type and features.”:

```
CONFIG_KEXEC=y or CONFIG_KEXEC_FILE=y
```

And both of them will select KEXEC_CORE:

```
CONFIG_KEXEC_CORE=y
```

Subsequently, CRASH_CORE is selected by KEXEC_CORE:

```
CONFIG_CRASH_CORE=y
```

2) Enable ”sysfs file system support” in ”Filesystem” -> ”Pseudo filesystems.” This is usually enabled by default:

```
CONFIG_SYSFS=y
```

Note that ”sysfs file system support” might not appear in the ”Pseudo filesystems” menu if ”Configure standard kernel features (expert users)” is not enabled in ”General Setup.” In this case, check the .config file itself to ensure that sysfs is turned on, as follows:

```
grep 'CONFIG_SYSFS' .config
```

3) Enable ”Compile the kernel with debug info” in ”Kernel hacking.”:

```
CONFIG_DEBUG_INFO=Y
```

This causes the kernel to be built with debug symbols. The dump analysis tools require a vmlinux with debug symbols in order to read and analyze a dump file.

Dump-capture kernel config options (Arch Independent)

1) Enable ”kernel crash dumps” support under ”Processor type and features”:

```
CONFIG_CRASH_DUMP=y
```

2) Enable ”/proc/vmcore support” under ”Filesystems” -> ”Pseudo filesystems”:

```
CONFIG_PROC_VMCORE=y
```

(CONFIG_PROC_VMCORE is set by default when CONFIG_CRASH_DUMP is selected.)

Dump-capture kernel config options (Arch Dependent, i386 and x86_64)

1) On i386, enable high memory support under ”Processor type and features”:

```
CONFIG_HIGHMEM64G=y
```

or:

```
CONFIG_HIGHMEM4G
```

2) With CONFIG_SMP=y, usually nr_cpus=1 need specified on the kernel command line when loading the dump-capture kernel because one CPU is enough for kdump kernel to dump vmcore on most of systems.

However, you can also specify nr_cpus=X to enable multiple processors in kdump kernel. In this case, ”disable_cpu_apicid=” is needed to tell kdump kernel which cpu is 1st kernel's BSP. Please refer to admin-guide/kernel-parameters.txt for more details.

With CONFIG_SMP=n, the above things are not related.

3) A relocatable kernel is suggested to be built by default. If not yet, enable ”Build a relocatable kernel” support under ”Processor type and features”:

```
CONFIG_RELOCATABLE=y
```

4) Use a suitable value for ”Physical address where the kernel is loaded” (under ”Processor type and features”). This only appears when ”kernel crash dumps” is enabled. A suitable value depends upon whether kernel is relocatable or not.

If you are using a relocatable kernel use CONFIG_PHYSICAL_START=0x100000 This will compile the kernel for physical address 1MB, but given the fact kernel is relocatable, it can be run from any physical address hence kexec boot loader will load it in memory region reserved for dump-capture kernel.

Otherwise it should be the start of memory region reserved for second kernel using boot parameter ”crashkernel=Y@X”. Here X is start of memory region reserved for dump-capture kernel. Generally X is 16MB (0x1000000). So you can set CONFIG_PHYSICAL_START=0x1000000

5) Make and install the kernel and its modules. DO NOT add this kernel to the boot loader configuration files.

Dump-capture kernel config options (Arch Dependent, ppc64)

1) Enable "Build a kdump crash kernel" support under "Kernel" options:

```
CONFIG_CRASH_DUMP=y
```

2) Enable "Build a relocatable kernel" support:

```
CONFIG_RELOCATABLE=y
```

Make and install the kernel and its modules.

Dump-capture kernel config options (Arch Dependent, arm)

- To use a relocatable kernel, Enable "AUTO_ZRELADDR" support under "Boot" options:

```
AUTO_ZRELADDR=y
```

Dump-capture kernel config options (Arch Dependent, arm64)

- Please note that kvm of the dump-capture kernel will not be enabled on non-VHE systems even if it is configured. This is because the CPU will not be reset to EL2 on panic.

17.1.3 crashkernel syntax

1) crashkernel=size@offset

Here 'size' specifies how much memory to reserve for the dump-capture kernel and 'offset' specifies the beginning of this reserved memory. For example, "crashkernel=64M@16M" tells the system kernel to reserve 64 MB of memory starting at physical address 0x01000000 (16MB) for the dump-capture kernel.

The crashkernel region can be automatically placed by the system kernel at run time. This is done by specifying the base address as 0, or omitting it all together:

```
crashkernel=256M@0
```

or:

```
crashkernel=256M
```

If the start address is specified, note that the start address of the kernel will be aligned to a value (which is Arch dependent), so if the start address is not then any space below the alignment point will be wasted.

2) range1:size1[,range2:size2,...][@offset]

While the "crashkernel=size[@offset]" syntax is sufficient for most configurations, sometimes it's handy to have the reserved memory dependent on the value of System RAM -- that's mostly for distributors that pre-setup the kernel command line to avoid a unbootable system after some memory has been removed from the machine.

The syntax is:

```
crashkernel=<range1>:<size1>[,<range2>:<size2>,...][@offset]
range=start-[end]
```

For example:

```
crashkernel=512M-2G:64M,2G-:128M
```

This would mean:

1) if the RAM is smaller than 512M, then don't reserve anything (this is the "rescue" case)
2) if the RAM size is between 512M and 2G (exclusive), then reserve 64M
3) if the RAM size is larger than 2G, then reserve 128M

3) crashkernel=size,high and crashkernel=size,low

If memory above 4G is preferred, crashkernel=size,high can be used to fulfill that. With it, physical memory is allowed to be allocated from top, so could be above 4G if system has more than 4G RAM installed. Otherwise, memory region will be allocated below 4G if available.

When crashkernel=X,high is passed, kernel could allocate physical memory region above 4G, low memory under 4G is needed in this case. There are three ways to get low memory:

1) Kernel will allocate at least 256M memory below 4G automatically if crashkernel=Y,low is not specified.
2) Let user specify low memory size instead.
3) Specified value 0 will disable low memory allocation:

```
crashkernel=0,low
```

Boot into System Kernel

1) Update the boot loader (such as grub, yaboot, or lilo) configuration files as necessary.
2) Boot the system kernel with the boot parameter "crashkernel=Y@X".

On x86 and x86_64, use "crashkernel=Y[@X]". Most of the time, the start address 'X' is not necessary, kernel will search a suitable area. Unless an explicit start address is expected.

On ppc64, use "crashkernel=128M@32M".

On s390x, typically use "crashkernel=xxM". The value of xx is dependent on the memory consumption of the kdump system. In general this is not dependent on the memory size of the production system.

On arm, the use of "crashkernel=Y@X" is no longer necessary; the kernel will automatically locate the crash kernel image within the first 512MB of RAM if X is not given.

On arm64, use "crashkernel=Y[@X]". Note that the start address of the kernel, X if explicitly specified, must be aligned to 2MiB (0x200000).

17.1.4 Load the Dump-capture Kernel

After booting to the system kernel, dump-capture kernel needs to be loaded.

Based on the architecture and type of image (relocatable or not), one can choose to load the uncompressed vmlinux or compressed bzImage/vmlinuz of dump-capture kernel. Following is the summary.

For i386 and x86_64:

- Use bzImage/vmlinuz if kernel is relocatable.
- Use vmlinux if kernel is not relocatable.

For ppc64:

- Use vmlinux

For s390x:

- Use image or bzImage

For arm:

- Use zImage

For arm64:

- Use vmlinux or Image

If you are using an uncompressed vmlinux image then use following command to load dump-capture kernel:

```
kexec -p <dump-capture-kernel-vmlinux-image> \
--initrd=<initrd-for-dump-capture-kernel> --args-linux \
--append="root=<root-dev> <arch-specific-options>"
```

If you are using a compressed bzImage/vmlinuz, then use following command to load dump-capture kernel:

```
kexec -p <dump-capture-kernel-bzImage> \
--initrd=<initrd-for-dump-capture-kernel> \
--append="root=<root-dev> <arch-specific-options>"
```

If you are using a compressed zImage, then use following command to load dump-capture kernel:

```
kexec --type zImage -p <dump-capture-kernel-bzImage> \
--initrd=<initrd-for-dump-capture-kernel> \
--dtb=<dtb-for-dump-capture-kernel> \
--append="root=<root-dev> <arch-specific-options>"
```

If you are using an uncompressed Image, then use following command to load dump-capture kernel:

```
kexec -p <dump-capture-kernel-Image> \
--initrd=<initrd-for-dump-capture-kernel> \
--append="root=<root-dev> <arch-specific-options>"
```

Following are the arch specific command line options to be used while loading dump-capture kernel.

For i386 and x86_64:

> ”1 irqpoll nr_cpus=1 reset_devices”

For ppc64:

> ”1 maxcpus=1 noirqdistrib reset_devices”

For s390x:

> ”1 nr_cpus=1 cgroup_disable=memory”

For arm:

> ”1 maxcpus=1 reset_devices”

For arm64:

> ”1 nr_cpus=1 reset_devices”

Notes on loading the dump-capture kernel:

- By default, the ELF headers are stored in ELF64 format to support systems with more than 4GB memory. On i386, kexec automatically checks if the physical RAM size exceeds the 4 GB limit and if not, uses ELF32. So, on non-PAE systems, ELF32 is always used.

  The --elf32-core-headers option can be used to force the generation of ELF32 headers. This is necessary because GDB currently cannot open vmcore files with ELF64 headers on 32-bit systems.
- The ”irqpoll” boot parameter reduces driver initialization failures due to shared interrupts in the dump-capture kernel.
- You must specify <root-dev> in the format corresponding to the root device name in the output of mount command.
- Boot parameter ”1” boots the dump-capture kernel into single-user mode without networking. If you want networking, use ”3”.
- We generally don't have to bring up a SMP kernel just to capture the dump. Hence generally it is useful either to build a UP dump-capture kernel or specify maxcpus=1 option while loading dump-capture kernel. Note, though maxcpus always works, you had better replace it with nr_cpus to save memory if supported by the current ARCH, such as x86.
- You should enable multi-cpu support in dump-capture kernel if you intend to use multi-thread programs with it, such as parallel dump feature of makedumpfile. Otherwise, the multi-thread program may have a great performance degradation. To enable multi-cpu support, you should bring up an SMP dump-capture kernel and specify maxcpus/nr_cpus, disable_cpu_apicid=[X] options while loading it.
- For s390x there are two kdump modes: If a ELF header is specified with the elfcorehdr= kernel parameter, it is used by the kdump kernel as it is done on all other architectures. If no elfcorehdr= kernel parameter is specified, the s390x kdump kernel dynamically creates the header. The second mode has the advantage that for CPU and memory hotplug, kdump has not to be reloaded with kexec_load().
- For s390x systems with many attached devices the ”cio_ignore” kernel parameter should be used for the kdump kernel in order to prevent allocation of kernel memory for devices

that are not relevant for kdump. The same applies to systems that use SCSI/FCP devices. In that case the "allow_lun_scan" zfcp module parameter should be set to zero before setting FCP devices online.

17.1.5 Kernel Panic

After successfully loading the dump-capture kernel as previously described, the system will reboot into the dump-capture kernel if a system crash is triggered. Trigger points are located in panic(), die(), die_nmi() and in the sysrq handler (ALT-SysRq-c).

The following conditions will execute a crash trigger point:

If a hard lockup is detected and "NMI watchdog" is configured, the system will boot into the dump-capture kernel (die_nmi()).

If die() is called, and it happens to be a thread with pid 0 or 1, or die() is called inside interrupt context or die() is called and panic_on_oops is set, the system will boot into the dump-capture kernel.

On powerpc systems when a soft-reset is generated, die() is called by all cpus and the system will boot into the dump-capture kernel.

For testing purposes, you can trigger a crash by using "ALT-SysRq-c", "echo c > /proc/sysrq-trigger" or write a module to force the panic.

17.1.6 Write Out the Dump File

After the dump-capture kernel is booted, write out the dump file with the following command:

```
cp /proc/vmcore <dump-file>
```

or use scp to write out the dump file between hosts on a network, e.g:

```
scp /proc/vmcore remote_username@remote_ip:<dump-file>
```

You can also use makedumpfile utility to write out the dump file with specified options to filter out unwanted contents, e.g:

```
makedumpfile -l --message-level 1 -d 31 /proc/vmcore <dump-file>
```

17.1.7 Analysis

Before analyzing the dump image, you should reboot into a stable kernel.

You can do limited analysis using GDB on the dump file copied out of /proc/vmcore. Use the debug vmlinux built with -g and run the following command:

```
gdb vmlinux <dump-file>
```

Stack trace for the task on processor 0, register display, and memory display work fine.

Note: GDB cannot analyze core files generated in ELF64 format for x86. On systems with a maximum of 4GB of memory, you can generate ELF32-format headers using the --elf32-core-headers kernel option on the dump kernel.

You can also use the Crash utility to analyze dump files in Kdump format. Crash is available at the following URL:

https://github.com/crash-utility/crash

Crash document can be found at:
https://crash-utility.github.io/

17.1.8 Trigger Kdump on WARN()

The kernel parameter, panic_on_warn, calls panic() in all WARN() paths. This will cause a kdump to occur at the panic() call. In cases where a user wants to specify this during runtime, /proc/sys/kernel/panic_on_warn can be set to 1 to achieve the same behaviour.

17.1.9 Trigger Kdump on add_taint()

The kernel parameter panic_on_taint facilitates a conditional call to panic() from within add_taint() whenever the value set in this bitmask matches with the bit flag being set by add_taint(). This will cause a kdump to occur at the add_taint()->panic() call.

17.1.11 GDB macros

```
#
# This file contains a few gdb macros (user defined commands) to extract
# useful information from kernel crashdump (kdump) like stack traces of
# all the processes or a particular process and trapinfo.
#
# These macros can be used by copying this file in .gdbinit (put in home
# directory or current directory) or by invoking gdb command with
# --command=<command-file-name> option
#

                set var $log = &prb->text_data_ring.data[$begin]
        end

        # prev & LOG_CONT && !(info->flags & LOG_PREIX)
```

```
        if (($prev_flags & 8) && !($info->flags & 4))
                set var $prefix = 0
        end

        # info->flags & LOG_CONT
        if ($info->flags & 8)
                # (prev & LOG_CONT && !(prev & LOG_NEWLINE))
                if (($prev_flags & 8) && !($prev_flags & 2))
                        set var $prefix = 0
                end
                # (!(info->flags & LOG_NEWLINE))
                if (!($info->flags & 2))
                        set var $newline = 0
                end
        end

        if ($prefix)
                printf "[%5lu.%06lu] ", $info->ts_nsec / 1000000000, $info->ts_
↪nsec % 1000000000
        end
        if ($text_len)
                eval "printf \"%%%d.%ds\", $log", $text_len, $text_len
        end
        if ($newline)
                printf "\n"
        end

        # handle dictionary data

        set var $dict = &$info->dev_info.subsystem[0]
        set var $dict_len = sizeof($info->dev_info.subsystem)
        if ($dict[0] != '\0')
                printf " SUBSYSTEM="
                set var $idx = 0
                while ($idx < $dict_len)
                        set var $c = $dict[$idx]
                        if ($c == '\0')
                                loop_break
                        else
                                if ($c < ' ' || $c >= 127 || $c == '\\')
                                        printf "\\x%02x", $c
                                else
                                        printf "%c", $c
                                end
                        end
                        set var $idx = $idx + 1
                end
                printf "\n"
        end

        set var $dict = &$info->dev_info.device[0]
```

```
        set var $dict_len = sizeof($info->dev_info.device)
        if ($dict[0] != '\0')
                printf " DEVICE="
                set var $idx = 0
                while ($idx < $dict_len)
                        set var $c = $dict[$idx]
                        if ($c == '\0')
                                loop_break
                        else
                                if ($c < ' ' || $c >= 127 || $c == '\\')
                                        printf "\\x%02x", $c
                                else
                                        printf "%c", $c
                                end
                        end
                        set var $idx = $idx + 1
                end
                printf "\n"
        end
end
document dump_record
        Dump a single record. The first parameter is the descriptor,
        the second parameter is the info, the third parameter is
        optional and specifies the previous record's flags, used for
        properly formatting continued lines.
end

define dmesg
        # definitions from kernel/printk/printk_ringbuffer.h
        set var $desc_committed = 1
        set var $desc_finalized = 2
        set var $desc_sv_bits = sizeof(long) * 8
        set var $desc_flags_shift = $desc_sv_bits - 2
        set var $desc_flags_mask = 3 << $desc_flags_shift
        set var $id_mask = ~$desc_flags_mask

        set var $desc_count = 1U << prb->desc_ring.count_bits
        set var $prev_flags = 0

        set var $id = prb->desc_ring.tail_id.counter
        set var $end_id = prb->desc_ring.head_id.counter

        while (1)
                set var $desc = &prb->desc_ring.descs[$id % $desc_count]
                set var $info = &prb->desc_ring.infos[$id % $desc_count]

                # skip non-committed record
                set var $state = 3 & ($desc->state_var.counter >> $desc_flags_
↪shift)
                if ($state == $desc_committed || $state == $desc_finalized)
                        dump_record $desc $info $prev_flags
```

```
                        set var $prev_flags = $info->flags
                end

                if ($id == $end_id)
                        loop_break
                end
                set var $id = ($id + 1) & $id_mask
        end
end
document dmesg
        print the kernel ring buffer
end
```

17.2 VMCOREINFO

17.2.1 What is it?

VMCOREINFO is a special ELF note section. It contains various information from the kernel like structure size, page size, symbol values, field offsets, etc. These data are packed into an ELF note section and used by user-space tools like crash and makedumpfile to analyze a kernel's memory layout.

17.2.2 Common variables

init_uts_ns.name.release

The version of the Linux kernel. Used to find the corresponding source code from which the kernel has been built. For example, crash uses it to find the corresponding vmlinux in order to process vmcore.

PAGE_SIZE

The size of a page. It is the smallest unit of data used by the memory management facilities. It is usually 4096 bytes of size and a page is aligned on 4096 bytes. Used for computing page addresses.

init_uts_ns

The UTS namespace which is used to isolate two specific elements of the system that relate to the uname(2) system call. It is named after the data structure used to store information returned by the uname(2) system call.

User-space tools can get the kernel name, host name, kernel release number, kernel version, architecture name and OS type from it.

(uts_namespace, name)

Offset of the name's member. Crash Utility and Makedumpfile get the start address of the init_uts_ns.name from this.

node_online_map

An array node_states[N_ONLINE] which represents the set of online nodes in a system, one bit position per node number. Used to keep track of which nodes are in the system and online.

swapper_pg_dir

The global page directory pointer of the kernel. Used to translate virtual to physical addresses.

_stext

Defines the beginning of the text section. In general, _stext indicates the kernel start address. Used to convert a virtual address from the direct kernel map to a physical address.

vmap_area_list

Stores the virtual area list. makedumpfile gets the vmalloc start value from this variable and its value is necessary for vmalloc translation.

mem_map

Physical addresses are translated to struct pages by treating them as an index into the mem_map array. Right-shifting a physical address PAGE_SHIFT bits converts it into a page frame number which is an index into that mem_map array.

Used to map an address to the corresponding struct page.

contig_page_data

Makedumpfile gets the pglist_data structure from this symbol, which is used to describe the memory layout.

User-space tools use this to exclude free pages when dumping memory.

mem_section|(mem_section, NR_SECTION_ROOTS)|(mem_section, section_mem_map)

The address of the mem_section array, its length, structure size, and the section_mem_map offset.

It exists in the sparse memory mapping model, and it is also somewhat similar to the mem_map variable, both of them are used to translate an address.

MAX_PHYSMEM_BITS

Defines the maximum supported physical address space memory.

page

The size of a page structure. struct page is an important data structure and it is widely used to compute contiguous memory.

pglist_data

The size of a pglist_data structure. This value is used to check if the pglist_data structure is valid. It is also used for checking the memory type.

zone

The size of a zone structure. This value is used to check if the zone structure has been found. It is also used for excluding free pages.

free_area

The size of a free_area structure. It indicates whether the free_area structure is valid or not. Useful when excluding free pages.

list_head

The size of a list_head structure. Used when iterating lists in a post-mortem analysis session.

nodemask_t

The size of a nodemask_t type. Used to compute the number of online nodes.

(page, flags|_refcount|mapping|lru|_mapcount|private|compound_order|compound_head)

User-space tools compute their values based on the offset of these variables. The variables are used when excluding unnecessary pages.

(pglist_data, node_zones|nr_zones|node_mem_map|node_start_pfn|node_spanned_pages|no

On NUMA machines, each NUMA node has a pg_data_t to describe its memory layout. On UMA machines there is a single pglist_data which describes the whole memory.

These values are used to check the memory type and to compute the virtual address for memory map.

(zone, free_area|vm_stat|spanned_pages)

Each node is divided into a number of blocks called zones which represent ranges within memory. A zone is described by a structure zone.

User-space tools compute required values based on the offset of these variables.

(free_area, free_list)

Offset of the free_list's member. This value is used to compute the number of free pages.

Each zone has a free_area structure array called free_area[NR_PAGE_ORDERS]. The free_list represents a linked list of free page blocks.

(list_head, next|prev)

Offsets of the list_head's members. list_head is used to define a circular linked list. User-space tools need these in order to traverse lists.

(vmap_area, va_start|list)

Offsets of the vmap_area's members. They carry vmalloc-specific information. Makedumpfile gets the start address of the vmalloc region from this.

(zone.free_area, NR_PAGE_ORDERS)

Free areas descriptor. User-space tools use this value to iterate the free_area ranges. NR_PAGE_ORDERS is used by the zone buddy allocator.

prb

A pointer to the printk ringbuffer (struct printk_ringbuffer). This may be pointing to the static boot ringbuffer or the dynamically allocated ringbuffer, depending on when the core dump occurred. Used by user-space tools to read the active kernel log buffer.

printk_rb_static

A pointer to the static boot printk ringbuffer. If @prb has a different value, this is useful for viewing the initial boot messages, which may have been overwritten in the dynamically allocated ringbuffer.

clear_seq

The sequence number of the printk() record after the last clear command. It indicates the first record after the last SYSLOG_ACTION_CLEAR, like issued by 'dmesg -c'. Used by user-space tools to dump a subset of the dmesg log.

printk_ringbuffer

The size of a printk_ringbuffer structure. This structure contains all information required for accessing the various components of the kernel log buffer.

(printk_ringbuffer, desc_ring|text_data_ring|dict_data_ring|fail)

Offsets for the various components of the printk ringbuffer. Used by user-space tools to view the kernel log buffer without requiring the declaration of the structure.

prb_desc_ring

The size of the prb_desc_ring structure. This structure contains information about the set of record descriptors.

(prb_desc_ring, count_bits|descs|head_id|tail_id)

Offsets for the fields describing the set of record descriptors. Used by user-space tools to be able to traverse the descriptors without requiring the declaration of the structure.

prb_desc

The size of the prb_desc structure. This structure contains information about a single record descriptor.

(prb_desc, info|state_var|text_blk_lpos|dict_blk_lpos)

Offsets for the fields describing a record descriptors. Used by user-space tools to be able to read descriptors without requiring the declaration of the structure.

prb_data_blk_lpos

The size of the prb_data_blk_lpos structure. This structure contains information about where the text or dictionary data (data block) is located within the respective data ring.

(prb_data_blk_lpos, begin|next)

Offsets for the fields describing the location of a data block. Used by user-space tools to be able to locate data blocks without requiring the declaration of the structure.

printk_info

The size of the printk_info structure. This structure contains all the meta-data for a record.

(printk_info, seq|ts_nsec|text_len|dict_len|caller_id)

Offsets for the fields providing the meta-data for a record. Used by user-space tools to be able to read the information without requiring the declaration of the structure.

prb_data_ring

The size of the prb_data_ring structure. This structure contains information about a set of data blocks.

(prb_data_ring, size_bits|data|head_lpos|tail_lpos)

Offsets for the fields describing a set of data blocks. Used by user-space tools to be able to access the data blocks without requiring the declaration of the structure.

atomic_long_t

The size of the atomic_long_t structure. Used by user-space tools to be able to copy the full structure, regardless of its architecture-specific implementation.

(atomic_long_t, counter)

Offset for the long value of an atomic_long_t variable. Used by user-space tools to access the long value without requiring the architecture-specific declaration.

(free_area.free_list, MIGRATE_TYPES)

The number of migrate types for pages. The free_list is described by the array. Used by tools to compute the number of free pages.

NR_FREE_PAGES

On linux-2.6.21 or later, the number of free pages is in vm_stat[NR_FREE_PAGES]. Used to get the number of free pages.

PG_lru|PG_private|PG_swapcache|PG_swapbacked|PG_slab|PG_hwpoision|PG_head_mask|PG

Page attributes. These flags are used to filter various unnecessary for dumping pages.

PAGE_BUDDY_MAPCOUNT_VALUE(~PG_buddy)|PAGE_OFFLINE_MAPCOUNT_VALUE(~PG_offlin

More page attributes. These flags are used to filter various unnecessary for dumping pages.

17.2.3 x86_64

phys_base

Used to convert the virtual address of an exported kernel symbol to its corresponding physical address.

init_top_pgt

Used to walk through the whole page table and convert virtual addresses to physical addresses. The init_top_pgt is somewhat similar to swapper_pg_dir, but it is only used in x86_64.

pgtable_l5_enabled

User-space tools need to know whether the crash kernel was in 5-level paging mode.

node_data

This is a struct pglist_data array and stores all NUMA nodes information. Makedumpfile gets the pglist_data structure from it.

(node_data, MAX_NUMNODES)

The maximum number of nodes in system.

KERNELOFFSET

The kernel randomization offset. Used to compute the page offset. If KASLR is disabled, this value is zero.

KERNEL_IMAGE_SIZE

Currently unused by Makedumpfile. Used to compute the module virtual address by Crash.

sme_mask

AMD-specific with SME support: it indicates the secure memory encryption mask. Makedumpfile tools need to know whether the crash kernel was encrypted. If SME is enabled in the first kernel, the crash kernel's page table entries (pgd/pud/pmd/pte) contain the memory encryption mask. This is used to remove the SME mask and obtain the true physical address.

Currently, sme_mask stores the value of the C-bit position. If needed, additional SME-relevant info can be placed in that variable.

For example:

```
[ misc                ][ enc bit  ][ other misc SME info       ]
0000_0000_0000_0000_1000_0000_0000_0000_0000_0000_..._0000
63   59   55   51   47   43   39   35   31   27   ... 3
```

17.2.4 x86_32

X86_PAE

Denotes whether physical address extensions are enabled. It has the cost of a higher page table lookup overhead, and also consumes more page table space per process. Used to check whether PAE was enabled in the crash kernel when converting virtual addresses to physical addresses.

17.2.5 ARM64

VA_BITS

The maximum number of bits for virtual addresses. Used to compute the virtual memory ranges.

kimage_voffset

The offset between the kernel virtual and physical mappings. Used to translate virtual to physical addresses.

PHYS_OFFSET

Indicates the physical address of the start of memory. Similar to kimage_voffset, which is used to translate virtual to physical addresses.

KERNELOFFSET

The kernel randomization offset. Used to compute the page offset. If KASLR is disabled, this value is zero.

KERNELPACMASK

The mask to extract the Pointer Authentication Code from a kernel virtual address.

TCR_EL1.T1SZ

Indicates the size offset of the memory region addressed by TTBR1_EL1. The region size is 2^(64-T1SZ) bytes.

TTBR1_EL1 is the table base address register specified by ARMv8-A architecture which is used to lookup the page-tables for the Virtual addresses in the higher VA range (refer to ARMv8 ARM document for more details).

MODULES_VADDR|MODULES_END|VMALLOC_START|VMALLOC_END|VMEMMAP_START|VMEM

Used to get the correct ranges:

MODULES_VADDR ~ MODULES_END-1 : Kernel module space. VMALLOC_START ~ VMALLOC_END-1 : vmalloc() / ioremap() space. VMEMMAP_START ~ VMEMMAP_END-1 : vmemmap region, used for struct page array.

17.2.6 arm

ARM_LPAE

It indicates whether the crash kernel supports large physical address extensions. Used to translate virtual to physical addresses.

17.2.7 s390

lowcore_ptr

An array with a pointer to the lowcore of every CPU. Used to print the psw and all registers information.

high_memory

Used to get the vmalloc_start address from the high_memory symbol.

(lowcore_ptr, NR_CPUS)

The maximum number of CPUs.

17.2.8 powerpc

node_data|(node_data, MAX_NUMNODES)

See above.

contig_page_data

See above.

vmemmap_list

The vmemmap_list maintains the entire vmemmap physical mapping. Used to get vmemmap list count and populated vmemmap regions info. If the vmemmap address translation information is stored in the crash kernel, it is used to translate vmemmap kernel virtual addresses.

mmu_vmemmap_psize

The size of a page. Used to translate virtual to physical addresses.

mmu_psize_defs

Page size definitions, i.e. 4k, 64k, or 16M.

Used to make vtop translations.

vmemmap_backing|(vmemmap_backing, list)|(vmemmap_backing, phys)|(vmemmap_backing, virt_addr)

The vmemmap virtual address space management does not have a traditional page table to track which virtual struct pages are backed by a physical mapping. The virtual to physical mappings are tracked in a simple linked list format.

User-space tools need to know the offset of list, phys and virt_addr when computing the count of vmemmap regions.

mmu_psize_def|(mmu_psize_def, shift)

The size of a struct mmu_psize_def and the offset of mmu_psize_def's member.

Used in vtop translations.

17.2.9 sh

node_data|(node_data, MAX_NUMNODES)

See above.

X2TLB

Indicates whether the crashed kernel enabled SH extended mode.

17.2.10 RISCV64

VA_BITS

The maximum number of bits for virtual addresses. Used to compute the virtual memory ranges.

PAGE_OFFSET

Indicates the virtual kernel start address of the direct-mapped RAM region.

phys_ram_base

Indicates the start physical RAM address.

MODULES_VADDR|MODULES_END|VMALLOC_START|VMALLOC_END|VMEMMAP_START|VMEM

Used to get the correct ranges:

- MODULES_VADDR ~ MODULES_END : Kernel module space.
- VMALLOC_START ~ VMALLOC_END : vmalloc() / ioremap() space.
- VMEMMAP_START ~ VMEMMAP_END : vmemmap space, used for struct page array.
- KERNEL_LINK_ADDR : start address of Kernel link and BPF

va_kernel_pa_offset

Indicates the offset between the kernel virtual and physical mappings. Used to translate virtual to physical addresses.

CHAPTER

EIGHTEEN

PERFORMANCE MONITOR SUPPORT

18.1 HiSilicon SoC uncore Performance Monitoring Unit (PMU)

The HiSilicon SoC chip includes various independent system device PMUs such as L3 cache (L3C), Hydra Home Agent (HHA) and DDRC. These PMUs are independent and have hardware logic to gather statistics and performance information.

The HiSilicon SoC encapsulates multiple CPU and IO dies. Each CPU cluster (CCL) is made up of 4 cpu cores sharing one L3 cache; each CPU die is called Super CPU cluster (SCCL) and is made up of 6 CCLs. Each SCCL has two HHAs (0 - 1) and four DDRCs (0 - 3), respectively.

18.1.1 HiSilicon SoC uncore PMU driver

Each device PMU has separate registers for event counting, control and interrupt, and the PMU driver shall register perf PMU drivers like L3C, HHA and DDRC etc. The available events and configuration options shall be described in the sysfs, see:

/sys/devices/hisi_sccl{X}_<l3c{Y}/hha{Y}/ddrc{Y}>/, or /sys/bus/event_source/devices/hisi_sccl{X}_
The "perf list" command shall list the available events from sysfs.

Each L3C, HHA and DDRC is registered as a separate PMU with perf. The PMU name will appear in event listing as hisi_sccl<sccl-id>_module<index-id>. where "sccl-id" is the identifier of the SCCL and "index-id" is the index of module.

e.g. hisi_sccl3_l3c0/rd_hit_cpipe is READ_HIT_CPIPE event of L3C index #0 in SCCL ID #3.

e.g. hisi_sccl1_hha0/rx_operations is RX_OPERATIONS event of HHA index #0 in SCCL ID #1.

The driver also provides a "cpumask" sysfs attribute, which shows the CPU core ID used to count the uncore PMU event.

Example usage of perf:

```
$# perf list
hisi_sccl3_l3c0/rd_hit_cpipe/ [kernel PMU event]
------------------------------------------
hisi_sccl3_l3c0/wr_hit_cpipe/ [kernel PMU event]
------------------------------------------
hisi_sccl1_l3c0/rd_hit_cpipe/ [kernel PMU event]
------------------------------------------
hisi_sccl1_l3c0/wr_hit_cpipe/ [kernel PMU event]
------------------------------------------
```

```
$# perf stat -a -e hisi_sccl3_l3c0/rd_hit_cpipe/ sleep 5
$# perf stat -a -e hisi_sccl3_l3c0/config=0x02/ sleep 5
```

For HiSilicon uncore PMU v2 whose identifier is 0x30, the topology is the same as PMU v1, but some new functions are added to the hardware.

1. L3C PMU supports filtering by core/thread within the cluster which can be specified as a bitmap:

```
$# perf stat -a -e hisi_sccl3_l3c0/config=0x02,tt_core=0x3/ sleep 5
```

This will only count the operations from core/thread 0 and 1 in this cluster.

2. Tracetag allow the user to chose to count only read, write or atomic operations via the tt_req parameeter in perf. The default value counts all operations. tt_req is 3bits, 3'b100 represents read operations, 3'b101 represents write operations, 3'b110 represents atomic store operations and 3'b111 represents atomic non-store operations, other values are reserved:

```
$# perf stat -a -e hisi_sccl3_l3c0/config=0x02,tt_req=0x4/ sleep 5
```

This will only count the read operations in this cluster.

3. Datasrc allows the user to check where the data comes from. It is 5 bits. Some important codes are as follows:

- 5'b00001: comes from L3C in this die;
- 5'b01000: comes from L3C in the cross-die;
- 5'b01001: comes from L3C which is in another socket;
- 5'b01110: comes from the local DDR;
- 5'b01111: comes from the cross-die DDR;
- 5'b10000: comes from cross-socket DDR;

etc, it is mainly helpful to find that the data source is nearest from the CPU cores. If datasrc_cfg is used in the multi-chips, the datasrc_skt shall be configured in perf command:

```
$# perf stat -a -e hisi_sccl3_l3c0/config=0xb9,datasrc_cfg=0xE/,
hisi_sccl3_l3c0/config=0xb9,datasrc_cfg=0xF/ sleep 5
```

4. Some HiSilicon SoCs encapsulate multiple CPU and IO dies. Each CPU die contains several Compute Clusters (CCLs). The I/O dies are called Super I/O clusters (SICL) containing multiple I/O clusters (ICLs). Each CCL/ICL in the SoC has a unique ID. Each ID is 11bits, include a 6-bit SCCL-ID and 5-bit CCL/ICL-ID. For I/O die, the ICL-ID is followed by:

- 5'b00000: I/O_MGMT_ICL;
- 5'b00001: Network_ICL;
- 5'b00011: HAC_ICL;
- 5'b10000: PCIe_ICL;

5. uring_channel: UC PMU events 0x47~0x59 supports filtering by tx request uring channel. It is 2 bits. Some important codes are as follows:

- 2'b11: count the events which sent to the uring_ext (MATA) channel;
- 2'b01: is the same as 2'b11;
- 2'b10: count the events which sent to the uring (non-MATA) channel;
- 2'b00: default value, count the events which sent to the both uring and uring_ext channel;

Users could configure IDs to count data come from specific CCL/ICL, by setting srcid_cmd & srcid_msk, and data desitined for specific CCL/ICL by setting tgtid_cmd & tgtid_msk. A set bit in srcid_msk/tgtid_msk means the PMU will not check the bit when matching against the srcid_cmd/tgtid_cmd.

If all of these options are disabled, it can works by the default value that doesn't distinguish the filter condition and ID information and will return the total counter values in the PMU counters.

The current driver does not support sampling. So "perf record" is unsupported. Also attach to a task is unsupported as the events are all uncore.

Note: Please contact the maintainer for a complete list of events supported for the PMU devices in the SoC and its information if needed.

18.2 HiSilicon PCIe Performance Monitoring Unit (PMU)

On Hip09, HiSilicon PCIe Performance Monitoring Unit (PMU) could monitor bandwidth, latency, bus utilization and buffer occupancy data of PCIe.

Each PCIe Core has a PMU to monitor multi Root Ports of this PCIe Core and all Endpoints downstream these Root Ports.

18.2.1 HiSilicon PCIe PMU driver

The PCIe PMU driver registers a perf PMU with the name of its sicl-id and PCIe Core id.:

```
/sys/bus/event_source/hisi_pcie<sicl>_core<core>
```

PMU driver provides description of available events and filter options in sysfs, see /sys/bus/event_source/devices/hisi_pcie<sicl>_core<core>.

The "format" directory describes all formats of the config (events) and config1 (filter options) fields of the perf_event_attr structure. The "events" directory describes all documented events shown in perf list.

The "identifier" sysfs file allows users to identify the version of the PMU hardware device.

The "bus" sysfs file allows users to get the bus number of Root Ports monitored by PMU.

Example usage of perf:

```
$# perf list
hisi_pcie0_core0/rx_mwr_latency/ [kernel PMU event]
hisi_pcie0_core0/rx_mwr_cnt/ [kernel PMU event]
--------------------------------------------

$# perf stat -e hisi_pcie0_core0/rx_mwr_latency/
```

```
$# perf stat -e hisi_pcie0_core0/rx_mwr_cnt/
$# perf stat -g -e hisi_pcie0_core0/rx_mwr_latency/ -e hisi_pcie0_core0/rx_mwr_
↪cnt/
```

The current driver does not support sampling. So "perf record" is unsupported. Also attach to a task is unsupported for PCIe PMU.

Filter options

1. Target filter

   PMU could only monitor the performance of traffic downstream target Root Ports or downstream target Endpoint. PCIe PMU driver support "port" and "bdf" interfaces for users, and these two interfaces aren't supported at the same time.

   - port

     "port" filter can be used in all PCIe PMU events, target Root Port can be selected by configuring the 16-bits-bitmap "port". Multi ports can be selected for AP-layer-events, and only one port can be selected for TL/DL-layer-events.

     For example, if target Root Port is 0000:00:00.0 (x8 lanes), bit0 of bitmap should be set, port=0x1; if target Root Port is 0000:00:04.0 (x4 lanes), bit8 is set, port=0x100; if these two Root Ports are both monitored, port=0x101.

     Example usage of perf:

     ```
     $# perf stat -e hisi_pcie0_core0/rx_mwr_latency,port=0x1/ sleep 5
     ```

   - bdf

     "bdf" filter can only be used in bandwidth events, target Endpoint is selected by configuring BDF to "bdf". Counter only counts the bandwidth of message requested by target Endpoint.

     For example, "bdf=0x3900" means BDF of target Endpoint is 0000:39:00.0.

     Example usage of perf:

     ```
     $# perf stat -e hisi_pcie0_core0/rx_mrd_flux,bdf=0x3900/ sleep 5
     ```

2. Trigger filter

   Event statistics start when the first time TLP length is greater/smaller than trigger condition. You can set the trigger condition by writing "trig_len", and set the trigger mode by writing "trig_mode". This filter can only be used in bandwidth events.

   For example, "trig_len=4" means trigger condition is 2^4 DW, "trig_mode=0" means statistics start when TLP length > trigger condition, "trig_mode=1" means start when TLP length < condition.

   Example usage of perf:

   ```
   $# perf stat -e hisi_pcie0_core0/rx_mrd_flux,trig_len=0x4,trig_mode=1/␣
   ↪sleep 5
   ```

3. Threshold filter

   Counter counts when TLP length within the specified range. You can set the threshold by writing "thr_len", and set the threshold mode by writing "thr_mode". This filter can only be used in bandwidth events.

   For example, "thr_len=4" means threshold is 2^4 DW, "thr_mode=0" means counter counts when TLP length >= threshold, and "thr_mode=1" means counts when TLP length < threshold.

   Example usage of perf:

```
$# perf stat -e hisi_pcie0_core0/rx_mrd_flux,thr_len=0x4,thr_mode=1/ sleep␣
↪5
```

4. TLP Length filter

   When counting bandwidth, the data can be composed of certain parts of TLP packets. You can specify it through "len_mode":

   - 2'b00: Reserved (Do not use this since the behaviour is undefined)
   - 2'b01: Bandwidth of TLP payloads
   - 2'b10: Bandwidth of TLP headers
   - 2'b11: Bandwidth of both TLP payloads and headers

   For example, "len_mode=2" means only counting the bandwidth of TLP headers and "len_mode=3" means the final bandwidth data is composed of both TLP headers and payloads. Default value if not specified is 2'b11.

   Example usage of perf:

```
$# perf stat -e hisi_pcie0_core0/rx_mrd_flux,len_mode=0x1/ sleep 5
```

18.3 HNS3 Performance Monitoring Unit (PMU)

HNS3(HiSilicon network system 3) Performance Monitoring Unit (PMU) is an End Point device to collect performance statistics of HiSilicon SoC NIC. On Hip09, each SICL(Super I/O cluster) has one PMU device.

HNS3 PMU supports collection of performance statistics such as bandwidth, latency, packet rate and interrupt rate.

Each HNS3 PMU supports 8 hardware events.

18.3.1 HNS3 PMU driver

The HNS3 PMU driver registers a perf PMU with the name of its sicl id.:

```
/sys/devices/hns3_pmu_sicl_<sicl_id>
```

PMU driver provides description of available events, filter modes, format, identifier and cpumask in sysfs.

The "events" directory describes the event code of all supported events shown in perf list.

The "filtermode" directory describes the supported filter modes of each event.

The "format" directory describes all formats of the config (events) and config1 (filter options) fields of the perf_event_attr structure.

The "identifier" file shows version of PMU hardware device.

The "bdf_min" and "bdf_max" files show the supported bdf range of each pmu device.

The "hw_clk_freq" file shows the hardware clock frequency of each pmu device.

Example usage of checking event code and subevent code:

```
$# cat /sys/devices/hns3_pmu_sicl_0/events/dly_tx_normal_to_mac_time
config=0x00204
$# cat /sys/devices/hns3_pmu_sicl_0/events/dly_tx_normal_to_mac_packet_num
config=0x10204
```

Each performance statistic has a pair of events to get two values to calculate real performance data in userspace.

The bits 0~15 of config (here 0x0204) are the true hardware event code. If two events have same value of bits 0~15 of config, that means they are event pair. And the bit 16 of config indicates getting counter 0 or counter 1 of hardware event.

After getting two values of event pair in userspace, the formula of computation to calculate real performance data is::

```
counter 0 / counter 1
```

Example usage of checking supported filter mode:

```
$# cat /sys/devices/hns3_pmu_sicl_0/filtermode/bw_ssu_rpu_byte_num
filter mode supported: global/port/port-tc/func/func-queue/
```

Example usage of perf:

```
$# perf list
hns3_pmu_sicl_0/bw_ssu_rpu_byte_num/ [kernel PMU event]
hns3_pmu_sicl_0/bw_ssu_rpu_time/     [kernel PMU event]
------------------------------------------

$# perf stat -g -e hns3_pmu_sicl_0/bw_ssu_rpu_byte_num,global=1/ -e hns3_pmu_
↪sicl_0/bw_ssu_rpu_time,global=1/ -I 1000
or
$# perf stat -g -e hns3_pmu_sicl_0/config=0x00002,global=1/ -e hns3_pmu_sicl_0/
↪config=0x10002,global=1/ -I 1000
```

Filter modes

1. global mode PMU collect performance statistics for all HNS3 PCIe functions of IO DIE. Set the "global" filter option to 1 will enable this mode. Example usage of perf:

```
$# perf stat -a -e hns3_pmu_sicl_0/config=0x1020F,global=1/ -I 1000
```

2. port mode PMU collect performance statistic of one whole physical port. The port id is same as mac id. The "tc" filter option must be set to 0xF in this mode, here tc stands for traffic class.

Example usage of perf:

```
$# perf stat -a -e hns3_pmu_sicl_0/config=0x1020F,port=0,tc=0xF/ -I 1000
```

3. port-tc mode PMU collect performance statistic of one tc of physical port. The port id is same as mac id. The "tc" filter option must be set to 0 ~ 7 in this mode. Example usage of perf:

```
$# perf stat -a -e hns3_pmu_sicl_0/config=0x1020F,port=0,tc=0/ -I 1000
```

4. func mode PMU collect performance statistic of one PF/VF. The function id is BDF of PF/VF, its conversion formula:

```
func = (bus << 8) + (device << 3) + (function)
```

for example:
BDF func 35:00.0 0x3500 35:00.1 0x3501 35:01.0 0x3508

In this mode, the "queue" filter option must be set to 0xFFFF. Example usage of perf:

```
$# perf stat -a -e hns3_pmu_sicl_0/config=0x1020F,bdf=0x3500,queue=0xFFFF/ -I␣
↪1000
```

5. func-queue mode PMU collect performance statistic of one queue of PF/VF. The function id is BDF of PF/VF, the "queue" filter option must be set to the exact queue id of function. Example usage of perf:

```
$# perf stat -a -e hns3_pmu_sicl_0/config=0x1020F,bdf=0x3500,queue=0/ -I 1000
```

6. func-intr mode PMU collect performance statistic of one interrupt of PF/VF. The function id is BDF of PF/VF, the "intr" filter option must be set to the exact interrupt id of function. Example usage of perf:

```
$# perf stat -a -e hns3_pmu_sicl_0/config=0x00301,bdf=0x3500,intr=0/ -I 1000
```

18.4 Freescale i.MX8 DDR Performance Monitoring Unit (PMU)

There are no performance counters inside the DRAM controller, so performance signals are brought out to the edge of the controller where a set of 4 x 32 bit counters is implemented. This is controlled by the CSV modes programmed in counter control register which causes a large number of PERF signals to be generated.

Selection of the value for each counter is done via the config registers. There is one register for each counter. Counter 0 is special in that it always counts "time" and when expired causes a lock on itself and the other counters and an interrupt is raised. If any other counter overflows, it continues counting, and no interrupt is raised.

The "format" directory describes format of the config (event ID) and config1/2 (AXI filter setting) fields of the perf_event_attr structure, see /sys/bus/event_source/ devices/imx8_ddr0/format/. The "events" directory describes the events types hardware supported that can be used with perf tool, see /sys/bus/event_source/ devices/imx8_ddr0/events/. The "caps" directory describes filter features implemented in DDR PMU, see /sys/bus/events_source/devices/imx8_ddr0/caps/.

```
perf stat -a -e imx8_ddr0/cycles/ cmd
perf stat -a -e imx8_ddr0/read/,imx8_ddr0/write/ cmd
```

AXI filtering is only used by CSV modes 0x41 (axid-read) and 0x42 (axid-write) to count reading or writing matches filter setting. Filter setting is various from different DRAM controller implementations, which is distinguished by quirks in the driver. You also can dump info from userspace, "caps" directory show the type of AXI filter (filter, enhanced_filter and super_filter). Value 0 for un-supported, and value 1 for supported.

- With DDR_CAP_AXI_ID_FILTER quirk(filter: 1, enhanced_filter: 0, super_filter: 0). Filter is defined with two configuration parts: --AXI_ID defines AxID matching value. --AXI_MASKING defines which bits of AxID are meaningful for the matching.
  - 0: corresponding bit is masked.
  - 1: corresponding bit is not masked, i.e. used to do the matching.

  AXI_ID and AXI_MASKING are mapped on DPCR1 register in performance counter. When non-masked bits are matching corresponding AXI_ID bits then counter is incremented. Perf counter is incremented if:

  ```
  AxID && AXI_MASKING == AXI_ID && AXI_MASKING
  ```

  This filter doesn't support filter different AXI ID for axid-read and axid-write event at the same time as this filter is shared between counters.

  ```
  perf stat -a -e imx8_ddr0/axid-read,axi_mask=0xMMMM,axi_id=0xDDDD/ cmd
  perf stat -a -e imx8_ddr0/axid-write,axi_mask=0xMMMM,axi_id=0xDDDD/ cmd
  ```

  Note: axi_mask is inverted in userspace(i.e. set bits are bits to mask), and it will be reverted in driver automatically. so that the user can just specify axi_id to monitor a specific id, rather than having to specify axi_mask.

  ```
  perf stat -a -e imx8_ddr0/axid-read,axi_id=0x12/ cmd, which will monitor␣
  ↪ARID=0x12
  ```

- With DDR_CAP_AXI_ID_FILTER_ENHANCED quirk(filter: 1, enhanced_filter: 1, super_filter: 0). This is an extension to the DDR_CAP_AXI_ID_FILTER quirk which permits counting the number of bytes (as opposed to the number of bursts) from DDR read and write transactions concurrently with another set of data counters.
- With DDR_CAP_AXI_ID_PORT_CHANNEL_FILTER quirk(filter: 0, enhanced_filter: 0, super_filter: 1). There is a limitation in previous AXI filter, it cannot filter different IDs at the same time as the filter is shared between counters. This quirk is the extension of AXI ID filter. One improvement is that counter 1-3 has their own filter, means that it supports concurrently filter various IDs. Another improvement is that counter 1-3 supports AXI PORT and CHANNEL selection. Support selecting address channel or data channel.

  Filter is defined with 2 configuration registers per counter 1-3. --Counter N MASK COMP register - including AXI_ID and AXI_MASKING. --Counter N MUX CNTL register - including AXI CHANNEL and AXI PORT.

  - 0: address channel
  - 1: data channel

  PMU in DDR subsystem, only one single port0 exists, so axi_port is reserved which should be 0.

```
perf stat -a -e imx8_ddr0/axid-read,axi_mask=0xMMMM,axi_id=0xDDDD,axi_
↪channel=0xH/ cmd
perf stat -a -e imx8_ddr0/axid-write,axi_mask=0xMMMM,axi_id=0xDDDD,axi_
↪channel=0xH/ cmd
```

Note: axi_channel is inverted in userspace, and it will be reverted in driver automatically. So that users do not need specify axi_channel if want to monitor data channel from DDR transactions, since data channel is more meaningful.

18.5 Qualcomm Technologies Level-2 Cache Performance Monitoring Unit (PMU)

This driver supports the L2 cache clusters found in Qualcomm Technologies Centriq SoCs. There are multiple physical L2 cache clusters, each with their own PMU. Each cluster has one or more CPUs associated with it.

There is one logical L2 PMU exposed, which aggregates the results from the physical PMUs.

The driver provides a description of its available events and configuration options in sysfs, see /sys/devices/l2cache_0.

The "format" directory describes the format of the events.

Events can be envisioned as a 2-dimensional array. Each column represents a group of events. There are 8 groups. Only one entry from each group can be in use at a time. If multiple events from the same group are specified, the conflicting events cannot be counted at the same time.

Events are specified as 0xCCG, where CC is 2 hex digits specifying the code (array row) and G specifies the group (column) 0-7.

In addition there is a cycle counter event specified by the value 0xFE which is outside the above scheme.

The driver provides a ”cpumask” sysfs attribute which contains a mask consisting of one CPU per cluster which will be used to handle all the PMU events on that cluster.

Examples for use with perf:

```
perf stat -e l2cache_0/config=0x001/,l2cache_0/config=0x042/ -a sleep 1

perf stat -e l2cache_0/config=0xfe/ -C 2 sleep 1
```

The driver does not support sampling, therefore ”perf record” will not work. Per-task perf sessions are not supported.

18.6 Qualcomm Datacenter Technologies L3 Cache Performance Monitoring Unit (PMU)

This driver supports the L3 cache PMUs found in Qualcomm Datacenter Technologies Centriq SoCs. The L3 cache on these SOCs is composed of multiple slices, shared by all cores within a socket. Each slice is exposed as a separate uncore perf PMU with device name l3cache_<socket>_<instance>. User space is responsible for aggregating across slices.

The driver provides a description of its available events and configuration options in sysfs, see /sys/devices/l3cache*. Given that these are uncore PMUs the driver also exposes a ”cpumask” sysfs attribute which contains a mask consisting of one CPU per socket which will be used to handle all the PMU events on that socket.

The hardware implements 32bit event counters and has a flat 8bit event space exposed via the ”event” format attribute. In addition to the 32bit physical counters the driver supports virtual 64bit hardware counters by using hardware counter chaining. This feature is exposed via the ”lc” (long counter) format flag. E.g.:

```
perf stat -e l3cache_0_0/read-miss,lc/
```

Given that these are uncore PMUs the driver does not support sampling, therefore ”perf record” will not work. Per-task perf sessions are not supported.

18.7 ARM Cache Coherent Network

CCN-504 is a ring-bus interconnect consisting of 11 crosspoints (XPs), with each crosspoint supporting up to two device ports, so nodes (devices) 0 and 1 are connected to crosspoint 0, nodes 2 and 3 to crosspoint 1 etc.

18.7.1 PMU (perf) driver

The CCN driver registers a perf PMU driver, which provides description of available events and configuration options in sysfs, see /sys/bus/event_source/devices/ccn*.

The "format" directory describes format of the config, config1 and config2 fields of the perf_event_attr structure. The "events" directory provides configuration templates for all documented events, that can be used with perf tool. For example "xp_valid_flit" is an equivalent of "type=0x8,event=0x4". Other parameters must be explicitly specified.

For events originating from device, "node" defines its index.

Crosspoint PMU events require "xp" (index), "bus" (bus number) and "vc" (virtual channel ID).

Crosspoint watchpoint-based events (special "event" value 0xfe) require "xp" and "vc" as above plus "port" (device port index), "dir" (transmit/receive direction), comparator values ("cmp_l" and "cmp_h") and "mask", being index of the comparator mask.

Masks are defined separately from the event description (due to limited number of the config values) in the "cmp_mask" directory, with first 8 configurable by user and additional 4 hard-coded for the most frequent use cases.

Cycle counter is described by a "type" value 0xff and does not require any other settings.

The driver also provides a "cpumask" sysfs attribute, which contains a single CPU ID, of the processor which will be used to handle all the CCN PMU events. It is recommended that the user space tools request the events on this processor (if not, the perf_event->cpu value will be overwritten anyway). In case of this processor being offlined, the events are migrated to another one and the attribute is updated.

Example of perf tool use:

```
/ # perf list | grep ccn
  ccn/cycles/                                        [Kernel PMU event]
<...>
  ccn/xp_valid_flit,xp=?,port=?,vc=?,dir=?/          [Kernel PMU event]
<...>

/ # perf stat -a -e ccn/cycles/,ccn/xp_valid_flit,xp=1,port=0,vc=1,dir=1/ \
                                                                      sleep 1
```

The driver does not support sampling, therefore "perf record" will not work. Per-task (without "-a") perf sessions are not supported.

18.8 Arm Coherent Mesh Network PMU

CMN-600 is a configurable mesh interconnect consisting of a rectangular grid of crosspoints (XPs), with each crosspoint supporting up to two device ports to which various AMBA CHI agents are attached.

CMN implements a distributed PMU design as part of its debug and trace functionality. This consists of a local monitor (DTM) at every XP, which counts up to 4 event signals from the connected device nodes and/or the XP itself. Overflow from these local counters is accumulated in up to 8 global counters implemented by the main controller (DTC), which provides overall PMU control and interrupts for global counter overflow.

18.8.1 PMU events

The PMU driver registers a single PMU device for the whole interconnect, see /sys/bus/event_source/devices/arm_cmn_0. Multi-chip systems may link more than one CMN together via external CCIX links - in this situation, each mesh counts its own events entirely independently, and additional PMU devices will be named arm_cmn_{1..n}.

Most events are specified in a format based directly on the TRM definitions - ”type” selects the respective node type, and ”eventid” the event number. Some events require an additional occupancy ID, which is specified by ”occupid”.

- Since RN-D nodes do not have any distinct events from RN-I nodes, they are treated as the same type (0xa), and the common event templates are named ”rnid_*”.
- The cycle counter is treated as a synthetic event belonging to the DTC node (”type” == 0x3, ”eventid” is ignored).
- XP events also encode the port and channel in the ”eventid” field, to match the underlying pmu_event0_id encoding for the pmu_event_sel register. The event templates are named with prefixes to cover all permutations.

By default each event provides an aggregate count over all nodes of the given type. To target a specific node, ”bynodeid” must be set to 1 and ”nodeid” to the appropriate value derived from the CMN configuration (as defined in the ”Node ID Mapping” section of the TRM).

18.8.2 Watchpoints

The PMU can also count watchpoint events to monitor specific flit traffic. Watchpoints are treated as a synthetic event type, and like PMU events can be global or targeted with a particular XP's ”nodeid” value. Since the watchpoint direction is otherwise implicit in the underlying register selection, separate events are provided for flit uploads and downloads.

The flit match value and mask are passed in config1 and config2 (”val” and ”mask” respectively). ”wp_dev_sel”, ”wp_chn_sel”, ”wp_grp” and ”wp_exclusive” are specified per the TRM definitions for dtm_wp_config0. Where a watchpoint needs to match fields from both match groups on the REQ or SNP channel, it can be specified as two events - one for each group - with the same nonzero ”combine” value. The count for such a pair of combined events will be attributed to the primary match. Watchpoint events with a ”combine” value of 0 are considered independent and will count individually.

18.9 APM X-Gene SoC Performance Monitoring Unit (PMU)

X-Gene SoC PMU consists of various independent system device PMUs such as L3 cache(s), I/O bridge(s), memory controller bridge(s) and memory controller(s). These PMU devices are loosely architected to follow the same model as the PMU for ARM cores. The PMUs share the same top level interrupt and status CSR region.

18.9.1 PMU (perf) driver

The xgene-pmu driver registers several perf PMU drivers. Each of the perf driver provides description of its available events and configuration options in sysfs, see /sys/devices/<l3cX/iobX/mcbX/mcX>/.

The "format" directory describes format of the config (event ID), config1 (agent ID) fields of the perf_event_attr structure. The "events" directory provides configuration templates for all supported event types that can be used with perf tool. For example, "l3c0/bank-fifo-full/" is an equivalent of "l3c0/config=0x0b/".

Most of the SoC PMU has a specific list of agent ID used for monitoring performance of a specific datapath. For example, agents of a L3 cache can be a specific CPU or an I/O bridge. Each PMU has a set of 2 registers capable of masking the agents from which the request come from. If the bit with the bit number corresponding to the agent is set, the event is counted only if it is caused by a request from that agent. Each agent ID bit is inversely mapped to a corresponding bit in "config1" field. By default, the event will be counted for all agent requests (config1 = 0x0). For all the supported agents of each PMU, please refer to APM X-Gene User Manual.

Each perf driver also provides a "cpumask" sysfs attribute, which contains a single CPU ID of the processor which will be used to handle all the PMU events.

Example for perf tool use:

```
/ # perf list | grep -e l3c -e iob -e mcb -e mc
  l3c0/ackq-full/                                    [Kernel PMU event]
<...>
  mcb1/mcb-csw-stall/                                [Kernel PMU event]

/ # perf stat -a -e l3c0/read-miss/,mcb1/csw-write-request/ sleep 1

/ # perf stat -a -e l3c0/read-miss,config1=0xfffffffffffffffe/ sleep 1
```

The driver does not support sampling, therefore "perf record" will not work. Per-task (without "-a") perf sessions are not supported.

18.10 ARM DynamIQ Shared Unit (DSU) PMU

ARM DynamIQ Shared Unit integrates one or more cores with an L3 memory system, control logic and external interfaces to form a multicore cluster. The PMU allows counting the various events related to the L3 cache, Snoop Control Unit etc, using 32bit independent counters. It also provides a 64bit cycle counter.

The PMU can only be accessed via CPU system registers and are common to the cores connected to the same DSU. Like most of the other uncore PMUs, DSU PMU doesn't support process specific events and cannot be used in sampling mode.

The DSU provides a bitmap for a subset of implemented events via hardware registers. There is no way for the driver to determine if the other events are available or not. Hence the driver exposes only those events advertised by the DSU, in "events" directory under:

```
/sys/bus/event_sources/devices/arm_dsu_<N>/
```

The user should refer to the TRM of the product to figure out the supported events and use the raw event code for the unlisted events.

The driver also exposes the CPUs connected to the DSU instance in ”associated_cpus”.

e.g usage:

```
perf stat -a -e arm_dsu_0/cycles/
```

18.11 Cavium ThunderX2 SoC Performance Monitoring Unit (PMU UNCORE)

The ThunderX2 SoC PMU consists of independent, system-wide, per-socket PMUs such as the Level 3 Cache (L3C), DDR4 Memory Controller (DMC) and Cavium Coherent Processor Interconnect (CCPI2).

The DMC has 8 interleaved channels and the L3C has 16 interleaved tiles. Events are counted for the default channel (i.e. channel 0) and prorated to the total number of channels/tiles.

The DMC and L3C support up to 4 counters, while the CCPI2 supports up to 8 counters. Counters are independently programmable to different events and can be started and stopped individually. None of the counters support an overflow interrupt. DMC and L3C counters are 32-bit and read every 2 seconds. The CCPI2 counters are 64-bit and assumed not to overflow in normal operation.

PMU UNCORE (perf) driver:

The thunderx2_pmu driver registers per-socket perf PMUs for the DMC and L3C devices. Each PMU can be used to count up to 4 (DMC/L3C) or up to 8 (CCPI2) events simultaneously. The PMUs provide a description of their available events and configuration options under sysfs, see /sys/devices/uncore_<l3c_S/dmc_S/ccpi2_S/>; S is the socket id.

The driver does not support sampling, therefore ”perf record” will not work. Per-task perf sessions are also not supported.

Examples:

```
# perf stat -a -e uncore_dmc_0/cnt_cycles/ sleep 1

# perf stat -a -e \
uncore_dmc_0/cnt_cycles/,\
uncore_dmc_0/data_transfers/,\
uncore_dmc_0/read_txns/,\
uncore_dmc_0/write_txns/ sleep 1

# perf stat -a -e \
uncore_l3c_0/read_request/,\
uncore_l3c_0/read_hit/,\
uncore_l3c_0/inv_request/,\
uncore_l3c_0/inv_hit/ sleep 1
```

18.12 Alibaba's T-Head SoC Uncore Performance Monitoring Unit (PMU)

The Yitian 710, custom-built by Alibaba Group's chip development business, T-Head, implements uncore PMU for performance and functional debugging to facilitate system maintenance.

18.12.1 DDR Sub-System Driveway (DRW) PMU Driver

Yitian 710 employs eight DDR5/4 channels, four on each die. Each DDR5 channel is independent of others to service system memory requests. And one DDR5 channel is split into two independent sub-channels. The DDR Sub-System Driveway implements separate PMUs for each sub-channel to monitor various performance metrics.

The Driveway PMU devices are named as ali_drw_<sys_base_addr> with perf. For example, ali_drw_21000 and ali_drw_21080 are two PMU devices for two sub-channels of the same channel in die 0. And the PMU device of die 1 is prefixed with ali_drw_400XXXXX, e.g. ali_drw_40021000.

Each sub-channel has 36 PMU counters in total, which is classified into four groups:

- Group 0: PMU Cycle Counter. This group has one pair of counters pmu_cycle_cnt_low and pmu_cycle_cnt_high, that is used as the cycle count based on DDRC core clock.
- Group 1: PMU Bandwidth Counters. This group has 8 counters that are used to count the total access number of either the eight bank groups in a selected rank, or four ranks separately in the first 4 counters. The base transfer unit is 64B.
- Group 2: PMU Retry Counters. This group has 10 counters, that intend to count the total retry number of each type of uncorrectable error.
- Group 3: PMU Common Counters. This group has 16 counters, that are used to count the common events.

For now, the Driveway PMU driver only uses counters in group 0 and group 3.

The DDR Controller (DDRCTL) and DDR PHY combine to create a complete solution for connecting an SoC application bus to DDR memory devices. The DDRCTL receives transactions Host Interface (HIF) which is custom-defined by Synopsys. These transactions are queued internally and scheduled for access while satisfying the SDRAM protocol timing requirements, transaction priorities, and dependencies between the transactions. The DDRCTL in turn issues commands on the DDR PHY Interface (DFI) to the PHY module, which launches and captures data to and from the SDRAM. The driveway PMUs have hardware logic to gather statistics and performance logging signals on HIF, DFI, etc.

By counting the READ, WRITE and RMW commands sent to the DDRC through the HIF interface, we could calculate the bandwidth. Example usage of counting memory data bandwidth:

```
perf stat \
  -e ali_drw_21000/hif_wr/ \
  -e ali_drw_21000/hif_rd/ \
  -e ali_drw_21000/hif_rmw/ \
  -e ali_drw_21000/cycle/ \
  -e ali_drw_21080/hif_wr/ \
  -e ali_drw_21080/hif_rd/ \
```

```
  -e ali_drw_21080/hif_rmw/ \
  -e ali_drw_21080/cycle/ \
  -e ali_drw_23000/hif_wr/ \
  -e ali_drw_23000/hif_rd/ \
  -e ali_drw_23000/hif_rmw/ \
  -e ali_drw_23000/cycle/ \
  -e ali_drw_23080/hif_wr/ \
  -e ali_drw_23080/hif_rd/ \
  -e ali_drw_23080/hif_rmw/ \
  -e ali_drw_23080/cycle/ \
  -e ali_drw_25000/hif_wr/ \
  -e ali_drw_25000/hif_rd/ \
  -e ali_drw_25000/hif_rmw/ \
  -e ali_drw_25000/cycle/ \
  -e ali_drw_25080/hif_wr/ \
  -e ali_drw_25080/hif_rd/ \
  -e ali_drw_25080/hif_rmw/ \
  -e ali_drw_25080/cycle/ \
  -e ali_drw_27000/hif_wr/ \
  -e ali_drw_27000/hif_rd/ \
  -e ali_drw_27000/hif_rmw/ \
  -e ali_drw_27000/cycle/ \
  -e ali_drw_27080/hif_wr/ \
  -e ali_drw_27080/hif_rd/ \
  -e ali_drw_27080/hif_rmw/ \
  -e ali_drw_27080/cycle/ -- sleep 10
```

Example usage of counting all memory read/write bandwidth by metric:

```
perf stat -M ddr_read_bandwidth.all -- sleep 10
perf stat -M ddr_write_bandwidth.all -- sleep 10
```

The average DRAM bandwidth can be calculated as follows:

- Read Bandwidth = perf_hif_rd * DDRC_WIDTH * DDRC_Freq / DDRC_Cycle
- Write Bandwidth = (perf_hif_wr + perf_hif_rmw) * DDRC_WIDTH * DDRC_Freq / DDRC_Cycle

Here, DDRC_WIDTH = 64 bytes.

The current driver does not support sampling. So ”perf record” is unsupported. Also attach to a task is unsupported as the events are all uncore.

18.13 Synopsys DesignWare Cores (DWC) PCIe Performance Monitoring Unit (PMU)

18.13.1 DesignWare Cores (DWC) PCIe PMU

The PMU is a PCIe configuration space register block provided by each PCIe Root Port in a Vendor-Specific Extended Capability named RAS D.E.S (Debug, Error injection, and Statistics).

As the name indicates, the RAS DES capability supports system level debugging, AER error injection, and collection of statistics. To facilitate collection of statistics, Synopsys DesignWare Cores PCIe controller provides the following two features:

- one 64-bit counter for Time Based Analysis (RX/TX data throughput and time spent in each low-power LTSSM state) and
- one 32-bit counter for Event Counting (error and non-error events for a specified lane)

Note: There is no interrupt for counter overflow.

Time Based Analysis

Using this feature you can obtain information regarding RX/TX data throughput and time spent in each low-power LTSSM state by the controller. The PMU measures data in two categories:

- Group#0: Percentage of time the controller stays in LTSSM states.
- Group#1: Amount of data processed (Units of 16 bytes).

Lane Event counters

Using this feature you can obtain Error and Non-Error information in specific lane by the controller. The PMU event is selected by all of:

- Group i
- Event j within the Group i
- Lane k

Some of the events only exist for specific configurations.

18.13.2 DesignWare Cores (DWC) PCIe PMU Driver

This driver adds PMU devices for each PCIe Root Port named based on the BDF of the Root Port. For example,

```
30:03.0 PCI bridge: Device 1ded:8000 (rev 01)
```

the PMU device name for this Root Port is dwc_rootport_3018.

The DWC PCIe PMU driver registers a perf PMU driver, which provides description of available events and configuration options in sysfs, see /sys/bus/event_source/devices/dwc_rootport_{bdf}.

The "format" directory describes format of the config fields of the perf_event_attr structure. The "events" directory provides configuration templates for all documented events. For example, "Rx_PCIe_TLP_Data_Payload" is an equivalent of "eventid=0x22,type=0x1".

The "perf list" command shall list the available events from sysfs, e.g.:

```
$# perf list | grep dwc_rootport
<...>
dwc_rootport_3018/Rx_PCIe_TLP_Data_Payload/        [Kernel PMU event]
<...>
dwc_rootport_3018/rx_memory_read,lane=?/                [Kernel PMU event]
```

Time Based Analysis Event Usage

Example usage of counting PCIe RX TLP data payload (Units of bytes):

```
$# perf stat -a -e dwc_rootport_3018/Rx_PCIe_TLP_Data_Payload/
```

The average RX/TX bandwidth can be calculated using the following formula:

> PCIe RX Bandwidth = Rx_PCIe_TLP_Data_Payload / Measure_Time_Window PCIe TX Bandwidth = Tx_PCIe_TLP_Data_Payload / Measure_Time_Window

Lane Event Usage

Each lane has the same event set and to avoid generating a list of hundreds of events, the user need to specify the lane ID explicitly, e.g.:

```
$# perf stat -a -e dwc_rootport_3018/rx_memory_read,lane=4/
```

The driver does not support sampling, therefore "perf record" will not work. Per-task (without "-a") perf sessions are not supported.

18.14 NVIDIA Tegra SoC Uncore Performance Monitoring Unit (PMU)

The NVIDIA Tegra SoC includes various system PMUs to measure key performance metrics like memory bandwidth, latency, and utilization:

- Scalable Coherency Fabric (SCF)
- NVLink-C2C0
- NVLink-C2C1
- CNVLink
- PCIE

18.14.1 PMU Driver

The PMUs in this document are based on ARM CoreSight PMU Architecture as described in document: ARM IHI 0091. Since this is a standard architecture, the PMUs are managed by a common driver "arm-cs-arch-pmu". This driver describes the available events and configuration of each PMU in sysfs. Please see the sections below to get the sysfs path of each PMU. Like other uncore PMU drivers, the driver provides "cpumask" sysfs attribute to show the CPU id used to handle the PMU event. There is also "associated_cpus" sysfs attribute, which contains a list of CPUs associated with the PMU instance.

18.14.2 SCF PMU

The SCF PMU monitors system level cache events, CPU traffic, and strongly-ordered (SO) PCIE write traffic to local/remote memory. Please see *Traffic Coverage* for more info about the PMU traffic coverage.

The events and configuration options of this PMU device are described in sysfs, see /sys/bus/event_sources/devices/nvidia_scf_pmu_<socket-id>.

Example usage:

- Count event id 0x0 in socket 0:

```
perf stat -a -e nvidia_scf_pmu_0/event=0x0/
```

- Count event id 0x0 in socket 1:

```
perf stat -a -e nvidia_scf_pmu_1/event=0x0/
```

18.14.3 NVLink-C2C0 PMU

The NVLink-C2C0 PMU monitors incoming traffic from a GPU/CPU connected with NVLink-C2C (Chip-2-Chip) interconnect. The type of traffic captured by this PMU varies dependent on the chip configuration:

- NVIDIA Grace Hopper Superchip: Hopper GPU is connected with Grace SoC.

  In this config, the PMU captures GPU ATS translated or EGM traffic from the GPU.

- NVIDIA Grace CPU Superchip: two Grace CPU SoCs are connected.

  In this config, the PMU captures read and relaxed ordered (RO) writes from PCIE device of the remote SoC.

Please see *Traffic Coverage* for more info about the PMU traffic coverage.

The events and configuration options of this PMU device are described in sysfs, see /sys/bus/event_sources/devices/nvidia_nvlink_c2c0_pmu_<socket-id>.

Example usage:

- Count event id 0x0 from the GPU/CPU connected with socket 0:

```
perf stat -a -e nvidia_nvlink_c2c0_pmu_0/event=0x0/
```

- Count event id 0x0 from the GPU/CPU connected with socket 1:

```
perf stat -a -e nvidia_nvlink_c2c0_pmu_1/event=0x0/
```

- Count event id 0x0 from the GPU/CPU connected with socket 2:

```
perf stat -a -e nvidia_nvlink_c2c0_pmu_2/event=0x0/
```

- Count event id 0x0 from the GPU/CPU connected with socket 3:

```
perf stat -a -e nvidia_nvlink_c2c0_pmu_3/event=0x0/
```

18.14.4 NVLink-C2C1 PMU

The NVLink-C2C1 PMU monitors incoming traffic from a GPU connected with NVLink-C2C (Chip-2-Chip) interconnect. This PMU captures untranslated GPU traffic, in contrast with NvLink-C2C0 PMU that captures ATS translated traffic. Please see *Traffic Coverage* for more info about the PMU traffic coverage.

The events and configuration options of this PMU device are described in sysfs, see /sys/bus/event_sources/devices/nvidia_nvlink_c2c1_pmu_<socket-id>.

Example usage:

- Count event id 0x0 from the GPU connected with socket 0:

```
perf stat -a -e nvidia_nvlink_c2c1_pmu_0/event=0x0/
```

- Count event id 0x0 from the GPU connected with socket 1:

```
perf stat -a -e nvidia_nvlink_c2c1_pmu_1/event=0x0/
```

- Count event id 0x0 from the GPU connected with socket 2:

```
perf stat -a -e nvidia_nvlink_c2c1_pmu_2/event=0x0/
```

- Count event id 0x0 from the GPU connected with socket 3:

```
perf stat -a -e nvidia_nvlink_c2c1_pmu_3/event=0x0/
```

18.14.5 CNVLink PMU

The CNVLink PMU monitors traffic from GPU and PCIE device on remote sockets to local memory. For PCIE traffic, this PMU captures read and relaxed ordered (RO) write traffic. Please see *Traffic Coverage* for more info about the PMU traffic coverage.

The events and configuration options of this PMU device are described in sysfs, see /sys/bus/event_sources/devices/nvidia_cnvlink_pmu_<socket-id>.

Each SoC socket can be connected to one or more sockets via CNVLink. The user can use "rem_socket" bitmap parameter to select the remote socket(s) to monitor. Each bit represents the socket number, e.g. "rem_socket=0xE" corresponds to socket 1 to 3. /sys/bus/event_sources/devices/nvidia_cnvlink_pmu_<socket-id>/format/rem_socket shows the valid bits that can be set in the "rem_socket" parameter.

The PMU can not distinguish the remote traffic initiator, therefore it does not provide filter to select the traffic source to monitor. It reports combined traffic from remote GPU and PCIE devices.

Example usage:

- Count event id 0x0 for the traffic from remote socket 1, 2, and 3 to socket 0:

```
perf stat -a -e nvidia_cnvlink_pmu_0/event=0x0,rem_socket=0xE/
```

- Count event id 0x0 for the traffic from remote socket 0, 2, and 3 to socket 1:

```
perf stat -a -e nvidia_cnvlink_pmu_1/event=0x0,rem_socket=0xD/
```

- Count event id 0x0 for the traffic from remote socket 0, 1, and 3 to socket 2:

```
perf stat -a -e nvidia_cnvlink_pmu_2/event=0x0,rem_socket=0xB/
```

- Count event id 0x0 for the traffic from remote socket 0, 1, and 2 to socket 3:

```
perf stat -a -e nvidia_cnvlink_pmu_3/event=0x0,rem_socket=0x7/
```

18.14.6 PCIE PMU

The PCIE PMU monitors all read/write traffic from PCIE root ports to local/remote memory. Please see *Traffic Coverage* for more info about the PMU traffic coverage.

The events and configuration options of this PMU device are described in sysfs, see /sys/bus/event_sources/devices/nvidia_pcie_pmu_<socket-id>.

Each SoC socket can support multiple root ports. The user can use "root_port" bitmap parameter to select the port(s) to monitor, i.e. "root_port=0xF" corresponds to root port 0 to 3. /sys/bus/event_sources/devices/nvidia_pcie_pmu_<socket-id>/format/root_port shows the valid bits that can be set in the "root_port" parameter.

Example usage:

- Count event id 0x0 from root port 0 and 1 of socket 0:

```
perf stat -a -e nvidia_pcie_pmu_0/event=0x0,root_port=0x3/
```

- Count event id 0x0 from root port 0 and 1 of socket 1:

```
perf stat -a -e nvidia_pcie_pmu_1/event=0x0,root_port=0x3/
```

18.14.7 Traffic Coverage

The PMU traffic coverage may vary dependent on the chip configuration:

- **NVIDIA Grace Hopper Superchip**: Hopper GPU is connected with Grace SoC.

  Example configuration with two Grace SoCs:

```

PCIE1 traffic represents strongly ordered (SO) writes.
PCIE2 traffic represents reads and relaxed ordered (RO) writes.
```

18.15 Amlogic SoC DDR Bandwidth Performance Monitoring Unit (PMU)

The Amlogic Meson G12 SoC contains a bandwidth monitor inside DRAM controller. The monitor includes 4 channels. Each channel can count the request accessing DRAM. The channel can count up to 3 AXI port simultaneously. It can be helpful to show if the performance bottleneck is on DDR bandwidth.

Currently, this driver supports the following 5 perf events:

- meson_ddr_bw/total_rw_bytes/
- meson_ddr_bw/chan_1_rw_bytes/
- meson_ddr_bw/chan_2_rw_bytes/
- meson_ddr_bw/chan_3_rw_bytes/
- meson_ddr_bw/chan_4_rw_bytes/

meson_ddr_bw/chan_{1,2,3,4}_rw_bytes/ events are channel-specific events. Each channel support filtering, which can let the channel to monitor individual IP module in SoC.

Below are DDR access request event filter keywords:

- arm - from CPU
- vpu_read1 - from OSD + VPP read
- gpu - from 3D GPU
- pcie - from PCIe controller
- hdcp - from HDCP controller
- hevc_front - from HEVC codec front end
- usb3_0 - from USB3.0 controller
- hevc_back - from HEVC codec back end
- h265enc - from HEVC encoder
- vpu_read2 - from DI read
- vpu_write1 - from VDIN write
- vpu_write2 - from di write
- vdec - from legacy codec video decoder
- hcodec - from H264 encoder
- ge2d - from ge2d
- spicc1 - from SPI controller 1
- usb0 - from USB2.0 controller 0
- dma - from system DMA controller 1
- arb0 - from arb0
- sd_emmc_b - from SD eMMC b controller

- usb1 - from USB2.0 controller 1
- audio - from Audio module
- sd_emmc_c - from SD eMMC c controller
- spicc2 - from SPI controller 2
- ethernet - from Ethernet controller

Examples:

- Show the total DDR bandwidth per seconds:

```
perf stat -a -e meson_ddr_bw/total_rw_bytes/ -I 1000 sleep 10
```

- Show individual DDR bandwidth from CPU and GPU respectively, as well as sum of them:

```
perf stat -a -e meson_ddr_bw/chan_1_rw_bytes,arm=1/ -I 1000 sleep 10
perf stat -a -e meson_ddr_bw/chan_2_rw_bytes,gpu=1/ -I 1000 sleep 10
perf stat -a -e meson_ddr_bw/chan_3_rw_bytes,arm=1,gpu=1/ -I 1000 sleep 10
```

18.16 CXL Performance Monitoring Unit (CPMU)

The CXL rev 3.0 specification provides a definition of CXL Performance Monitoring Unit in section 13.2: Performance Monitoring.

CXL components (e.g. Root Port, Switch Upstream Port, End Point) may have any number of CPMU instances. CPMU capabilities are fully discoverable from the devices. The specification provides event definitions for all CXL protocol message types and a set of additional events for things commonly counted on CXL devices (e.g. DRAM events).

18.16.1 CPMU driver

The CPMU driver registers a perf PMU with the name pmu_mem<X>.<Y> on the CXL bus representing the Yth CPMU for memX.

/sys/bus/cxl/device/pmu_mem<X>.<Y>

The associated PMU is registered as

/sys/bus/event_sources/devices/cxl_pmu_mem<X>.<Y>

In common with other CXL bus devices, the id has no specific meaning and the relationship to specific CXL device should be established via the device parent of the device on the CXL bus.

PMU driver provides description of available events and filter options in sysfs.

The "format" directory describes all formats of the config (event vendor id, group id and mask) config1 (threshold, filter enables) and config2 (filter parameters) fields of the perf_event_attr structure. The "events" directory describes all documented events show in perf list.

The events shown in perf list are the most fine grained events with a single bit of the event mask set. More general events may be enable by setting multiple mask bits in config. For example, all Device to Host Read Requests may be captured on a single counter by setting the bits for all of

- d2h_req_rdcurr
- d2h_req_rdown
- d2h_req_rdshared
- d2h_req_rdany
- d2h_req_rdownnodata

Example of usage:

```
$#perf list
cxl_pmu_mem0.0/clock_ticks/                        [Kernel PMU event]
cxl_pmu_mem0.0/d2h_req_rdshared/                   [Kernel PMU event]
cxl_pmu_mem0.0/h2d_req_snpcur/                     [Kernel PMU event]
cxl_pmu_mem0.0/h2d_req_snpdata/                    [Kernel PMU event]
cxl_pmu_mem0.0/h2d_req_snpinv/                     [Kernel PMU event]
------------------------------------------------------------

$# perf stat -a -e cxl_pmu_mem0.0/clock_ticks/ -e cxl_pmu_mem0.0/d2h_req_
↪rdshared/
```

Vendor specific events may also be available and if so can be used via

$# perf stat -a -e cxl_pmu_mem0.0/vid=VID,gid=GID,mask=MASK/

The driver does not support sampling so "perf record" is unsupported. It only supports system-wide counting so attaching to a task is unsupported.

18.17 Ampere SoC Performance Monitoring Unit (PMU)

Ampere SoC PMU is a generic PMU IP that follows Arm CoreSight PMU architecture. Therefore, the driver is implemented as a submodule of arm_cspmu driver. At the first phase it's used for counting MCU events on AmpereOne.

18.17.1 MCU PMU events

The PMU driver supports setting filters for "rank", "bank", and "threshold". Note, that the filters are per PMU instance rather than per event.

Example for perf tool use:

```
/ # perf list ampere

  ampere_mcu_pmu_0/act_sent/                         [Kernel PMU event]
  <...>
  ampere_mcu_pmu_1/rd_sent/                          [Kernel PMU event]
  <...>

/ # perf stat -a -e ampere_mcu_pmu_0/act_sent,bank=5,rank=3,threshold=2/,
↪ampere_mcu_pmu_1/rd_sent/ \
      sleep 1
```

CHAPTER

NINETEEN

PSTORE BLOCK OOPS/PANIC LOGGER

19.1 Introduction

pstore block (pstore/blk) is an oops/panic logger that writes its logs to a block device and non-block device before the system crashes. You can get these log files by mounting pstore filesystem like:

```
mount -t pstore pstore /sys/fs/pstore
```

19.2 pstore block concepts

pstore/blk provides efficient configuration method for pstore/blk, which divides all configurations into two parts, configurations for user and configurations for driver.

Configurations for user determine how pstore/blk works, such as pmsg_size, kmsg_size and so on. All of them support both Kconfig and module parameters, but module parameters have priority over Kconfig.

Configurations for driver are all about block device and non-block device, such as total_size of block device and read/write operations.

19.3 Configurations for user

All of these configurations support both Kconfig and module parameters, but module parameters have priority over Kconfig.

Here is an example for module parameters:

```
pstore_blk.blkdev=/dev/mmcblk0p7 pstore_blk.kmsg_size=64 best_effort=y
```

The detail of each configurations may be of interest to you.

19.3.1 blkdev

The block device to use. Most of the time, it is a partition of block device. It's required for pstore/blk. It is also used for MTD device.

When pstore/blk is built as a module, ”blkdev” accepts the following variants:

1. /dev/<disk_name> represents the device number of disk
2. /dev/<disk_name><decimal> represents the device number of partition - device number of disk plus the partition number
3. /dev/<disk_name>p<decimal> - same as the above; this form is used when disk name of partitioned disk ends with a digit.

When pstore/blk is built into the kernel, ”blkdev” accepts the following variants:

1. <hex_major><hex_minor> device number in hexadecimal representation, with no leading 0x, for example b302.
2. PARTUUID=00112233-4455-6677-8899-AABBCCDDEEFF represents the unique id of a partition if the partition table provides it. The UUID may be either an EFI/GPT UUID, or refer to an MSDOS partition using the format SSSSSSSS-PP, where SSSSSSSS is a zero-filled hex representation of the 32-bit ”NT disk signature”, and PP is a zero-filled hex representation of the 1-based partition number.
3. PARTUUID=<UUID>/PARTNROFF=<int> to select a partition in relation to a partition with a known unique id.
4. <major>:<minor> major and minor number of the device separated by a colon.

It accepts the following variants for MTD device:

1. <device name> MTD device name. ”pstore” is recommended.
2. <device number> MTD device number.

19.3.2 kmsg_size

The chunk size in KB for oops/panic front-end. It **MUST** be a multiple of 4. It's optional if you do not care about the oops/panic log.

There are multiple chunks for oops/panic front-end depending on the remaining space except other pstore front-ends.

pstore/blk will log to oops/panic chunks one by one, and always overwrite the oldest chunk if there is no more free chunk.

19.3.3 pmsg_size

The chunk size in KB for pmsg front-end. It **MUST** be a multiple of 4. It's optional if you do not care about the pmsg log.

Unlike oops/panic front-end, there is only one chunk for pmsg front-end.

Pmsg is a user space accessible pstore object. Writes to */dev/pmsg0* are appended to the chunk. On reboot the contents are available in */sys/fs/pstore/pmsg-pstore-blk-0*.

19.3.4 console_size

The chunk size in KB for console front-end. It **MUST** be a multiple of 4. It's optional if you do not care about the console log.

Similar to pmsg front-end, there is only one chunk for console front-end.

All log of console will be appended to the chunk. On reboot the contents are available in */sys/fs/pstore/console-pstore-blk-0*.

19.3.5 ftrace_size

The chunk size in KB for ftrace front-end. It **MUST** be a multiple of 4. It's optional if you do not care about the ftrace log.

Similar to oops front-end, there are multiple chunks for ftrace front-end depending on the count of cpu processors. Each chunk size is equal to ftrace_size / processors_count.

All log of ftrace will be appended to the chunk. On reboot the contents are combined and available in */sys/fs/pstore/ftrace-pstore-blk-0*.

Persistent function tracing might be useful for debugging software or hardware related hangs. Here is an example of usage:

```
# mount -t pstore pstore /sys/fs/pstore
# mount -t debugfs debugfs /sys/kernel/debug/
# echo 1 > /sys/kernel/debug/pstore/record_ftrace
# reboot -f
[...]
# mount -t pstore pstore /sys/fs/pstore
# tail /sys/fs/pstore/ftrace-pstore-blk-0

```

19.3.6 max_reason

Limiting which kinds of kmsg dumps are stored can be controlled via the `max_reason` value, as defined in include/linux/kmsg_dump.h's `enum kmsg_dump_reason`. For example, to store both Oopses and Panics, `max_reason` should be set to 2 (KMSG_DUMP_OOPS), to store only Panics `max_reason` should be set to 1 (KMSG_DUMP_PANIC). Setting this to 0 (KMSG_DUMP_UNDEF), means the reason filtering will be controlled by the `printk.always_kmsg_dump` boot param: if unset, it'll be KMSG_DUMP_OOPS, otherwise KMSG_DUMP_MAX.

19.4 Configurations for driver

A device driver uses `register_pstore_device` with `struct pstore_device_info` to register to pstore/blk.

int **register_pstore_device**(struct *pstore_device_info* *dev)

register non-block device to pstore/blk

Parameters

struct pstore_device_info *dev
non-block device information

Return

- 0 - OK
- Others - something error.

void **unregister_pstore_device**(struct *pstore_device_info* *dev)

unregister non-block device from pstore/blk

Parameters

struct pstore_device_info *dev
non-block device information

19.5 Compression and header

Block device is large enough for uncompressed oops data. Actually we do not recommend data compression because pstore/blk will insert some information into the first line of oops/panic data. For example:

```
Panic: Total 16 times
```

It means that it's OOPS|Panic for the 16th time since the first booting. Sometimes the number of occurrences of oops|panic since the first booting is important to judge whether the system is stable.

The following line is inserted by pstore filesystem. For example:

```
Oops#2 Part1
```

It means that it's OOPS for the 2nd time on the last boot.

19.6 Reading the data

The dump data can be read from the pstore filesystem. The format for these files is `dmesg-pstore-blk-[N]` for oops/panic front-end, `pmsg-pstore-blk-0` for pmsg front-end and so on. The timestamp of the dump file records the trigger time. To delete a stored record from block device, simply unlink the respective pstore file.

19.7 Attentions in panic read/write APIs

If on panic, the kernel is not going to run for much longer, the tasks will not be scheduled and most kernel resources will be out of service. It looks like a single-threaded program running on a single-core computer.

The following points require special attention for panic read/write APIs:

1. Can **NOT** allocate any memory. If you need memory, just allocate while the block driver is initializing rather than waiting until the panic.
2. Must be polled, **NOT** interrupt driven. No task schedule any more. The block driver should delay to ensure the write succeeds, but NOT sleep.
3. Can **NOT** take any lock. There is no other task, nor any shared resource; you are safe to break all locks.
4. Just use CPU to transfer. Do not use DMA to transfer unless you are sure that DMA will not keep lock.
5. Control registers directly. Please control registers directly rather than use Linux kernel resources. Do I/O map while initializing rather than wait until a panic occurs.
6. Reset your block device and controller if necessary. If you are not sure of the state of your block device and controller when a panic occurs, you are safe to stop and reset them.

pstore/blk supports psblk_blkdev_info(), which is defined in *linux/pstore_blk.h*, to get information of using block device, such as the device number, sector count and start sector of the whole disk.

19.8 pstore block internals

For developer reference, here are all the important structures and APIs:

struct **psz_buffer**

header of zone to flush to storage

Definition:

```
struct psz_buffer {
#define PSZ_SIG (0x43474244) ;
    uint32_t sig;
    atomic_t datalen;
    atomic_t start;
    uint8_t data[];
};
```

Members

sig

signature to indicate header (PSZ_SIG xor PSZONE-type value)

datalen

length of data in **data**

start

offset into **data** where the beginning of the stored bytes begin

data

zone data.

struct **psz_kmsg_header**

kmsg dump-specific header to flush to storage

Definition:

```
struct psz_kmsg_header {
#define PSTORE_KMSG_HEADER_MAGIC 0x4dfc3ae5 ;
    uint32_t magic;
    struct timespec64 time;
    bool compressed;
    uint32_t counter;
    enum kmsg_dump_reason reason;
    uint8_t data[];
};
```

Members

magic

magic num for kmsg dump header

time

kmsg dump trigger time

compressed

whether conpressed

counter
kmsg dump counter

reason
the kmsg dump reason (e.g. oops, panic, etc)

data
pointer to log data

Description

This is a sub-header for a kmsg dump, trailing after *psz_buffer*.

struct **pstore_zone**
single stored buffer

Definition:

```
struct pstore_zone {
    loff_t off;
    const char *name;
    enum pstore_type_id type;
    struct psz_buffer *buffer;
    struct psz_buffer *oldbuf;
    size_t buffer_size;
    bool should_recover;
    atomic_t dirty;
};
```

Members

off
zone offset of storage

name
front-end name for this zone

type
front-end type for this zone

buffer
pointer to data buffer managed by this zone

oldbuf
pointer to old data buffer

buffer_size
bytes in **buffer->data**

should_recover
whether this zone should recover from storage

dirty
whether the data in **buffer** dirty

Description

zone structure in memory.

struct **psz_context**

all about running state of pstore/zone

Definition:

```
struct psz_context {
    struct pstore_zone **kpszs;
    struct pstore_zone *ppsz;
    struct pstore_zone *cpsz;
    struct pstore_zone **fpszs;
    unsigned int kmsg_max_cnt;
    unsigned int kmsg_read_cnt;
    unsigned int kmsg_write_cnt;
    unsigned int pmsg_read_cnt;
    unsigned int console_read_cnt;
    unsigned int ftrace_max_cnt;
    unsigned int ftrace_read_cnt;
    unsigned int oops_counter;
    unsigned int panic_counter;
    atomic_t recovered;
    atomic_t on_panic;
    struct mutex pstore_zone_info_lock;
    struct pstore_zone_info *pstore_zone_info;
    struct pstore_info pstore;
};
```

Members

kpszs
kmsg dump storage zones

ppsz
pmsg storage zone

cpsz
console storage zone

fpszs
ftrace storage zones

kmsg_max_cnt
max count of **kpszs**

kmsg_read_cnt
counter of total read kmsg dumps

kmsg_write_cnt
counter of total kmsg dump writes

pmsg_read_cnt
counter of total read pmsg zone

console_read_cnt
counter of total read console zone

ftrace_max_cnt
max count of **fpszs**

ftrace_read_cnt
counter of max read ftrace zone

oops_counter
counter of oops dumps

panic_counter
counter of panic dumps

recovered
whether finished recovering data from storage

on_panic
whether panic is happening

pstore_zone_info_lock
lock to **pstore_zone_info**

pstore_zone_info
information from backend

pstore
structure for pstore

enum **psz_flush_mode**
flush mode for psz_zone_write()

Constants

FLUSH_NONE
do not flush to storage but update data on memory

FLUSH_PART
just flush part of data including meta data to storage

FLUSH_META
just flush meta data of zone to storage

FLUSH_ALL
flush all of zone

int **psz_recovery**(struct *psz_context* *cxt)
recover data from storage

Parameters

struct psz_context *cxt
the context of pstore/zone

Description

recovery means reading data back from storage after rebooting

Return

0 on success, others on failure.

struct **pstore_zone_info**
pstore/zone back-end driver structure

Definition:

```
struct pstore_zone_info {
    struct module *owner;
    const char *name;
    unsigned long total_size;
    unsigned long kmsg_size;
    int max_reason;
    unsigned long pmsg_size;
    unsigned long console_size;
    unsigned long ftrace_size;
    pstore_zone_read_op read;
    pstore_zone_write_op write;
    pstore_zone_erase_op erase;
    pstore_zone_write_op panic_write;
};
```

Members

owner
Module which is responsible for this back-end driver.

name
Name of the back-end driver.

total_size
The total size in bytes pstore/zone can use. It must be greater than 4096 and be multiple of 4096.

kmsg_size
The size of oops/panic zone. Zero means disabled, otherwise, it must be multiple of SECTOR_SIZE(512 Bytes).

max_reason
Maximum kmsg dump reason to store.

pmsg_size
The size of pmsg zone which is the same as **kmsg_size**.

console_size
The size of console zone which is the same as **kmsg_size**.

ftrace_size
The size of ftrace zone which is the same as **kmsg_size**.

read
The general read operation. Both of the function parameters **size** and **offset** are relative value to storage. On success, the number of bytes should be returned, others mean error.

write
The same as **read**, but the following error number: -EBUSY means try to write again later. -ENOMSG means to try next zone.

erase
The general erase operation for device with special removing job. Both of the function parameters **size** and **offset** are relative value to storage. Return 0 on success and others on failure.

panic_write
The write operation only used for panic case. It's optional if you do not care panic log. The parameters are relative value to storage. On success, the number of bytes should be returned, others excluding -ENOMSG mean error. -ENOMSG means to try next zone.

struct **pstore_device_info**
back-end pstore/blk driver structure.

Definition:

```
struct pstore_device_info {
    unsigned int flags;
    struct pstore_zone_info zone;
};
```

Members

flags
Refer to macro starting with PSTORE_FLAGS defined in linux/pstore.h. It means what front-ends this device support. Zero means all backends for compatible.

zone
The *struct pstore_zone_info* details.

struct **pstore_blk_config**
the pstore_blk backend configuration

Definition:

```
struct pstore_blk_config {
    char device[80];
    enum kmsg_dump_reason max_reason;
    unsigned long kmsg_size;
    unsigned long pmsg_size;
    unsigned long console_size;
    unsigned long ftrace_size;
};
```

Members

device
Name of the desired block device

max_reason
Maximum kmsg dump reason to store to block device

kmsg_size
Total size of for kmsg dumps

pmsg_size
Total size of the pmsg storage area

console_size
Total size of the console storage area

ftrace_size
Total size for ftrace logging data (for all CPUs)

int **pstore_blk_get_config**(struct *pstore_blk_config* *info)

get a copy of the pstore_blk backend configuration

Parameters

struct pstore_blk_config *info

The sturct pstore_blk_config to be filled in

Description

Failure returns negative error code, and success returns 0.

This is the beginning of a section with information of interest to application developers. Documents covering various aspects of the kernel ABI will be found here.

CHAPTER

TWENTY

RULES ON HOW TO ACCESS INFORMATION IN SYSFS

The kernel-exported sysfs exports internal kernel implementation details and depends on internal kernel structures and layout. It is agreed upon by the kernel developers that the Linux kernel does not provide a stable internal API. Therefore, there are aspects of the sysfs interface that may not be stable across kernel releases.

To minimize the risk of breaking users of sysfs, which are in most cases low-level userspace applications, with a new kernel release, the users of sysfs must follow some rules to use an as-abstract-as-possible way to access this filesystem. The current udev and HAL programs already implement this and users are encouraged to plug, if possible, into the abstractions these programs provide instead of accessing sysfs directly.

But if you really do want or need to access sysfs directly, please follow the following rules and then your programs should work with future versions of the sysfs interface.

- **Do not use libsysfs**
  It makes assumptions about sysfs which are not true. Its API does not offer any abstraction, it exposes all the kernel driver-core implementation details in its own API. Therefore it is not better than reading directories and opening the files yourself. Also, it is not actively maintained, in the sense of reflecting the current kernel development. The goal of providing a stable interface to sysfs has failed; it causes more problems than it solves. It violates many of the rules in this document.

- **sysfs is always at `/sys`**
  Parsing `/proc/mounts` is a waste of time. Other mount points are a system configuration bug you should not try to solve. For test cases, possibly support a `SYSFS_PATH` environment variable to overwrite the application's behavior, but never try to search for sysfs. Never try to mount it, if you are not an early boot script.

- **devices are only "devices"**
  There is no such thing like class-, bus-, physical devices, interfaces, and such that you can rely on in userspace. Everything is just simply a "device". Class-, bus-, physical, ... types are just kernel implementation details which should not be expected by applications that look for devices in sysfs.

  The properties of a device are:

  - devpath (`/devices/pci0000:00/0000:00:1d.1/usb2/2-2/2-2:1.0`)
    - identical to the DEVPATH value in the event sent from the kernel at device creation and removal
    - the unique key to the device at that point in time

    * the kernel's path to the device directory without the leading `/sys`, and always starting with a slash
    * all elements of a devpath must be real directories. Symlinks pointing to /sys/devices must always be resolved to their real target and the target path must be used to access the device. That way the devpath to the device matches the devpath of the kernel used at event time.
    * using or exposing symlink values as elements in a devpath string is a bug in the application
  - kernel name (`sda`, `tty`, `0000:00:1f.2`, ...)
    * a directory name, identical to the last element of the devpath
    * applications need to handle spaces and characters like `!` in the name
  - subsystem (`block`, `tty`, `pci`, ...)
    * simple string, never a path or a link
    * retrieved by reading the "subsystem"-link and using only the last element of the target path
  - driver (`tg3`, `ata_piix`, `uhci_hcd`)
    * a simple string, which may contain spaces, never a path or a link
    * it is retrieved by reading the "driver"-link and using only the last element of the target path
    * devices which do not have "driver"-link just do not have a driver; copying the driver value in a child device context is a bug in the application
  - attributes
    * the files in the device directory or files below subdirectories of the same device directory
    * accessing attributes reached by a symlink pointing to another device, like the "device"-link, is a bug in the application

  Everything else is just a kernel driver-core implementation detail that should not be assumed to be stable across kernel releases.

- **Properties of parent devices never belong into a child device.**
  Always look at the parent devices themselves for determining device context properties. If the device `eth0` or `sda` does not have a "driver"-link, then this device does not have a driver. Its value is empty. Never copy any property of the parent-device into a child-device. Parent device properties may change dynamically without any notice to the child device.

- **Hierarchy in a single device tree**
  There is only one valid place in sysfs where hierarchy can be examined and this is below: `/sys/devices.` It is planned that all device directories will end up in the tree below this directory.

- **Classification by subsystem**
  There are currently three places for classification of devices: `/sys/block, /sys/class` and `/sys/bus.` It is planned that these will not contain any device directories themselves, but only flat lists of symlinks pointing to the unified `/sys/devices` tree. All

three places have completely different rules on how to access device information. It is planned to merge all three classification directories into one place at `/sys/subsystem`, following the layout of the bus directories. All buses and classes, including the converted block subsystem, will show up there. The devices belonging to a subsystem will create a symlink in the "devices" directory at `/sys/subsystem/<name>/devices`,

If `/sys/subsystem` exists, `/sys/bus`, `/sys/class` and `/sys/block` can be ignored. If it does not exist, you always have to scan all three places, as the kernel is free to move a subsystem from one place to the other, as long as the devices are still reachable by the same subsystem name.

Assuming `/sys/class/<subsystem>` and `/sys/bus/<subsystem>`, or `/sys/block` and `/sys/class/block` are not interchangeable is a bug in the application.

- **Block**
  The converted block subsystem at `/sys/class/block` or `/sys/subsystem/block` will contain the links for disks and partitions at the same level, never in a hierarchy. Assuming the block subsystem to contain only disks and not partition devices in the same flat list is a bug in the application.

- **"device"-link and <subsystem>:<kernel name>-links**
  Never depend on the "device"-link. The "device"-link is a workaround for the old layout, where class devices are not created in `/sys/devices/` like the bus devices. If the link-resolving of a device directory does not end in `/sys/devices/`, you can use the "device"-link to find the parent devices in `/sys/devices/`, That is the single valid use of the "device"-link; it must never appear in any path as an element. Assuming the existence of the "device"-link for a device in `/sys/devices/` is a bug in the application. Accessing `/sys/class/net/eth0/device` is a bug in the application.

  Never depend on the class-specific links back to the `/sys/class` directory. These links are also a workaround for the design mistake that class devices are not created in `/sys/devices.` If a device directory does not contain directories for child devices, these links may be used to find the child devices in `/sys/class.` That is the single valid use of these links; they must never appear in any path as an element. Assuming the existence of these links for devices which are real child device directories in the `/sys/devices` tree is a bug in the application.

  It is planned to remove all these links when all class device directories live in `/sys/devices.`

- **Position of devices along device chain can change.**
  Never depend on a specific parent device position in the devpath, or the chain of parent devices. The kernel is free to insert devices into the chain. You must always request the parent device you are looking for by its subsystem value. You need to walk up the chain until you find the device that matches the expected subsystem. Depending on a specific position of a parent device or exposing relative paths using `../` to access the chain of parents is a bug in the application.

- **When reading and writing sysfs device attribute files, avoid dependency**
  on specific error codes wherever possible. This minimizes coupling to the error handling implementation within the kernel.

  In general, failures to read or write sysfs device attributes shall propagate errors wherever possible. Common errors include, but are not limited to:

  `-EIO`: The read or store operation is not supported, typically returned by the

sysfs system itself if the read or store pointer is `NULL`.

`-ENXIO`: The read or store operation failed

Error codes will not be changed without good reason, and should a change to error codes result in user-space breakage, it will be fixed, or the the offending change will be reverted.

Userspace applications can, however, expect the format and contents of the attribute files to remain consistent in the absence of a version attribute change in the context of a given attribute.

This is the beginning of a section with information of interest to application developers and system integrators doing analysis of the Linux kernel for safety critical applications. Documents supporting analysis of kernel interactions with applications, and key kernel subsystems expectations will be found here.

TWENTYONE

DISCOVERING LINUX KERNEL SUBSYSTEMS USED BY A WORKLOAD

Authors

- Shuah Khan <skhan@linuxfoundation.org>
- Shefali Sharma <sshefali021@gmail.com>

maintained-by
Shuah Khan <skhan@linuxfoundation.org>

21.1 Key Points

- Understanding system resources necessary to build and run a workload is important.
- Linux tracing and strace can be used to discover the system resources in use by a workload. The completeness of the system usage information depends on the completeness of coverage of a workload.
- Performance and security of the operating system can be analyzed with the help of tools such as: perf, stress-ng, paxtest.
- Once we discover and understand the workload needs, we can focus on them to avoid regressions and use it to evaluate safety considerations.

21.2 Methodology

strace is a diagnostic, instructional, and debugging tool and can be used to discover the system resources in use by a workload. Once we discover and understand the workload needs, we can focus on them to avoid regressions and use it to evaluate safety considerations. We use strace tool to trace workloads.

This method of tracing using strace tells us the system calls invoked by the workload and doesn't include all the system calls that can be invoked by it. In addition, this tracing method tells us just the code paths within these system calls that are invoked. As an example, if a workload opens a file and reads from it successfully, then the success path is the one that is traced. Any error paths in that system call will not be traced. If there is a workload that provides full coverage of a workload then the method outlined here will trace and find all possible code paths. The completeness of the system usage information depends on the completeness of coverage of a workload.

The goal is tracing a workload on a system running a default kernel without requiring custom kernel installs.

21.3 How do we gather fine-grained system information?

strace tool can be used to trace system calls made by a process and signals it receives. System calls are the fundamental interface between an application and the operating system kernel. They enable a program to request services from the kernel. For instance, the open() system call in Linux is used to provide access to a file in the file system. strace enables us to track all the system calls made by an application. It lists all the system calls made by a process and their resulting output.

You can generate profiling data combining strace and perf record tools to record the events and information associated with a process. This provides insight into the process. ”perf annotate” tool generates the statistics of each instruction of the program. This document goes over the details of how to gather fine-grained information on a workload's usage of system resources.

We used strace to trace the perf, stress-ng, paxtest workloads to illustrate our methodology to discover resources used by a workload. This process can be applied to trace other workloads.

21.4 Getting the system ready for tracing

Before we can get started we will show you how to get your system ready. We assume that you have a Linux distribution running on a physical system or a virtual machine. Most distributions will include strace command. Let’s install other tools that aren’t usually included to build Linux kernel. Please note that the following works on Debian based distributions. You might have to find equivalent packages on other Linux distributions.

Install tools to build Linux kernel and tools in kernel repository. scripts/ver_linux is a good way to check if your system already has the necessary tools:

```
sudo apt-get build-essentials flex bison yacc
sudo apt install libelf-dev systemtap-sdt-dev libaudit-dev libslang2-dev␣
↪libperl-dev libdw-dev
```

cscope is a good tool to browse kernel sources. Let's install it now:

```
sudo apt-get install cscope
```

Install stress-ng and paxtest:

```
apt-get install stress-ng
apt-get install paxtest
```

21.5 Workload overview

As mentioned earlier, we used strace to trace perf bench, stress-ng and paxtest workloads to show how to analyze a workload and identify Linux subsystems used by these workloads. Let's start with an overview of these three workloads to get a better understanding of what they do and how to use them.

21.5.1 perf bench (all) workload

The perf bench command contains multiple multi-threaded microkernel benchmarks for executing different subsystems in the Linux kernel and system calls. This allows us to easily measure the impact of changes, which can help mitigate performance regressions. It also acts as a common benchmarking framework, enabling developers to easily create test cases, integrate transparently, and use performance-rich tooling subsystems.

21.5.2 Stress-ng netdev stressor workload

stress-ng is used for performing stress testing on the kernel. It allows you to exercise various physical subsystems of the computer, as well as interfaces of the OS kernel, using ”stressor-s”. They are available for CPU, CPU cache, devices, I/O, interrupts, file system, memory, network, operating system, pipelines, schedulers, and virtual machines. Please refer to the stress-ng man-page to find the description of all the available stressor-s. The netdev stressor starts specified number (N) of workers that exercise various netdevice ioctl commands across all the available network devices.

21.5.3 paxtest kiddie workload

paxtest is a program that tests buffer overflows in the kernel. It tests kernel enforcements over memory usage. Generally, execution in some memory segments makes buffer overflows possible. It runs a set of programs that attempt to subvert memory usage. It is used as a regression test suite for PaX, but might be useful to test other memory protection patches for the kernel. We used paxtest kiddie mode which looks for simple vulnerabilities.

21.6 What is strace and how do we use it?

As mentioned earlier, strace which is a useful diagnostic, instructional, and debugging tool and can be used to discover the system resources in use by a workload. It can be used:

- To see how a process interacts with the kernel.
- To see why a process is failing or hanging.
- For reverse engineering a process.
- To find the files on which a program depends.
- For analyzing the performance of an application.
- For troubleshooting various problems related to the operating system.

In addition, strace can generate run-time statistics on times, calls, and errors for each system call and report a summary when program exits, suppressing the regular output. This attempts to show system time (CPU time spent running in the kernel) independent of wall clock time. We plan to use these features to get information on workload system usage.

strace command supports basic, verbose, and stats modes. strace command when run in verbose mode gives more detailed information about the system calls invoked by a process.

Running strace -c generates a report of the percentage of time spent in each system call, the total time in seconds, the microseconds per call, the total number of calls, the count of each system call that has failed with an error and the type of system call made.

- Usage: strace <command we want to trace>
- Verbose mode usage: strace -v <command>
- Gather statistics: strace -c <command>

We used the "-c" option to gather fine-grained run-time statistics in use by three workloads we have chose for this analysis.

- perf
- stress-ng
- paxtest

21.7 What is cscope and how do we use it?

Now let's look at cscope, a command line tool for browsing C, C++ or Java code-bases. We can use it to find all the references to a symbol, global definitions, functions called by a function, functions calling a function, text strings, regular expression patterns, files including a file.

We can use cscope to find which system call belongs to which subsystem. This way we can find the kernel subsystems used by a process when it is executed.

Let's checkout the latest Linux repository and build cscope database:

```
git clone git://git.kernel.org/pub/scm/linux/kernel/git/torvalds/linux.git␣
↪linux
cd linux
cscope -R -p10  # builds cscope.out database before starting browse session
cscope -d -p10  # starts browse session on cscope.out database
```

Note: Run "cscope -R -p10" to build the database and c"scope -d -p10" to enter into the browsing session. cscope by default cscope.out database. To get out of this mode press ctrl+d. -p option is used to specify the number of file path components to display. -p10 is optimal for browsing kernel sources.

21.8 What is perf and how do we use it?

Perf is an analysis tool based on Linux 2.6+ systems, which abstracts the CPU hardware difference in performance measurement in Linux, and provides a simple command line interface. Perf is based on the perf_events interface exported by the kernel. It is very useful for profiling the system and finding performance bottlenecks in an application.

If you haven't already checked out the Linux mainline repository, you can do so and then build kernel and perf tool:

```
git clone git://git.kernel.org/pub/scm/linux/kernel/git/torvalds/linux.git␣
↪linux
cd linux
make -j3 all
cd tools/perf
make
```

Note: The perf command can be built without building the kernel in the repository and can be run on older kernels. However matching the kernel and perf revisions gives more accurate information on the subsystem usage.

We used ”perf stat” and ”perf bench” options. For a detailed information on the perf tool, run ”perf -h”.

21.8.1 perf stat

The perf stat command generates a report of various hardware and software events. It does so with the help of hardware counter registers found in modern CPUs that keep the count of these activities. ”perf stat cal” shows stats for cal command.

21.8.2 Perf bench

The perf bench command contains multiple multi-threaded microkernel benchmarks for executing different subsystems in the Linux kernel and system calls. This allows us to easily measure the impact of changes, which can help mitigate performance regressions. It also acts as a common benchmarking framework, enabling developers to easily create test cases, integrate transparently, and use performance-rich tooling.

”perf bench all” command runs the following benchmarks:

- sched/messaging
- sched/pipe
- syscall/basic
- mem/memcpy
- mem/memset

21.9 What is stress-ng and how do we use it?

As mentioned earlier, stress-ng is used for performing stress testing on the kernel. It allows you to exercise various physical subsystems of the computer, as well as interfaces of the OS kernel, using stressor-s. They are available for CPU, CPU cache, devices, I/O, interrupts, file system, memory, network, operating system, pipelines, schedulers, and virtual machines.

The netdev stressor starts N workers that exercise various netdevice ioctl commands across all the available network devices. The following ioctls are exercised:

- SIOCGIFCONF, SIOCGIFINDEX, SIOCGIFNAME, SIOCGIFFLAGS
- SIOCGIFADDR, SIOCGIFNETMASK, SIOCGIFMETRIC, SIOCGIFMTU
- SIOCGIFHWADDR, SIOCGIFMAP, SIOCGIFTXQLEN

The following command runs the stressor:

```
stress-ng --netdev 1 -t 60 --metrics command.
```

We can use the perf record command to record the events and information associated with a process. This command records the profiling data in the perf.data file in the same directory.

Using the following commands you can record the events associated with the netdev stressor, view the generated report perf.data and annotate the to view the statistics of each instruction of the program:

```
perf record stress-ng --netdev 1 -t 60 --metrics command.
perf report
perf annotate
```

21.10 What is paxtest and how do we use it?

paxtest is a program that tests buffer overflows in the kernel. It tests kernel enforcements over memory usage. Generally, execution in some memory segments makes buffer overflows possible. It runs a set of programs that attempt to subvert memory usage. It is used as a regression test suite for PaX, and will be useful to test other memory protection patches for the kernel.

paxtest provides kiddie and blackhat modes. The paxtest kiddie mode runs in normal mode, whereas the blackhat mode tries to get around the protection of the kernel testing for vulnerabilities. We focus on the kiddie mode here and combine ”paxtest kiddie” run with ”perf record” to collect CPU stack traces for the paxtest kiddie run to see which function is calling other functions in the performance profile. Then the ”dwarf” (DWARF's Call Frame Information) mode can be used to unwind the stack.

The following command can be used to view resulting report in call-graph format:

```
perf record --call-graph dwarf paxtest kiddie
perf report --stdio
```

21.11 Tracing workloads

Now that we understand the workloads, let's start tracing them.

21.11.1 Tracing perf bench all workload

Run the following command to trace perf bench all workload:

```
strace -c perf bench all
```

System Calls made by the workload

The below table shows the system calls invoked by the workload, number of times each system call is invoked, and the corresponding Linux subsystem.

System Call	# calls	Linux Subsystem	System Call (API)
getppid	10000001	Process Mgmt	sys_getpid()
clone	1077	Process Mgmt.	sys_clone()
prctl	23	Process Mgmt.	sys_prctl()
prlimit64	7	Process Mgmt.	sys_prlimit64()
getpid	10	Process Mgmt.	sys_getpid()
uname	3	Process Mgmt.	sys_uname()
sysinfo	1	Process Mgmt.	sys_sysinfo()
getuid	1	Process Mgmt.	sys_getuid()
getgid	1	Process Mgmt.	sys_getgid()
geteuid	1	Process Mgmt.	sys_geteuid()
getegid	1	Process Mgmt.	sys_getegid
close	49951	Filesystem	sys_close()
pipe	604	Filesystem	sys_pipe()
openat	48560	Filesystem	sys_opennat()
fstat	8338	Filesystem	sys_fstat()
stat	1573	Filesystem	sys_stat()
pread64	9646	Filesystem	sys_pread64()
getdents64	1873	Filesystem	sys_getdents64()
access	3	Filesystem	sys_access()
lstat	1880	Filesystem	sys_lstat()

eventfd2	192	Filesystem	sys_eventfd2()
mmap	243	Memory Mgmt.	sys_mmap()
mprotect	32	Memory Mgmt.	sys_mprotect()

continues on next page

Table 1 – continued from previous page

System Call	# calls	Linux Subsystem	System Call (API)
brk	21	Memory Mgmt.	sys_brk()
munmap	128	Memory Mgmt.	sys_munmap()
set_mempolicy	156	Memory Mgmt.	sys_set_mempolicy()
set_tid_address	1	Process Mgmt.	sys_set_tid_address()
set_robust_list	1	Futex	sys_set_robust_list()
futex	341	Futex	sys_futex()
sched_getaffinity	79	Scheduler	sys_sched_getaffinity()
sched_setaffinity	223	Scheduler	sys_sched_setaffinity()
socketpair	202	Network	sys_socketpair()
rt_sigprocmask	21	Signal	sys_rt_sigprocmask()
rt_sigaction	36	Signal	sys_rt_sigaction()
rt_sigreturn	2	Signal	sys_rt_sigreturn()
wait4	889	Time	sys_wait4()
clock_nanosleep	37	Time	sys_clock_nanosleep()
capget	4	Capability	sys_capget()

21.11.2 Tracing stress-ng netdev stressor workload

Run the following command to trace stress-ng netdev stressor workload:

```
strace -c  stress-ng --netdev 1 -t 60 --metrics
```

System Calls made by the workload

The below table shows the system calls invoked by the workload, number of times each system call is invoked, and the corresponding Linux subsystem.

System Call	# calls	Linux Subsystem	System Call (API)
openat	74	Filesystem	sys_openat()
close	75	Filesystem	sys_close()
read	58	Filesystem	sys_read()
fstat	20	Filesystem	sys_fstat()
flock	10	Filesystem	sys_flock()
write	7	Filesystem	sys_write()
getdents64	8	Filesystem	sys_getdents64()
pread64	8	Filesystem	sys_pread64()
lseek	1	Filesystem	sys_lseek()

TWENTYTWO

ACPI SUPPORT

Here we document in detail how to interact with various mechanisms in the Linux ACPI support.

22.1 Upgrading ACPI tables via initrd

22.1.1 What is this about

If the ACPI_TABLE_UPGRADE compile option is true, it is possible to upgrade the ACPI execution environment that is defined by the ACPI tables via upgrading the ACPI tables provided by the BIOS with an instrumented, modified, more recent version one, or installing brand new ACPI tables.

When building initrd with kernel in a single image, option ACPI_TABLE_OVERRIDE_VIA_BUILTIN_INITRD should also be true for this feature to work.

For a full list of ACPI tables that can be upgraded/installed, take a look at the char **table_sigs[MAX_ACPI_SIGNATURE];* definition in drivers/acpi/tables.c.

All ACPI tables iasl (Intel's ACPI compiler and disassembler) knows should be overridable, except:

- ACPI_SIG_RSDP (has a signature of 6 bytes)
- ACPI_SIG_FACS (does not have an ordinary ACPI table header)

Both could get implemented as well.

22.1.2 What is this for

Complain to your platform/BIOS vendor if you find a bug which is so severe that a workaround is not accepted in the Linux kernel. And this facility allows you to upgrade the buggy tables before your platform/BIOS vendor releases an upgraded BIOS binary.

This facility can be used by platform/BIOS vendors to provide a Linux compatible environment without modifying the underlying platform firmware.

This facility also provides a powerful feature to easily debug and test ACPI BIOS table compatibility with the Linux kernel by modifying old platform provided ACPI tables or inserting new ACPI tables.

It can and should be enabled in any kernel because there is no functional change with not instrumented initrds.

22.1.3 How does it work

```
# Extract the machine's ACPI tables:
cd /tmp
acpidump >acpidump
acpixtract -a acpidump
# Disassemble, modify and recompile them:
iasl -d *.dat
# For example add this statement into a _PRT (PCI Routing Table) function
# of the DSDT:
Store("HELLO WORLD", debug)
# And increase the OEM Revision. For example, before modification:
DefinitionBlock ("DSDT.aml", "DSDT", 2, "INTEL ", "TEMPLATE", 0x00000000)
# After modification:
DefinitionBlock ("DSDT.aml", "DSDT", 2, "INTEL ", "TEMPLATE", 0x00000001)
iasl -sa dsdt.dsl
# Add the raw ACPI tables to an uncompressed cpio archive.
# They must be put into a /kernel/firmware/acpi directory inside the cpio
# archive. Note that if the table put here matches a platform table
# (similar Table Signature, and similar OEMID, and similar OEM Table ID)
# with a more recent OEM Revision, the platform table will be upgraded by
# this table. If the table put here doesn't match a platform table
# (dissimilar Table Signature, or dissimilar OEMID, or dissimilar OEM Table
# ID), this table will be appended.
mkdir -p kernel/firmware/acpi
cp dsdt.aml kernel/firmware/acpi
# A maximum of "NR_ACPI_INITRD_TABLES (64)" tables are currently allowed
# (see osl.c):
iasl -sa facp.dsl
iasl -sa ssdt1.dsl
cp facp.aml kernel/firmware/acpi
cp ssdt1.aml kernel/firmware/acpi
# The uncompressed cpio archive must be the first. Other, typically
# compressed cpio archives, must be concatenated on top of the uncompressed
# one. Following command creates the uncompressed cpio archive and
# concatenates the original initrd on top:
find kernel | cpio -H newc --create > /boot/instrumented_initrd
cat /boot/initrd >>/boot/instrumented_initrd
# reboot with increased acpi debug level, e.g. boot params:
acpi.debug_level=0x2 acpi.debug_layer=0xFFFFFFFF
# and check your syslog:
[    1.268089] ACPI: PCI Interrupt Routing Table [\_SB_.PCI0._PRT]
[    1.272091] [ACPI Debug]  String [0x0B] "HELLO WORLD"
```

iasl is able to disassemble and recompile quite a lot different, also static ACPI tables.

22.1.4 Where to retrieve userspace tools

iasl and acpixtract are part of Intel's ACPICA project: https://acpica.org/

and should be packaged by distributions (for example in the acpica package on SUSE).

acpidump can be found in Len Browns pmtools: ftp://kernel.org/pub/linux/kernel/people/lenb/acpi/utils/pmtools/acpidump

This tool is also part of the acpica package on SUSE. Alternatively, used ACPI tables can be retrieved via sysfs in latest kernels: /sys/firmware/acpi/tables

22.2 SSDT Overlays

In order to support ACPI open-ended hardware configurations (e.g. development boards) we need a way to augment the ACPI configuration provided by the firmware image. A common example is connecting sensors on I2C / SPI buses on development boards.

Although this can be accomplished by creating a kernel platform driver or recompiling the firmware image with updated ACPI tables, neither is practical: the former proliferates board specific kernel code while the latter requires access to firmware tools which are often not publicly available.

Because ACPI supports external references in AML code a more practical way to augment firmware ACPI configuration is by dynamically loading user defined SSDT tables that contain the board specific information.

For example, to enumerate a Bosch BMA222E accelerometer on the I2C bus of the Minnowboard MAX development board exposed via the LSE connector [1], the following ASL code can be used:

```
DefinitionBlock ("minnowmax.aml", "SSDT", 1, "Vendor", "Accel", 0x00000003)
{
    External (\_SB.I2C6, DeviceObj)

    Scope (\_SB.I2C6)
    {
        Device (STAC)
        {
            Name (_HID, "BMA222E")
            Name (RBUF, ResourceTemplate ()
            {
                I2cSerialBus (0x0018, ControllerInitiated, 0x00061A80,
                            AddressingMode7Bit, "\\_SB.I2C6", 0x00,
                            ResourceConsumer, ,)
                GpioInt (Edge, ActiveHigh, Exclusive, PullDown, 0x0000,
                        "\\_SB.GPO2", 0x00, ResourceConsumer, , )
                { // Pin list
                    0
                }
            })

            Method (_CRS, 0, Serialized)
```

```
            {
                Return (RBUF)
            }
        }
    }
}
```

which can then be compiled to AML binary format:

```
$ iasl minnowmax.asl

Intel ACPI Component Architecture
ASL Optimizing Compiler version 20140214-64 [Mar 29 2014]
Copyright (c) 2000 - 2014 Intel Corporation

ASL Input:     minnomax.asl - 30 lines, 614 bytes, 7 keywords
AML Output:    minnowmax.aml - 165 bytes, 6 named objects, 1 executable opcodes
```

[1] https://www.elinux.org/Minnowboard:MinnowMax#Low_Speed_Expansion_.28Top.29

The resulting AML code can then be loaded by the kernel using one of the methods below.

22.2.1 Loading ACPI SSDTs from initrd

This option allows loading of user defined SSDTs from initrd and it is useful when the system does not support EFI or when there is not enough EFI storage.

It works in a similar way with initrd based ACPI tables override/upgrade: SSDT AML code must be placed in the first, uncompressed, initrd under the "kernel/firmware/acpi" path. Multiple files can be used and this will translate in loading multiple tables. Only SSDT and OEM tables are allowed. See initrd_table_override.txt for more details.

Here is an example:

```
# Add the raw ACPI tables to an uncompressed cpio archive.
# They must be put into a /kernel/firmware/acpi directory inside the
# cpio archive.
# The uncompressed cpio archive must be the first.
# Other, typically compressed cpio archives, must be
# concatenated on top of the uncompressed one.
mkdir -p kernel/firmware/acpi
cp ssdt.aml kernel/firmware/acpi

# Create the uncompressed cpio archive and concatenate the original initrd
# on top:
find kernel | cpio -H newc --create > /boot/instrumented_initrd
cat /boot/initrd >>/boot/instrumented_initrd
```

22.2.2 Loading ACPI SSDTs from EFI variables

This is the preferred method, when EFI is supported on the platform, because it allows a persistent, OS independent way of storing the user defined SSDTs. There is also work underway to implement EFI support for loading user defined SSDTs and using this method will make it easier to convert to the EFI loading mechanism when that will arrive. To enable it, the CONFIG_EFI_CUSTOM_SSDT_OVERLAYS should be chosen to y.

In order to load SSDTs from an EFI variable the `"efivar_ssdt=..."` kernel command line parameter can be used (the name has a limitation of 16 characters). The argument for the option is the variable name to use. If there are multiple variables with the same name but with different vendor GUIDs, all of them will be loaded.

In order to store the AML code in an EFI variable the efivarfs filesystem can be used. It is enabled and mounted by default in /sys/firmware/efi/efivars in all recent distribution.

Creating a new file in /sys/firmware/efi/efivars will automatically create a new EFI variable. Updating a file in /sys/firmware/efi/efivars will update the EFI variable. Please note that the file name needs to be specially formatted as ”Name-GUID” and that the first 4 bytes in the file (little-endian format) represent the attributes of the EFI variable (see EFI_VARIABLE_MASK in include/linux/efi.h). Writing to the file must also be done with one write operation.

For example, you can use the following bash script to create/update an EFI variable with the content from a given file:

```
#!/bin/sh -e

while [ -n "$1" ]; do
        case "$1" in
        "-f") filename="$2"; shift;;
        "-g") guid="$2"; shift;;
        *) name="$1";;
        esac
        shift
done

usage()
{
        echo "Syntax: ${0##*/} -f filename [ -g guid ] name"
        exit 1
}

[ -n "$name" -a -f "$filename" ] || usage

EFIVARFS="/sys/firmware/efi/efivars"

[ -d "$EFIVARFS" ] || exit 2

if stat -tf $EFIVARFS | grep -q -v de5e81e4; then
        mount -t efivarfs none $EFIVARFS
fi

# try to pick up an existing GUID
```

```
[ -n "$guid" ] || guid=$(find "$EFIVARFS" -name "$name-*" | head -n1 | cut -f2-
↪ -d-)

# use a randomly generated GUID
[ -n "$guid" ] || guid="$(cat /proc/sys/kernel/random/uuid)"

# efivarfs expects all of the data in one write
tmp=$(mktemp)
/bin/echo -ne "\007\000\000\000" | cat - $filename > $tmp
dd if=$tmp of="$EFIVARFS/$name-$guid" bs=$(stat -c %s $tmp)
rm $tmp
```

22.2.3 Loading ACPI SSDTs from configfs

This option allows loading of user defined SSDTs from user space via the configfs interface. The CONFIG_ACPI_CONFIGFS option must be select and configfs must be mounted. In the following examples, we assume that configfs has been mounted in /sys/kernel/config.

New tables can be loading by creating new directories in /sys/kernel/config/acpi/table and writing the SSDT AML code in the aml attribute:

```
cd /sys/kernel/config/acpi/table
mkdir my_ssdt
cat ~/ssdt.aml > my_ssdt/aml
```

22.3 Collaborative Processor Performance Control (CPPC)

22.3.1 CPPC

CPPC defined in the ACPI spec describes a mechanism for the OS to manage the performance of a logical processor on a contiguous and abstract performance scale. CPPC exposes a set of registers to describe abstract performance scale, to request performance levels and to measure per-cpu delivered performance.

For more details on CPPC please refer to the ACPI specification at:

http://uefi.org/specifications

Some of the CPPC registers are exposed via sysfs under:

```
/sys/devices/system/cpu/cpuX/acpi_cppc/
```

for each cpu X:

```
$ ls -lR  /sys/devices/system/cpu/cpu0/acpi_cppc/
/sys/devices/system/cpu/cpu0/acpi_cppc/:
total 0
-r--r--r-- 1 root root 65536 Mar  5 19:38 feedback_ctrs
-r--r--r-- 1 root root 65536 Mar  5 19:38 highest_perf
-r--r--r-- 1 root root 65536 Mar  5 19:38 lowest_freq
```

```
-r--r--r-- 1 root root 65536 Mar  5 19:38 lowest_nonlinear_perf
-r--r--r-- 1 root root 65536 Mar  5 19:38 lowest_perf
-r--r--r-- 1 root root 65536 Mar  5 19:38 nominal_freq
-r--r--r-- 1 root root 65536 Mar  5 19:38 nominal_perf
-r--r--r-- 1 root root 65536 Mar  5 19:38 reference_perf
-r--r--r-- 1 root root 65536 Mar  5 19:38 wraparound_time
```

- highest_perf : Highest performance of this processor (abstract scale).
- nominal_perf : Highest sustained performance of this processor (abstract scale).
- lowest_nonlinear_perf : Lowest performance of this processor with nonlinear power savings (abstract scale).
- lowest_perf : Lowest performance of this processor (abstract scale).
- lowest_freq : CPU frequency corresponding to lowest_perf (in MHz).
- nominal_freq : CPU frequency corresponding to nominal_perf (in MHz). The above frequencies should only be used to report processor performance in frequency instead of abstract scale. These values should not be used for any functional decisions.
- feedback_ctrs : Includes both Reference and delivered performance counter. Reference counter ticks up proportional to processor's reference performance. Delivered counter ticks up proportional to processor's delivered performance.
- wraparound_time: Minimum time for the feedback counters to wraparound (seconds).
- reference_perf : Performance level at which reference performance counter accumulates (abstract scale).

22.3.2 Computing Average Delivered Performance

Below describes the steps to compute the average performance delivered by taking two different snapshots of feedback counters at time T1 and T2.

T1: Read feedback_ctrs as fbc_t1
Wait or run some workload

T2: Read feedback_ctrs as fbc_t2

```
delivered_counter_delta = fbc_t2[del] - fbc_t1[del]
reference_counter_delta = fbc_t2[ref] - fbc_t1[ref]

delivered_perf = (reference_perf x delivered_counter_delta) / reference_
↪counter_delta
```

22.4 ACPI Fan Performance States

When the optional _FPS object is present under an ACPI device representing a fan (for example, PNP0C0B or INT3404), the ACPI fan driver creates additional "state*" attributes in the sysfs directory of the ACPI device in question. These attributes list properties of fan performance states.

For more information on _FPS refer to the ACPI specification at:

http://uefi.org/specifications

For instance, the contents of the INT3404 ACPI device sysfs directory may look as follows:

```
$ ls -l /sys/bus/acpi/devices/INT3404:00/
total 0
...
-r--r--r-- 1 root root 4096 Dec 13 20:38 state0
-r--r--r-- 1 root root 4096 Dec 13 20:38 state1
-r--r--r-- 1 root root 4096 Dec 13 20:38 state10
-r--r--r-- 1 root root 4096 Dec 13 20:38 state11
-r--r--r-- 1 root root 4096 Dec 13 20:38 state2
-r--r--r-- 1 root root 4096 Dec 13 20:38 state3
-r--r--r-- 1 root root 4096 Dec 13 20:38 state4
-r--r--r-- 1 root root 4096 Dec 13 20:38 state5
-r--r--r-- 1 root root 4096 Dec 13 20:38 state6
-r--r--r-- 1 root root 4096 Dec 13 20:38 state7
-r--r--r-- 1 root root 4096 Dec 13 20:38 state8
-r--r--r-- 1 root root 4096 Dec 13 20:38 state9
-r--r--r-- 1 root root 4096 Dec 13 01:00 status
...
```

where each of the "state*" files represents one performance state of the fan and contains a colon-separated list of 5 integer numbers (fields) with the following interpretation:

```
control_percent:trip_point_index:speed_rpm:noise_level_mdb:power_mw
```

- `control_percent`: The percent value to be used to set the fan speed to a specific level using the _FSL object (0-100).
- `trip_point_index`: The active cooling trip point number that corresponds to this performance state (0-9).
- `speed_rpm`: Speed of the fan in rotations per minute.
- `noise_level_mdb`: Audible noise emitted by the fan in this state in millidecibels.
- `power_mw`: Power draw of the fan in this state in milliwatts.

For example:

```
$cat /sys/bus/acpi/devices/INT3404:00/state1
25:0:3200:12500:1250
```

When a given field is not populated or its value provided by the platform firmware is invalid, the "not-defined" string is shown instead of the value.

22.4.1 ACPI Fan Fine Grain Control

When _FIF object specifies support for fine grain control, then fan speed can be set from 0 to 100% with the recommended minimum ”step size” via _FSL object. User can adjust fan speed using thermal sysfs cooling device.

Here use can look at fan performance states for a reference speed (speed_rpm) and set it by changing cooling device cur_state. If the fine grain control is supported then user can also adjust to some other speeds which are not defined in the performance states.

The support of fine grain control is presented via sysfs attribute ”fine_grain_control”. If fine grain control is present, this attribute will show ”1” otherwise ”0”.

This sysfs attribute is presented in the same directory as performance states.

22.4.2 ACPI Fan Performance Feedback

The optional _FST object provides status information for the fan device. This includes field to provide current fan speed in revolutions per minute at which the fan is rotating.

This speed is presented in the sysfs using the attribute ”fan_speed_rpm”, in the same directory as performance states.

CHAPTER

TWENTYTHREE

ATA OVER ETHERNET (AOE)

23.1 Introduction

ATA over Ethernet is a network protocol that provides simple access to block storage on the LAN.

http://support.coraid.com/documents/AoEr11.txt

The EtherDrive (R) HOWTO for 2.6 and 3.x kernels is found at ...

http://support.coraid.com/support/linux/EtherDrive-2.6-HOWTO.html

It has many tips and hints! Please see, especially, recommended tunings for virtual memory:

http://support.coraid.com/support/linux/EtherDrive-2.6-HOWTO-5.html#ss5.19

The aoetools are userland programs that are designed to work with this driver. The aoetools are on sourceforge.

http://aoetools.sourceforge.net/

The scripts in this Documentation/admin-guide/aoe directory are intended to document the use of the driver and are not necessary if you install the aoetools.

23.2 Creating Device Nodes

Users of udev should find the block device nodes created automatically, but to create all the necessary device nodes, use the udev configuration rules provided in udev.txt (in this directory).

There is a udev-install.sh script that shows how to install these rules on your system.

There is also an autoload script that shows how to edit /etc/modprobe.d/aoe.conf to ensure that the aoe module is loaded when necessary. Preloading the aoe module is preferable to autoloading, however, because AoE discovery takes a few seconds. It can be confusing when an AoE device is not present the first time the a command is run but appears a second later.

23.3 Using Device Nodes

”cat /dev/etherd/err” blocks, waiting for error diagnostic output, like any retransmitted packets.

”echo eth2 eth4 > /dev/etherd/interfaces” tells the aoe driver to limit ATA over Ethernet traffic to eth2 and eth4. AoE traffic from untrusted networks should be ignored as a matter of security. See also the aoe_iflist driver option described below.

”echo > /dev/etherd/discover” tells the driver to find out what AoE devices are available.

In the future these character devices may disappear and be replaced by sysfs counterparts. Using the commands in aoetools insulates users from these implementation details.

The block devices are named like this:

```
e{shelf}.{slot}
e{shelf}.{slot}p{part}
```

... so that ”e0.2” is the third blade from the left (slot 2) in the first shelf (shelf address zero). That's the whole disk. The first partition on that disk would be ”e0.2p1”.

23.4 Using sysfs

Each aoe block device in /sys/block has the extra attributes of state, mac, and netif. The state attribute is ”up” when the device is ready for I/O and ”down” if detected but unusable. The ”down,closewait” state shows that the device is still open and cannot come up again until it has been closed.

The mac attribute is the ethernet address of the remote AoE device. The netif attribute is the network interface on the localhost through which we are communicating with the remote AoE device.

There is a script in this directory that formats this information in a convenient way. Users with aoetools should use the aoe-stat command:

```
root@makki root# sh Documentation/admin-guide/aoe/status.sh
   e10.0            eth3              up
   e10.1            eth3              up
   e10.2            eth3              up
   e10.3            eth3              up
   e10.4            eth3              up
   e10.5            eth3              up
   e10.6            eth3              up
   e10.7            eth3              up
   e10.8            eth3              up
   e10.9            eth3              up
    e4.0            eth1              up
    e4.1            eth1              up
    e4.2            eth1              up
    e4.3            eth1              up
```

```
    e4.4            eth1            up
    e4.5            eth1            up
    e4.6            eth1            up
    e4.7            eth1            up
    e4.8            eth1            up
    e4.9            eth1            up
```

Use /sys/module/aoe/parameters/aoe_iflist (or better, the driver option discussed below) instead of /dev/etherd/interfaces to limit AoE traffic to the network interfaces in the given whitespace-separated list. Unlike the old character device, the sysfs entry can be read from as well as written to.

It's helpful to trigger discovery after setting the list of allowed interfaces. The aoe-tools package provides an aoe-discover script for this purpose. You can also directly use the /dev/etherd/discover special file described above.

23.5 Driver Options

There is a boot option for the built-in aoe driver and a corresponding module parameter, aoe_iflist. Without this option, all network interfaces may be used for ATA over Ethernet. Here is a usage example for the module parameter:

```
modprobe aoe_iflist="eth1 eth3"
```

The aoe_deadsecs module parameter determines the maximum number of seconds that the driver will wait for an AoE device to provide a response to an AoE command. After aoe_deadsecs seconds have elapsed, the AoE device will be marked as ”down”. A value of zero is supported for testing purposes and makes the aoe driver keep trying AoE commands forever.

The aoe_maxout module parameter has a default of 128. This is the maximum number of unresponded packets that will be sent to an AoE target at one time.

The aoe_dyndevs module parameter defaults to 1, meaning that the driver will assign a block device minor number to a discovered AoE target based on the order of its discovery. With dynamic minor device numbers in use, a greater range of AoE shelf and slot addresses can be supported. Users with udev will never have to think about minor numbers. Using aoe_dyndevs=0 allows device nodes to be pre-created using a static minor-number scheme with the aoe-mkshelf script in the aoetools.

23.6 TODO

There is a potential for deadlock when allocating a struct sk_buff for data that needs to be written out to aoe storage. If the data is being written from a dirty page in order to free that page, and if there are no other pages available, then deadlock may occur when a free page is needed for the sk_buff allocation. This situation has not been observed, but it would be nice to eliminate any potential for deadlock under memory pressure.

Because ATA over Ethernet is not fragmented by the kernel's IP code, the destructor member of the struct sk_buff is available to the aoe driver. By using a mempool for allocating all but

the first few sk_buffs, and by registering a destructor, we should be able to efficiently allocate sk_buffs without introducing any potential for deadlock.

23.7 Example of udev rules

```
# These rules tell udev what device nodes to create for aoe support.
# They may be installed along the following lines.  Check the section
# 8 udev manpage to see whether your udev supports SUBSYSTEM, and
# whether it uses one or two equal signs for SUBSYSTEM and KERNEL.
#
#   ecashin@makki ~$ su
#   Password:
#   bash# find /etc -type f -name udev.conf
#   /etc/udev/udev.conf
#   bash# grep udev_rules= /etc/udev/udev.conf
#   udev_rules="/etc/udev/rules.d/"
#   bash# ls /etc/udev/rules.d/
#   10-wacom.rules  50-udev.rules
#   bash# cp /path/to/linux/Documentation/admin-guide/aoe/udev.txt \
#           /etc/udev/rules.d/60-aoe.rules
#

# aoe char devices
SUBSYSTEM=="aoe", KERNEL=="discover",   NAME="etherd/%k", GROUP="disk",␣
↪MODE="0220"
SUBSYSTEM=="aoe", KERNEL=="err",        NAME="etherd/%k", GROUP="disk",␣
↪MODE="0440"
SUBSYSTEM=="aoe", KERNEL=="interfaces", NAME="etherd/%k", GROUP="disk",␣
↪MODE="0220"
SUBSYSTEM=="aoe", KERNEL=="revalidate", NAME="etherd/%k", GROUP="disk",␣
↪MODE="0220"
SUBSYSTEM=="aoe", KERNEL=="flush",      NAME="etherd/%k", GROUP="disk",␣
↪MODE="0220"

# aoe block devices
KERNEL=="etherd*",       GROUP="disk"
```

23.8 Example of udev install rules script

```
# install the aoe-specific udev rules from udev.txt into
# the system's udev configuration
#

me="`basename $0`"

# find udev.conf, often /etc/udev/udev.conf
# (or environment can specify where to find udev.conf)
```

```
#
if test -z "$conf"; then
        if test -r /etc/udev/udev.conf; then
                conf=/etc/udev/udev.conf
        else
                conf="`find /etc -type f -name udev.conf 2> /dev/null`"
                if test -z "$conf" || test ! -r "$conf"; then
                        echo "$me Error: no udev.conf found" 1>&2
                        exit 1
                fi
        fi
fi

# find the directory where udev rules are stored, often
# /etc/udev/rules.d
#
rules_d="`sed -n '/^udev_rules=/{ s!udev_rules=!!; s!\"!!g; p; }'
 ↪$conf`"
if test -z "$rules_d" ; then
        rules_d=/etc/udev/rules.d
fi
if test ! -d "$rules_d"; then
        echo "$me Error: cannot find udev rules directory" 1>&2
        exit 1
fi
sh -xc "cp `dirname $0`/udev.txt $rules_d/60-aoe.rules"
```

23.9 Example script to get status

```
#! /bin/sh
# collate and present sysfs information about AoE storage
#
# A more complete version of this script is aoe-stat, in the
# aoetools.

set -e
format="%8s\t%8s\t%8s\n"
me=`basename $0`
sysd=${sysfs_dir:-/sys}

# printf "$format" device mac netif state

# Suse 9.1 Pro doesn't put /sys in /etc/mtab
#test -z "`mount | grep sysfs`" && {
test ! -d "$sysd/block" && {
        echo "$me Error: sysfs is not mounted" 1>&2
        exit 1
}
```

```
for d in `ls -d $sysd/block/etherd* 2>/dev/null | grep -v p` end; do
        # maybe ls comes up empty, so we use "end"
        test $d = end && continue

        dev=`echo "$d" | sed 's/.*!//'`
        printf "$format" \
                "$dev" \
                "`cat \"$d/netif\"`" \
                "`cat \"$d/state\"`"
done | sort
```

23.10 Example of AoE autoload script

```
#!/bin/sh
# set aoe to autoload by installing the
# aliases in /etc/modprobe.d/

f=/etc/modprobe.d/aoe.conf

if test ! -r $f || test ! -w $f; then
        echo "cannot configure $f for module autoloading" 1>&2
        exit 1
fi

grep major-152 $f >/dev/null
if [ $? = 1 ]; then
        echo alias block-major-152 aoe >> $f
        echo alias char-major-152 aoe >> $f
fi
```

```

24.2.4 4. Userspace Programming

The cfag12864bfb describes a framebuffer device (/dev/fbX).

It has a size of 1024 bytes = 1 Kbyte. Each bit represents one pixel. If the bit is high, the pixel will turn on. If the pixel is low, the pixel will turn off.

You can use the framebuffer as a file: fopen, fwrite, fclose... Although the LCD won't get updated until the next refresh time arrives.

Also, you can mmap the framebuffer: open & mmap, munmap & close... which is the best option for most uses.

Check samples/auxdisplay/cfag12864b-example.c for a real working userspace complete program with usage examples.

CHAPTER

TWENTYFIVE

A BLOCK LAYER CACHE (BCACHE)

Say you've got a big slow raid 6, and an ssd or three. Wouldn't it be nice if you could use them as cache... Hence bcache.

The bcache wiki can be found at:
https://bcache.evilpiepirate.org

This is the git repository of bcache-tools:
https://git.kernel.org/pub/scm/linux/kernel/git/colyli/bcache-tools.git/

The latest bcache kernel code can be found from mainline Linux kernel:
https://git.kernel.org/pub/scm/linux/kernel/git/torvalds/linux.git/

It's designed around the performance characteristics of SSDs - it only allocates in erase block sized buckets, and it uses a hybrid btree/log to track cached extents (which can be anywhere from a single sector to the bucket size). It's designed to avoid random writes at all costs; it fills up an erase block sequentially, then issues a discard before reusing it.

Both writethrough and writeback caching are supported. Writeback defaults to off, but can be switched on and off arbitrarily at runtime. Bcache goes to great lengths to protect your data - it reliably handles unclean shutdown. (It doesn't even have a notion of a clean shutdown; bcache simply doesn't return writes as completed until they're on stable storage).

Writeback caching can use most of the cache for buffering writes - writing dirty data to the backing device is always done sequentially, scanning from the start to the end of the index.

Since random IO is what SSDs excel at, there generally won't be much benefit to caching large sequential IO. Bcache detects sequential IO and skips it; it also keeps a rolling average of the IO sizes per task, and as long as the average is above the cutoff it will skip all IO from that task - instead of caching the first 512k after every seek. Backups and large file copies should thus entirely bypass the cache.

In the event of a data IO error on the flash it will try to recover by reading from disk or invalidating cache entries. For unrecoverable errors (meta data or dirty data), caching is automatically disabled; if dirty data was present in the cache it first disables writeback caching and waits for all dirty data to be flushed.

Getting started: You'll need bcache util from the bcache-tools repository. Both the cache device and backing device must be formatted before use:

```
bcache make -B /dev/sdb
bcache make -C /dev/sdc
```

bcache make has the ability to format multiple devices at the same time - if you format your backing devices and cache device at the same time, you won't have to manually attach:

```
bcache make -B /dev/sda /dev/sdb -C /dev/sdc
```

If your bcache-tools is not updated to latest version and does not have the unified *bcache* utility, you may use the legacy *make-bcache* utility to format bcache device with same -B and -C parameters.

bcache-tools now ships udev rules, and bcache devices are known to the kernel immediately. Without udev, you can manually register devices like this:

```
echo /dev/sdb > /sys/fs/bcache/register
echo /dev/sdc > /sys/fs/bcache/register
```

Registering the backing device makes the bcache device show up in /dev; you can now format it and use it as normal. But the first time using a new bcache device, it'll be running in passthrough mode until you attach it to a cache. If you are thinking about using bcache later, it is recommended to setup all your slow devices as bcache backing devices without a cache, and you can choose to add a caching device later. See 'ATTACHING' section below.

The devices show up as:

```
/dev/bcache<N>
```

As well as (with udev):

```
/dev/bcache/by-uuid/<uuid>
/dev/bcache/by-label/<label>
```

To get started:

```
mkfs.ext4 /dev/bcache0
mount /dev/bcache0 /mnt
```

You can control bcache devices through sysfs at /sys/block/bcache<N>/bcache . You can also control them through /sys/fs//bcache/<cset-uuid>/ .

Cache devices are managed as sets; multiple caches per set isn't supported yet but will allow for mirroring of metadata and dirty data in the future. Your new cache set shows up as /sys/fs/bcache/<UUID>

25.1 Attaching

After your cache device and backing device are registered, the backing device must be attached to your cache set to enable caching. Attaching a backing device to a cache set is done thusly, with the UUID of the cache set in /sys/fs/bcache:

```
echo <CSET-UUID> > /sys/block/bcache0/bcache/attach
```

This only has to be done once. The next time you reboot, just reregister all your bcache devices. If a backing device has data in a cache somewhere, the /dev/bcache<N> device won't be created until the cache shows up - particularly important if you have writeback caching turned on.

If you're booting up and your cache device is gone and never coming back, you can force run the backing device:

```
echo 1 > /sys/block/sdb/bcache/running
```

(You need to use /sys/block/sdb (or whatever your backing device is called), not /sys/block/bcache0, because bcache0 doesn't exist yet. If you're using a partition, the bcache directory would be at /sys/block/sdb/sdb2/bcache)

The backing device will still use that cache set if it shows up in the future, but all the cached data will be invalidated. If there was dirty data in the cache, don't expect the filesystem to be recoverable - you will have massive filesystem corruption, though ext4's fsck does work miracles.

25.2 Error Handling

Bcache tries to transparently handle IO errors to/from the cache device without affecting normal operation; if it sees too many errors (the threshold is configurable, and defaults to 0) it shuts down the cache device and switches all the backing devices to passthrough mode.

- For reads from the cache, if they error we just retry the read from the backing device.
- For writethrough writes, if the write to the cache errors we just switch to invalidating the data at that lba in the cache (i.e. the same thing we do for a write that bypasses the cache)
- For writeback writes, we currently pass that error back up to the filesystem/userspace. This could be improved - we could retry it as a write that skips the cache so we don't have to error the write.
- When we detach, we first try to flush any dirty data (if we were running in writeback mode). It currently doesn't do anything intelligent if it fails to read some of the dirty data, though.

25.3 Howto/cookbook

A) Starting a bcache with a missing caching device

If registering the backing device doesn't help, it's already there, you just need to force it to run without the cache:

```
host:~# echo /dev/sdb1 > /sys/fs/bcache/register
[  119.844831] bcache: register_bcache() error opening /dev/sdb1: device␣
↪already registered
```

Next, you try to register your caching device if it's present. However if it's absent, or registration fails for some reason, you can still start your bcache without its cache, like so:

```
host:/sys/block/sdb/sdb1/bcache# echo 1 > running
```

Note that this may cause data loss if you were running in writeback mode.

B) Bcache does not find its cache:

```
host:/sys/block/md5/bcache# echo 0226553a-37cf-41d5-b3ce-8b1e944543a8 >␣
↪attach
[ 1933.455082] bcache: bch_cached_dev_attach() Couldn't find uuid for md5␣
↪in set
```

```
[ 1933.478179] bcache: __cached_dev_store() Can't attach 0226553a-37cf-
↪41d5-b3ce-8b1e944543a8
[ 1933.478179] : cache set not found
```

In this case, the caching device was simply not registered at boot or disappeared and came back, and needs to be (re-)registered:

```
host:/sys/block/md5/bcache# echo /dev/sdh2 > /sys/fs/bcache/register
```

C) Corrupt bcache crashes the kernel at device registration time:

This should never happen. If it does happen, then you have found a bug! Please report it to the bcache development list: linux-bcache@vger.kernel.org

Be sure to provide as much information that you can including kernel dmesg output if available so that we may assist.

D) Recovering data without bcache:

If bcache is not available in the kernel, a filesystem on the backing device is still available at an 8KiB offset. So either via a loopdev of the backing device created with --offset 8K, or any value defined by --data-offset when you originally formatted bcache with *bcache make*.

For example:

```
losetup -o 8192 /dev/loop0 /dev/your_bcache_backing_dev
```

This should present your unmodified backing device data in /dev/loop0

If your cache is in writethrough mode, then you can safely discard the cache device without losing data.

E) Wiping a cache device

```
host:~# wipefs -a /dev/sdh2
16 bytes were erased at offset 0x1018 (bcache)
they were: c6 85 73 f6 4e 1a 45 ca 82 65 f5 7f 48 ba 6d 81
```

After you boot back with bcache enabled, you recreate the cache and attach it:

```
host:~# bcache make -C /dev/sdh2
UUID:                   7be7e175-8f4c-4f99-94b2-9c904d227045
Set UUID:               5bc072a8-ab17-446d-9744-e247949913c1
version:                0
nbuckets:               106874
block_size:             1
bucket_size:            1024
nr_in_set:              1
nr_this_dev:            0
first_bucket:           1
[  650.511912] bcache: run_cache_set() invalidating existing data
[  650.549228] bcache: register_cache() registered cache device sdh2
```

start backing device with missing cache:

```
host:/sys/block/md5/bcache# echo 1 > running
```

attach new cache:

```
host:/sys/block/md5/bcache# echo 5bc072a8-ab17-446d-9744-e247949913c1 > attach
[  865.276616] bcache: bch_cached_dev_attach() Caching md5 as bcache0 on set␣
↪5bc072a8-ab17-446d-9744-e247949913c1
```

F) Remove or replace a caching device:

```
host:/sys/block/sda/sda7/bcache# echo 1 > detach
[  695.872542] bcache: cached_dev_detach_finish() Caching disabled for sda7

host:~# wipefs -a /dev/nvme0n1p4
wipefs: error: /dev/nvme0n1p4: probing initialization failed: Device or␣
↪resource busy
Ooops, it's disabled, but not unregistered, so it's still protected
```

We need to go and unregister it:

```
host:/sys/fs/bcache/b7ba27a1-2398-4649-8ae3-0959f57ba128# ls -l cache0
lrwxrwxrwx 1 root root 0 Feb 25 18:33 cache0 -> ../../../devices/pci0000:00/
↪0000:00:1d.0/0000:70:00.0/nvme/nvme0/nvme0n1/nvme0n1p4/bcache/
host:/sys/fs/bcache/b7ba27a1-2398-4649-8ae3-0959f57ba128# echo 1 > stop
kernel: [  917.041908] bcache: cache_set_free() Cache set b7ba27a1-2398-4649-
↪8ae3-0959f57ba128 unregistered
```

Now we can wipe it:

```
host:~# wipefs -a /dev/nvme0n1p4
/dev/nvme0n1p4: 16 bytes were erased at offset 0x00001018 (bcache): c6 85 73␣
↪f6 4e 1a 45 ca 82 65 f5 7f 48 ba 6d 81
```

G) dm-crypt and bcache

First setup bcache unencrypted and then install dmcrypt on top of /dev/bcache<N> This will work faster than if you dmcrypt both the backing and caching devices and then install bcache on top. [benchmarks?]

H) Stop/free a registered bcache to wipe and/or recreate it

Suppose that you need to free up all bcache references so that you can fdisk run and re-register a changed partition table, which won't work if there are any active backing or caching devices left on it:

1) Is it present in /dev/bcache* ? (there are times where it won't be)

   If so, it's easy:

   ```
   host:/sys/block/bcache0/bcache# echo 1 > stop
   ```

2) But if your backing device is gone, this won't work:

```
host:/sys/block/bcache0# cd bcache
bash: cd: bcache: No such file or directory
```

In this case, you may have to unregister the dmcrypt block device that references this bcache to free it up:

```
host:~# dmsetup remove oldds1
bcache: bcache_device_free() bcache0 stopped
bcache: cache_set_free() Cache set 5bc072a8-ab17-446d-9744-e247949913c1␣
↪unregistered
```

This causes the backing bcache to be removed from /sys/fs/bcache and then it can be reused. This would be true of any block device stacking where bcache is a lower device.

3) In other cases, you can also look in /sys/fs/bcache/:

```
host:/sys/fs/bcache# ls -l */{cache?,bdev?}
lrwxrwxrwx 1 root root 0 Mar  5 09:39 0226553a-37cf-41d5-b3ce-8b1e944543a8/
↪bdev1 -> ../../../devices/virtual/block/dm-1/bcache/
lrwxrwxrwx 1 root root 0 Mar  5 09:39 0226553a-37cf-41d5-b3ce-8b1e944543a8/
↪cache0 -> ../../../devices/virtual/block/dm-4/bcache/
lrwxrwxrwx 1 root root 0 Mar  5 09:39 5bc072a8-ab17-446d-9744-e247949913c1/
↪cache0 -> ../../../devices/pci0000:00/0000:00:01.0/0000:01:00.0/ata10/
↪host9/target9:0:0/9:0:0:0/block/sdl/sdl2/bcache/
```

The device names will show which UUID is relevant, cd in that directory and stop the cache:

```
host:/sys/fs/bcache/5bc072a8-ab17-446d-9744-e247949913c1# echo 1 > stop
```

This will free up bcache references and let you reuse the partition for other purposes.

25.4 Troubleshooting performance

Bcache has a bunch of config options and tunables. The defaults are intended to be reasonable for typical desktop and server workloads, but they're not what you want for getting the best possible numbers when benchmarking.

- Backing device alignment

  The default metadata size in bcache is 8k. If your backing device is RAID based, then be sure to align this by a multiple of your stride width using *bcache make --data-offset*. If you intend to expand your disk array in the future, then multiply a series of primes by your raid stripe size to get the disk multiples that you would like.

  For example: If you have a 64k stripe size, then the following offset would provide alignment for many common RAID5 data spindle counts:

  ```
  64k * 2*2*2*3*3*5*7 bytes = 161280k
  ```

  That space is wasted, but for only 157.5MB you can grow your RAID 5 volume to the following data-spindle counts without re-aligning:

```
3,4,5,6,7,8,9,10,12,14,15,18,20,21 ...
```

- Bad write performance

  If write performance is not what you expected, you probably wanted to be running in writeback mode, which isn't the default (not due to a lack of maturity, but simply because in writeback mode you'll lose data if something happens to your SSD):

```
# echo writeback > /sys/block/bcache0/bcache/cache_mode
```

- Bad performance, or traffic not going to the SSD that you'd expect

  By default, bcache doesn't cache everything. It tries to skip sequential IO - because you really want to be caching the random IO, and if you copy a 10 gigabyte file you probably don't want that pushing 10 gigabytes of randomly accessed data out of your cache.

  But if you want to benchmark reads from cache, and you start out with fio writing an 8 gigabyte test file - so you want to disable that:

```
# echo 0 > /sys/block/bcache0/bcache/sequential_cutoff
```

  To set it back to the default (4 mb), do:

```
# echo 4M > /sys/block/bcache0/bcache/sequential_cutoff
```

- Traffic's still going to the spindle/still getting cache misses

  In the real world, SSDs don't always keep up with disks - particularly with slower SSDs, many disks being cached by one SSD, or mostly sequential IO. So you want to avoid being bottlenecked by the SSD and having it slow everything down.

  To avoid that bcache tracks latency to the cache device, and gradually throttles traffic if the latency exceeds a threshold (it does this by cranking down the sequential bypass).

  You can disable this if you need to by setting the thresholds to 0:

```
# echo 0 > /sys/fs/bcache/<cache set>/congested_read_threshold_us
# echo 0 > /sys/fs/bcache/<cache set>/congested_write_threshold_us
```

  The default is 2000 us (2 milliseconds) for reads, and 20000 for writes.

- Still getting cache misses, of the same data

  One last issue that sometimes trips people up is actually an old bug, due to the way cache coherency is handled for cache misses. If a btree node is full, a cache miss won't be able to insert a key for the new data and the data won't be written to the cache.

  In practice this isn't an issue because as soon as a write comes along it'll cause the btree node to be split, and you need almost no write traffic for this to not show up enough to be noticeable (especially since bcache's btree nodes are huge and index large regions of the device). But when you're benchmarking, if you're trying to warm the cache by reading a bunch of data and there's no other traffic - that can be a problem.

  Solution: warm the cache by doing writes, or use the testing branch (there's a fix for the issue there).

25.5 Sysfs - backing device

Available at /sys/block/<bdev>/bcache, /sys/block/bcache*/bcache and (if attached) /sys/fs/bcache/<cset-uuid>/bdev*

attach
Echo the UUID of a cache set to this file to enable caching.

cache_mode
Can be one of either writethrough, writeback, writearound or none.

clear_stats
Writing to this file resets the running total stats (not the day/hour/5 minute decaying versions).

detach
Write to this file to detach from a cache set. If there is dirty data in the cache, it will be flushed first.

dirty_data
Amount of dirty data for this backing device in the cache. Continuously updated unlike the cache set's version, but may be slightly off.

label
Name of underlying device.

readahead
Size of readahead that should be performed. Defaults to 0. If set to e.g. 1M, it will round cache miss reads up to that size, but without overlapping existing cache entries.

running
1 if bcache is running (i.e. whether the /dev/bcache device exists, whether it's in passthrough mode or caching).

sequential_cutoff
A sequential IO will bypass the cache once it passes this threshold; the most recent 128 IOs are tracked so sequential IO can be detected even when it isn't all done at once.

sequential_merge
If non zero, bcache keeps a list of the last 128 requests submitted to compare against all new requests to determine which new requests are sequential continuations of previous requests for the purpose of determining sequential cutoff. This is necessary if the sequential cutoff value is greater than the maximum acceptable sequential size for any single request.

state
The backing device can be in one of four different states:

no cache: Has never been attached to a cache set.

clean: Part of a cache set, and there is no cached dirty data.

dirty: Part of a cache set, and there is cached dirty data.

inconsistent: The backing device was forcibly run by the user when there was dirty data cached but the cache set was unavailable; whatever data was on the backing device has likely been corrupted.

stop
Write to this file to shut down the bcache device and close the backing device.

writeback_delay
When dirty data is written to the cache and it previously did not contain any, waits some number of seconds before initiating writeback. Defaults to 30.

writeback_percent
If nonzero, bcache tries to keep around this percentage of the cache dirty by throttling background writeback and using a PD controller to smoothly adjust the rate.

writeback_rate
Rate in sectors per second - if writeback_percent is nonzero, background writeback is throttled to this rate. Continuously adjusted by bcache but may also be set by the user.

writeback_running
If off, writeback of dirty data will not take place at all. Dirty data will still be added to the cache until it is mostly full; only meant for benchmarking. Defaults to on.

25.5.1 Sysfs - backing device stats

There are directories with these numbers for a running total, as well as versions that decay over the past day, hour and 5 minutes; they're also aggregated in the cache set directory as well.

bypassed
Amount of IO (both reads and writes) that has bypassed the cache

cache_hits, cache_misses, cache_hit_ratio
Hits and misses are counted per individual IO as bcache sees them; a partial hit is counted as a miss.

cache_bypass_hits, cache_bypass_misses
Hits and misses for IO that is intended to skip the cache are still counted, but broken out here.

cache_miss_collisions
Counts instances where data was going to be inserted into the cache from a cache miss, but raced with a write and data was already present (usually 0 since the synchronization for cache misses was rewritten)

25.5.2 Sysfs - cache set

Available at /sys/fs/bcache/<cset-uuid>

average_key_size
Average data per key in the btree.

bdev<0..n>
Symlink to each of the attached backing devices.

block_size
Block size of the cache devices.

btree_cache_size
Amount of memory currently used by the btree cache

bucket_size
Size of buckets

cache<0..n>
Symlink to each of the cache devices comprising this cache set.

cache_available_percent
Percentage of cache device which doesn't contain dirty data, and could potentially be used for writeback. This doesn't mean this space isn't used for clean cached data; the unused statistic (in priority_stats) is typically much lower.

clear_stats
Clears the statistics associated with this cache

dirty_data
Amount of dirty data is in the cache (updated when garbage collection runs).

flash_vol_create
Echoing a size to this file (in human readable units, k/M/G) creates a thinly provisioned volume backed by the cache set.

io_error_halflife, io_error_limit
These determines how many errors we accept before disabling the cache. Each error is decayed by the half life (in # ios). If the decaying count reaches io_error_limit dirty data is written out and the cache is disabled.

journal_delay_ms
Journal writes will delay for up to this many milliseconds, unless a cache flush happens sooner. Defaults to 100.

root_usage_percent
Percentage of the root btree node in use. If this gets too high the node will split, increasing the tree depth.

stop
Write to this file to shut down the cache set - waits until all attached backing devices have been shut down.

tree_depth
Depth of the btree (A single node btree has depth 0).

unregister
Detaches all backing devices and closes the cache devices; if dirty data is present it will disable writeback caching and wait for it to be flushed.

25.5.3 Sysfs - cache set internal

This directory also exposes timings for a number of internal operations, with separate files for average duration, average frequency, last occurrence and max duration: garbage collection, btree read, btree node sorts and btree splits.

active_journal_entries
Number of journal entries that are newer than the index.

btree_nodes
Total nodes in the btree.

btree_used_percent
Average fraction of btree in use.

bset_tree_stats
Statistics about the auxiliary search trees

btree_cache_max_chain
Longest chain in the btree node cache's hash table

cache_read_races
Counts instances where while data was being read from the cache, the bucket was reused and invalidated - i.e. where the pointer was stale after the read completed. When this occurs the data is reread from the backing device.

trigger_gc
Writing to this file forces garbage collection to run.

25.5.4 Sysfs - Cache device

Available at /sys/block/<cdev>/bcache

block_size
Minimum granularity of writes - should match hardware sector size.

btree_written
Sum of all btree writes, in (kilo/mega/giga) bytes

bucket_size
Size of buckets

cache_replacement_policy
One of either lru, fifo or random.

discard
Boolean; if on a discard/TRIM will be issued to each bucket before it is reused. Defaults to off, since SATA TRIM is an unqueued command (and thus slow).

freelist_percent
Size of the freelist as a percentage of nbuckets. Can be written to to increase the number of buckets kept on the freelist, which lets you artificially reduce the size of the cache at runtime. Mostly for testing purposes (i.e. testing how different size caches affect your hit rate), but since buckets are discarded when they move on to the freelist will also make the SSD's garbage collection easier by effectively giving it more reserved space.

io_errors
Number of errors that have occurred, decayed by io_error_halflife.

metadata_written
Sum of all non data writes (btree writes and all other metadata).

nbuckets
Total buckets in this cache

priority_stats
Statistics about how recently data in the cache has been accessed. This can reveal your working set size. Unused is the percentage of the cache that doesn't contain any data. Metadata is bcache's metadata overhead. Average is the average priority of cache buckets. Next is a list of quantiles with the priority threshold of each.

written

Sum of all data that has been written to the cache; comparison with btree_written gives the amount of write inflation in bcache.

CHAPTER

TWENTYSIX

THE ANDROID BINDERFS FILESYSTEM

Android binderfs is a filesystem for the Android binder IPC mechanism. It allows to dynamically add and remove binder devices at runtime. Binder devices located in a new binderfs instance are independent of binder devices located in other binderfs instances. Mounting a new binderfs instance makes it possible to get a set of private binder devices.

26.1 Mounting binderfs

Android binderfs can be mounted with:

```
mkdir /dev/binderfs
mount -t binder binder /dev/binderfs
```

at which point a new instance of binderfs will show up at `/dev/binderfs`. In a fresh instance of binderfs no binder devices will be present. There will only be a `binder-control` device which serves as the request handler for binderfs. Mounting another binderfs instance at a different location will create a new and separate instance from all other binderfs mounts. This is identical to the behavior of e.g. `devpts` and `tmpfs`. The Android binderfs filesystem can be mounted in user namespaces.

26.2 Options

max
: binderfs instances can be mounted with a limit on the number of binder devices that can be allocated. The `max=<count>` mount option serves as a per-instance limit. If `max=<count>` is set then only `<count>` number of binder devices can be allocated in this binderfs instance.

stats
: Using `stats=global` enables global binder statistics. `stats=global` is only available for a binderfs instance mounted in the initial user namespace. An attempt to use the option to mount a binderfs instance in another user namespace will return a permission error.

26.3 Allocating binder Devices

To allocate a new binder device in a binderfs instance a request needs to be sent through the `binder-control` device node. A request is sent in the form of an ioctl().

What a program needs to do is to open the `binder-control` device node and send a `BINDER_CTL_ADD` request to the kernel. Users of binderfs need to tell the kernel which name the new binder device should get. By default a name can only contain up to `BINDERFS_MAX_NAME` chars including the terminating zero byte.

Once the request is made via an ioctl() passing a `struct binder_device` with the name to the kernel it will allocate a new binder device and return the major and minor number of the new device in the struct (This is necessary because binderfs allocates a major device number dynamically.). After the ioctl() returns there will be a new binder device located under /dev/binderfs with the chosen name.

26.4 Deleting binder Devices

Binderfs binder devices can be deleted via unlink(). This means that the rm() tool can be used to delete them. Note that the `binder-control` device cannot be deleted since this would make the binderfs instance unusable. The `binder-control` device will be deleted when the binderfs instance is unmounted and all references to it have been dropped.

26.5 Binder features

Assuming an instance of binderfs has been mounted at `/dev/binderfs`, the features supported by the binder driver can be located under `/dev/binderfs/features/`. The presence of individual files can be tested to determine whether a particular feature is supported by the driver.

Example:

```
cat /dev/binderfs/features/oneway_spam_detection
1
```

CHAPTER

TWENTYSEVEN

KERNEL SUPPORT FOR MISCELLANEOUS BINARY FORMATS (BINFMT_MISC)

This Kernel feature allows you to invoke almost (for restrictions see below) every program by simply typing its name in the shell. This includes for example compiled Java(TM), Python or Emacs programs.

To achieve this you must tell binfmt_misc which interpreter has to be invoked with which binary. Binfmt_misc recognises the binary-type by matching some bytes at the beginning of the file with a magic byte sequence (masking out specified bits) you have supplied. Binfmt_misc can also recognise a filename extension aka `.com` or `.exe`.

First you must mount binfmt_misc:

```
mount binfmt_misc -t binfmt_misc /proc/sys/fs/binfmt_misc
```

To actually register a new binary type, you have to set up a string looking like `:name:type:offset:magic:mask:interpreter:flags` (where you can choose the `:` upon your needs) and echo it to `/proc/sys/fs/binfmt_misc/register`.

Here is what the fields mean:

- **`name`**
  is an identifier string. A new /proc file will be created with this name below `/proc/sys/fs/binfmt_misc`; cannot contain slashes `/` for obvious reasons.
- **`type`**
  is the type of recognition. Give `M` for magic and `E` for extension.
- **`offset`**
  is the offset of the magic/mask in the file, counted in bytes. This defaults to 0 if you omit it (i.e. you write `:name:type::magic...`). Ignored when using filename extension matching.
- **`magic`**
  is the byte sequence binfmt_misc is matching for. The magic string may contain hex-encoded characters like `\x0a` or `\xA4`. Note that you must escape any NUL bytes; parsing halts at the first one. In a shell environment you might have to write `\\x0a` to prevent the shell from eating your `\`. If you chose filename extension matching, this is the extension to be recognised (without the `.`, the `\x0a` specials are not allowed). Extension matching is case sensitive, and slashes `/` are not allowed!
- **`mask`**
  is an (optional, defaults to all 0xff) mask. You can mask out some bits from matching by supplying a string like magic and as long as magic. The mask is anded with the

byte sequence of the file. Note that you must escape any NUL bytes; parsing halts at the first one. Ignored when using filename extension matching.

- **`interpreter`**
  is the program that should be invoked with the binary as first argument (specify the full path)
- **`flags`**
  is an optional field that controls several aspects of the invocation of the interpreter. It is a string of capital letters, each controls a certain aspect. The following flags are supported:

  `P` - preserve-argv[0]
  Legacy behavior of binfmt_misc is to overwrite the original argv[0] with the full path to the binary. When this flag is included, binfmt_misc will add an argument to the argument vector for this purpose, thus preserving the original `argv[0]`. e.g. If your interp is set to `/bin/foo` and you run `blah` (which is in `/usr/local/bin`), then the kernel will execute `/bin/foo` with `argv[]` set to `["/bin/foo", "/usr/local/bin/blah", "blah"]`. The interp has to be aware of this so it can execute `/usr/local/bin/blah` with `argv[]` set to `["blah"]`.

  `O` - open-binary
  Legacy behavior of binfmt_misc is to pass the full path of the binary to the interpreter as an argument. When this flag is included, binfmt_misc will open the file for reading and pass its descriptor as an argument, instead of the full path, thus allowing the interpreter to execute non-readable binaries. This feature should be used with care - the interpreter has to be trusted not to emit the contents of the non-readable binary.

  `C` - credentials
  Currently, the behavior of binfmt_misc is to calculate the credentials and security token of the new process according to the interpreter. When this flag is included, these attributes are calculated according to the binary. It also implies the `O` flag. This feature should be used with care as the interpreter will run with root permissions when a setuid binary owned by root is run with binfmt_misc.

  `F` - fix binary
  The usual behaviour of binfmt_misc is to spawn the binary lazily when the misc format file is invoked. However, this doesn't work very well in the face of mount namespaces and changeroots, so the `F` mode opens the binary as soon as the emulation is installed and uses the opened image to spawn the emulator, meaning it is always available once installed, regardless of how the environment changes.

There are some restrictions:

- the whole register string may not exceed 1920 characters
- the magic must reside in the first 128 bytes of the file, i.e. offset+size(magic) has to be less than 128
- the interpreter string may not exceed 127 characters

To use binfmt_misc you have to mount it first. You can mount it with `mount -t binfmt_misc`

`none /proc/sys/fs/binfmt_misc` command, or you can add a line `none /proc/sys/fs/binfmt_misc binfmt_misc defaults 0 0` to your `/etc/fstab` so it auto mounts on boot.

You may want to add the binary formats in one of your `/etc/rc` scripts during boot-up. Read the manual of your init program to figure out how to do this right.

Think about the order of adding entries! Later added entries are matched first!

A few examples (assumed you are in `/proc/sys/fs/binfmt_misc`):

- enable support for em86 (like binfmt_em86, for Alpha AXP only):

```
echo ':i386:M::\x7fELF\x01\x00\x00\x00\x00\x00\x00\x00\x00\x00\x00\x00\x02\
↪x00\x03:\xff\xff\xff\xff\xff\xfe\xfe\xff\xff\xff\xff\xff\xff\xff\xff\xff\
↪xfb\xff\xff:/bin/em86:' > register
echo ':i486:M::\x7fELF\x01\x00\x00\x00\x00\x00\x00\x00\x00\x00\x00\x00\x02\
↪x00\x06:\xff\xff\xff\xff\xff\xfe\xfe\xff\xff\xff\xff\xff\xff\xff\xff\xff\
↪xfb\xff\xff:/bin/em86:' > register
```

- enable support for packed DOS applications (pre-configured dosemu hdimages):

```
echo ':DEXE:M::\x0eDEX::/usr/bin/dosexec:' > register
```

- enable support for Windows executables using wine:

```
echo ':DOSWin:M::MZ::/usr/local/bin/wine:' > register
```

For java support see *Java(tm) Binary Kernel Support for Linux v1.03*

You can enable/disable binfmt_misc or one binary type by echoing 0 (to disable) or 1 (to enable) to `/proc/sys/fs/binfmt_misc/status` or `/proc/.../the_name`. Catting the file tells you the current status of `binfmt_misc/the_entry`.

You can remove one entry or all entries by echoing -1 to `/proc/.../the_name` or `/proc/sys/fs/binfmt_misc/status`.

27.1 Hints

If you want to pass special arguments to your interpreter, you can write a wrapper script for it. See *Documentation/admin-guide/java.rst* for an example.

Your interpreter should NOT look in the PATH for the filename; the kernel passes it the full filename (or the file descriptor) to use. Using `$PATH` can cause unexpected behaviour and can be a security hazard.

Richard Günther <rguenth@tat.physik.uni-tuebingen.de>

CHAPTER

TWENTYEIGHT

BLOCK DEVICES

28.1 Floppy Driver

28.1.1 FAQ list:

A FAQ list may be found in the fdutils package (see below), and also at <https://fdutils.linux.lu/faq.html>.

28.1.2 LILO configuration options (Thinkpad users, read this)

The floppy driver is configured using the 'floppy=' option in lilo. This option can be typed at the boot prompt, or entered in the lilo configuration file.

Example: If your kernel is called linux-2.6.9, type the following line at the lilo boot prompt (if you have a thinkpad):

```
linux-2.6.9 floppy=thinkpad
```

You may also enter the following line in /etc/lilo.conf, in the description of linux-2.6.9:

```
append = "floppy=thinkpad"
```

Several floppy related options may be given, example:

```
linux-2.6.9 floppy=daring floppy=two_fdc
append = "floppy=daring floppy=two_fdc"
```

If you give options both in the lilo config file and on the boot prompt, the option strings of both places are concatenated, the boot prompt options coming last. That's why there are also options to restore the default behavior.

28.1.3 Module configuration options

If you use the floppy driver as a module, use the following syntax:

```
modprobe floppy floppy="<options>"
```

Example:

```
modprobe floppy floppy="omnibook messages"
```

If you need certain options enabled every time you load the floppy driver, you can put:

```
options floppy floppy="omnibook messages"
```

in a configuration file in /etc/modprobe.d/.

The floppy driver related options are:

floppy=asus_pci
Sets the bit mask to allow only units 0 and 1. (default)

floppy=daring
Tells the floppy driver that you have a well behaved floppy controller. This allows more efficient and smoother operation, but may fail on certain controllers. This may speed up certain operations.

floppy=0,daring
Tells the floppy driver that your floppy controller should be used with caution.

floppy=one_fdc
Tells the floppy driver that you have only one floppy controller. (default)

floppy=two_fdc / floppy=<address>,two_fdc
Tells the floppy driver that you have two floppy controllers. The second floppy controller is assumed to be at <address>. This option is not needed if the second controller is at address 0x370, and if you use the 'cmos' option.

floppy=thinkpad
Tells the floppy driver that you have a Thinkpad. Thinkpads use an inverted convention for the disk change line.

floppy=0,thinkpad
Tells the floppy driver that you don't have a Thinkpad.

floppy=omnibook / floppy=nodma
Tells the floppy driver not to use Dma for data transfers. This is needed on HP Omnibooks, which don't have a workable DMA channel for the floppy driver. This option is also useful if you frequently get ”Unable to allocate DMA memory” messages. Indeed, dma memory needs to be continuous in physical memory, and is thus harder to find, whereas non-dma buffers may be allocated in virtual memory. However, I advise against this if you have an FDC without a FIFO (8272A or 82072). 82072A and later are OK. You also need at least a 486 to use nodma. If you use nodma mode, I suggest you also set the FIFO threshold to 10 or lower, in order to limit the number of data transfer interrupts.

If you have a FIFO-able FDC, the floppy driver automatically falls back on non DMA mode if no DMA-able memory can be found. If you want to avoid this,

explicitly ask for 'yesdma'.

floppy=yesdma
Tells the floppy driver that a workable DMA channel is available. (default)

floppy=nofifo
Disables the FIFO entirely. This is needed if you get "Bus master arbitration error" messages from your Ethernet card (or from other devices) while accessing the floppy.

floppy=usefifo
Enables the FIFO. (default)

floppy=<threshold>,fifo_depth
Sets the FIFO threshold. This is mostly relevant in DMA mode. If this is higher, the floppy driver tolerates more interrupt latency, but it triggers more interrupts (i.e. it imposes more load on the rest of the system). If this is lower, the interrupt latency should be lower too (faster processor). The benefit of a lower threshold is less interrupts.

To tune the fifo threshold, switch on over/underrun messages using 'floppy-control --messages'. Then access a floppy disk. If you get a huge amount of "Over/Underrun - retrying" messages, then the fifo threshold is too low. Try with a higher value, until you only get an occasional Over/Underrun. It is a good idea to compile the floppy driver as a module when doing this tuning. Indeed, it allows to try different fifo values without rebooting the machine for each test. Note that you need to do 'floppycontrol --messages' every time you re-insert the module.

Usually, tuning the fifo threshold should not be needed, as the default (0xa) is reasonable.

floppy=<drive>,<type>,cmos
Sets the CMOS type of <drive> to <type>. This is mandatory if you have more than two floppy drives (only two can be described in the physical CMOS), or if your BIOS uses non-standard CMOS types. The CMOS types are:

0	Use the value of the physical CMOS
1	5 1/4 DD
2	5 1/4 HD
3	3 1/2 DD
4	3 1/2 HD
5	3 1/2 ED
6	3 1/2 ED
16	unknown or not installed

(Note: there are two valid types for ED drives. This is because 5 was initially chosen to represent floppy *tapes*, and 6 for ED drives. AMI ignored this, and used 5 for ED drives. That's why the floppy driver handles both.)

floppy=unexpected_interrupts
Print a warning message when an unexpected interrupt is received. (default)

floppy=no_unexpected_interrupts / floppy=L40SX
Don't print a message when an unexpected interrupt is received. This is needed on IBM L40SX laptops in certain video modes. (There seems to be an interaction

between video and floppy. The unexpected interrupts affect only performance, and can be safely ignored.)

floppy=broken_dcl
Don't use the disk change line, but assume that the disk was changed whenever the device node is reopened. Needed on some boxes where the disk change line is broken or unsupported. This should be regarded as a stopgap measure, indeed it makes floppy operation less efficient due to unneeded cache flushings, and slightly more unreliable. Please verify your cable, connection and jumper settings if you have any DCL problems. However, some older drives, and also some laptops are known not to have a DCL.

floppy=debug
Print debugging messages.

floppy=messages
Print informational messages for some operations (disk change notifications, warnings about over and underruns, and about autodetection).

floppy=silent_dcl_clear
Uses a less noisy way to clear the disk change line (which doesn't involve seeks). Implied by 'daring' option.

floppy=<nr>,irq
Sets the floppy IRQ to <nr> instead of 6.

floppy=<nr>,dma
Sets the floppy DMA channel to <nr> instead of 2.

floppy=slow
Use PS/2 stepping rate:

```
PS/2 floppies have much slower step rates than regular floppies.
It's been recommended that take about 1/4 of the default speed
in some more extreme cases.
```

28.1.4 Supporting utilities and additional documentation:

Additional parameters of the floppy driver can be configured at runtime. Utilities which do this can be found in the fdutils package. This package also contains a new version of mtools which allows to access high capacity disks (up to 1992K on a high density 3 1/2 disk!). It also contains additional documentation about the floppy driver.

The latest version can be found at fdutils homepage:

https://fdutils.linux.lu

The fdutils releases can be found at:

https://fdutils.linux.lu/download.html

http://www.tux.org/pub/knaff/fdutils/

ftp://metalab.unc.edu/pub/Linux/utils/disk-management/

28.1.5 Reporting problems about the floppy driver

If you have a question or a bug report about the floppy driver, mail me at Alain.Knaff@poboxes.com . If you post to Usenet, preferably use comp.os.linux.hardware. As the volume in these groups is rather high, be sure to include the word "floppy" (or "FLOPPY") in the subject line. If the reported problem happens when mounting floppy disks, be sure to mention also the type of the filesystem in the subject line.

Be sure to read the FAQ before mailing/posting any bug reports!

Alain

28.2 Network Block Device (TCP version)

28.2.1 1) Overview

What is it: With this compiled in the kernel (or as a module), Linux can use a remote server as one of its block devices. So every time the client computer wants to read, e.g., /dev/nb0, it sends a request over TCP to the server, which will reply with the data read. This can be used for stations with low disk space (or even diskless) to borrow disk space from another computer. Unlike NFS, it is possible to put any filesystem on it, etc.

For more information, or to download the nbd-client and nbd-server tools, go to https://github.com/NetworkBlockDevice/nbd.

The nbd kernel module need only be installed on the client system, as the nbd-server is completely in userspace. In fact, the nbd-server has been successfully ported to other operating systems, including Windows.

28.2.2 A) NBD parameters

max_part
Number of partitions per device (default: 0).

nbds_max
Number of block devices that should be initialized (default: 16).

28.3 Linux and parallel port IDE devices

PARIDE v1.03 (c) 1997-8 Grant Guenther <grant@torque.net> PATA_PARPORT (c) 2023 Ondrej Zary

28.3.1 1. Introduction

Owing to the simplicity and near universality of the parallel port interface to personal computers, many external devices such as portable hard-disk, CD-ROM, LS-120 and tape drives use the parallel port to connect to their host computer. While some devices (notably scanners) use ad-hoc methods to pass commands and data through the parallel port interface, most external devices are actually identical to an internal model, but with a parallel-port adapter chip added in. Some of the original parallel port adapters were little more than mechanisms for multiplexing a SCSI bus. (The Iomega PPA-3 adapter used in the ZIP drives is an example of this approach). Most current designs, however, take a different approach. The adapter chip reproduces a small ISA or IDE bus in the external device and the communication protocol provides operations for reading and writing device registers, as well as data block transfer functions. Sometimes, the device being addressed via the parallel cable is a standard SCSI controller like an NCR 5380. The ”ditto” family of external tape drives use the ISA replicator to interface a floppy disk controller, which is then connected to a floppy-tape mechanism. The vast majority of external parallel port devices, however, are now based on standard IDE type devices, which require no intermediate controller. If one were to open up a parallel port CD-ROM drive, for instance, one would find a standard ATAPI CD-ROM drive, a power supply, and a single adapter that interconnected a standard PC parallel port cable and a standard IDE cable. It is usually possible to exchange the CD-ROM device with any other device using the IDE interface.

The document describes the support in Linux for parallel port IDE devices. It does not cover parallel port SCSI devices, ”ditto” tape drives or scanners. Many different devices are supported by the parallel port IDE subsystem, including:

- MicroSolutions backpack CD-ROM
- MicroSolutions backpack PD/CD
- MicroSolutions backpack hard-drives
- MicroSolutions backpack 8000t tape drive
- SyQuest EZ-135, EZ-230 & SparQ drives
- Avatar Shark
- Imation Superdisk LS-120
- Maxell Superdisk LS-120
- FreeCom Power CD
- Hewlett-Packard 5GB and 8GB tape drives
- Hewlett-Packard 7100 and 7200 CD-RW drives

as well as most of the clone and no-name products on the market.

To support such a wide range of devices, pata_parport is actually structured in two parts. There is a base pata_parport module which provides an interface to kernel libata subsystem, registry and some common methods for accessing the parallel ports.

The second component is a set of low-level protocol drivers for each of the parallel port IDE adapter chips. Thanks to the interest and encouragement of Linux users from many parts of the world, support is available for almost all known adapter protocols:

aten	ATEN EH-100	(HK)
bpck	Microsolutions backpack	(US)
comm	DataStor (old-type) "commuter" adapter	(TW)
dstr	DataStor EP-2000	(TW)
epat	Shuttle EPAT	(UK)
epia	Shuttle EPIA	(UK)
fit2	FIT TD-2000	(US)
fit3	FIT TD-3000	(US)
friq	Freecom IQ cable	(DE)
frpw	Freecom Power	(DE)
kbic	KingByte KBIC-951A and KBIC-971A	(TW)
ktti	KT Technology PHd adapter	(SG)
on20	OnSpec 90c20	(US)
on26	OnSpec 90c26	(US)

28.3.2 2. Using pata_parport subsystem

While configuring the Linux kernel, you may choose either to build the pata_parport drivers into your kernel, or to build them as modules.

In either case, you will need to select "Parallel port IDE device support" and at least one of the parallel port communication protocols. If you do not know what kind of parallel port adapter is used in your drive, you could begin by checking the file names and any text files on your DOS installation floppy. Alternatively, you can look at the markings on the adapter chip itself. That's usually sufficient to identify the correct device.

You can actually select all the protocol modules, and allow the pata_parport subsystem to try them all for you.

For the "brand-name" products listed above, here are the protocol and high-level drivers that you would use:

Manufacturer	Model	Protocol
MicroSolutions	CD-ROM	bpck
MicroSolutions	PD drive	bpck
MicroSolutions	hard-drive	bpck
MicroSolutions	8000t tape	bpck
SyQuest	EZ, SparQ	epat
Imation	Superdisk	epat
Maxell	Superdisk	friq
Avatar	Shark	epat
FreeCom	CD-ROM	frpw
Hewlett-Packard	5GB Tape	epat
Hewlett-Packard	7200e (CD)	epat
Hewlett-Packard	7200e (CD-R)	epat

All parports and all protocol drivers are probed automatically unless probe=0 parameter is used. So just ”modprobe epat” is enough for a Imation SuperDisk drive to work.

Manual device creation:

```
# echo "port protocol mode unit delay" >/sys/bus/pata_parport/new_device
```

where:

port	parport name (or ”auto” for all parports)
protocol	protocol name (or ”auto” for all protocols)
mode	mode number (protocol-specific) or -1 for probe
unit	unit number (for backpack only, see below)
delay	I/O delay (see troubleshooting section below)

If you happen to be using a MicroSolutions backpack device, you will also need to know the unit ID number for each drive. This is usually the last two digits of the drive's serial number (but read MicroSolutions' documentation about this).

If you omit the parameters from the end, defaults will be used, e.g.:

Probe all parports with all protocols:

```
# echo auto >/sys/bus/pata_parport/new_device
```

Probe parport0 using protocol epat and mode 4 (EPP-16):

```
# echo "parport0 epat 4" >/sys/bus/pata_parport/new_device
```

Probe parport0 using all protocols:

```
# echo "parport0 auto" >/sys/bus/pata_parport/new_device
```

Probe all parports using protoocol epat:

```
# echo "auto epat" >/sys/bus/pata_parport/new_device
```

Deleting devices:

```
# echo pata_parport.0 >/sys/bus/pata_parport/delete_device
```

28.3.3 3. Troubleshooting

3.1 Use EPP mode if you can

The most common problems that people report with the pata_parport drivers concern the parallel port CMOS settings. At this time, none of the protocol modules support ECP mode, or any ECP combination modes. If you are able to do so, please set your parallel port into EPP mode using your CMOS setup procedure.

3.2 Check the port delay

Some parallel ports cannot reliably transfer data at full speed. To offset the errors, the protocol modules introduce a ”port delay” between each access to the i/o ports. Each protocol sets a default value for this delay. In most cases, the user can override the default and set it to 0 - resulting in somewhat higher transfer rates. In some rare cases (especially with older 486 systems) the default delays are not long enough. if you experience corrupt data transfers, or unexpected failures, you may wish to increase the port delay.

3.3 Some drives need a printer reset

There appear to be a number of ”noname” external drives on the market that do not always power up correctly. We have noticed this with some drives based on OnSpec and older Freecom adapters. In these rare cases, the adapter can often be reinitialised by issuing a ”printer reset” on the parallel port. As the reset operation is potentially disruptive in multiple device environments, the pata_parport drivers will not do it automatically. You can however, force a printer reset by doing:

```
insmod lp reset=1
rmmod lp
```

If you have one of these marginal cases, you should probably build your pata_parport drivers as modules, and arrange to do the printer reset before loading the pata_parport drivers.

28.4 Using the RAM disk block device with Linux

28.4.1 1) Overview

The RAM disk driver is a way to use main system memory as a block device. It is required for initrd, an initial filesystem used if you need to load modules in order to access the root filesystem (see *Using the initial RAM disk (initrd)*). It can also be used for a temporary filesystem for crypto work, since the contents are erased on reboot.

The RAM disk dynamically grows as more space is required. It does this by using RAM from the buffer cache. The driver marks the buffers it is using as dirty so that the VM subsystem does not try to reclaim them later.

The RAM disk supports up to 16 RAM disks by default, and can be reconfigured to support an unlimited number of RAM disks (at your own risk). Just change the configuration symbol BLK_DEV_RAM_COUNT in the Block drivers config menu and (re)build the kernel.

To use RAM disk support with your system, run './MAKEDEV ram' from the /dev directory. RAM disks are all major number 1, and start with minor number 0 for /dev/ram0, etc. If used, modern kernels use /dev/ram0 for an initrd.

The new RAM disk also has the ability to load compressed RAM disk images, allowing one to squeeze more programs onto an average installation or rescue floppy disk.

28.4.2 2) Parameters

2a) Kernel Command Line Parameters

ramdisk_size=N
Size of the ramdisk.

This parameter tells the RAM disk driver to set up RAM disks of N k size. The default is 4096 (4 MB).

2b) Module parameters

rd_nr
/dev/ramX devices created.

max_part
Maximum partition number.

rd_size
See ramdisk_size.

28.4.3 3) Using "rdev"

"rdev" is an obsolete, deprecated, antiquated utility that could be used to set the boot device in a Linux kernel image.

Instead of using rdev, just place the boot device information on the kernel command line and pass it to the kernel from the bootloader.

You can also pass arguments to the kernel by setting FDARGS in arch/x86/boot/Makefile and specify in initrd image by setting FDINITRD in arch/x86/boot/Makefile.

Some of the kernel command line boot options that may apply here are:

```
ramdisk_start=N
ramdisk_size=M
```

If you make a boot disk that has LILO, then for the above, you would use:

```
append = "ramdisk_start=N ramdisk_size=M"
```

28.4.4 4) An Example of Creating a Compressed RAM Disk

To create a RAM disk image, you will need a spare block device to construct it on. This can be the RAM disk device itself, or an unused disk partition (such as an unmounted swap partition). For this example, we will use the RAM disk device, "/dev/ram0".

Note: This technique should not be done on a machine with less than 8 MB of RAM. If using a spare disk partition instead of /dev/ram0, then this restriction does not apply.

a) Decide on the RAM disk size that you want. Say 2 MB for this example. Create it by writing to the RAM disk device. (This step is not currently required, but may be in the future.) It is wise to zero out the area (esp. for disks) so that maximal compression is achieved for the unused blocks of the image that you are about to create:

```
dd if=/dev/zero of=/dev/ram0 bs=1k count=2048
```

b) Make a filesystem on it. Say ext2fs for this example:

```
mke2fs -vm0 /dev/ram0 2048
```

c) Mount it, copy the files you want to it (eg: /etc/* /dev/* ...) and unmount it again.

d) Compress the contents of the RAM disk. The level of compression will be approximately 50% of the space used by the files. Unused space on the RAM disk will compress to almost nothing:

```
dd if=/dev/ram0 bs=1k count=2048 | gzip -v9 > /tmp/ram_image.gz
```

e) Put the kernel onto the floppy:

```
dd if=zImage of=/dev/fd0 bs=1k
```

f) Put the RAM disk image onto the floppy, after the kernel. Use an offset that is slightly larger than the kernel, so that you can put another (possibly larger) kernel onto the same floppy later without overlapping the RAM disk image. An offset of 400 kB for kernels about 350 kB in size would be reasonable. Make sure offset+size of ram_image.gz is not larger than the total space on your floppy (usually 1440 kB):

```
dd if=/tmp/ram_image.gz of=/dev/fd0 bs=1k seek=400
```

g) Make sure that you have already specified the boot information in FDARGS and FDINITRD or that you use a bootloader to pass kernel command line boot options to the kernel.

That is it. You now have your boot/root compressed RAM disk floppy. Some users may wish to combine steps (d) and (f) by using a pipe.

Paul Gortmaker 12/95

28.4.5 Changelog:

SEPT-2020 :

Removed usage of "rdev"

10-22-04 :
Updated to reflect changes in command line options, remove obsolete references, general cleanup. James Nelson (james4765@gmail.com)

28.5 zram: Compressed RAM-based block devices

28.5.1 Introduction

The zram module creates RAM-based block devices named /dev/zram<id> (<id> = 0, 1, ...). Pages written to these disks are compressed and stored in memory itself. These disks allow very fast I/O and compression provides good amounts of memory savings. Some of the use cases include /tmp storage, use as swap disks, various caches under /var and maybe many more. :)

Statistics for individual zram devices are exported through sysfs nodes at /sys/block/zram<id>/

28.5.2 Usage

There are several ways to configure and manage zram device(-s):

a) using zram and zram_control sysfs attributes

b) using zramctl utility, provided by util-linux (util-linux@vger.kernel.org).

In this document we will describe only 'manual' zram configuration steps, IOW, zram and zram_control sysfs attributes.

In order to get a better idea about zramctl please consult util-linux documentation, zramctl man-page or *zramctl --help*. Please be informed that zram maintainers do not develop/maintain util-linux or zramctl, should you have any questions please contact util-linux@vger.kernel.org

Following shows a typical sequence of steps for using zram.

28.5.3 WARNING

For the sake of simplicity we skip error checking parts in most of the examples below. However, it is your sole responsibility to handle errors.

zram sysfs attributes always return negative values in case of errors. The list of possible return codes:

-EBUSY	an attempt to modify an attribute that cannot be changed once the device has been initialised. Please reset device first.
-ENOMEM	zram was not able to allocate enough memory to fulfil your needs.
-EINVAL	invalid input has been provided.

If you use 'echo', the returned value is set by the 'echo' utility, and, in general case, something like:

```
echo 3 > /sys/block/zram0/max_comp_streams
if [ $? -ne 0 ]; then
        handle_error
fi
```

should suffice.

28.5.4 1) Load Module

```
modprobe zram num_devices=4
```

This creates 4 devices: /dev/zram{0,1,2,3}

num_devices parameter is optional and tells zram how many devices should be pre-created. Default: 1.

28.5.5 2) Set max number of compression streams

Regardless of the value passed to this attribute, ZRAM will always allocate multiple compression streams - one per online CPU - thus allowing several concurrent compression operations. The number of allocated compression streams goes down when some of the CPUs become offline. There is no single-compression-stream mode anymore, unless you are running a UP system or have only 1 CPU online.

To find out how many streams are currently available:

```
cat /sys/block/zram0/max_comp_streams
```

28.5.6 3) Select compression algorithm

Using comp_algorithm device attribute one can see available and currently selected (shown in square brackets) compression algorithms, or change the selected compression algorithm (once the device is initialised there is no way to change compression algorithm).

Examples:

```
#show supported compression algorithms
cat /sys/block/zram0/comp_algorithm
lzo [lz4]

#select lzo compression algorithm
echo lzo > /sys/block/zram0/comp_algorithm
```

For the time being, the *comp_algorithm* content does not necessarily show every compression algorithm supported by the kernel. We keep this list primarily to simplify device configuration and one can configure a new device with a compression algorithm that is not listed in *comp_algorithm*. The thing is that, internally, ZRAM uses Crypto API and, if some of the algorithms were built as modules, it's impossible to list all of them using, for instance, /proc/crypto or any other method. This, however, has an advantage of permitting the usage of custom crypto compression modules (implementing S/W or H/W compression).

28.5.7 4) Set Disksize

Set disk size by writing the value to sysfs node 'disksize'. The value can be either in bytes or you can use mem suffixes. Examples:

```
# Initialize /dev/zram0 with 50MB disksize
echo $((50*1024*1024)) > /sys/block/zram0/disksize

# Using mem suffixes
echo 256K > /sys/block/zram0/disksize
echo 512M > /sys/block/zram0/disksize
echo 1G > /sys/block/zram0/disksize
```

Note: There is little point creating a zram of greater than twice the size of memory since we expect a 2:1 compression ratio. Note that zram uses about 0.1% of the size of the disk when not in use so a huge zram is wasteful.

28.5.8 5) Set memory limit: Optional

Set memory limit by writing the value to sysfs node 'mem_limit'. The value can be either in bytes or you can use mem suffixes. In addition, you could change the value in runtime. Examples:

```
# limit /dev/zram0 with 50MB memory
echo $((50*1024*1024)) > /sys/block/zram0/mem_limit

# Using mem suffixes
echo 256K > /sys/block/zram0/mem_limit
echo 512M > /sys/block/zram0/mem_limit
echo 1G > /sys/block/zram0/mem_limit

# To disable memory limit
echo 0 > /sys/block/zram0/mem_limit
```

28.5.9 6) Activate

```
mkswap /dev/zram0
swapon /dev/zram0

mkfs.ext4 /dev/zram1
mount /dev/zram1 /tmp
```

28.5.10 7) Add/remove zram devices

zram provides a control interface, which enables dynamic (on-demand) device addition and removal.

In order to add a new /dev/zramX device, perform a read operation on the hot_add attribute. This will return either the new device's device id (meaning that you can use /dev/zram<id>) or an error code.

Example:

```
cat /sys/class/zram-control/hot_add
1
```

To remove the existing /dev/zramX device (where X is a device id) execute:

```
echo X > /sys/class/zram-control/hot_remove
```

28.5.11 8) Stats

Per-device statistics are exported as various nodes under /sys/block/zram<id>/

A brief description of exported device attributes follows. For more details please read Documentation/ABI/testing/sysfs-block-zram.

Name	access	description
disksize	RW	show and set the device's disk size
initstate	RO	shows the initialization state of the device
reset	WO	trigger device reset
mem_used_max	WO	reset the *mem_used_max* counter (see later)
mem_limit	WO	specifies the maximum amount of memory ZRAM can use to store the compressed data
writeback_limit	WO	specifies the maximum amount of write IO zram can write out to backing device as 4KB unit
writeback_limit_enable	RW	show and set writeback_limit feature
max_comp_streams	RW	the number of possible concurrent compress operations
comp_algorithm	RW	show and change the compression algorithm
compact	WO	trigger memory compaction
debug_stat	RO	this file is used for zram debugging purposes
backing_dev	RW	set up backend storage for zram to write out
idle	WO	mark allocated slot as idle

User space is advised to use the following files to read the device statistics.

File /sys/block/zram<id>/stat

Represents block layer statistics. Read Documentation/block/stat.rst for details.

File /sys/block/zram<id>/io_stat

The stat file represents device's I/O statistics not accounted by block layer and, thus, not available in zram<id>/stat file. It consists of a single line of text and contains the following stats separated by whitespace:

failed_reads	The number of failed reads
failed_writes	The number of failed writes
invalid_io	The number of non-page-size-aligned I/O requests
notify_free	Depending on device usage scenario it may account a) the number of pages freed because of swap slot free notifications b) the number of pages freed because of REQ_OP_DISCARD requests sent by bio. The former ones are sent to a swap block device when a swap slot is freed, which implies that this disk is being used as a swap disk. The latter ones are sent by filesystem mounted with discard option, whenever some data blocks are getting discarded.

File /sys/block/zram<id>/mm_stat

The mm_stat file represents the device's mm statistics. It consists of a single line of text and contains the following stats separated by whitespace:

orig_data_size	uncompressed size of data stored in this disk. Unit: bytes
compr_data_size	compressed size of data stored in this disk
mem_used_total	the amount of memory allocated for this disk. This includes allocator fragmentation and metadata overhead, allocated for this disk. So, allocator space efficiency can be calculated using compr_data_size and this statistic. Unit: bytes
mem_limit	the maximum amount of memory ZRAM can use to store the compressed data
mem_used_max	the maximum amount of memory zram has consumed to store the data
same_pages	the number of same element filled pages written to this disk. No memory is allocated for such pages.
pages_compacted	the number of pages freed during compaction
huge_pages	the number of incompressible pages
huge_pages_since	the number of incompressible pages since zram set up

File /sys/block/zram<id>/bd_stat

The bd_stat file represents a device's backing device statistics. It consists of a single line of text and contains the following stats separated by whitespace:

bd_count	size of data written in backing device. Unit: 4K bytes
bd_reads	the number of reads from backing device Unit: 4K bytes
bd_writes	the number of writes to backing device Unit: 4K bytes

28.5.12 9) Deactivate

```
swapoff /dev/zram0
umount /dev/zram1
```

28.5.13 10) Reset

Write any positive value to 'reset' sysfs node:

```
echo 1 > /sys/block/zram0/reset
echo 1 > /sys/block/zram1/reset
```

This frees all the memory allocated for the given device and resets the disksize to zero. You must set the disksize again before reusing the device.

28.5.14 Optional Feature

writeback

With CONFIG_ZRAM_WRITEBACK, zram can write idle/incompressible page to backing storage rather than keeping it in memory. To use the feature, admin should set up backing device via:

```
echo /dev/sda5 > /sys/block/zramX/backing_dev
```

before disksize setting. It supports only partitions at this moment. If admin wants to use incompressible page writeback, they could do it via:

```
echo huge > /sys/block/zramX/writeback
```

To use idle page writeback, first, user need to declare zram pages as idle:

```
echo all > /sys/block/zramX/idle
```

From now on, any pages on zram are idle pages. The idle mark will be removed until someone requests access of the block. IOW, unless there is access request, those pages are still idle pages. Additionally, when CONFIG_ZRAM_TRACK_ENTRY_ACTIME is enabled pages can be marked as idle based on how long (in seconds) it's been since they were last accessed:

```
echo 86400 > /sys/block/zramX/idle
```

In this example all pages which haven't been accessed in more than 86400 seconds (one day) will be marked idle.

Admin can request writeback of those idle pages at right timing via:

```
echo idle > /sys/block/zramX/writeback
```

With the command, zram will writeback idle pages from memory to the storage.

Additionally, if a user choose to writeback only huge and idle pages this can be accomplished with:

```
echo huge_idle > /sys/block/zramX/writeback
```

If a user chooses to writeback only incompressible pages (pages that none of algorithms can compress) this can be accomplished with:

```
echo incompressible > /sys/block/zramX/writeback
```

If an admin wants to write a specific page in zram device to the backing device, they could write a page index into the interface:

```
echo "page_index=1251" > /sys/block/zramX/writeback
```

If there are lots of write IO with flash device, potentially, it has flash wearout problem so that admin needs to design write limitation to guarantee storage health for entire product life.

To overcome the concern, zram supports ”writeback_limit” feature. The ”writeback_limit_enable”'s default value is 0 so that it doesn't limit any writeback. IOW, if admin wants to apply writeback budget, they should enable writeback_limit_enable via:

```
$ echo 1 > /sys/block/zramX/writeback_limit_enable
```

Once writeback_limit_enable is set, zram doesn't allow any writeback until admin sets the budget via /sys/block/zramX/writeback_limit.

(If admin doesn't enable writeback_limit_enable, writeback_limit's value assigned via /sys/block/zramX/writeback_limit is meaningless.)

If admin wants to limit writeback as per-day 400M, they could do it like below:

```
$ MB_SHIFT=20
$ 4K_SHIFT=12
$ echo $((400<<MB_SHIFT>>4K_SHIFT)) > \
        /sys/block/zram0/writeback_limit.
$ echo 1 > /sys/block/zram0/writeback_limit_enable
```

If admins want to allow further write again once the budget is exhausted, they could do it like below:

```
$ echo $((400<<MB_SHIFT>>4K_SHIFT)) > \
        /sys/block/zram0/writeback_limit
```

If an admin wants to see the remaining writeback budget since last set:

```
$ cat /sys/block/zramX/writeback_limit
```

If an admin wants to disable writeback limit, they could do:

```
$ echo 0 > /sys/block/zramX/writeback_limit_enable
```

The writeback_limit count will reset whenever you reset zram (e.g., system reboot, echo 1 > /sys/block/zramX/reset) so keeping how many of writeback happened until you reset the zram to allocate extra writeback budget in next setting is user's job.

If admin wants to measure writeback count in a certain period, they could know it via /sys/block/zram0/bd_stat's 3rd column.

recompression

With CONFIG_ZRAM_MULTI_COMP, zram can recompress pages using alternative (secondary) compression algorithms. The basic idea is that alternative compression algorithm can provide better compression ratio at a price of (potentially) slower compression/decompression speeds. Alternative compression algorithm can, for example, be more successful compressing huge pages (those that default algorithm failed to compress). Another application is idle pages recompression - pages that are cold and sit in the memory can be recompressed using more effective algorithm and, hence, reduce zsmalloc memory usage.

With CONFIG_ZRAM_MULTI_COMP, zram supports up to 4 compression algorithms: one primary and up to 3 secondary ones. Primary zram compressor is explained in "3) Select compression algorithm", secondary algorithms are configured using recomp_algorithm device attribute.

Example::

```
#show supported recompression algorithms
cat /sys/block/zramX/recomp_algorithm
#1: lzo lzo-rle lz4 lz4hc [zstd]
#2: lzo lzo-rle lz4 [lz4hc] zstd
```

Alternative compression algorithms are sorted by priority. In the example above, zstd is used as the first alternative algorithm, which has priority of 1, while lz4hc is configured as a compression algorithm with priority 2. Alternative compression algorithm's priority is provided during algorithms configuration::

```
#select zstd recompression algorithm, priority 1
echo "algo=zstd priority=1" > /sys/block/zramX/recomp_algorithm

#select deflate recompression algorithm, priority 2
echo "algo=deflate priority=2" > /sys/block/zramX/recomp_algorithm
```

Another device attribute that CONFIG_ZRAM_MULTI_COMP enables is recompress, which controls recompression.

Examples::

```
#IDLE pages recompression is activated by `idle` mode
echo "type=idle" > /sys/block/zramX/recompress

#HUGE pages recompression is activated by `huge` mode
echo "type=huge" > /sys/block/zram0/recompress

#HUGE_IDLE pages recompression is activated by `huge_idle` mode
echo "type=huge_idle" > /sys/block/zramX/recompress
```

The number of idle pages can be significant, so user-space can pass a size threshold (in bytes) to the recompress knob: zram will recompress only pages of equal or greater size::

```
#recompress all pages larger than 3000 bytes
echo "threshold=3000" > /sys/block/zramX/recompress

#recompress idle pages larger than 2000 bytes
echo "type=idle threshold=2000" > /sys/block/zramX/recompress
```

Recompression of idle pages requires memory tracking.

During re-compression for every page, that matches re-compression criteria, ZRAM iterates the list of registered alternative compression algorithms in order of their priorities. ZRAM stops either when re-compression was successful (re-compressed object is smaller in size than the original one) and matches re-compression criteria (e.g. size threshold) or when there are no secondary algorithms left to try. If none of the secondary algorithms can successfully re-compressed the page such a page is marked as incompressible, so ZRAM will not attempt to re-compress it in the future.

This re-compression behaviour, when it iterates through the list of registered compression algorithms, increases our chances of finding the algorithm that successfully compresses a particular page. Sometimes, however, it is convenient (and sometimes even necessary) to limit recompression to only one particular algorithm so that it will not try any other algorithms. This can be achieved by providing a algo=NAME parameter::

```
#use zstd algorithm only (if registered)
echo "type=huge algo=zstd" > /sys/block/zramX/recompress
```

28.5.15 memory tracking

With CONFIG_ZRAM_MEMORY_TRACKING, user can know information of the zram block. It could be useful to catch cold or incompressible pages of the process with*pagemap.

If you enable the feature, you could see block state via /sys/kernel/debug/zram/zram0/block_state". The output is as follows:

```
300    75.033841 .wh...
301    63.806904 s.....
302    63.806919 ..hi..
303    62.801919 ....r.
304   146.781902 ..hi.n
```

First column
zram's block index.

Second column
access time since the system was booted

Third column
state of the block:

s:
same page

w:
written page to backing store

h:
huge page

i:
idle page

r:
recompressed page (secondary compression algorithm)

n:
none (including secondary) of algorithms could compress it

First line of above example says 300th block is accessed at 75.033841sec and the block's state is huge so it is written back to the backing storage. It's a debugging feature so anyone shouldn't rely on it to work properly.

Nitin Gupta ngupta@vflare.org

28.6 Distributed Replicated Block Device - DRBD

28.6.1 Description

DRBD is a shared-nothing, synchronously replicated block device. It is designed to serve as a building block for high availability clusters and in this context, is a "drop-in" replacement for shared storage. Simplistically, you could see it as a network RAID 1.

Please visit https://www.drbd.org to find out more.

kernel data structure for DRBD-9

This describes the in kernel data structure for DRBD-9. Starting with Linux v3.14 we are reorganizing DRBD to use this data structure.

Basic Data Structure

A node has a number of DRBD resources. Each such resource has a number of devices (aka volumes) and connections to other nodes ("peer nodes"). Each DRBD device is represented by a block device locally.

The DRBD objects are interconnected to form a matrix as depicted below; a drbd_peer_device object sits at each intersection between a drbd_device and a drbd_connection:

```
/--------------+---------------+.....+---------------\
|   resource   |    device     |     |    device     |
+--------------+---------------+.....+---------------+
|  connection  |  peer_device  |     |  peer_device  |
+--------------+---------------+.....+---------------+
:              :               :     :               :
:              :               :     :               :
+--------------+---------------+.....+---------------+
|  connection  |  peer_device  |     |  peer_device  |
\--------------+---------------+.....+---------------/
```

In this table, horizontally, devices can be accessed from resources by their volume number. Likewise, peer_devices can be accessed from connections by their volume number. Objects

in the vertical direction are connected by double linked lists. There are back pointers from peer_devices to their connections a devices, and from connections and devices to their resource.

All resources are in the drbd_resources double-linked list. In addition, all devices can be accessed by their minor device number via the drbd_devices idr.

The drbd_resource, drbd_connection, and drbd_device objects are reference counted. The peer_device objects only serve to establish the links between devices and connections; their lifetime is determined by the lifetime of the device and connection which they reference.

TWENTYNINE

BOOT CONFIGURATION

Author
Masami Hiramatsu <mhiramat@kernel.org>

29.1 Overview

The boot configuration expands the current kernel command line to support additional key-value data when booting the kernel in an efficient way. This allows administrators to pass a structured-Key config file.

29.2 Config File Syntax

The boot config syntax is a simple structured key-value. Each key consists of dot-connected-words, and key and value are connected by =. The value has to be terminated by semi-colon (`;`) or newline (`\n`). For array value, array entries are separated by comma (`,`).

```
KEY[.WORD[...]] = VALUE[, VALUE2[...]][;]
```

Unlike the kernel command line syntax, spaces are OK around the comma and =.

Each key word must contain only alphabets, numbers, dash (`-`) or underscore (`_`). And each value only contains printable characters or spaces except for delimiters such as semi-colon (`;`), new-line (`\n`), comma (`,`), hash (`#`) and closing brace (`}`).

If you want to use those delimiters in a value, you can use either double- quotes (`"VALUE"`) or single-quotes (`'VALUE'`) to quote it. Note that you can not escape these quotes.

There can be a key which doesn't have value or has an empty value. Those keys are used for checking if the key exists or not (like a boolean).

29.2.1 Key-Value Syntax

The boot config file syntax allows user to merge partially same word keys by brace. For example:

```
foo.bar.baz = value1
foo.bar.qux.quux = value2
```

These can be written also in:

```
foo.bar {
   baz = value1
   qux.quux = value2
}
```

Or more shorter, written as following:

```
foo.bar { baz = value1; qux.quux = value2 }
```

In both styles, same key words are automatically merged when parsing it at boot time. So you can append similar trees or key-values.

29.2.2 Same-key Values

It is prohibited that two or more values or arrays share a same-key. For example,:

```
foo = bar, baz
foo = qux  # !ERROR! we can not re-define same key
```

If you want to update the value, you must use the override operator `:=` explicitly. For example:

```
foo = bar, baz
foo := qux
```

then, the `qux` is assigned to `foo` key. This is useful for overriding the default value by adding (partial) custom bootconfigs without parsing the default bootconfig.

If you want to append the value to existing key as an array member, you can use `+=` operator. For example:

```
foo = bar, baz
foo += qux
```

In this case, the key `foo` has `bar`, `baz` and `qux`.

Moreover, sub-keys and a value can coexist under a parent key. For example, following config is allowed.:

```
foo = value1
foo.bar = value2
foo := value3 # This will update foo's value.
```

Note, since there is no syntax to put a raw value directly under a structured key, you have to define it outside of the brace. For example:

```
foo {
    bar = value1
    bar {
        baz = value2
        qux = value3
    }
}
```

Also, the order of the value node under a key is fixed. If there are a value and subkeys, the value is always the first child node of the key. Thus if user specifies subkeys first, e.g.:

```
foo.bar = value1
foo = value2
```

In the program (and /proc/bootconfig), it will be shown as below:

```
foo = value2
foo.bar = value1
```

29.2.3 Comments

The config syntax accepts shell-script style comments. The comments starting with hash (”#”) until newline (”n”) will be ignored.

```
# comment line
foo = value # value is set to foo.
bar = 1, # 1st element
      2, # 2nd element
      3  # 3rd element
```

This is parsed as below:

```
foo = value
bar = 1, 2, 3
```

Note that you can not put a comment between value and delimiter(`,` or `;`). This means following config has a syntax error

```
key = 1 # comment
      ,2
```

29.3 /proc/bootconfig

/proc/bootconfig is a user-space interface of the boot config. Unlike /proc/cmdline, this file shows the key-value style list. Each key-value pair is shown in each line with following style:

```
KEY[.WORDS...] = "[VALUE]"[,"VALUE2"...]
```

29.4 Boot Kernel With a Boot Config

There are two options to boot the kernel with bootconfig: attaching the bootconfig to the initrd image or embedding it in the kernel itself.

29.4.1 Attaching a Boot Config to Initrd

Since the boot configuration file is loaded with initrd by default, it will be added to the end of the initrd (initramfs) image file with padding, size, checksum and 12-byte magic word as below.

[initrd][bootconfig][padding][size(le32)][checksum(le32)][#BOOTCONFIGn]

The size and checksum fields are unsigned 32bit little endian value.

When the boot configuration is added to the initrd image, the total file size is aligned to 4 bytes. To fill the gap, null characters (`\0`) will be added. Thus the `size` is the length of the bootconfig file + padding bytes.

The Linux kernel decodes the last part of the initrd image in memory to get the boot configuration data. Because of this "piggyback" method, there is no need to change or update the boot loader and the kernel image itself as long as the boot loader passes the correct initrd file size. If by any chance, the boot loader passes a longer size, the kernel fails to find the bootconfig data.

To do this operation, Linux kernel provides `bootconfig` command under tools/bootconfig, which allows admin to apply or delete the config file to/from initrd image. You can build it by the following command:

```
# make -C tools/bootconfig
```

To add your boot config file to initrd image, run bootconfig as below (Old data is removed automatically if exists):

```
# tools/bootconfig/bootconfig -a your-config /boot/initrd.img-X.Y.Z
```

To remove the config from the image, you can use -d option as below:

```
# tools/bootconfig/bootconfig -d /boot/initrd.img-X.Y.Z
```

Then add "bootconfig" on the normal kernel command line to tell the kernel to look for the bootconfig at the end of the initrd file. Alternatively, build your kernel with the `CONFIG_BOOT_CONFIG_FORCE` Kconfig option selected.

29.4.2 Embedding a Boot Config into Kernel

If you can not use initrd, you can also embed the bootconfig file in the kernel by Kconfig options. In this case, you need to recompile the kernel with the following configs:

```
CONFIG_BOOT_CONFIG_EMBED=y
CONFIG_BOOT_CONFIG_EMBED_FILE="/PATH/TO/BOOTCONFIG/FILE"
```

`CONFIG_BOOT_CONFIG_EMBED_FILE` requires an absolute path or a relative path to the bootconfig file from source tree or object tree. The kernel will embed it as the default bootconfig.

Just as when attaching the bootconfig to the initrd, you need `bootconfig` option on the kernel command line to enable the embedded bootconfig, or, alternatively, build your kernel with the `CONFIG_BOOT_CONFIG_FORCE` Kconfig option selected.

Note that even if you set this option, you can override the embedded bootconfig by another bootconfig which attached to the initrd.

29.5 Kernel parameters via Boot Config

In addition to the kernel command line, the boot config can be used for passing the kernel parameters. All the key-value pairs under `kernel` key will be passed to kernel cmdline directly. Moreover, the key-value pairs under `init` will be passed to init process via the cmdline. The parameters are concatenated with user-given kernel cmdline string as the following order, so that the command line parameter can override bootconfig parameters (this depends on how the subsystem handles parameters but in general, earlier parameter will be overwritten by later one.):

```
[bootconfig params][cmdline params] -- [bootconfig init params][cmdline init␣
↪params]
```

Here is an example of the bootconfig file for kernel/init parameters.:

```
kernel {
  root = 01234567-89ab-cdef-0123-456789abcd
}
init {
 splash
}
```

This will be copied into the kernel cmdline string as the following:

```
root="01234567-89ab-cdef-0123-456789abcd" -- splash
```

If user gives some other command line like,:

```
ro bootconfig -- quiet
```

The final kernel cmdline will be the following:

```
root="01234567-89ab-cdef-0123-456789abcd" ro bootconfig -- splash quiet
```

29.6 Config File Limitation

Currently the maximum config size size is 32KB and the total key-words (not key-value entries) must be under 1024 nodes. Note: this is not the number of entries but nodes, an entry must consume more than 2 nodes (a key-word and a value). So theoretically, it will be up to 512 key-value pairs. If keys contains 3 words in average, it can contain 256 key-value pairs. In most cases, the number of config items will be under 100 entries and smaller than 8KB, so it would be enough. If the node number exceeds 1024, parser returns an error even if the file size is smaller than 32KB. (Note that this maximum size is not including the padding null characters.) Anyway, since bootconfig command verifies it when appending a boot config to initrd image, user can notice it before boot.

29.7 Bootconfig APIs

User can query or loop on key-value pairs, also it is possible to find a root (prefix) key node and find key-values under that node.

If you have a key string, you can query the value directly with the key using xbc_find_value(). If you want to know what keys exist in the boot config, you can use xbc_for_each_key_value() to iterate key-value pairs. Note that you need to use xbc_array_for_each_value() for accessing each array's value, e.g.:

```
vnode = NULL;
xbc_find_value("key.word", &vnode);
if (vnode && xbc_node_is_array(vnode))
   xbc_array_for_each_value(vnode, value) {
     printk("%s ", value);
   }
```

If you want to focus on keys which have a prefix string, you can use xbc_find_node() to find a node by the prefix string, and iterate keys under the prefix node with xbc_node_for_each_key_value().

But the most typical usage is to get the named value under prefix or get the named array under prefix as below:

```
root = xbc_find_node("key.prefix");
value = xbc_node_find_value(root, "option", &vnode);
...
xbc_node_for_each_array_value(root, "array-option", value, anode) {
   ...
}
```

This accesses a value of ”key.prefix.option” and an array of ”key.prefix.array-option”.

Locking is not needed, since after initialization, the config becomes read-only. All data and keys must be copied if you need to modify it.

29.8 Functions and structures

uint32_t **xbc_calc_checksum**(void *data, uint32_t size)

Calculate checksum of bootconfig

Parameters

void *data
Bootconfig data.

uint32_t size
The size of the bootconfig data.

Description

Calculate the checksum value of the bootconfig data. The checksum will be used with the BOOTCONFIG_MAGIC and the size for embedding the bootconfig in the initrd image.

bool **xbc_node_is_value**(struct xbc_node *node)

Test the node is a value node

Parameters

struct xbc_node *node
An XBC node.

Description

Test the **node** is a value node and return true if a value node, false if not.

bool **xbc_node_is_key**(struct xbc_node *node)

Test the node is a key node

Parameters

struct xbc_node *node
An XBC node.

Description

Test the **node** is a key node and return true if a key node, false if not.

bool **xbc_node_is_array**(struct xbc_node *node)

Test the node is an arraied value node

Parameters

struct xbc_node *node
An XBC node.

Description

Test the **node** is an arraied value node.

bool **xbc_node_is_leaf**(struct xbc_node *node)

Test the node is a leaf key node

Parameters

struct xbc_node *node
An XBC node.

Description

Test the **node** is a leaf key node which is a key node and has a value node or no child. Returns true if it is a leaf node, or false if not. Note that the leaf node can have subkey nodes in addition to the value node.

const char ***xbc_find_value**(const char *key, struct xbc_node **vnode)

Find a value which matches the key

Parameters

const char *key
Search key

struct xbc_node **vnode
A container pointer of XBC value node.

Description

Search a value whose key matches **key** from whole of XBC tree and return the value if found. Found value node is stored in ***vnode**. Note that this can return 0-length string and store NULL in ***vnode** for key-only (non-value) entry.

struct xbc_node ***xbc_find_node**(const char *key)

Find a node which matches the key

Parameters

const char *key
Search key

Description

Search a (key) node whose key matches **key** from whole of XBC tree and return the node if found. If not found, returns NULL.

struct xbc_node ***xbc_node_get_subkey**(struct xbc_node *node)

Return the first subkey node if exists

Parameters

struct xbc_node *node
Parent node

Description

Return the first subkey node of the **node**. If the **node** has no child or only value node, this will return NULL.

xbc_array_for_each_value

xbc_array_for_each_value (anode, value)

Iterate value nodes on an array

Parameters

anode
An XBC arraied value node

value
A value

Description

Iterate array value nodes and values starts from **anode**. This is expected to be used with xbc_find_value() and *xbc_node_find_value()*, so that user can process each array entry node.

xbc_node_for_each_child

`xbc_node_for_each_child (parent, child)`

Iterate child nodes

Parameters

parent
An XBC node.

child
Iterated XBC node.

Description

Iterate child nodes of **parent**. Each child nodes are stored to **child**. The **child** can be mixture of a value node and subkey nodes.

xbc_node_for_each_subkey

`xbc_node_for_each_subkey (parent, child)`

Iterate child subkey nodes

Parameters

parent
An XBC node.

child
Iterated XBC node.

Description

Iterate subkey nodes of **parent**. Each child nodes are stored to **child**. The **child** is only the subkey node.

xbc_node_for_each_array_value

`xbc_node_for_each_array_value (node, key, anode, value)`

Iterate array entries of geven key

Parameters

node
An XBC node.

key
A key string searched under **node**

anode
Iterated XBC node of array entry.

value
Iterated value of array entry.

Description

Iterate array entries of given **key** under **node**. Each array entry node is stored to **anode** and **value**. If the **node** doesn't have **key** node, it does nothing. Note that even if the found key node has only one value (not array) this executes block once. However, if the found key node has no value (key-only node), this does nothing. So don't use this for testing the key-value pair existence.

xbc_node_for_each_key_value

`xbc_node_for_each_key_value (node, knode, value)`

Iterate key-value pairs under a node

Parameters

node
An XBC node.

knode
Iterated key node

value
Iterated value string

Description

Iterate key-value pairs under **node**. Each key node and value string are stored in **knode** and **value** respectively.

xbc_for_each_key_value

`xbc_for_each_key_value (knode, value)`

Iterate key-value pairs

Parameters

knode
Iterated key node

value
Iterated value string

Description

Iterate key-value pairs in whole XBC tree. Each key node and value string are stored in **knode** and **value** respectively.

int **xbc_node_compose_key**(struct xbc_node *node, char *buf, size_t size)
Compose full key string of the XBC node

Parameters

struct xbc_node *node
An XBC node.

char *buf
A buffer to store the key.

size_t size
The size of the **buf**.

Description

Compose the full-length key of the **node** into **buf**. Returns the total length of the key stored in **buf**. Or returns -EINVAL if **node** is NULL, and -ERANGE if the key depth is deeper than max depth.

int **xbc_get_info**(int *node_size, size_t *data_size)

Get the information of loaded boot config

Parameters

int *node_size
A pointer to store the number of nodes.

size_t *data_size
A pointer to store the size of bootconfig data.

Description

Get the number of used nodes in **node_size** if it is not NULL, and the size of bootconfig data in **data_size** if it is not NULL. Return 0 if the boot config is initialized, or return -ENODEV.

struct xbc_node ***xbc_root_node**(void)

Get the root node of extended boot config

Parameters

void
no arguments

Description

Return the address of root node of extended boot config. If the extended boot config is not initiized, return NULL.

int **xbc_node_index**(struct xbc_node *node)

Get the index of XBC node

Parameters

struct xbc_node *node
A target node of getting index.

Description

Return the index number of **node** in XBC node list.

struct xbc_node ***xbc_node_get_parent**(struct xbc_node *node)

Get the parent XBC node

Parameters

struct xbc_node *node
An XBC node.

Description

Return the parent node of **node**. If the node is top node of the tree, return NULL.

struct xbc_node ***xbc_node_get_child**(struct xbc_node *node)

Get the child XBC node

Parameters

struct xbc_node *node
An XBC node.

Description

Return the first child node of **node**. If the node has no child, return NULL.

struct xbc_node ***xbc_node_get_next**(struct xbc_node *node)
Get the next sibling XBC node

Parameters

struct xbc_node *node
An XBC node.

Description

Return the NEXT sibling node of **node**. If the node has no next sibling, return NULL. Note that even if this returns NULL, it doesn't mean **node** has no siblings. (You also has to check whether the parent's child node is **node** or not.)

const char ***xbc_node_get_data**(struct xbc_node *node)
Get the data of XBC node

Parameters

struct xbc_node *node
An XBC node.

Description

Return the data (which is always a null terminated string) of **node**. If the node has invalid data, warn and return NULL.

struct xbc_node ***xbc_node_find_subkey**(struct xbc_node *parent, const char *key)
Find a subkey node which matches given key

Parameters

struct xbc_node *parent
An XBC node.

const char *key
A key string.

Description

Search a key node under **parent** which matches **key**. The **key** can contain several words jointed with '.'. If **parent** is NULL, this searches the node from whole tree. Return NULL if no node is matched.

const char ***xbc_node_find_value**(struct xbc_node *parent, const char *key, struct xbc_node **vnode)
Find a value node which matches given key

Parameters

struct xbc_node *parent
An XBC node.

const char *key
A key string.

struct xbc_node **vnode
A container pointer of found XBC node.

Description

Search a value node under **parent** whose (parent) key node matches **key**, store it in ***vnode**, and returns the value string. The **key** can contain several words jointed with '.'. If **parent** is NULL, this searches the node from whole tree. Return the value string if a matched key found, return NULL if no node is matched. Note that this returns 0-length string and stores NULL in ***vnode** if the key has no value. And also it will return the value of the first entry if the value is an array.

int **xbc_node_compose_key_after**(struct xbc_node *root, struct xbc_node *node, char *buf, size_t size)

Compose partial key string of the XBC node

Parameters

struct xbc_node *root
Root XBC node

struct xbc_node *node
Target XBC node.

char *buf
A buffer to store the key.

size_t size
The size of the **buf**.

Description

Compose the partial key of the **node** into **buf**, which is starting right after **root** (**root** is not included.) If **root** is NULL, this returns full key words of **node**. Returns the total length of the key stored in **buf**. Returns -EINVAL if **node** is NULL or **root** is not the ancestor of **node** or **root** is **node**, or returns -ERANGE if the key depth is deeper than max depth. This is expected to be used with xbc_find_node() to list up all (child) keys under given key.

struct xbc_node ***xbc_node_find_next_leaf**(struct xbc_node *root, struct xbc_node *node)

Find the next leaf node under given node

Parameters

struct xbc_node *root
An XBC root node

struct xbc_node *node
An XBC node which starts from.

Description

Search the next leaf node (which means the terminal key node) of **node** under **root** node (including **root** node itself). Return the next node or NULL if next leaf node is not found.

const char ***xbc_node_find_next_key_value**(struct xbc_node *root, struct xbc_node **leaf)

Find the next key-value pair nodes

Parameters

struct xbc_node *root
An XBC root node

struct xbc_node **leaf
A container pointer of XBC node which starts from.

Description

Search the next leaf node (which means the terminal key node) of ***leaf** under **root** node. Returns the value and update ***leaf** if next leaf node is found, or NULL if no next leaf node is found. Note that this returns 0-length string if the key has no value, or the value of the first entry if the value is an array.

void **xbc_exit**(void)
Clean up all parsed bootconfig

Parameters

void
no arguments

Description

This clears all data structures of parsed bootconfig on memory. If you need to reuse *xbc_init()* with new boot config, you can use this.

int **xbc_init**(const char *data, size_t size, const char **emsg, int *epos)
Parse given XBC file and build XBC internal tree

Parameters

const char *data
The boot config text original data

size_t size
The size of **data**

const char **emsg
A pointer of const char * to store the error message

int *epos
A pointer of int to store the error position

Description

This parses the boot config text in **data**. **size** must be smaller than XBC_DATA_MAX. Return the number of stored nodes (>0) if succeeded, or -errno if there is any error. In error cases, **emsg** will be updated with an error message and **epos** will be updated with the error position which is the byte offset of **buf**. If the error is not a parser error, **epos** will be -1.

CHAPTER

THIRTY

LINUX BRAILLE CONSOLE

To get early boot messages on a braille device (before userspace screen readers can start), you first need to compile the support for the usual serial console (see *Documentation/admin-guide/serial-console.rst*), and for braille device (in *Device Drivers → Accessibility support → Console on braille device*).

Then you need to specify a `console=brl`, option on the kernel command line, the format is:

```
console=brl,serial_options...
```

where `serial_options...` are the same as described in *Documentation/admin-guide/serial-console.rst*.

So for instance you can use `console=brl,ttyS0` if the braille device is connected to the first serial port, and `console=brl,ttyS0,115200` to override the baud rate to 115200, etc.

By default, the braille device will just show the last kernel message (console mode). To review previous messages, press the Insert key to switch to the VT review mode. In review mode, the arrow keys permit to browse in the VT content, `PAGE-UP/PAGE-DOWN` keys go at the top/bottom of the screen, and the `HOME` key goes back to the cursor, hence providing very basic screen reviewing facility.

Sound feedback can be obtained by adding the `braille_console.sound=1` kernel parameter.

For simplicity, only one braille console can be enabled, other uses of `console=brl,...` will be discarded. Also note that it does not interfere with the console selection mechanism described in *Documentation/admin-guide/serial-console.rst*.

For now, only the VisioBraille device is supported.

Samuel Thibault <samuel.thibault@ens-lyon.org>

CHAPTER

THIRTYONE

BTMRVL DRIVER

All commands are used via debugfs interface.

31.1 Set/get driver configurations

Path: /debug/btmrvl/config/

gpiogap=[n], hscfgcmd

These commands are used to configure the host sleep parameters:: bit 8:0 -- Gap bit 16:8 -- GPIO

where GPIO is the pin number of GPIO used to wake up the host. It could be any valid GPIO pin# (e.g. 0-7) or 0xff (SDIO interface wakeup will be used instead).

where Gap is the gap in milli seconds between wakeup signal and wakeup event, or 0xff for special host sleep setting.

Usage:

```
# Use SDIO interface to wake up the host and set GAP to 0x80:
echo 0xff80 > /debug/btmrvl/config/gpiogap
echo 1 > /debug/btmrvl/config/hscfgcmd

# Use GPIO pin #3 to wake up the host and set GAP to 0xff:
echo 0x03ff >  /debug/btmrvl/config/gpiogap
echo 1 > /debug/btmrvl/config/hscfgcmd
```

psmode=[n], pscmd

These commands are used to enable/disable auto sleep mode

where the option is:

```
1       -- Enable auto sleep mode
0       -- Disable auto sleep mode
```

Usage:

```
# Enable auto sleep mode
echo 1 > /debug/btmrvl/config/psmode
echo 1 > /debug/btmrvl/config/pscmd

# Disable auto sleep mode
```

```
echo 0 > /debug/btmrvl/config/psmode
echo 1 > /debug/btmrvl/config/pscmd
```

hsmode=[n], hscmd
These commands are used to enable host sleep or wake up firmware

where the option is:

```
1       -- Enable host sleep
0       -- Wake up firmware
```

Usage:

```
# Enable host sleep
echo 1 > /debug/btmrvl/config/hsmode
echo 1 > /debug/btmrvl/config/hscmd

# Wake up firmware
echo 0 > /debug/btmrvl/config/hsmode
echo 1 > /debug/btmrvl/config/hscmd
```

31.2 Get driver status

Path: /debug/btmrvl/status/

Usage:

```
cat /debug/btmrvl/status/<args>
```

where the args are:

curpsmode
This command displays current auto sleep status.

psstate
This command display the power save state.

hsstate
This command display the host sleep state.

txdnldrdy
This command displays the value of Tx download ready flag.

31.3 Issuing a raw hci command

Use hcitool to issue raw hci command, refer to hcitool manual

Usage:

```
Hcitool cmd <ogf> <ocf> [Parameters]
```

Interface Control Command:

```
hcitool cmd 0x3f 0x5b 0xf5 0x01 0x00    --Enable All interface
hcitool cmd 0x3f 0x5b 0xf5 0x01 0x01    --Enable Wlan interface

32.1.1 1. Control Groups

1.1 What are cgroups ?

Control Groups provide a mechanism for aggregating/partitioning sets of tasks, and all their future children, into hierarchical groups with specialized behaviour.

Definitions:

A *cgroup* associates a set of tasks with a set of parameters for one or more subsystems.

A *subsystem* is a module that makes use of the task grouping facilities provided by cgroups to treat groups of tasks in particular ways. A subsystem is typically a "resource controller" that schedules a resource or applies per-cgroup limits, but it may be anything that wants to act on a group of processes, e.g. a virtualization subsystem.

A *hierarchy* is a set of cgroups arranged in a tree, such that every task in the system is in exactly one of the cgroups in the hierarchy, and a set of subsystems; each subsystem has system-specific state attached to each cgroup in the hierarchy. Each hierarchy has an instance of the cgroup virtual filesystem associated with it.

At any one time there may be multiple active hierarchies of task cgroups. Each hierarchy is a partition of all tasks in the system.

User-level code may create and destroy cgroups by name in an instance of the cgroup virtual file system, specify and query to which cgroup a task is assigned, and list the task PIDs assigned to a cgroup. Those creations and assignments only affect the hierarchy associated with that instance of the cgroup file system.

On their own, the only use for cgroups is for simple job tracking. The intention is that other subsystems hook into the generic cgroup support to provide new attributes for cgroups, such as accounting/limiting the resources which processes in a cgroup can access. For example, cpusets (see *CPUSETS*) allow you to associate a set of CPUs and a set of memory nodes with the tasks in each cgroup.

1.2 Why are cgroups needed ?

There are multiple efforts to provide process aggregations in the Linux kernel, mainly for resource-tracking purposes. Such efforts include cpusets, CKRM/ResGroups, UserBeanCounters, and virtual server namespaces. These all require the basic notion of a grouping/partitioning of processes, with newly forked processes ending up in the same group (cgroup) as their parent process.

The kernel cgroup patch provides the minimum essential kernel mechanisms required to efficiently implement such groups. It has minimal impact on the system fast paths, and provides hooks for specific subsystems such as cpusets to provide additional behaviour as desired.

Multiple hierarchy support is provided to allow for situations where the division of tasks into cgroups is distinctly different for different subsystems - having parallel hierarchies allows each hierarchy to be a natural division of tasks, without having to handle complex combinations of tasks that would be present if several unrelated subsystems needed to be forced into the same tree of cgroups.

At one extreme, each resource controller or subsystem could be in a separate hierarchy; at the other extreme, all subsystems would be attached to the same hierarchy.

As an example of a scenario (originally proposed by vatsa@in.ibm.com) that can benefit from multiple hierarchies, consider a large university server with various users - students, professors, system tasks etc. The resource planning for this server could be along the following lines:

```
CPU :          "Top cpuset"
                /       \
        CPUSet1         CPUSet2
           |               |
        (Professors)    (Students)

        In addition (system tasks) are attached to topcpuset (so
        that they can run anywhere) with a limit of 20%

Memory : Professors (50%), Students (30%), system (20%)

Disk : Professors (50%), Students (30%), system (20%)

Network : WWW browsing (20%), Network File System (60%), others (20%)
                         / \
        Professors (15%)  students (5%)
```

Browsers like Firefox/Lynx go into the WWW network class, while (k)nfsd goes into the NFS network class.

At the same time Firefox/Lynx will share an appropriate CPU/Memory class depending on who launched it (prof/student).

With the ability to classify tasks differently for different resources (by putting those resource subsystems in different hierarchies), the admin can easily set up a script which receives exec notifications and depending on who is launching the browser he can:

```
# echo browser_pid > /sys/fs/cgroup/<restype>/<userclass>/tasks
```

With only a single hierarchy, he now would potentially have to create a separate cgroup for every browser launched and associate it with appropriate network and other resource class. This may lead to proliferation of such cgroups.

Also let's say that the administrator would like to give enhanced network access temporarily to a student's browser (since it is night and the user wants to do online gaming :)) OR give one of the student's simulation apps enhanced CPU power.

With ability to write PIDs directly to resource classes, it's just a matter of:

```
# echo pid > /sys/fs/cgroup/network/<new_class>/tasks
(after some time)
# echo pid > /sys/fs/cgroup/network/<orig_class>/tasks
```

Without this ability, the administrator would have to split the cgroup into multiple separate ones and then associate the new cgroups with the new resource classes.

1.3 How are cgroups implemented ?

Control Groups extends the kernel as follows:

- Each task in the system has a reference-counted pointer to a css_set.
- A css_set contains a set of reference-counted pointers to cgroup_subsys_state objects, one for each cgroup subsystem registered in the system. There is no direct link from a task to the cgroup of which it's a member in each hierarchy, but this can be determined by following pointers through the cgroup_subsys_state objects. This is because accessing the subsystem state is something that's expected to happen frequently and in performance-critical code, whereas operations that require a task's actual cgroup assignments (in particular, moving between cgroups) are less common. A linked list runs through the cg_list field of each task_struct using the css_set, anchored at css_set->tasks.
- A cgroup hierarchy filesystem can be mounted for browsing and manipulation from user space.
- You can list all the tasks (by PID) attached to any cgroup.

The implementation of cgroups requires a few, simple hooks into the rest of the kernel, none in performance-critical paths:

- in init/main.c, to initialize the root cgroups and initial css_set at system boot.
- in fork and exit, to attach and detach a task from its css_set.

In addition, a new file system of type ”cgroup” may be mounted, to enable browsing and modifying the cgroups presently known to the kernel. When mounting a cgroup hierarchy, you may specify a comma-separated list of subsystems to mount as the filesystem mount options. By default, mounting the cgroup filesystem attempts to mount a hierarchy containing all registered subsystems.

If an active hierarchy with exactly the same set of subsystems already exists, it will be reused for the new mount. If no existing hierarchy matches, and any of the requested subsystems are in use in an existing hierarchy, the mount will fail with -EBUSY. Otherwise, a new hierarchy is activated, associated with the requested subsystems.

It's not currently possible to bind a new subsystem to an active cgroup hierarchy, or to unbind a subsystem from an active cgroup hierarchy. This may be possible in future, but is fraught with nasty error-recovery issues.

When a cgroup filesystem is unmounted, if there are any child cgroups created below the top-level cgroup, that hierarchy will remain active even though unmounted; if there are no child cgroups then the hierarchy will be deactivated.

No new system calls are added for cgroups - all support for querying and modifying cgroups is via this cgroup file system.

Each task under /proc has an added file named 'cgroup' displaying, for each active hierarchy, the subsystem names and the cgroup name as the path relative to the root of the cgroup file system.

Each cgroup is represented by a directory in the cgroup file system containing the following files describing that cgroup:

- tasks: list of tasks (by PID) attached to that cgroup. This list is not guaranteed to be sorted. Writing a thread ID into this file moves the thread into this cgroup.
- cgroup.procs: list of thread group IDs in the cgroup. This list is not guaranteed to be sorted or free of duplicate TGIDs, and userspace should sort/uniquify the list if this property is required. Writing a thread group ID into this file moves all threads in that group into this cgroup.
- notify_on_release flag: run the release agent on exit?
- release_agent: the path to use for release notifications (this file exists in the top cgroup only)

Other subsystems such as cpusets may add additional files in each cgroup dir.

New cgroups are created using the mkdir system call or shell command. The properties of a cgroup, such as its flags, are modified by writing to the appropriate file in that cgroups directory, as listed above.

The named hierarchical structure of nested cgroups allows partitioning a large system into nested, dynamically changeable, ”soft-partitions”.

The attachment of each task, automatically inherited at fork by any children of that task, to a cgroup allows organizing the work load on a system into related sets of tasks. A task may be re-attached to any other cgroup, if allowed by the permissions on the necessary cgroup file system directories.

When a task is moved from one cgroup to another, it gets a new css_set pointer - if there's an already existing css_set with the desired collection of cgroups then that group is reused, otherwise a new css_set is allocated. The appropriate existing css_set is located by looking into a hash table.

To allow access from a cgroup to the css_sets (and hence tasks) that comprise it, a set of cg_cgroup_link objects form a lattice; each cg_cgroup_link is linked into a list of cg_cgroup_links for a single cgroup on its cgrp_link_list field, and a list of cg_cgroup_links for a single css_set on its cg_link_list.

Thus the set of tasks in a cgroup can be listed by iterating over each css_set that references the cgroup, and sub-iterating over each css_set's task set.

The use of a Linux virtual file system (vfs) to represent the cgroup hierarchy provides for a familiar permission and name space for cgroups, with a minimum of additional kernel code.

1.4 What does notify_on_release do ?

If the notify_on_release flag is enabled (1) in a cgroup, then whenever the last task in the cgroup leaves (exits or attaches to some other cgroup) and the last child cgroup of that cgroup is removed, then the kernel runs the command specified by the contents of the "release_agent" file in that hierarchy's root directory, supplying the pathname (relative to the mount point of the cgroup file system) of the abandoned cgroup. This enables automatic removal of abandoned cgroups. The default value of notify_on_release in the root cgroup at system boot is disabled (0). The default value of other cgroups at creation is the current value of their parents' notify_on_release settings. The default value of a cgroup hierarchy's release_agent path is empty.

1.5 What does clone_children do ?

This flag only affects the cpuset controller. If the clone_children flag is enabled (1) in a cgroup, a new cpuset cgroup will copy its configuration from the parent during initialization.

1.6 How do I use cgroups ?

To start a new job that is to be contained within a cgroup, using the "cpuset" cgroup subsystem, the steps are something like:

```
1) mount -t tmpfs cgroup_root /sys/fs/cgroup
2) mkdir /sys/fs/cgroup/cpuset
3) mount -t cgroup -ocpuset cpuset /sys/fs/cgroup/cpuset
4) Create the new cgroup by doing mkdir's and write's (or echo's) in
   the /sys/fs/cgroup/cpuset virtual file system.
5) Start a task that will be the "founding father" of the new job.
6) Attach that task to the new cgroup by writing its PID to the
   /sys/fs/cgroup/cpuset tasks file for that cgroup.
7) fork, exec or clone the job tasks from this founding father task.
```

For example, the following sequence of commands will setup a cgroup named "Charlie", containing just CPUs 2 and 3, and Memory Node 1, and then start a subshell 'sh' in that cgroup:

```
mount -t tmpfs cgroup_root /sys/fs/cgroup
mkdir /sys/fs/cgroup/cpuset
mount -t cgroup cpuset -ocpuset /sys/fs/cgroup/cpuset
cd /sys/fs/cgroup/cpuset
mkdir Charlie
cd Charlie
/bin/echo 2-3 > cpuset.cpus
/bin/echo 1 > cpuset.mems
/bin/echo $$ > tasks
sh
```

```
# The subshell 'sh' is now running in cgroup Charlie
# The next line should display '/Charlie'
cat /proc/self/cgroup
```

32.1.2 2. Usage Examples and Syntax

2.1 Basic Usage

Creating, modifying, using cgroups can be done through the cgroup virtual filesystem.

To mount a cgroup hierarchy with all available subsystems, type:

```
# mount -t cgroup xxx /sys/fs/cgroup
```

The "xxx" is not interpreted by the cgroup code, but will appear in /proc/mounts so may be any useful identifying string that you like.

Note: Some subsystems do not work without some user input first. For instance, if cpusets are enabled the user will have to populate the cpus and mems files for each new cgroup created before that group can be used.

As explained in section *1.2 Why are cgroups needed?* you should create different hierarchies of cgroups for each single resource or group of resources you want to control. Therefore, you should mount a tmpfs on /sys/fs/cgroup and create directories for each cgroup resource or resource group:

```
# mount -t tmpfs cgroup_root /sys/fs/cgroup
# mkdir /sys/fs/cgroup/rg1
```

To mount a cgroup hierarchy with just the cpuset and memory subsystems, type:

```
# mount -t cgroup -o cpuset,memory hier1 /sys/fs/cgroup/rg1
```

While remounting cgroups is currently supported, it is not recommend to use it. Remounting allows changing bound subsystems and release_agent. Rebinding is hardly useful as it only works when the hierarchy is empty and release_agent itself should be replaced with conventional fsnotify. The support for remounting will be removed in the future.

To Specify a hierarchy's release_agent:

```
# mount -t cgroup -o cpuset,release_agent="/sbin/cpuset_release_agent" \
  xxx /sys/fs/cgroup/rg1
```

Note that specifying 'release_agent' more than once will return failure.

Note that changing the set of subsystems is currently only supported when the hierarchy consists of a single (root) cgroup. Supporting the ability to arbitrarily bind/unbind subsystems from an existing cgroup hierarchy is intended to be implemented in the future.

Then under /sys/fs/cgroup/rg1 you can find a tree that corresponds to the tree of the cgroups in the system. For instance, /sys/fs/cgroup/rg1 is the cgroup that holds the whole system.

If you want to change the value of release_agent:

```
# echo "/sbin/new_release_agent" > /sys/fs/cgroup/rg1/release_agent
```

It can also be changed via remount.

If you want to create a new cgroup under /sys/fs/cgroup/rg1:

```
# cd /sys/fs/cgroup/rg1
# mkdir my_cgroup
```

Now you want to do something with this cgroup:

cd my_cgroup

In this directory you can find several files:

```
# ls
cgroup.procs notify_on_release tasks
(plus whatever files added by the attached subsystems)
```

Now attach your shell to this cgroup:

```
# /bin/echo $$ > tasks
```

You can also create cgroups inside your cgroup by using mkdir in this directory:

```
# mkdir my_sub_cs
```

To remove a cgroup, just use rmdir:

```
# rmdir my_sub_cs
```

This will fail if the cgroup is in use (has cgroups inside, or has processes attached, or is held alive by other subsystem-specific reference).

2.2 Attaching processes

```
# /bin/echo PID > tasks
```

Note that it is PID, not PIDs. You can only attach ONE task at a time. If you have several tasks to attach, you have to do it one after another:

```
# /bin/echo PID1 > tasks
# /bin/echo PID2 > tasks
        ...
# /bin/echo PIDn > tasks
```

You can attach the current shell task by echoing 0:

```
# echo 0 > tasks
```

You can use the cgroup.procs file instead of the tasks file to move all threads in a threadgroup at once. Echoing the PID of any task in a threadgroup to cgroup.procs causes all tasks in that

threadgroup to be attached to the cgroup. Writing 0 to cgroup.procs moves all tasks in the writing task's threadgroup.

Note: Since every task is always a member of exactly one cgroup in each mounted hierarchy, to remove a task from its current cgroup you must move it into a new cgroup (possibly the root cgroup) by writing to the new cgroup's tasks file.

Note: Due to some restrictions enforced by some cgroup subsystems, moving a process to another cgroup can fail.

2.3 Mounting hierarchies by name

Passing the name=<x> option when mounting a cgroups hierarchy associates the given name with the hierarchy. This can be used when mounting a pre-existing hierarchy, in order to refer to it by name rather than by its set of active subsystems. Each hierarchy is either nameless, or has a unique name.

The name should match [w.-]+

When passing a name=<x> option for a new hierarchy, you need to specify subsystems manually; the legacy behaviour of mounting all subsystems when none are explicitly specified is not supported when you give a subsystem a name.

The name of the subsystem appears as part of the hierarchy description in /proc/mounts and /proc/<pid>/cgroups.

32.1.3 3. Kernel API

3.1 Overview

Each kernel subsystem that wants to hook into the generic cgroup system needs to create a cgroup_subsys object. This contains various methods, which are callbacks from the cgroup system, along with a subsystem ID which will be assigned by the cgroup system.

Other fields in the cgroup_subsys object include:

- subsys_id: a unique array index for the subsystem, indicating which entry in cgroup->subsys[] this subsystem should be managing.
- name: should be initialized to a unique subsystem name. Should be no longer than MAX_CGROUP_TYPE_NAMELEN.
- early_init: indicate if the subsystem needs early initialization at system boot.

Each cgroup object created by the system has an array of pointers, indexed by subsystem ID; this pointer is entirely managed by the subsystem; the generic cgroup code will never touch this pointer.

3.2 Synchronization

There is a global mutex, cgroup_mutex, used by the cgroup system. This should be taken by anything that wants to modify a cgroup. It may also be taken to prevent cgroups from being modified, but more specific locks may be more appropriate in that situation.

See kernel/cgroup.c for more details.

Subsystems can take/release the cgroup_mutex via the functions cgroup_lock()/cgroup_unlock().

Accessing a task's cgroup pointer may be done in the following ways: - while holding cgroup_mutex - while holding the task's alloc_lock (via task_lock()) - inside an rcu_read_lock() section via rcu_dereference()

3.3 Subsystem API

Each subsystem should:

- add an entry in linux/cgroup_subsys.h
- define a cgroup_subsys object called <name>_cgrp_subsys

Each subsystem may export the following methods. The only mandatory methods are css_alloc/free. Any others that are null are presumed to be successful no-ops.

`struct cgroup_subsys_state *css_alloc(struct cgroup *cgrp)` (cgroup_mutex held by caller)

Called to allocate a subsystem state object for a cgroup. The subsystem should allocate its subsystem state object for the passed cgroup, returning a pointer to the new object on success or a ERR_PTR() value. On success, the subsystem pointer should point to a structure of type cgroup_subsys_state (typically embedded in a larger subsystem-specific object), which will be initialized by the cgroup system. Note that this will be called at initialization to create the root subsystem state for this subsystem; this case can be identified by the passed cgroup object having a NULL parent (since it's the root of the hierarchy) and may be an appropriate place for initialization code.

`int css_online(struct cgroup *cgrp)` (cgroup_mutex held by caller)

Called after @cgrp successfully completed all allocations and made visible to cgroup_for_each_child/descendant_*() iterators. The subsystem may choose to fail creation by returning -errno. This callback can be used to implement reliable state sharing and propagation along the hierarchy. See the comment on cgroup_for_each_descendant_pre() for details.

`void css_offline(struct cgroup *cgrp);` (cgroup_mutex held by caller)

This is the counterpart of css_online() and called iff css_online() has succeeded on @cgrp. This signifies the beginning of the end of @cgrp. @cgrp is being removed and the subsystem should start dropping all references it's holding on @cgrp. When all references are dropped, cgroup removal will proceed to the next step - css_free(). After this callback, @cgrp should be considered dead to the subsystem.

`void css_free(struct cgroup *cgrp)` (cgroup_mutex held by caller)

The cgroup system is about to free @cgrp; the subsystem should free its subsystem state object. By the time this method is called, @cgrp is completely unused; @cgrp->parent is still valid.

(Note - can also be called for a newly-created cgroup if an error occurs after this subsystem's create() method has been called for the new cgroup).

`int can_attach(struct cgroup *cgrp, struct cgroup_taskset *tset)` (cgroup_mutex held by caller)

Called prior to moving one or more tasks into a cgroup; if the subsystem returns an error, this will abort the attach operation. @tset contains the tasks to be attached and is guaranteed to have at least one task in it.

If there are multiple tasks in the taskset, then:

- it's guaranteed that all are from the same thread group
- @tset contains all tasks from the thread group whether or not they're switching cgroups
- the first task is the leader

Each @tset entry also contains the task's old cgroup and tasks which aren't switching cgroup can be skipped easily using the cgroup_taskset_for_each() iterator. Note that this isn't called on a fork. If this method returns 0 (success) then this should remain valid while the caller holds cgroup_mutex and it is ensured that either attach() or cancel_attach() will be called in future.

`void css_reset(struct cgroup_subsys_state *css)` (cgroup_mutex held by caller)

An optional operation which should restore @css's configuration to the initial state. This is currently only used on the unified hierarchy when a subsystem is disabled on a cgroup through "cgroup.subtree_control" but should remain enabled because other subsystems depend on it. cgroup core makes such a css invisible by removing the associated interface files and invokes this callback so that the hidden subsystem can return to the initial neutral state. This prevents unexpected resource control from a hidden css and ensures that the configuration is in the initial state when it is made visible again later.

`void cancel_attach(struct cgroup *cgrp, struct cgroup_taskset *tset)` (cgroup_mutex held by caller)

Called when a task attach operation has failed after can_attach() has succeeded. A subsystem whose can_attach() has some side-effects should provide this function, so that the subsystem can implement a rollback. If not, not necessary. This will be called only about subsystems whose can_attach() operation have succeeded. The parameters are identical to can_attach().

`void attach(struct cgroup *cgrp, struct cgroup_taskset *tset)` (cgroup_mutex held by caller)

Called after the task has been attached to the cgroup, to allow any post-attachment activity that requires memory allocations or blocking. The parameters are identical to can_attach().

`void fork(struct task_struct *task)`

Called when a task is forked into a cgroup.

`void exit(struct task_struct *task)`

Called during task exit.

`void free(struct task_struct *task)`

Called when the task_struct is freed.

`void bind(struct cgroup *root)` (cgroup_mutex held by caller)

Called when a cgroup subsystem is rebound to a different hierarchy and root cgroup. Currently this will only involve movement between the default hierarchy (which never has sub-cgroups) and a hierarchy that is being created/destroyed (and hence has no sub-cgroups).

32.1.4 4. Extended attribute usage

cgroup filesystem supports certain types of extended attributes in its directories and files. The current supported types are:

- Trusted (XATTR_TRUSTED)
- Security (XATTR_SECURITY)

Both require CAP_SYS_ADMIN capability to set.

Like in tmpfs, the extended attributes in cgroup filesystem are stored using kernel memory and it's advised to keep the usage at minimum. This is the reason why user defined extended attributes are not supported, since any user can do it and there's no limit in the value size.

The current known users for this feature are SELinux to limit cgroup usage in containers and systemd for assorted meta data like main PID in a cgroup (systemd creates a cgroup per service).

32.1.5 5. Questions

```
Q: what's up with this '/bin/echo' ?
A: bash's builtin 'echo' command does not check calls to write() against
   errors. If you use it in the cgroup file system, you won't be
   able to tell whether a command succeeded or failed.

Q: When I attach processes, only the first of the line gets really attached !
A: We can only return one error code per call to write(). So you should also
   put only ONE PID.
```

32.2 Block IO Controller

32.2.1 Overview

cgroup subsys ”blkio” implements the block io controller. There seems to be a need of various kinds of IO control policies (like proportional BW, max BW) both at leaf nodes as well as at intermediate nodes in a storage hierarchy. Plan is to use the same cgroup based management interface for blkio controller and based on user options switch IO policies in the background.

One IO control policy is throttling policy which can be used to specify upper IO rate limits on devices. This policy is implemented in generic block layer and can be used on leaf nodes as well as higher level logical devices like device mapper.

32.2.2 HOWTO

Throttling/Upper Limit policy

Enable Block IO controller:

```
CONFIG_BLK_CGROUP=y
```

Enable throttling in block layer:

```
CONFIG_BLK_DEV_THROTTLING=y
```

Mount blkio controller (see cgroups.txt, Why are cgroups needed?):

```
mount -t cgroup -o blkio none /sys/fs/cgroup/blkio
```

Specify a bandwidth rate on particular device for root group. The format for policy is "<major>:<minor> <bytes_per_second>":

```
echo "8:16  1048576" > /sys/fs/cgroup/blkio/blkio.throttle.read_bps_device
```

This will put a limit of 1MB/second on reads happening for root group on device having major/minor number 8:16.

Run dd to read a file and see if rate is throttled to 1MB/s or not:

```
# dd iflag=direct if=/mnt/common/zerofile of=/dev/null bs=4K count=1024
1024+0 records in
1024+0 records out
4194304 bytes (4.2 MB) copied, 4.0001 s, 1.0 MB/s
```

Limits for writes can be put using blkio.throttle.write_bps_device file.

32.2.3 Hierarchical Cgroups

Throttling implements hierarchy support; however, throttling's hierarchy support is enabled iff "sane_behavior" is enabled from cgroup side, which currently is a development option and not publicly available.

If somebody created a hierarchy like as follows:

```
   root
   /  \
test1 test2
   |
test3
```

Throttling with "sane_behavior" will handle the hierarchy correctly. For throttling, all limits apply to the whole subtree while all statistics are local to the IOs directly generated by tasks in that cgroup.

Throttling without "sane_behavior" enabled from cgroup side will practically treat all groups at same level as if it looks like the following:

```
        pivot
     /  /   \  \
root  test1 test2  test3
```

32.2.4 Various user visible config options

CONFIG_BLK_CGROUP
Block IO controller.

CONFIG_BFQ_CGROUP_DEBUG
Debug help. Right now some additional stats file show up in cgroup if this option is enabled.

CONFIG_BLK_DEV_THROTTLING
Enable block device throttling support in block layer.

32.2.5 Details of cgroup files

Proportional weight policy files

blkio.bfq.weight
Specifies per cgroup weight. This is default weight of the group on all the devices until and unless overridden by per device rule (see *blkio.bfq.weight_device* below).

Currently allowed range of weights is from 1 to 1000. For more details, see Documentation/block/bfq-iosched.rst.

blkio.bfq.weight_device
Specifies per cgroup per device weights, overriding the default group weight. For more details, see Documentation/block/bfq-iosched.rst.

Following is the format:

```
# echo dev_maj:dev_minor weight > blkio.bfq.weight_device
```

Configure weight=300 on /dev/sdb (8:16) in this cgroup:

```
# echo 8:16 300 > blkio.bfq.weight_device
# cat blkio.bfq.weight_device
dev     weight
8:16    300
```

Configure weight=500 on /dev/sda (8:0) in this cgroup:

```
# echo 8:0 500 > blkio.bfq.weight_device
# cat blkio.bfq.weight_device
dev     weight
8:0     500
8:16    300
```

Remove specific weight for /dev/sda in this cgroup:

```
# echo 8:0 0 > blkio.bfq.weight_device
# cat blkio.bfq.weight_device
dev     weight
8:16    300
```

blkio.time
Disk time allocated to cgroup per device in milliseconds. First two fields specify the major and minor number of the device and third field specifies the disk time allocated to group in milliseconds.

blkio.sectors
Number of sectors transferred to/from disk by the group. First two fields specify the major and minor number of the device and third field specifies the number of sectors transferred by the group to/from the device.

blkio.io_service_bytes
Number of bytes transferred to/from the disk by the group. These are further divided by the type of operation - read or write, sync or async. First two fields specify the major and minor number of the device, third field specifies the operation type and the fourth field specifies the number of bytes.

blkio.io_serviced
Number of IOs (bio) issued to the disk by the group. These are further divided by the type of operation - read or write, sync or async. First two fields specify the major and minor number of the device, third field specifies the operation type and the fourth field specifies the number of IOs.

blkio.io_service_time
Total amount of time between request dispatch and request completion for the IOs done by this cgroup. This is in nanoseconds to make it meaningful for flash devices too. For devices with queue depth of 1, this time represents the actual service time. When queue_depth > 1, that is no longer true as requests may be served out of order. This may cause the service time for a given IO to include the service time of multiple IOs when served out of order which may result in total io_service_time > actual time elapsed. This time is further divided by the type of operation - read or write, sync or async. First two fields specify the major and minor number of the device, third field specifies the operation type and the fourth field specifies the io_service_time in ns.

blkio.io_wait_time
Total amount of time the IOs for this cgroup spent waiting in the scheduler queues for service. This can be greater than the total time elapsed since it is cumulative io_wait_time for all IOs. It is not a measure of total time the cgroup spent waiting but rather a measure of the wait_time for its individual IOs. For devices with queue_depth > 1 this metric does not include the time spent waiting for service once the IO is dispatched to the device but till it actually gets serviced (there might be a time lag here due to re-ordering of requests by the device). This is in nanoseconds to make it meaningful for flash devices too. This time is further divided by the type of operation - read or write, sync or async. First two fields specify the major and minor number of the device, third field specifies the operation type and the fourth field specifies the io_wait_time in ns.

blkio.io_merged
Total number of bios/requests merged into requests belonging to this cgroup.

This is further divided by the type of operation - read or write, sync or async.

blkio.io_queued
Total number of requests queued up at any given instant for this cgroup. This is further divided by the type of operation - read or write, sync or async.

blkio.avg_queue_size
Debugging aid only enabled if CONFIG_BFQ_CGROUP_DEBUG=y. The average queue size for this cgroup over the entire time of this cgroup's existence. Queue size samples are taken each time one of the queues of this cgroup gets a timeslice.

blkio.group_wait_time
Debugging aid only enabled if CONFIG_BFQ_CGROUP_DEBUG=y. This is the amount of time the cgroup had to wait since it became busy (i.e., went from 0 to 1 request queued) to get a timeslice for one of its queues. This is different from the io_wait_time which is the cumulative total of the amount of time spent by each IO in that cgroup waiting in the scheduler queue. This is in nanoseconds. If this is read when the cgroup is in a waiting (for timeslice) state, the stat will only report the group_wait_time accumulated till the last time it got a timeslice and will not include the current delta.

blkio.empty_time
Debugging aid only enabled if CONFIG_BFQ_CGROUP_DEBUG=y. This is the amount of time a cgroup spends without any pending requests when not being served, i.e., it does not include any time spent idling for one of the queues of the cgroup. This is in nanoseconds. If this is read when the cgroup is in an empty state, the stat will only report the empty_time accumulated till the last time it had a pending request and will not include the current delta.

blkio.idle_time
Debugging aid only enabled if CONFIG_BFQ_CGROUP_DEBUG=y. This is the amount of time spent by the IO scheduler idling for a given cgroup in anticipation of a better request than the existing ones from other queues/cgroups. This is in nanoseconds. If this is read when the cgroup is in an idling state, the stat will only report the idle_time accumulated till the last idle period and will not include the current delta.

blkio.dequeue
Debugging aid only enabled if CONFIG_BFQ_CGROUP_DEBUG=y. This gives the statistics about how many a times a group was dequeued from service tree of the device. First two fields specify the major and minor number of the device and third field specifies the number of times a group was dequeued from a particular device.

blkio.*_recursive
Recursive version of various stats. These files show the same information as their non-recursive counterparts but include stats from all the descendant cgroups.

Throttling/Upper limit policy files

blkio.throttle.read_bps_device
Specifies upper limit on READ rate from the device. IO rate is specified in bytes per second. Rules are per device. Following is the format:

```
echo "<major>:<minor>  <rate_bytes_per_second>" > /cgrp/blkio.
↪throttle.read_bps_device
```

blkio.throttle.write_bps_device
Specifies upper limit on WRITE rate to the device. IO rate is specified in bytes per second. Rules are per device. Following is the format:

```
echo "<major>:<minor>  <rate_bytes_per_second>" > /cgrp/blkio.
↪throttle.write_bps_device
```

blkio.throttle.read_iops_device
Specifies upper limit on READ rate from the device. IO rate is specified in IO per second. Rules are per device. Following is the format:

```
echo "<major>:<minor>  <rate_io_per_second>" > /cgrp/blkio.
↪throttle.read_iops_device
```

blkio.throttle.write_iops_device
Specifies upper limit on WRITE rate to the device. IO rate is specified in io per second. Rules are per device. Following is the format:

```
echo "<major>:<minor>  <rate_io_per_second>" > /cgrp/blkio.
↪throttle.write_iops_device
```

Note: If both BW and IOPS rules are specified for a device, then IO is subjected to both the constraints.

blkio.throttle.io_serviced
Number of IOs (bio) issued to the disk by the group. These are further divided by the type of operation - read or write, sync or async. First two fields specify the major and minor number of the device, third field specifies the operation type and the fourth field specifies the number of IOs.

blkio.throttle.io_service_bytes
Number of bytes transferred to/from the disk by the group. These are further divided by the type of operation - read or write, sync or async. First two fields specify the major and minor number of the device, third field specifies the operation type and the fourth field specifies the number of bytes.

Common files among various policies

blkio.reset_stats
Writing an int to this file will result in resetting all the stats for that cgroup.

32.3 CPU Accounting Controller

The CPU accounting controller is used to group tasks using cgroups and account the CPU usage of these groups of tasks.

The CPU accounting controller supports multi-hierarchy groups. An accounting group accumulates the CPU usage of all of its child groups and the tasks directly present in its group.

Accounting groups can be created by first mounting the cgroup filesystem:

```
# mount -t cgroup -ocpuacct none /sys/fs/cgroup
```

With the above step, the initial or the parent accounting group becomes visible at /sys/fs/cgroup. At bootup, this group includes all the tasks in the system. /sys/fs/cgroup/tasks lists the tasks in this cgroup. /sys/fs/cgroup/cpuacct.usage gives the CPU time (in nanoseconds) obtained by this group which is essentially the CPU time obtained by all the tasks in the system.

New accounting groups can be created under the parent group /sys/fs/cgroup:

```
# cd /sys/fs/cgroup
# mkdir g1
# echo $$ > g1/tasks
```

The above steps create a new group g1 and move the current shell process (bash) into it. CPU time consumed by this bash and its children can be obtained from g1/cpuacct.usage and the same is accumulated in /sys/fs/cgroup/cpuacct.usage also.

cpuacct.stat file lists a few statistics which further divide the CPU time obtained by the cgroup into user and system times. Currently the following statistics are supported:

user: Time spent by tasks of the cgroup in user mode. system: Time spent by tasks of the cgroup in kernel mode.

user and system are in USER_HZ unit.

cpuacct controller uses percpu_counter interface to collect user and system times. This has two side effects:

- It is theoretically possible to see wrong values for user and system times. This is because percpu_counter_read() on 32bit systems isn't safe against concurrent writes.
- It is possible to see slightly outdated values for user and system times due to the batch processing nature of percpu_counter.

32.4 CPUSETS

32.4.1 1. Cpusets

1.1 What are cpusets ?

Cpusets provide a mechanism for assigning a set of CPUs and Memory Nodes to a set of tasks. In this document ”Memory Node” refers to an on-line node that contains memory.

Cpusets constrain the CPU and Memory placement of tasks to only the resources within a task's current cpuset. They form a nested hierarchy visible in a virtual file system. These are the essential hooks, beyond what is already present, required to manage dynamic job placement on large systems.

Cpusets use the generic cgroup subsystem described in *Control Groups*.

Requests by a task, using the sched_setaffinity(2) system call to include CPUs in its CPU affinity mask, and using the mbind(2) and set_mempolicy(2) system calls to include Memory Nodes in its memory policy, are both filtered through that task's cpuset, filtering out any CPUs or Memory Nodes not in that cpuset. The scheduler will not schedule a task on a CPU that is not allowed in its cpus_allowed vector, and the kernel page allocator will not allocate a page on a node that is not allowed in the requesting task's mems_allowed vector.

User level code may create and destroy cpusets by name in the cgroup virtual file system, manage the attributes and permissions of these cpusets and which CPUs and Memory Nodes are assigned to each cpuset, specify and query to which cpuset a task is assigned, and list the task pids assigned to a cpuset.

1.2 Why are cpusets needed ?

The management of large computer systems, with many processors (CPUs), complex memory cache hierarchies and multiple Memory Nodes having non-uniform access times (NUMA) presents additional challenges for the efficient scheduling and memory placement of processes.

Frequently more modest sized systems can be operated with adequate efficiency just by letting the operating system automatically share the available CPU and Memory resources amongst the requesting tasks.

But larger systems, which benefit more from careful processor and memory placement to reduce memory access times and contention, and which typically represent a larger investment for the customer, can benefit from explicitly placing jobs on properly sized subsets of the system.

This can be especially valuable on:

- Web Servers running multiple instances of the same web application,
- Servers running different applications (for instance, a web server and a database), or
- NUMA systems running large HPC applications with demanding performance characteristics.

These subsets, or ”soft partitions” must be able to be dynamically adjusted, as the job mix changes, without impacting other concurrently executing jobs. The location of the running jobs pages may also be moved when the memory locations are changed.

The kernel cpuset patch provides the minimum essential kernel mechanisms required to efficiently implement such subsets. It leverages existing CPU and Memory Placement facilities in the Linux kernel to avoid any additional impact on the critical scheduler or memory allocator code.

1.3 How are cpusets implemented ?

Cpusets provide a Linux kernel mechanism to constrain which CPUs and Memory Nodes are used by a process or set of processes.

The Linux kernel already has a pair of mechanisms to specify on which CPUs a task may be scheduled (sched_setaffinity) and on which Memory Nodes it may obtain memory (mbind, set_mempolicy).

Cpusets extends these two mechanisms as follows:

- Cpusets are sets of allowed CPUs and Memory Nodes, known to the kernel.
- Each task in the system is attached to a cpuset, via a pointer in the task structure to a reference counted cgroup structure.
- Calls to sched_setaffinity are filtered to just those CPUs allowed in that task's cpuset.
- Calls to mbind and set_mempolicy are filtered to just those Memory Nodes allowed in that task's cpuset.
- The root cpuset contains all the systems CPUs and Memory Nodes.
- For any cpuset, one can define child cpusets containing a subset of the parents CPU and Memory Node resources.
- The hierarchy of cpusets can be mounted at /dev/cpuset, for browsing and manipulation from user space.
- A cpuset may be marked exclusive, which ensures that no other cpuset (except direct ancestors and descendants) may contain any overlapping CPUs or Memory Nodes.
- You can list all the tasks (by pid) attached to any cpuset.

The implementation of cpusets requires a few, simple hooks into the rest of the kernel, none in performance critical paths:

- in init/main.c, to initialize the root cpuset at system boot.
- in fork and exit, to attach and detach a task from its cpuset.
- in sched_setaffinity, to mask the requested CPUs by what's allowed in that task's cpuset.

- in sched.c migrate_live_tasks(), to keep migrating tasks within the CPUs allowed by their cpuset, if possible.
- in the mbind and set_mempolicy system calls, to mask the requested Memory Nodes by what's allowed in that task's cpuset.
- in page_alloc.c, to restrict memory to allowed nodes.
- in vmscan.c, to restrict page recovery to the current cpuset.

You should mount the ”cgroup” filesystem type in order to enable browsing and modifying the cpusets presently known to the kernel. No new system calls are added for cpusets - all support for querying and modifying cpusets is via this cpuset file system.

The /proc/<pid>/status file for each task has four added lines, displaying the task's cpus_allowed (on which CPUs it may be scheduled) and mems_allowed (on which Memory Nodes it may obtain memory), in the two formats seen in the following example:

```
Cpus_allowed:   ffffffff,ffffffff,ffffffff,ffffffff
Cpus_allowed_list:      0-127
Mems_allowed:   ffffffff,ffffffff
Mems_allowed_list:      0-63
```

Each cpuset is represented by a directory in the cgroup file system containing (on top of the standard cgroup files) the following files describing that cpuset:

- cpuset.cpus: list of CPUs in that cpuset
- cpuset.mems: list of Memory Nodes in that cpuset
- cpuset.memory_migrate flag: if set, move pages to cpusets nodes
- cpuset.cpu_exclusive flag: is cpu placement exclusive?
- cpuset.mem_exclusive flag: is memory placement exclusive?
- cpuset.mem_hardwall flag: is memory allocation hardwalled
- cpuset.memory_pressure: measure of how much paging pressure in cpuset
- cpuset.memory_spread_page flag: if set, spread page cache evenly on allowed nodes
- cpuset.memory_spread_slab flag: if set, spread slab cache evenly on allowed nodes
- cpuset.sched_load_balance flag: if set, load balance within CPUs on that cpuset
- cpuset.sched_relax_domain_level: the searching range when migrating tasks

In addition, only the root cpuset has the following file:

- cpuset.memory_pressure_enabled flag: compute memory_pressure?

New cpusets are created using the mkdir system call or shell command. The properties of a cpuset, such as its flags, allowed CPUs and Memory Nodes, and attached tasks, are modified by writing to the appropriate file in that cpusets directory, as listed above.

The named hierarchical structure of nested cpusets allows partitioning a large system into nested, dynamically changeable, ”soft-partitions”.

The attachment of each task, automatically inherited at fork by any children of that task, to a cpuset allows organizing the work load on a system into related sets of tasks such that each set is constrained to using the CPUs and Memory Nodes of a particular cpuset. A task may

be re-attached to any other cpuset, if allowed by the permissions on the necessary cpuset file system directories.

Such management of a system ”in the large” integrates smoothly with the detailed placement done on individual tasks and memory regions using the sched_setaffinity, mbind and set_mempolicy system calls.

The following rules apply to each cpuset:

- Its CPUs and Memory Nodes must be a subset of its parents.
- It can't be marked exclusive unless its parent is.
- If its cpu or memory is exclusive, they may not overlap any sibling.

These rules, and the natural hierarchy of cpusets, enable efficient enforcement of the exclusive guarantee, without having to scan all cpusets every time any of them change to ensure nothing overlaps a exclusive cpuset. Also, the use of a Linux virtual file system (vfs) to represent the cpuset hierarchy provides for a familiar permission and name space for cpusets, with a minimum of additional kernel code.

The cpus and mems files in the root (top_cpuset) cpuset are read-only. The cpus file automatically tracks the value of cpu_online_mask using a CPU hotplug notifier, and the mems file automatically tracks the value of node_states[N_MEMORY]--i.e., nodes with memory--using the cpuset_track_online_nodes() hook.

The cpuset.effective_cpus and cpuset.effective_mems files are normally read-only copies of cpuset.cpus and cpuset.mems files respectively. If the cpuset cgroup filesystem is mounted with the special ”cpuset_v2_mode” option, the behavior of these files will become similar to the corresponding files in cpuset v2. In other words, hotplug events will not change cpuset.cpus and cpuset.mems. Those events will only affect cpuset.effective_cpus and cpuset.effective_mems which show the actual cpus and memory nodes that are currently used by this cpuset. See *Control Group v2* for more information about cpuset v2 behavior.

1.4 What are exclusive cpusets ?

If a cpuset is cpu or mem exclusive, no other cpuset, other than a direct ancestor or descendant, may share any of the same CPUs or Memory Nodes.

A cpuset that is cpuset.mem_exclusive *or* cpuset.mem_hardwall is ”hardwalled”, i.e. it restricts kernel allocations for page, buffer and other data commonly shared by the kernel across multiple users. All cpusets, whether hardwalled or not, restrict allocations of memory for user space. This enables configuring a system so that several independent jobs can share common kernel data, such as file system pages, while isolating each job's user allocation in its own cpuset. To do this, construct a large mem_exclusive cpuset to hold all the jobs, and construct child, non-mem_exclusive cpusets for each individual job. Only a small amount of typical kernel memory, such as requests from interrupt handlers, is allowed to be taken outside even a mem_exclusive cpuset.

1.5 What is memory_pressure ?

The memory_pressure of a cpuset provides a simple per-cpuset metric of the rate that the tasks in a cpuset are attempting to free up in use memory on the nodes of the cpuset to satisfy additional memory requests.

This enables batch managers monitoring jobs running in dedicated cpusets to efficiently detect what level of memory pressure that job is causing.

This is useful both on tightly managed systems running a wide mix of submitted jobs, which may choose to terminate or re-prioritize jobs that are trying to use more memory than allowed on the nodes assigned to them, and with tightly coupled, long running, massively parallel scientific computing jobs that will dramatically fail to meet required performance goals if they start to use more memory than allowed to them.

This mechanism provides a very economical way for the batch manager to monitor a cpuset for signs of memory pressure. It's up to the batch manager or other user code to decide what to do about it and take action.

==>

> Unless this feature is enabled by writing "1" to the special file /dev/cpuset/memory_pressure_enabled, the hook in the rebalance code of __alloc_pages() for this metric reduces to simply noticing that the cpuset_memory_pressure_enabled flag is zero. So only systems that enable this feature will compute the metric.

Why a per-cpuset, running average:

> Because this meter is per-cpuset, rather than per-task or mm, the system load imposed by a batch scheduler monitoring this metric is sharply reduced on large systems, because a scan of the tasklist can be avoided on each set of queries.
>
> Because this meter is a running average, instead of an accumulating counter, a batch scheduler can detect memory pressure with a single read, instead of having to read and accumulate results for a period of time.
>
> Because this meter is per-cpuset rather than per-task or mm, the batch scheduler can obtain the key information, memory pressure in a cpuset, with a single read, rather than having to query and accumulate results over all the (dynamically changing) set of tasks in the cpuset.

A per-cpuset simple digital filter (requires a spinlock and 3 words of data per-cpuset) is kept, and updated by any task attached to that cpuset, if it enters the synchronous (direct) page reclaim code.

A per-cpuset file provides an integer number representing the recent (half-life of 10 seconds) rate of direct page reclaims caused by the tasks in the cpuset, in units of reclaims attempted per second, times 1000.

1.6 What is memory spread ?

There are two boolean flag files per cpuset that control where the kernel allocates pages for the file system buffers and related in kernel data structures. They are called 'cpuset.memory_spread_page' and 'cpuset.memory_spread_slab'.

If the per-cpuset boolean flag file 'cpuset.memory_spread_page' is set, then the kernel will spread the file system buffers (page cache) evenly over all the nodes that the faulting task is allowed to use, instead of preferring to put those pages on the node where the task is running.

If the per-cpuset boolean flag file 'cpuset.memory_spread_slab' is set, then the kernel will spread some file system related slab caches, such as for inodes and dentries evenly over all the nodes that the faulting task is allowed to use, instead of preferring to put those pages on the node where the task is running.

The setting of these flags does not affect anonymous data segment or stack segment pages of a task.

By default, both kinds of memory spreading are off, and memory pages are allocated on the node local to where the task is running, except perhaps as modified by the task's NUMA mempolicy or cpuset configuration, so long as sufficient free memory pages are available.

When new cpusets are created, they inherit the memory spread settings of their parent.

Setting memory spreading causes allocations for the affected page or slab caches to ignore the task's NUMA mempolicy and be spread instead. Tasks using mbind() or set_mempolicy() calls to set NUMA mempolicies will not notice any change in these calls as a result of their containing task's memory spread settings. If memory spreading is turned off, then the currently specified NUMA mempolicy once again applies to memory page allocations.

Both 'cpuset.memory_spread_page' and 'cpuset.memory_spread_slab' are boolean flag files. By default they contain ”0”, meaning that the feature is off for that cpuset. If a ”1” is written to that file, then that turns the named feature on.

The implementation is simple.

Setting the flag 'cpuset.memory_spread_page' turns on a per-process flag PFA_SPREAD_PAGE for each task that is in that cpuset or subsequently joins that cpuset. The page allocation calls for the page cache is modified to perform an inline check for this PFA_SPREAD_PAGE task flag, and if set, a call to a new routine cpuset_mem_spread_node() returns the node to prefer for the allocation.

Similarly, setting 'cpuset.memory_spread_slab' turns on the flag PFA_SPREAD_SLAB, and appropriately marked slab caches will allocate pages from the node returned by cpuset_mem_spread_node().

The cpuset_mem_spread_node() routine is also simple. It uses the value of a per-task rotor cpuset_mem_spread_rotor to select the next node in the current task's mems_allowed to prefer for the allocation.

This memory placement policy is also known (in other contexts) as round-robin or interleave.

This policy can provide substantial improvements for jobs that need to place thread local data on the corresponding node, but that need to access large file system data sets that need to be spread across the several nodes in the jobs cpuset in order to fit. Without this policy, especially for jobs that might have one thread reading in the data set, the memory allocation across the nodes in the jobs cpuset can become very uneven.

1.7 What is sched_load_balance ?

The kernel scheduler (kernel/sched/core.c) automatically load balances tasks. If one CPU is underutilized, kernel code running on that CPU will look for tasks on other more overloaded CPUs and move those tasks to itself, within the constraints of such placement mechanisms as cpusets and sched_setaffinity.

The algorithmic cost of load balancing and its impact on key shared kernel data structures such as the task list increases more than linearly with the number of CPUs being balanced. So the scheduler has support to partition the systems CPUs into a number of sched domains such that it only load balances within each sched domain. Each sched domain covers some subset of the CPUs in the system; no two sched domains overlap; some CPUs might not be in any sched domain and hence won't be load balanced.

Put simply, it costs less to balance between two smaller sched domains than one big one, but doing so means that overloads in one of the two domains won't be load balanced to the other one.

By default, there is one sched domain covering all CPUs, including those marked isolated using the kernel boot time ”isolcpus=” argument. However, the isolated CPUs will not participate in load balancing, and will not have tasks running on them unless explicitly assigned.

This default load balancing across all CPUs is not well suited for the following two situations:

1) On large systems, load balancing across many CPUs is expensive. If the system is managed using cpusets to place independent jobs on separate sets of CPUs, full load balancing is unnecessary.

2) Systems supporting realtime on some CPUs need to minimize system overhead on those CPUs, including avoiding task load balancing if that is not needed.

When the per-cpuset flag ”cpuset.sched_load_balance” is enabled (the default setting), it requests that all the CPUs in that cpusets allowed 'cpuset.cpus' be contained in a single sched domain, ensuring that load balancing can move a task (not otherwised pinned, as by sched_setaffinity) from any CPU in that cpuset to any other.

When the per-cpuset flag ”cpuset.sched_load_balance” is disabled, then the scheduler will avoid load balancing across the CPUs in that cpuset, --except-- in so far as is necessary because some overlapping cpuset has ”sched_load_balance” enabled.

So, for example, if the top cpuset has the flag ”cpuset.sched_load_balance” enabled, then the scheduler will have one sched domain covering all CPUs, and the setting of the ”cpuset.sched_load_balance” flag in any other cpusets won't matter, as we're already fully load balancing.

Therefore in the above two situations, the top cpuset flag ”cpuset.sched_load_balance” should be disabled, and only some of the smaller, child cpusets have this flag enabled.

When doing this, you don't usually want to leave any unpinned tasks in the top cpuset that might use non-trivial amounts of CPU, as such tasks may be artificially constrained to some subset of CPUs, depending on the particulars of this flag setting in descendant cpusets. Even if such a task could use spare CPU cycles in some other CPUs, the kernel scheduler might not consider the possibility of load balancing that task to that underused CPU.

Of course, tasks pinned to a particular CPU can be left in a cpuset that disables ”cpuset.sched_load_balance” as those tasks aren't going anywhere else anyway.

There is an impedance mismatch here, between cpusets and sched domains. Cpusets are hierarchical and nest. Sched domains are flat; they don't overlap and each CPU is in at most one sched domain.

It is necessary for sched domains to be flat because load balancing across partially overlapping sets of CPUs would risk unstable dynamics that would be beyond our understanding. So if each of two partially overlapping cpusets enables the flag 'cpuset.sched_load_balance', then we form a single sched domain that is a superset of both. We won't move a task to a CPU outside its cpuset, but the scheduler load balancing code might waste some compute cycles considering that possibility.

This mismatch is why there is not a simple one-to-one relation between which cpusets have the flag ”cpuset.sched_load_balance” enabled, and the sched domain configuration. If a cpuset enables the flag, it will get balancing across all its CPUs, but if it disables the flag, it will only be assured of no load balancing if no other overlapping cpuset enables the flag.

If two cpusets have partially overlapping 'cpuset.cpus' allowed, and only one of them has this flag enabled, then the other may find its tasks only partially load balanced, just on the overlapping CPUs. This is just the general case of the top_cpuset example given a few paragraphs above. In the general case, as in the top cpuset case, don't leave tasks that might use non-trivial amounts of CPU in such partially load balanced cpusets, as they may be artificially constrained to some subset of the CPUs allowed to them, for lack of load balancing to the other CPUs.

CPUs in ”cpuset.isolcpus” were excluded from load balancing by the isolcpus= kernel boot option, and will never be load balanced regardless of the value of ”cpuset.sched_load_balance” in any cpuset.

1.7.1 sched_load_balance implementation details.

The per-cpuset flag 'cpuset.sched_load_balance' defaults to enabled (contrary to most cpuset flags.) When enabled for a cpuset, the kernel will ensure that it can load balance across all the CPUs in that cpuset (makes sure that all the CPUs in the cpus_allowed of that cpuset are in the same sched domain.)

If two overlapping cpusets both have 'cpuset.sched_load_balance' enabled, then they will be (must be) both in the same sched domain.

If, as is the default, the top cpuset has 'cpuset.sched_load_balance' enabled, then by the above that means there is a single sched domain covering the whole system, regardless of any other cpuset settings.

The kernel commits to user space that it will avoid load balancing where it can. It will pick as fine a granularity partition of sched domains as it can while still providing load balancing for any set of CPUs allowed to a cpuset having 'cpuset.sched_load_balance' enabled.

The internal kernel cpuset to scheduler interface passes from the cpuset code to the scheduler code a partition of the load balanced CPUs in the system. This partition is a set of subsets (represented as an array of struct cpumask) of CPUs, pairwise disjoint, that cover all the CPUs that must be load balanced.

The cpuset code builds a new such partition and passes it to the scheduler sched domain setup code, to have the sched domains rebuilt as necessary, whenever:

- the 'cpuset.sched_load_balance' flag of a cpuset with non-empty CPUs changes,
- or CPUs come or go from a cpuset with this flag enabled,

- or 'cpuset.sched_relax_domain_level' value of a cpuset with non-empty CPUs and with this flag enabled changes,
- or a cpuset with non-empty CPUs and with this flag enabled is removed,
- or a cpu is offlined/onlined.

This partition exactly defines what sched domains the scheduler should setup - one sched domain for each element (struct cpumask) in the partition.

The scheduler remembers the currently active sched domain partitions. When the scheduler routine partition_sched_domains() is invoked from the cpuset code to update these sched domains, it compares the new partition requested with the current, and updates its sched domains, removing the old and adding the new, for each change.

1.8 What is sched_relax_domain_level ?

In sched domain, the scheduler migrates tasks in 2 ways; periodic load balance on tick, and at time of some schedule events.

When a task is woken up, scheduler try to move the task on idle CPU. For example, if a task A running on CPU X activates another task B on the same CPU X, and if CPU Y is X's sibling and performing idle, then scheduler migrate task B to CPU Y so that task B can start on CPU Y without waiting task A on CPU X.

And if a CPU run out of tasks in its runqueue, the CPU try to pull extra tasks from other busy CPUs to help them before it is going to be idle.

Of course it takes some searching cost to find movable tasks and/or idle CPUs, the scheduler might not search all CPUs in the domain every time. In fact, in some architectures, the searching ranges on events are limited in the same socket or node where the CPU locates, while the load balance on tick searches all.

For example, assume CPU Z is relatively far from CPU X. Even if CPU Z is idle while CPU X and the siblings are busy, scheduler can't migrate woken task B from X to Z since it is out of its searching range. As the result, task B on CPU X need to wait task A or wait load balance on the next tick. For some applications in special situation, waiting 1 tick may be too long.

The 'cpuset.sched_relax_domain_level' file allows you to request changing this searching range as you like. This file takes int value which indicates size of searching range in levels ideally as follows, otherwise initial value -1 that indicates the cpuset has no request.

-1	no request. use system default or follow request of others.
0	no search.
1	search siblings (hyperthreads in a core).
2	search cores in a package.
3	search cpus in a node [= system wide on non-NUMA system]
4	search nodes in a chunk of node [on NUMA system]
5	search system wide [on NUMA system]

The system default is architecture dependent. The system default can be changed using the relax_domain_level= boot parameter.

This file is per-cpuset and affect the sched domain where the cpuset belongs to. Therefore if the flag 'cpuset.sched_load_balance' of a cpuset is disabled, then 'cpuset.sched_relax_domain_level'

have no effect since there is no sched domain belonging the cpuset.

If multiple cpusets are overlapping and hence they form a single sched domain, the largest value among those is used. Be careful, if one requests 0 and others are -1 then 0 is used.

Note that modifying this file will have both good and bad effects, and whether it is acceptable or not depends on your situation. Don't modify this file if you are not sure.

If your situation is:

- The migration costs between each cpu can be assumed considerably small(for you) due to your special application's behavior or special hardware support for CPU cache etc.
- The searching cost doesn't have impact(for you) or you can make the searching cost enough small by managing cpuset to compact etc.
- The latency is required even it sacrifices cache hit rate etc. then increasing 'sched_relax_domain_level' would benefit you.

1.9 How do I use cpusets ?

In order to minimize the impact of cpusets on critical kernel code, such as the scheduler, and due to the fact that the kernel does not support one task updating the memory placement of another task directly, the impact on a task of changing its cpuset CPU or Memory Node placement, or of changing to which cpuset a task is attached, is subtle.

If a cpuset has its Memory Nodes modified, then for each task attached to that cpuset, the next time that the kernel attempts to allocate a page of memory for that task, the kernel will notice the change in the task's cpuset, and update its per-task memory placement to remain within the new cpusets memory placement. If the task was using mempolicy MPOL_BIND, and the nodes to which it was bound overlap with its new cpuset, then the task will continue to use whatever subset of MPOL_BIND nodes are still allowed in the new cpuset. If the task was using MPOL_BIND and now none of its MPOL_BIND nodes are allowed in the new cpuset, then the task will be essentially treated as if it was MPOL_BIND bound to the new cpuset (even though its NUMA placement, as queried by get_mempolicy(), doesn't change). If a task is moved from one cpuset to another, then the kernel will adjust the task's memory placement, as above, the next time that the kernel attempts to allocate a page of memory for that task.

If a cpuset has its 'cpuset.cpus' modified, then each task in that cpuset will have its allowed CPU placement changed immediately. Similarly, if a task's pid is written to another cpuset's 'tasks' file, then its allowed CPU placement is changed immediately. If such a task had been bound to some subset of its cpuset using the sched_setaffinity() call, the task will be allowed to run on any CPU allowed in its new cpuset, negating the effect of the prior sched_setaffinity() call.

In summary, the memory placement of a task whose cpuset is changed is updated by the kernel, on the next allocation of a page for that task, and the processor placement is updated immediately.

Normally, once a page is allocated (given a physical page of main memory) then that page stays on whatever node it was allocated, so long as it remains allocated, even if the cpusets memory placement policy 'cpuset.mems' subsequently changes. If the cpuset flag file 'cpuset.memory_migrate' is set true, then when tasks are attached to that cpuset, any pages that task had allocated to it on nodes in its previous cpuset are migrated to the task's new

cpuset. The relative placement of the page within the cpuset is preserved during these migration operations if possible. For example if the page was on the second valid node of the prior cpuset then the page will be placed on the second valid node of the new cpuset.

Also if 'cpuset.memory_migrate' is set true, then if that cpuset's 'cpuset.mems' file is modified, pages allocated to tasks in that cpuset, that were on nodes in the previous setting of 'cpuset.mems', will be moved to nodes in the new setting of 'mems.' Pages that were not in the task's prior cpuset, or in the cpuset's prior 'cpuset.mems' setting, will not be moved.

There is an exception to the above. If hotplug functionality is used to remove all the CPUs that are currently assigned to a cpuset, then all the tasks in that cpuset will be moved to the nearest ancestor with non-empty cpus. But the moving of some (or all) tasks might fail if cpuset is bound with another cgroup subsystem which has some restrictions on task attaching. In this failing case, those tasks will stay in the original cpuset, and the kernel will automatically update their cpus_allowed to allow all online CPUs. When memory hotplug functionality for removing Memory Nodes is available, a similar exception is expected to apply there as well. In general, the kernel prefers to violate cpuset placement, over starving a task that has had all its allowed CPUs or Memory Nodes taken offline.

There is a second exception to the above. GFP_ATOMIC requests are kernel internal allocations that must be satisfied, immediately. The kernel may drop some request, in rare cases even panic, if a GFP_ATOMIC alloc fails. If the request cannot be satisfied within the current task's cpuset, then we relax the cpuset, and look for memory anywhere we can find it. It's better to violate the cpuset than stress the kernel.

To start a new job that is to be contained within a cpuset, the steps are:

1) mkdir /sys/fs/cgroup/cpuset
2) mount -t cgroup -ocpuset cpuset /sys/fs/cgroup/cpuset
3) Create the new cpuset by doing mkdir's and write's (or echo's) in the /sys/fs/cgroup/cpuset virtual file system.
4) Start a task that will be the ”founding father” of the new job.
5) Attach that task to the new cpuset by writing its pid to the /sys/fs/cgroup/cpuset tasks file for that cpuset.
6) fork, exec or clone the job tasks from this founding father task.

For example, the following sequence of commands will setup a cpuset named ”Charlie”, containing just CPUs 2 and 3, and Memory Node 1, and then start a subshell 'sh' in that cpuset:

```
mount -t cgroup -ocpuset cpuset /sys/fs/cgroup/cpuset
cd /sys/fs/cgroup/cpuset
mkdir Charlie
cd Charlie
/bin/echo 2-3 > cpuset.cpus
/bin/echo 1 > cpuset.mems
/bin/echo $$ > tasks
sh
# The subshell 'sh' is now running in cpuset Charlie
# The next line should display '/Charlie'
cat /proc/self/cpuset
```

There are ways to query or modify cpusets:

- via the cpuset file system directly, using the various cd, mkdir, echo, cat, rmdir commands from the shell, or their equivalent from C.
- via the C library libcpuset.
- via the C library libcgroup. (https://github.com/libcgroup/libcgroup/)
- via the python application cset. (http://code.google.com/p/cpuset/)

The sched_setaffinity calls can also be done at the shell prompt using SGI's runon or Robert Love's taskset. The mbind and set_mempolicy calls can be done at the shell prompt using the numactl command (part of Andi Kleen's numa package).

32.4.2 2. Usage Examples and Syntax

2.1 Basic Usage

Creating, modifying, using the cpusets can be done through the cpuset virtual filesystem.

To mount it, type: # mount -t cgroup -o cpuset cpuset /sys/fs/cgroup/cpuset

Then under /sys/fs/cgroup/cpuset you can find a tree that corresponds to the tree of the cpusets in the system. For instance, /sys/fs/cgroup/cpuset is the cpuset that holds the whole system.

If you want to create a new cpuset under /sys/fs/cgroup/cpuset:

```
# cd /sys/fs/cgroup/cpuset
# mkdir my_cpuset
```

Now you want to do something with this cpuset:

```
# cd my_cpuset
```

In this directory you can find several files:

```
# ls
cgroup.clone_children  cpuset.memory_pressure
cgroup.event_control   cpuset.memory_spread_page
cgroup.procs           cpuset.memory_spread_slab
cpuset.cpu_exclusive   cpuset.mems
cpuset.cpus            cpuset.sched_load_balance
cpuset.mem_exclusive   cpuset.sched_relax_domain_level
cpuset.mem_hardwall    notify_on_release
cpuset.memory_migrate  tasks
```

Reading them will give you information about the state of this cpuset: the CPUs and Memory Nodes it can use, the processes that are using it, its properties. By writing to these files you can manipulate the cpuset.

Set some flags:

```
# /bin/echo 1 > cpuset.cpu_exclusive
```

Add some cpus:

```
# /bin/echo 0-7 > cpuset.cpus
```

Add some mems:

```
# /bin/echo 0-7 > cpuset.mems
```

Now attach your shell to this cpuset:

```
# /bin/echo $$ > tasks
```

You can also create cpusets inside your cpuset by using mkdir in this directory:

```
# mkdir my_sub_cs
```

To remove a cpuset, just use rmdir:

```
# rmdir my_sub_cs
```

This will fail if the cpuset is in use (has cpusets inside, or has processes attached).

Note that for legacy reasons, the "cpuset" filesystem exists as a wrapper around the cgroup filesystem.

The command:

```
mount -t cpuset X /sys/fs/cgroup/cpuset
```

is equivalent to:

```
mount -t cgroup -ocpuset,noprefix X /sys/fs/cgroup/cpuset
echo "/sbin/cpuset_release_agent" > /sys/fs/cgroup/cpuset/release_agent
```

2.2 Adding/removing cpus

This is the syntax to use when writing in the cpus or mems files in cpuset directories:

```
# /bin/echo 1-4 > cpuset.cpus         -> set cpus list to cpus 1,2,3,4
# /bin/echo 1,2,3,4 > cpuset.cpus     -> set cpus list to cpus 1,2,3,4
```

To add a CPU to a cpuset, write the new list of CPUs including the CPU to be added. To add 6 to the above cpuset:

```
# /bin/echo 1-4,6 > cpuset.cpus       -> set cpus list to cpus 1,2,3,4,6
```

Similarly to remove a CPU from a cpuset, write the new list of CPUs without the CPU to be removed.

To remove all the CPUs:

```
# /bin/echo "" > cpuset.cpus          -> clear cpus list
```

2.3 Setting flags

The syntax is very simple:

```
# /bin/echo 1 > cpuset.cpu_exclusive  -> set flag 'cpuset.cpu_exclusive'
# /bin/echo 0 > cpuset.cpu_exclusive  -> unset flag 'cpuset.cpu_exclusive'
```

2.4 Attaching processes

```
# /bin/echo PID > tasks
```

Note that it is PID, not PIDs. You can only attach ONE task at a time. If you have several tasks to attach, you have to do it one after another:

```
# /bin/echo PID1 > tasks
# /bin/echo PID2 > tasks
      ...
# /bin/echo PIDn > tasks
```

32.4.3 3. Questions

Q:
what's up with this '/bin/echo' ?

A:
bash's builtin 'echo' command does not check calls to write() against errors. If you use it in the cpuset file system, you won't be able to tell whether a command succeeded or failed.

Q:
When I attach processes, only the first of the line gets really attached !

A:
We can only return one error code per call to write(). So you should also put only ONE pid.

32.4.4 4. Contact

Web: http://www.bullopensource.org/cpuset

32.5 Device Whitelist Controller

32.5.1 1. Description

Implement a cgroup to track and enforce open and mknod restrictions on device files. A device cgroup associates a device access whitelist with each cgroup. A whitelist entry has 4 fields. 'type' is a (all), c (char), or b (block). 'all' means it applies to all types and all major and minor numbers. Major and minor are either an integer or * for all. Access is a composition of r (read), w (write), and m (mknod).

The root device cgroup starts with rwm to 'all'. A child device cgroup gets a copy of the parent. Administrators can then remove devices from the whitelist or add new entries. A child cgroup can never receive a device access which is denied by its parent.

32.5.2 2. User Interface

An entry is added using devices.allow, and removed using devices.deny. For instance:

```
echo 'c 1:3 mr' > /sys/fs/cgroup/1/devices.allow
```

allows cgroup 1 to read and mknod the device usually known as /dev/null. Doing:

```
echo a > /sys/fs/cgroup/1/devices.deny
```

will remove the default 'a *:* rwm' entry. Doing:

```
echo a > /sys/fs/cgroup/1/devices.allow
```

will add the 'a *:* rwm' entry to the whitelist.

32.5.3 3. Security

Any task can move itself between cgroups. This clearly won't suffice, but we can decide the best way to adequately restrict movement as people get some experience with this. We may just want to require CAP_SYS_ADMIN, which at least is a separate bit from CAP_MKNOD. We may want to just refuse moving to a cgroup which isn't a descendant of the current one. Or we may want to use CAP_MAC_ADMIN, since we really are trying to lock down root.

CAP_SYS_ADMIN is needed to modify the whitelist or move another task to a new cgroup. (Again we'll probably want to change that).

A cgroup may not be granted more permissions than the cgroup's parent has.

32.5.4 4. Hierarchy

device cgroups maintain hierarchy by making sure a cgroup never has more access permissions than its parent. Every time an entry is written to a cgroup's devices.deny file, all its children will have that entry removed from their whitelist and all the locally set whitelist entries will be re-evaluated. In case one of the locally set whitelist entries would provide more access than the cgroup's parent, it'll be removed from the whitelist.

Example:

```
  A
 / \
    B

group        behavior       exceptions
A            allow          "b 8:* rwm", "c 116:1 rw"
B            deny           "c 1:3 rwm", "c 116:2 rwm", "b 3:* rwm"
```

If a device is denied in group A:

```
# echo "c 116:* r" > A/devices.deny
```

it'll propagate down and after revalidating B's entries, the whitelist entry ”c 116:2 rwm” will be removed:

```
group        whitelist entries                        denied devices
A            all                                      "b 8:* rwm", "c 116:* rw"
B            "c 1:3 rwm", "b 3:* rwm"                 all the rest
```

In case parent's exceptions change and local exceptions are not allowed anymore, they'll be deleted.

Notice that new whitelist entries will not be propagated:

```
  A
 / \
    B

group        whitelist entries                        denied devices
A            "c 1:3 rwm", "c 1:5 r"                   all the rest
B            "c 1:3 rwm", "c 1:5 r"                   all the rest
```

when adding `c *:3 rwm`:

```
# echo "c *:3 rwm" >A/devices.allow
```

the result:

```
group        whitelist entries                        denied devices
A            "c *:3 rwm", "c 1:5 r"                   all the rest
B            "c 1:3 rwm", "c 1:5 r"                   all the rest
```

but now it'll be possible to add new entries to B:

```
# echo "c 2:3 rwm" >B/devices.allow
# echo "c 50:3 r" >B/devices.allow
```

or even:

```
# echo "c *:3 rwm" >B/devices.allow
```

Allowing or denying all by writing 'a' to devices.allow or devices.deny will not be possible once the device cgroups has children.

4.1 Hierarchy (internal implementation)

device cgroups is implemented internally using a behavior (ALLOW, DENY) and a list of exceptions. The internal state is controlled using the same user interface to preserve compatibility with the previous whitelist-only implementation. Removal or addition of exceptions that will reduce the access to devices will be propagated down the hierarchy. For every propagated exception, the effective rules will be re-evaluated based on current parent's access rules.

32.6 Cgroup Freezer

The cgroup freezer is useful to batch job management system which start and stop sets of tasks in order to schedule the resources of a machine according to the desires of a system administrator. This sort of program is often used on HPC clusters to schedule access to the cluster as a whole. The cgroup freezer uses cgroups to describe the set of tasks to be started/stopped by the batch job management system. It also provides a means to start and stop the tasks composing the job.

The cgroup freezer will also be useful for checkpointing running groups of tasks. The freezer allows the checkpoint code to obtain a consistent image of the tasks by attempting to force the tasks in a cgroup into a quiescent state. Once the tasks are quiescent another task can walk /proc or invoke a kernel interface to gather information about the quiesced tasks. Checkpointed tasks can be restarted later should a recoverable error occur. This also allows the checkpointed tasks to be migrated between nodes in a cluster by copying the gathered information to another node and restarting the tasks there.

Sequences of SIGSTOP and SIGCONT are not always sufficient for stopping and resuming tasks in userspace. Both of these signals are observable from within the tasks we wish to freeze. While SIGSTOP cannot be caught, blocked, or ignored it can be seen by waiting or ptracing parent tasks. SIGCONT is especially unsuitable since it can be caught by the task. Any programs designed to watch for SIGSTOP and SIGCONT could be broken by attempting to use SIGSTOP and SIGCONT to stop and resume tasks. We can demonstrate this problem using nested bash shells:

```
$ echo $$
16644
$ bash
$ echo $$
16690

From a second, unrelated bash shell:
$ kill -SIGSTOP 16690
$ kill -SIGCONT 16690

<at this point 16690 exits and causes 16644 to exit too>
```

This happens because bash can observe both signals and choose how it responds to them.

Another example of a program which catches and responds to these signals is gdb. In fact any program designed to use ptrace is likely to have a problem with this method of stopping and resuming tasks.

In contrast, the cgroup freezer uses the kernel freezer code to prevent the freeze/unfreeze cycle

from becoming visible to the tasks being frozen. This allows the bash example above and gdb to run as expected.

The cgroup freezer is hierarchical. Freezing a cgroup freezes all tasks belonging to the cgroup and all its descendant cgroups. Each cgroup has its own state (self-state) and the state inherited from the parent (parent-state). Iff both states are THAWED, the cgroup is THAWED.

The following cgroupfs files are created by cgroup freezer.

- freezer.state: Read-write.

  When read, returns the effective state of the cgroup - "THAWED", "FREEZING" or "FROZEN". This is the combined self and parent-states. If any is freezing, the cgroup is freezing (FREEZING or FROZEN).

  FREEZING cgroup transitions into FROZEN state when all tasks belonging to the cgroup and its descendants become frozen. Note that a cgroup reverts to FREEZING from FROZEN after a new task is added to the cgroup or one of its descendant cgroups until the new task is frozen.

  When written, sets the self-state of the cgroup. Two values are allowed - "FROZEN" and "THAWED". If FROZEN is written, the cgroup, if not already freezing, enters FREEZING state along with all its descendant cgroups.

  If THAWED is written, the self-state of the cgroup is changed to THAWED. Note that the effective state may not change to THAWED if the parent-state is still freezing. If a cgroup's effective state becomes THAWED, all its descendants which are freezing because of the cgroup also leave the freezing state.

- freezer.self_freezing: Read only.

  Shows the self-state. 0 if the self-state is THAWED; otherwise, 1. This value is 1 iff the last write to freezer.state was "FROZEN".

- freezer.parent_freezing: Read only.

  Shows the parent-state. 0 if none of the cgroup's ancestors is frozen; otherwise, 1.

The root cgroup is non-freezable and the above interface files don't exist.

- Examples of usage:

```
# mkdir /sys/fs/cgroup/freezer
# mount -t cgroup -ofreezer freezer /sys/fs/cgroup/freezer
# mkdir /sys/fs/cgroup/freezer/0
# echo $some_pid > /sys/fs/cgroup/freezer/0/tasks
```

to get status of the freezer subsystem:

```
# cat /sys/fs/cgroup/freezer/0/freezer.state
THAWED
```

to freeze all tasks in the container:

```
# echo FROZEN > /sys/fs/cgroup/freezer/0/freezer.state
# cat /sys/fs/cgroup/freezer/0/freezer.state
FREEZING
```

```
# cat /sys/fs/cgroup/freezer/0/freezer.state
FROZEN
```

to unfreeze all tasks in the container:

```
# echo THAWED > /sys/fs/cgroup/freezer/0/freezer.state
# cat /sys/fs/cgroup/freezer/0/freezer.state
THAWED
```

This is the basic mechanism which should do the right thing for user space task in a simple scenario.

32.7 HugeTLB Controller

HugeTLB controller can be created by first mounting the cgroup filesystem.

mount -t cgroup -o hugetlb none /sys/fs/cgroup

With the above step, the initial or the parent HugeTLB group becomes visible at /sys/fs/cgroup. At bootup, this group includes all the tasks in the system. /sys/fs/cgroup/tasks lists the tasks in this cgroup.

New groups can be created under the parent group /sys/fs/cgroup:

```
# cd /sys/fs/cgroup
# mkdir g1
# echo $$ > g1/tasks
```

The above steps create a new group g1 and move the current shell process (bash) into it.

Brief summary of control files:

```
hugetlb.<hugepagesize>.rsvd.limit_in_bytes            # set/show limit of
 ↪"hugepagesize" hugetlb reservations
hugetlb.<hugepagesize>.rsvd.max_usage_in_bytes        # show max "hugepagesize
 ↪" hugetlb reservations and no-reserve faults
hugetlb.<hugepagesize>.rsvd.usage_in_bytes            # show current␣
 ↪reservations and no-reserve faults for "hugepagesize" hugetlb
hugetlb.<hugepagesize>.rsvd.failcnt                   # show the number of␣
 ↪allocation failure due to HugeTLB reservation limit
hugetlb.<hugepagesize>.limit_in_bytes                 # set/show limit of
 ↪"hugepagesize" hugetlb faults
hugetlb.<hugepagesize>.max_usage_in_bytes             # show max "hugepagesize
 ↪" hugetlb  usage recorded
hugetlb.<hugepagesize>.usage_in_bytes                 # show current usage for
 ↪"hugepagesize" hugetlb
hugetlb.<hugepagesize>.failcnt                        # show the number of␣
 ↪allocation failure due to HugeTLB usage limit
hugetlb.<hugepagesize>.numa_stat                      # show the numa␣
 ↪information of the hugetlb memory charged to this cgroup
```

For a system supporting three hugepage sizes (64k, 32M and 1G), the control files include:

```
hugetlb.1GB.limit_in_bytes
hugetlb.1GB.max_usage_in_bytes
hugetlb.1GB.numa_stat
hugetlb.1GB.usage_in_bytes
hugetlb.1GB.failcnt
hugetlb.1GB.rsvd.limit_in_bytes
hugetlb.1GB.rsvd.max_usage_in_bytes
hugetlb.1GB.rsvd.usage_in_bytes
hugetlb.1GB.rsvd.failcnt
hugetlb.64KB.limit_in_bytes
hugetlb.64KB.max_usage_in_bytes
hugetlb.64KB.numa_stat
hugetlb.64KB.usage_in_bytes
hugetlb.64KB.failcnt
hugetlb.64KB.rsvd.limit_in_bytes
hugetlb.64KB.rsvd.max_usage_in_bytes
hugetlb.64KB.rsvd.usage_in_bytes
hugetlb.64KB.rsvd.failcnt
hugetlb.32MB.limit_in_bytes
hugetlb.32MB.max_usage_in_bytes
hugetlb.32MB.numa_stat
hugetlb.32MB.usage_in_bytes
hugetlb.32MB.failcnt
hugetlb.32MB.rsvd.limit_in_bytes
hugetlb.32MB.rsvd.max_usage_in_bytes
hugetlb.32MB.rsvd.usage_in_bytes
hugetlb.32MB.rsvd.failcnt
```

1. Page fault accounting

hugetlb.<hugepagesize>.limit_in_bytes hugetlb.<hugepagesize>.max_usage_in_bytes hugetlb.<hugepagesize>.usage_in_bytes hugetlb.<hugepagesize>.failcnt

The HugeTLB controller allows users to limit the HugeTLB usage (page fault) per control group and enforces the limit during page fault. Since HugeTLB doesn't support page reclaim, enforcing the limit at page fault time implies that, the application will get SIGBUS signal if it tries to fault in HugeTLB pages beyond its limit. Therefore the application needs to know exactly how many HugeTLB pages it uses before hand, and the sysadmin needs to make sure that there are enough available on the machine for all the users to avoid processes getting SIGBUS.

2. Reservation accounting

hugetlb.<hugepagesize>.rsvd.limit_in_bytes hugetlb.<hugepagesize>.rsvd.max_usage_in_bytes hugetlb.<hugepagesize>.rsvd.usage_in_bytes hugetlb.<hugepagesize>.rsvd.failcnt

The HugeTLB controller allows to limit the HugeTLB reservations per control group and enforces the controller limit at reservation time and at the fault of HugeTLB memory for which no reservation exists. Since reservation limits are enforced at reservation time (on mmap or shget), reservation limits never causes the application to get SIGBUS signal if the memory was reserved before hand. For MAP_NORESERVE allocations, the reservation limit behaves the same as the fault limit, enforcing memory usage at fault time and causing the application to receive a SIGBUS if it's crossing its limit.

Reservation limits are superior to page fault limits described above, since reservation limits

are enforced at reservation time (on mmap or shget), and never causes the application to get SIGBUS signal if the memory was reserved before hand. This allows for easier fallback to alternatives such as non-HugeTLB memory for example. In the case of page fault accounting, it's very hard to avoid processes getting SIGBUS since the sysadmin needs precisely know the HugeTLB usage of all the tasks in the system and make sure there is enough pages to satisfy all requests. Avoiding tasks getting SIGBUS on overcommited systems is practically impossible with page fault accounting.

3. Caveats with shared memory

For shared HugeTLB memory, both HugeTLB reservation and page faults are charged to the first task that causes the memory to be reserved or faulted, and all subsequent uses of this reserved or faulted memory is done without charging.

Shared HugeTLB memory is only uncharged when it is unreserved or deallocated. This is usually when the HugeTLB file is deleted, and not when the task that caused the reservation or fault has exited.

4. Caveats with HugeTLB cgroup offline.

When a HugeTLB cgroup goes offline with some reservations or faults still charged to it, the behavior is as follows:

- The fault charges are charged to the parent HugeTLB cgroup (reparented),
- the reservation charges remain on the offline HugeTLB cgroup.

This means that if a HugeTLB cgroup gets offlined while there is still HugeTLB reservations charged to it, that cgroup persists as a zombie until all HugeTLB reservations are uncharged. HugeTLB reservations behave in this manner to match the memory controller whose cgroups also persist as zombie until all charged memory is uncharged. Also, the tracking of HugeTLB reservations is a bit more complex compared to the tracking of HugeTLB faults, so it is significantly harder to reparent reservations at offline time.

32.8 Memory Resource Controller(Memcg) Implementation Memo

Last Updated: 2010/2

Base Kernel Version: based on 2.6.33-rc7-mm(candidate for 34).

Because VM is getting complex (one of reasons is memcg...), memcg's behavior is complex. This is a document for memcg's internal behavior. Please note that implementation details can be changed.

(*) Topics on API should be in *Memory Resource Controller*)

32.8.1 0. How to record usage ?

2 objects are used.

page_cgroup ....an object per page.

Allocated at boot or memory hotplug. Freed at memory hot removal.

swap_cgroup ... an entry per swp_entry.

Allocated at swapon(). Freed at swapoff().

The page_cgroup has USED bit and double count against a page_cgroup never occurs. swap_cgroup is used only when a charged page is swapped-out.

32.8.2 1. Charge

a page/swp_entry may be charged (usage += PAGE_SIZE) at

mem_cgroup_try_charge()

32.8.3 2. Uncharge

a page/swp_entry may be uncharged (usage -= PAGE_SIZE) by

mem_cgroup_uncharge()
Called when a page's refcount goes down to 0.

mem_cgroup_uncharge_swap()
Called when swp_entry's refcnt goes down to 0. A charge against swap disappears.

32.8.4 3. charge-commit-cancel

Memcg pages are charged in two steps:

- mem_cgroup_try_charge()
- mem_cgroup_commit_charge() or mem_cgroup_cancel_charge()

At try_charge(), there are no flags to say ”this page is charged”. at this point, usage += PAGE_SIZE.

At commit(), the page is associated with the memcg.

At cancel(), simply usage -= PAGE_SIZE.

Under below explanation, we assume CONFIG_SWAP=y.

32.8.5 4. Anonymous

Anonymous page is newly allocated at

- page fault into MAP_ANONYMOUS mapping.
- Copy-On-Write.

4.1 Swap-in. At swap-in, the page is taken from swap-cache. There are 2 cases.

(a) If the SwapCache is newly allocated and read, it has no charges.

(b) If the SwapCache has been mapped by processes, it has been charged already.

4.2 Swap-out. At swap-out, typical state transition is below.

(a) add to swap cache. (marked as SwapCache) swp_entry's refcnt += 1.

(b) fully unmapped. swp_entry's refcnt += # of ptes.

(c) write back to swap.

(d) delete from swap cache. (remove from SwapCache) swp_entry's refcnt -= 1.

Finally, at task exit, (e) zap_pte() is called and swp_entry's refcnt -=1 -> 0.

32.8.6 5. Page Cache

Page Cache is charged at - filemap_add_folio().

The logic is very clear. (About migration, see below)

Note:
__remove_from_page_cache() is called by remove_from_page_cache() and __remove_mapping().

32.8.7 6. Shmem(tmpfs) Page Cache

The best way to understand shmem's page state transition is to read mm/shmem.c.

But brief explanation of the behavior of memcg around shmem will be helpful to understand the logic.

Shmem's page (just leaf page, not direct/indirect block) can be on

- radix-tree of shmem's inode.
- SwapCache.
- Both on radix-tree and SwapCache. This happens at swap-in and swap-out,

It's charged when...

- A new page is added to shmem's radix-tree.
- A swp page is read. (move a charge from swap_cgroup to page_cgroup)

32.8.8 7. Page Migration

mem_cgroup_migrate()

32.8.9 8. LRU

Each memcg has its own vector of LRUs (inactive anon, active anon, inactive file, active file, unevictable) of pages from each node, each LRU handled under a single lru_lock for that memcg and node.

32.8.10 9. Typical Tests.

Tests for racy cases.

9.1 Small limit to memcg.

When you do test to do racy case, it's good test to set memcg's limit to be very small rather than GB. Many races found in the test under xKB or xxMB limits.

(Memory behavior under GB and Memory behavior under MB shows very different situation.)

9.2 Shmem

Historically, memcg's shmem handling was poor and we saw some amount of troubles here. This is because shmem is page-cache but can be SwapCache. Test with shmem/tmpfs is always good test.

9.3 Migration

For NUMA, migration is an another special case. To do easy test, cpuset is useful. Following is a sample script to do migration:

```
mount -t cgroup -o cpuset none /opt/cpuset

mkdir /opt/cpuset/01
echo 1 > /opt/cpuset/01/cpuset.cpus
echo 0 > /opt/cpuset/01/cpuset.mems
echo 1 > /opt/cpuset/01/cpuset.memory_migrate
mkdir /opt/cpuset/02
echo 1 > /opt/cpuset/02/cpuset.cpus
echo 1 > /opt/cpuset/02/cpuset.mems
echo 1 > /opt/cpuset/02/cpuset.memory_migrate
```

In above set, when you moves a task from 01 to 02, page migration to node 0 to node 1 will occur. Following is a script to migrate all under cpuset.:

```
--
move_task()
{
for pid in $1
do
        /bin/echo $pid >$2/tasks 2>/dev/null
        echo -n $pid
        echo -n " "
done
echo END
}

G1_TASK=`cat ${G1}/tasks`
G2_TASK=`cat ${G2}/tasks`
move_task "${G1_TASK}" ${G2} &
--
```

9.4 Memory hotplug

memory hotplug test is one of good test.

to offline memory, do following:

```
# echo offline > /sys/devices/system/memory/memoryXXX/state
```

(XXX is the place of memory)

This is an easy way to test page migration, too.

9.5 nested cgroups

Use tests like the following for testing nested cgroups:

```
mkdir /opt/cgroup/01/child_a
mkdir /opt/cgroup/01/child_b

set limit to 01.
add limit to 01/child_b
run jobs under child_a and child_b
```

create/delete following groups at random while jobs are running:

```
/opt/cgroup/01/child_a/child_aa
/opt/cgroup/01/child_b/child_bb
/opt/cgroup/01/child_c
```

running new jobs in new group is also good.

9.6 Mount with other subsystems

Mounting with other subsystems is a good test because there is a race and lock dependency with other cgroup subsystems.

example:

```
# mount -t cgroup none /cgroup -o cpuset,memory,cpu,devices
```

and do task move, mkdir, rmdir etc...under this.

9.7 swapoff

Besides management of swap is one of complicated parts of memcg, call path of swap-in at swapoff is not same as usual swap-in path.. It's worth to be tested explicitly.

For example, test like following is good:

(Shell-A):

```
# mount -t cgroup none /cgroup -o memory
# mkdir /cgroup/test
# echo 40M > /cgroup/test/memory.limit_in_bytes
# echo 0 > /cgroup/test/tasks
```

Run malloc(100M) program under this. You'll see 60M of swaps.

(Shell-B):

```
# move all tasks in /cgroup/test to /cgroup
# /sbin/swapoff -a
# rmdir /cgroup/test
# kill malloc task.
```

Of course, tmpfs v.s. swapoff test should be tested, too.

9.8 OOM-Killer

Out-of-memory caused by memcg's limit will kill tasks under the memcg. When hierarchy is used, a task under hierarchy will be killed by the kernel.

In this case, panic_on_oom shouldn't be invoked and tasks in other groups shouldn't be killed.

It's not difficult to cause OOM under memcg as following.

Case A) when you can swapoff:

```
#swapoff -a
#echo 50M > /memory.limit_in_bytes
```

run 51M of malloc

Case B) when you use mem+swap limitation:

```
#echo 50M > memory.limit_in_bytes
#echo 50M > memory.memsw.limit_in_bytes
```

run 51M of malloc

9.9 Move charges at task migration

Charges associated with a task can be moved along with task migration.

(Shell-A):

```
#mkdir /cgroup/A
#echo $$ >/cgroup/A/tasks
```

run some programs which uses some amount of memory in /cgroup/A.

(Shell-B):

```
#mkdir /cgroup/B
#echo 1 >/cgroup/B/memory.move_charge_at_immigrate
#echo "pid of the program running in group A" >/cgroup/B/tasks
```

You can see charges have been moved by reading `*.usage_in_bytes` or memory.stat of both A and B.

See 8.2 of *Memory Resource Controller* to see what value should be written to move_charge_at_immigrate.

9.10 Memory thresholds

Memory controller implements memory thresholds using cgroups notification API. You can use tools/cgroup/cgroup_event_listener.c to test it.

(Shell-A) Create cgroup and run event listener:

```
# mkdir /cgroup/A
# ./cgroup_event_listener /cgroup/A/memory.usage_in_bytes 5M
```

(Shell-B) Add task to cgroup and try to allocate and free memory:

```
# echo $$ >/cgroup/A/tasks
# a="$(dd if=/dev/zero bs=1M count=10)"
# a=
```

You will see message from cgroup_event_listener every time you cross the thresholds.

Use /cgroup/A/memory.memsw.usage_in_bytes to test memsw thresholds.

It's good idea to test root cgroup as well.

32.9 Memory Resource Controller

Caution: This document is hopelessly outdated and it asks for a complete rewrite. It still contains a useful information so we are keeping it here but make sure to check the current code if you need a deeper understanding.

Note: The Memory Resource Controller has generically been referred to as the memory controller in this document. Do not confuse memory controller used here with the memory controller that is used in hardware.

Hint: When we mention a cgroup (cgroupfs's directory) with memory controller, we call it "memory cgroup". When you see git-log and source code, you'll see patch's title and function names tend to use "memcg". In this document, we avoid using it.

32.9.1 Benefits and Purpose of the memory controller

The memory controller isolates the memory behaviour of a group of tasks from the rest of the system. The article on LWN[12] mentions some probable uses of the memory controller. The memory controller can be used to

a. Isolate an application or a group of applications Memory-hungry applications can be isolated and limited to a smaller amount of memory.

b. Create a cgroup with a limited amount of memory; this can be used as a good alternative to booting with mem=XXXX.

c. Virtualization solutions can control the amount of memory they want to assign to a virtual machine instance.

d. A CD/DVD burner could control the amount of memory used by the rest of the system to ensure that burning does not fail due to lack of available memory.

e. There are several other use cases; find one or use the controller just for fun (to learn and hack on the VM subsystem).

Current Status: linux-2.6.34-mmotm(development version of 2010/April)

Features:

- accounting anonymous pages, file caches, swap caches usage and limiting them.
- pages are linked to per-memcg LRU exclusively, and there is no global LRU.
- optionally, memory+swap usage can be accounted and limited.
- hierarchical accounting
- soft limit
- moving (recharging) account at moving a task is selectable.

[12] Corbet, Jonathan, Controlling memory use in cgroups, http://lwn.net/Articles/243795/

- usage threshold notifier
- memory pressure notifier
- oom-killer disable knob and oom-notifier
- Root cgroup has no limit controls.

Kernel memory support is a work in progress, and the current version provides basically functionality. (See *section 2.7*)

Brief summary of control files.

tasks	attach a task(thread) and show list of threads
cgroup.procs	show list of processes
cgroup.event_control	an interface for event_fd() This knob is not available on CONFIG_PREEMPT_RT systems.
memory.usage_in_bytes	show current usage for memory (See 5.5 for details)
memory.memsw.usage_in_bytes	show current usage for memory+Swap (See 5.5 for details)
memory.limit_in_bytes	set/show limit of memory usage
memory.memsw.limit_in_bytes	set/show limit of memory+Swap usage
memory.failcnt	show the number of memory usage hits limits
memory.memsw.failcnt	show the number of memory+Swap hits limits
memory.max_usage_in_bytes	show max memory usage recorded
memory.memsw.max_usage_in_bytes	show max memory+Swap usage recorded
memory.soft_limit_in_bytes	set/show soft limit of memory usage This knob is not available on CONFIG_PREEMPT_RT systems.
memory.stat	show various statistics
memory.use_hierarchy	set/show hierarchical account enabled This knob is deprecated and shouldn't be used.
memory.force_empty	trigger forced page reclaim
memory.pressure_level	set memory pressure notifications
memory.swappiness	set/show swappiness parameter of vmscan (See sysctl's vm.swappiness)
memory.move_charge_at_immigrate	set/show controls of moving charges This knob is deprecated and shouldn't be used.
memory.oom_control	set/show oom controls.
memory.numa_stat	show the number of memory usage per numa node
memory.kmem.limit_in_bytes	Deprecated knob to set and read the kernel memory hard limit. Kernel hard limit is not supported since 5.16. Writing any value to do file will not have any effect same as if nokmem kernel parameter was specified. Kernel memory is still charged and reported by memory.kmem.usage_in_bytes.
memory.kmem.usage_in_bytes	show current kernel memory allocation
memory.kmem.failcnt	show the number of kernel memory usage hits limits
memory.kmem.max_usage_in_bytes	show max kernel memory usage recorded
memory.kmem.tcp.limit_in_bytes	set/show hard limit for tcp buf memory
memory.kmem.tcp.usage_in_bytes	show current tcp buf memory allocation
memory.kmem.tcp.failcnt	show the number of tcp buf memory usage hits limits
memory.kmem.tcp.max_usage_in_bytes	show max tcp buf memory usage recorded

32.9.2 1. History

The memory controller has a long history. A request for comments for the memory controller was posted by Balbir Singh[1]. At the time the RFC was posted there were several implementations for memory control. The goal of the RFC was to build consensus and agreement for the minimal features required for memory control. The first RSS controller was posted by Balbir Singh[2] in Feb 2007. Pavel Emelianov[3][4][5] has since posted three versions of the RSS controller. At OLS, at the resource management BoF, everyone suggested that we handle both page cache and RSS together. Another request was raised to allow user space handling of OOM. The current memory controller is at version 6; it combines both mapped (RSS) and unmapped Page Cache Control[11].

32.9.3 2. Memory Control

Memory is a unique resource in the sense that it is present in a limited amount. If a task requires a lot of CPU processing, the task can spread its processing over a period of hours, days, months or years, but with memory, the same physical memory needs to be reused to accomplish the task.

The memory controller implementation has been divided into phases. These are:

1. Memory controller
2. mlock(2) controller
3. Kernel user memory accounting and slab control
4. user mappings length controller

The memory controller is the first controller developed.

2.1. Design

The core of the design is a counter called the page_counter. The page_counter tracks the current memory usage and limit of the group of processes associated with the controller. Each cgroup has a memory controller specific data structure (mem_cgroup) associated with it.

2.2. Accounting

Listing 1: Figure 1: Hierarchy of Accounting

```
            +--------------------+
            |  mem_cgroup        |
            |  (page_counter)    |
            +--------------------+
             /            ^      \
            /             |       \
       +---------------+  |        +---------------+
       | mm_struct     |  |....    | mm_struct     |
       |               |  |        |               |
       +---------------+  |        +---------------+
                          |
                          + --------------+
                                          |
       +---------------+           +------+--------+
       | page          +---------->  page_cgroup|
       |               |           |               |
       +---------------+           +---------------+
```

Figure 1 shows the important aspects of the controller

1. Accounting happens per cgroup
2. Each mm_struct knows about which cgroup it belongs to
3. Each page has a pointer to the page_cgroup, which in turn knows the cgroup it belongs to

The accounting is done as follows: mem_cgroup_charge_common() is invoked to set up the necessary data structures and check if the cgroup that is being charged is over its limit. If it is, then reclaim is invoked on the cgroup. More details can be found in the reclaim section of this document. If everything goes well, a page meta-data-structure called page_cgroup is updated. page_cgroup has its own LRU on cgroup. (*) page_cgroup structure is allocated at boot/memory-hotplug time.

2.2.1 Accounting details

All mapped anon pages (RSS) and cache pages (Page Cache) are accounted. Some pages which are never reclaimable and will not be on the LRU are not accounted. We just account pages under usual VM management.

RSS pages are accounted at page_fault unless they've already been accounted for earlier. A file page will be accounted for as Page Cache when it's inserted into inode (xarray). While it's mapped into the page tables of processes, duplicate accounting is carefully avoided.

An RSS page is unaccounted when it's fully unmapped. A PageCache page is unaccounted when it's removed from xarray. Even if RSS pages are fully unmapped (by kswapd), they may exist as SwapCache in the system until they are really freed. Such SwapCaches are also accounted. A swapped-in page is accounted after adding into swapcache.

Note: The kernel does swapin-readahead and reads multiple swaps at once. Since page's memcg recorded into swap whatever memsw enabled, the page will be accounted after swapin.

At page migration, accounting information is kept.

Note: we just account pages-on-LRU because our purpose is to control amount of used pages; not-on-LRU pages tend to be out-of-control from VM view.

2.3 Shared Page Accounting

Shared pages are accounted on the basis of the first touch approach. The cgroup that first touches a page is accounted for the page. The principle behind this approach is that a cgroup that aggressively uses a shared page will eventually get charged for it (once it is uncharged from the cgroup that brought it in -- this will happen on memory pressure).

But see *section 8.2* when moving a task to another cgroup, its pages may be recharged to the new cgroup, if move_charge_at_immigrate has been chosen.

2.4 Swap Extension

Swap usage is always recorded for each of cgroup. Swap Extension allows you to read and limit it.

When CONFIG_SWAP is enabled, following files are added.

- memory.memsw.usage_in_bytes.
- memory.memsw.limit_in_bytes.

memsw means memory+swap. Usage of memory+swap is limited by memsw.limit_in_bytes.

Example: Assume a system with 4G of swap. A task which allocates 6G of memory (by mistake) under 2G memory limitation will use all swap. In this case, setting memsw.limit_in_bytes=3G will prevent bad use of swap. By using the memsw limit, you can avoid system OOM which can be caused by swap shortage.

2.4.1 why 'memory+swap' rather than swap

The global LRU(kswapd) can swap out arbitrary pages. Swap-out means to move account from memory to swap...there is no change in usage of memory+swap. In other words, when we want to limit the usage of swap without affecting global LRU, memory+swap limit is better than just limiting swap from an OS point of view.

2.4.2. What happens when a cgroup hits memory.memsw.limit_in_bytes

When a cgroup hits memory.memsw.limit_in_bytes, it's useless to do swap-out in this cgroup. Then, swap-out will not be done by cgroup routine and file caches are dropped. But as mentioned above, global LRU can do swapout memory from it for sanity of the system's memory management state. You can't forbid it by cgroup.

2.5 Reclaim

Each cgroup maintains a per cgroup LRU which has the same structure as global VM. When a cgroup goes over its limit, we first try to reclaim memory from the cgroup so as to make space for the new pages that the cgroup has touched. If the reclaim is unsuccessful, an OOM routine is invoked to select and kill the bulkiest task in the cgroup. (See *10. OOM Control* below.)

The reclaim algorithm has not been modified for cgroups, except that pages that are selected for reclaiming come from the per-cgroup LRU list.

Note: Reclaim does not work for the root cgroup, since we cannot set any limits on the root cgroup.

Note: When panic_on_oom is set to "2", the whole system will panic.

When oom event notifier is registered, event will be delivered. (See *oom_control* section)

2.6 Locking

Lock order is as follows:

```
Page lock (PG_locked bit of page->flags)
  mm->page_table_lock or split pte_lock
    folio_memcg_lock (memcg->move_lock)
      mapping->i_pages lock
        lruvec->lru_lock.
```

Per-node-per-memcgroup LRU (cgroup's private LRU) is guarded by lruvec->lru_lock; PG_lru bit of page->flags is cleared before isolating a page from its LRU under lruvec->lru_lock.

2.7 Kernel Memory Extension

With the Kernel memory extension, the Memory Controller is able to limit the amount of kernel memory used by the system. Kernel memory is fundamentally different than user memory, since it can't be swapped out, which makes it possible to DoS the system by consuming too much of this precious resource.

Kernel memory accounting is enabled for all memory cgroups by default. But it can be disabled system-wide by passing cgroup.memory=nokmem to the kernel at boot time. In this case, kernel memory will not be accounted at all.

Kernel memory limits are not imposed for the root cgroup. Usage for the root cgroup may or may not be accounted. The memory used is accumulated into memory.kmem.usage_in_bytes, or in a separate counter when it makes sense. (currently only for tcp).

The main "kmem" counter is fed into the main counter, so kmem charges will also be visible from the user counter.

Currently no soft limit is implemented for kernel memory. It is future work to trigger slab reclaim when those limits are reached.

2.7.1 Current Kernel Memory resources accounted

stack pages:
every process consumes some stack pages. By accounting into kernel memory, we prevent new processes from being created when the kernel memory usage is too high.

slab pages:
pages allocated by the SLAB or SLUB allocator are tracked. A copy of each kmem_cache is created every time the cache is touched by the first time from inside the memcg. The creation is done lazily, so some objects can still be skipped while the cache is being created. All objects in a slab page should belong to the same memcg. This only fails to hold when a task is migrated to a different memcg during the page allocation by the cache.

sockets memory pressure:
some sockets protocols have memory pressure thresholds. The Memory Controller allows them to be controlled individually per cgroup, instead of globally.

tcp memory pressure:
sockets memory pressure for the tcp protocol.

2.7.2 Common use cases

Because the "kmem" counter is fed to the main user counter, kernel memory can never be limited completely independently of user memory. Say "U" is the user limit, and "K" the kernel limit. There are three possible ways limits can be set:

U != 0, K = unlimited:
This is the standard memcg limitation mechanism already present before kmem accounting. Kernel memory is completely ignored.

U != 0, K < U:
Kernel memory is a subset of the user memory. This setup is useful in deployments where the total amount of memory per-cgroup is overcommitted. Overcommitting kernel memory limits is definitely not recommended, since the box can still run out of non-reclaimable memory. In this case, the admin could set up K so that the sum of all groups is never greater than the total memory, and freely set U at the cost of his QoS.

> **Warning:** In the current implementation, memory reclaim will NOT be triggered for a cgroup when it hits K while staying below U, which makes this setup impractical.

U != 0, K >= U:
Since kmem charges will also be fed to the user counter and reclaim will be triggered for the cgroup for both kinds of memory. This setup gives the admin a unified view of memory, and it is also useful for people who just want to track kernel memory usage.

32.9.4 3. User Interface

To use the user interface:

1. Enable CONFIG_CGROUPS and CONFIG_MEMCG options
2. Prepare the cgroups (see *Why are cgroups needed?* for the background information):

```
# mount -t tmpfs none /sys/fs/cgroup
# mkdir /sys/fs/cgroup/memory
# mount -t cgroup none /sys/fs/cgroup/memory -o memory
```

3. Make the new group and move bash into it:

```
# mkdir /sys/fs/cgroup/memory/0
# echo $$ > /sys/fs/cgroup/memory/0/tasks
```

4. Since now we're in the 0 cgroup, we can alter the memory limit:

```
# echo 4M > /sys/fs/cgroup/memory/0/memory.limit_in_bytes
```

The limit can now be queried:

```
# cat /sys/fs/cgroup/memory/0/memory.limit_in_bytes
4194304
```

Note: We can use a suffix (k, K, m, M, g or G) to indicate values in kilo, mega or gigabytes. (Here, Kilo, Mega, Giga are Kibibytes, Mebibytes, Gibibytes.)

Note: We can write "-1" to reset the `*.limit_in_bytes(unlimited)`.

Note: We cannot set limits on the root cgroup any more.

We can check the usage:

```
# cat /sys/fs/cgroup/memory/0/memory.usage_in_bytes
1216512
```

A successful write to this file does not guarantee a successful setting of this limit to the value written into the file. This can be due to a number of factors, such as rounding up to page boundaries or the total availability of memory on the system. The user is required to re-read this file after a write to guarantee the value committed by the kernel:

```
# echo 1 > memory.limit_in_bytes
# cat memory.limit_in_bytes
4096
```

The memory.failcnt field gives the number of times that the cgroup limit was exceeded.

The memory.stat file gives accounting information. Now, the number of caches, RSS and Active pages/Inactive pages are shown.

32.9.5 4. Testing

For testing features and implementation, see memcg_test.txt.

Performance test is also important. To see pure memory controller's overhead, testing on tmpfs will give you good numbers of small overheads. Example: do kernel make on tmpfs.

Page-fault scalability is also important. At measuring parallel page fault test, multi-process test may be better than multi-thread test because it has noise of shared objects/status.

But the above two are testing extreme situations. Trying usual test under memory controller is always helpful.

4.1 Troubleshooting

Sometimes a user might find that the application under a cgroup is terminated by the OOM killer. There are several causes for this:

1. The cgroup limit is too low (just too low to do anything useful)
2. The user is using anonymous memory and swap is turned off or too low

A sync followed by echo 1 > /proc/sys/vm/drop_caches will help get rid of some of the pages cached in the cgroup (page cache pages).

To know what happens, disabling OOM_Kill as per *"10. OOM Control"* (below) and seeing what happens will be helpful.

4.2 Task migration

When a task migrates from one cgroup to another, its charge is not carried forward by default. The pages allocated from the original cgroup still remain charged to it, the charge is dropped when the page is freed or reclaimed.

You can move charges of a task along with task migration. See *8. "Move charges at task migration"*

4.3 Removing a cgroup

A cgroup can be removed by rmdir, but as discussed in *sections 4.1* and *4.2*, a cgroup might have some charge associated with it, even though all tasks have migrated away from it. (because we charge against pages, not against tasks.)

We move the stats to parent, and no change on the charge except uncharging from the child.

Charges recorded in swap information is not updated at removal of cgroup. Recorded information is discarded and a cgroup which uses swap (swapcache) will be charged as a new owner of it.

32.9.6 5. Misc. interfaces

5.1 force_empty

memory.force_empty interface is provided to make cgroup's memory usage empty. When writing anything to this:

```
# echo 0 > memory.force_empty
```

the cgroup will be reclaimed and as many pages reclaimed as possible.

The typical use case for this interface is before calling rmdir(). Though rmdir() offlines memcg, but the memcg may still stay there due to charged file caches. Some out-of-use page caches may keep charged until memory pressure happens. If you want to avoid that, force_empty will be useful.

5.2 stat file

memory.stat file includes following statistics:

- per-memory cgroup local status

cache	# of bytes of page cache memory.
rss	# of bytes of anonymous and swap cache memory (includes transparent hugepages).
rss_huge	# of bytes of anonymous transparent hugepages.
mapped_file	# of bytes of mapped file (includes tmpfs/shmem)
pgpgin	# of charging events to the memory cgroup. The charging event happens each time a page is accounted as either mapped anon page(RSS) or cache page(Page Cache) to the cgroup.
pgpgout	# of uncharging events to the memory cgroup. The uncharging event happens each time a page is unaccounted from the cgroup.
swap	# of bytes of swap usage
swapcached	# of bytes of swap cached in memory
dirty	# of bytes that are waiting to get written back to the disk.
writeback	# of bytes of file/anon cache that are queued for syncing to disk.
inactive_anon	# of bytes of anonymous and swap cache memory on inactive LRU list.
active_anon	# of bytes of anonymous and swap cache memory on active LRU list.
inactive_file	# of bytes of file-backed memory and MADV_FREE anonymous memory (LazyFree pages) on inactive LRU list.
active_file	# of bytes of file-backed memory on active LRU list.
unevictable	# of bytes of memory that cannot be reclaimed (mlocked etc).

- status considering hierarchy (see memory.use_hierarchy settings):

hierarchical_memory_limit	# of bytes of memory limit with regard to hierarchy under which the memory cgroup is
hierarchical_memsw_limit	# of bytes of memory+swap limit with regard to hierarchy under which memory cgroup is.
total_<counter>	# hierarchical version of <counter>, which in addition to the cgroup's own value includes the sum of all hierarchical children's values of <counter>, i.e. total_cache

- additional vm parameters (depends on CONFIG_DEBUG_VM):

recent_rotated_anon	VM internal parameter. (see mm/vmscan.c)
recent_rotated_file	VM internal parameter. (see mm/vmscan.c)
recent_scanned_anon	VM internal parameter. (see mm/vmscan.c)
recent_scanned_file	VM internal parameter. (see mm/vmscan.c)

Hint: recent_rotated means recent frequency of LRU rotation. recent_scanned means recent # of scans to LRU. showing for better debug please see the code for meanings.

Note: Only anonymous and swap cache memory is listed as part of 'rss' stat. This should not be confused with the true 'resident set size' or the amount of physical memory used by the cgroup.

'rss + mapped_file" will give you resident set size of cgroup.

(Note: file and shmem may be shared among other cgroups. In that case, mapped_file is accounted only when the memory cgroup is owner of page cache.)

5.3 swappiness

Overrides /proc/sys/vm/swappiness for the particular group. The tunable in the root cgroup corresponds to the global swappiness setting.

Please note that unlike during the global reclaim, limit reclaim enforces that 0 swappiness really prevents from any swapping even if there is a swap storage available. This might lead to memcg OOM killer if there are no file pages to reclaim.

5.4 failcnt

A memory cgroup provides memory.failcnt and memory.memsw.failcnt files. This failcnt(== failure count) shows the number of times that a usage counter hit its limit. When a memory cgroup hits a limit, failcnt increases and memory under it will be reclaimed.

You can reset failcnt by writing 0 to failcnt file:

```
# echo 0 > .../memory.failcnt
```

5.5 usage_in_bytes

For efficiency, as other kernel components, memory cgroup uses some optimization to avoid unnecessary cacheline false sharing. usage_in_bytes is affected by the method and doesn't show 'exact' value of memory (and swap) usage, it's a fuzz value for efficient access. (Of course, when necessary, it's synchronized.) If you want to know more exact memory usage, you should use RSS+CACHE(+SWAP) value in memory.stat(see 5.2).

5.6 numa_stat

This is similar to numa_maps but operates on a per-memcg basis. This is useful for providing visibility into the numa locality information within an memcg since the pages are allowed to be allocated from any physical node. One of the use cases is evaluating application performance by combining this information with the application's CPU allocation.

Each memcg's numa_stat file includes ”total”, ”file”, ”anon” and ”unevictable” per-node page counts including ”hierarchical_<counter>” which sums up all hierarchical children's values in addition to the memcg's own value.

The output format of memory.numa_stat is:

```
total=<total pages> N0=<node 0 pages> N1=<node 1 pages> ...
file=<total file pages> N0=<node 0 pages> N1=<node 1 pages> ...
anon=<total anon pages> N0=<node 0 pages> N1=<node 1 pages> ...
unevictable=<total anon pages> N0=<node 0 pages> N1=<node 1 pages> ...
hierarchical_<counter>=<counter pages> N0=<node 0 pages> N1=<node 1 pages> ...
```

The ”total” count is sum of file + anon + unevictable.

32.9.7 6. Hierarchy support

The memory controller supports a deep hierarchy and hierarchical accounting. The hierarchy is created by creating the appropriate cgroups in the cgroup filesystem. Consider for example, the following cgroup filesystem hierarchy:

```
    root
  /  |   \
 /   |    \
a    b     c
           | \
           |  \
           d   e
```

In the diagram above, with hierarchical accounting enabled, all memory usage of e, is accounted to its ancestors up until the root (i.e, c and root). If one of the ancestors goes over its limit, the reclaim algorithm reclaims from the tasks in the ancestor and the children of the ancestor.

6.1 Hierarchical accounting and reclaim

Hierarchical accounting is enabled by default. Disabling the hierarchical accounting is deprecated. An attempt to do it will result in a failure and a warning printed to dmesg.

For compatibility reasons writing 1 to memory.use_hierarchy will always pass:

```
# echo 1 > memory.use_hierarchy
```

32.9.8 7. Soft limits

Soft limits allow for greater sharing of memory. The idea behind soft limits is to allow control groups to use as much of the memory as needed, provided

a. There is no memory contention

b. They do not exceed their hard limit

When the system detects memory contention or low memory, control groups are pushed back to their soft limits. If the soft limit of each control group is very high, they are pushed back as much as possible to make sure that one control group does not starve the others of memory.

Please note that soft limits is a best-effort feature; it comes with no guarantees, but it does its best to make sure that when memory is heavily contended for, memory is allocated based on the soft limit hints/setup. Currently soft limit based reclaim is set up such that it gets invoked from balance_pgdat (kswapd).

7.1 Interface

Soft limits can be setup by using the following commands (in this example we assume a soft limit of 256 MiB):

```
# echo 256M > memory.soft_limit_in_bytes
```

If we want to change this to 1G, we can at any time use:

```
# echo 1G > memory.soft_limit_in_bytes
```

Note: Soft limits take effect over a long period of time, since they involve reclaiming memory for balancing between memory cgroups

Note: It is recommended to set the soft limit always below the hard limit, otherwise the hard limit will take precedence.

32.9.9 8. Move charges at task migration (DEPRECATED!)

THIS IS DEPRECATED!

It's expensive and unreliable! It's better practice to launch workload tasks directly from inside their target cgroup. Use dedicated workload cgroups to allow fine-grained policy adjustments without having to move physical pages between control domains.

Users can move charges associated with a task along with task migration, that is, uncharge task's pages from the old cgroup and charge them to the new cgroup. This feature is not supported in !CONFIG_MMU environments because of lack of page tables.

8.1 Interface

This feature is disabled by default. It can be enabled (and disabled again) by writing to memory.move_charge_at_immigrate of the destination cgroup.

If you want to enable it:

```
# echo (some positive value) > memory.move_charge_at_immigrate
```

Note: Each bits of move_charge_at_immigrate has its own meaning about what type of charges should be moved. See *section 8.2* for details.

Note: Charges are moved only when you move mm->owner, in other words, a leader of a thread group.

Note: If we cannot find enough space for the task in the destination cgroup, we try to make space by reclaiming memory. Task migration may fail if we cannot make enough space.

Note: It can take several seconds if you move charges much.

And if you want disable it again:

```
# echo 0 > memory.move_charge_at_immigrate
```

8.2 Type of charges which can be moved

Each bit in move_charge_at_immigrate has its own meaning about what type of charges should be moved. But in any case, it must be noted that an account of a page or a swap can be moved only when it is charged to the task's current (old) memory cgroup.

bit	what type of charges would be moved ?
0	A charge of an anonymous page (or swap of it) used by the target task. You must enable Swap Extension (see 2.4) to enable move of swap charges.
1	A charge of file pages (normal file, tmpfs file (e.g. ipc shared memory) and swaps of tmpfs file) mmapped by the target task. Unlike the case of anonymous pages, file pages (and swaps) in the range mmapped by the task will be moved even if the task hasn't done page fault, i.e. they might not be the task's "RSS", but other task's "RSS" that maps the same file. And mapcount of the page is ignored (the page can be moved even if page_mapcount(page) > 1). You must enable Swap Extension (see 2.4) to enable move of swap charges.

8.3 TODO

- All of moving charge operations are done under cgroup_mutex. It's not good behavior to hold the mutex too long, so we may need some trick.

32.9.10 9. Memory thresholds

Memory cgroup implements memory thresholds using the cgroups notification API (see cgroups.txt). It allows to register multiple memory and memsw thresholds and gets notifications when it crosses.

To register a threshold, an application must:

- create an eventfd using eventfd(2);
- open memory.usage_in_bytes or memory.memsw.usage_in_bytes;
- write string like "<event_fd> <fd of memory.usage_in_bytes> <threshold>" to cgroup.event_control.

Application will be notified through eventfd when memory usage crosses threshold in any direction.

It's applicable for root and non-root cgroup.

32.9.11 10. OOM Control

memory.oom_control file is for OOM notification and other controls.

Memory cgroup implements OOM notifier using the cgroup notification API (See cgroups.txt). It allows to register multiple OOM notification delivery and gets notification when OOM happens.

To register a notifier, an application must:

- create an eventfd using eventfd(2)
- open memory.oom_control file
- write string like "<event_fd> <fd of memory.oom_control>" to cgroup.event_control

The application will be notified through eventfd when OOM happens. OOM notification doesn't work for the root cgroup.

You can disable the OOM-killer by writing "1" to memory.oom_control file, as:

#echo 1 > memory.oom_control

If OOM-killer is disabled, tasks under cgroup will hang/sleep in memory cgroup's OOM-waitqueue when they request accountable memory.

For running them, you have to relax the memory cgroup's OOM status by

- enlarge limit or reduce usage.

To reduce usage,

- kill some tasks.
- move some tasks to other group with account migration.
- remove some files (on tmpfs?)

Then, stopped tasks will work again.

At reading, current status of OOM is shown.

- oom_kill_disable 0 or 1 (if 1, oom-killer is disabled)
- under_oom 0 or 1 (if 1, the memory cgroup is under OOM, tasks may be stopped.)
- oom_kill integer counter The number of processes belonging to this cgroup killed by any kind of OOM killer.

32.9.12 11. Memory Pressure

The pressure level notifications can be used to monitor the memory allocation cost; based on the pressure, applications can implement different strategies of managing their memory resources. The pressure levels are defined as following:

The ”low” level means that the system is reclaiming memory for new allocations. Monitoring this reclaiming activity might be useful for maintaining cache level. Upon notification, the program (typically ”Activity Manager”) might analyze vmstat and act in advance (i.e. prematurely shutdown unimportant services).

The ”medium” level means that the system is experiencing medium memory pressure, the system might be making swap, paging out active file caches, etc. Upon this event applications may decide to further analyze vmstat/zoneinfo/memcg or internal memory usage statistics and free any resources that can be easily reconstructed or re-read from a disk.

The ”critical” level means that the system is actively thrashing, it is about to out of memory (OOM) or even the in-kernel OOM killer is on its way to trigger. Applications should do whatever they can to help the system. It might be too late to consult with vmstat or any other statistics, so it's advisable to take an immediate action.

By default, events are propagated upward until the event is handled, i.e. the events are not pass-through. For example, you have three cgroups: A->B->C. Now you set up an event listener on cgroups A, B and C, and suppose group C experiences some pressure. In this situation, only group C will receive the notification, i.e. groups A and B will not receive it. This is done to avoid excessive ”broadcasting” of messages, which disturbs the system and which is especially bad if we are low on memory or thrashing. Group B, will receive notification only if there are no event listeners for group C.

There are three optional modes that specify different propagation behavior:

- ”default”: this is the default behavior specified above. This mode is the same as omitting the optional mode parameter, preserved by backwards compatibility.
- ”hierarchy”: events always propagate up to the root, similar to the default behavior, except that propagation continues regardless of whether there are event listeners at each level, with the ”hierarchy” mode. In the above example, groups A, B, and C will receive notification of memory pressure.
- ”local”: events are pass-through, i.e. they only receive notifications when memory pressure is experienced in the memcg for which the notification is registered. In the above example, group C will receive notification if registered for ”local” notification and the group experiences memory pressure. However, group B will never receive notification, regardless if there is an event listener for group C or not, if group B is registered for local notification.

The level and event notification mode (”hierarchy” or ”local”, if necessary) are specified by a comma-delimited string, i.e. ”low,hierarchy” specifies hierarchical, pass-through, notification for all ancestor memcgs. Notification that is the default, non pass-through behavior, does not specify a mode. ”medium,local” specifies pass-through notification for the medium level.

The file memory.pressure_level is only used to setup an eventfd. To register a notification, an application must:

- create an eventfd using eventfd(2);
- open memory.pressure_level;
- write string as ”<event_fd> <fd of memory.pressure_level> <level[,mode]>” to cgroup.event_control.

Application will be notified through eventfd when memory pressure is at the specific level (or higher). Read/write operations to memory.pressure_level are no implemented.

Test:

Here is a small script example that makes a new cgroup, sets up a memory limit, sets up a notification in the cgroup and then makes child cgroup experience a critical pressure:

```
# cd /sys/fs/cgroup/memory/
# mkdir foo
# cd foo
# cgroup_event_listener memory.pressure_level low,hierarchy &
# echo 8000000 > memory.limit_in_bytes
# echo 8000000 > memory.memsw.limit_in_bytes
# echo $$ > tasks
# dd if=/dev/zero | read x
```

(Expect a bunch of notifications, and eventually, the oom-killer will trigger.)

32.9.13 12. TODO

1. Make per-cgroup scanner reclaim not-shared pages first
2. Teach controller to account for shared-pages
3. Start reclamation in the background when the limit is not yet hit but the usage is getting closer

32.9.14 Summary

Overall, the memory controller has been a stable controller and has been commented and discussed quite extensively in the community.

32.10 Misc controller

Please refer "Misc" documentation in *Control Group v2*

32.11 Network classifier cgroup

The Network classifier cgroup provides an interface to tag network packets with a class identifier (classid).

The Traffic Controller (tc) can be used to assign different priorities to packets from different cgroups. Also, Netfilter (iptables) can use this tag to perform actions on such packets.

Creating a net_cls cgroups instance creates a net_cls.classid file. This net_cls.classid value is initialized to 0.

You can write hexadecimal values to net_cls.classid; the format for these values is 0xAAAABBBB; AAAA is the major handle number and BBBB is the minor handle number. Reading net_cls.classid yields a decimal result.

Example:

```
mkdir /sys/fs/cgroup/net_cls
mount -t cgroup -onet_cls net_cls /sys/fs/cgroup/net_cls
mkdir /sys/fs/cgroup/net_cls/0
echo 0x100001 >  /sys/fs/cgroup/net_cls/0/net_cls.classid
```

- setting a 10:1 handle:

```
cat /sys/fs/cgroup/net_cls/0/net_cls.classid
1048577
```

- configuring tc:

```
tc qdisc add dev eth0 root handle 10: htb
tc class add dev eth0 parent 10: classid 10:1 htb rate 40mbit
```

- creating traffic class 10:1:

```
tc filter add dev eth0 parent 10: protocol ip prio 10 handle 1: cgroup
```

configuring iptables, basic example:

```
iptables -A OUTPUT -m cgroup ! --cgroup 0x100001 -j DROP
```

32.12 Network priority cgroup

The Network priority cgroup provides an interface to allow an administrator to dynamically set the priority of network traffic generated by various applications

Nominally, an application would set the priority of its traffic via the SO_PRIORITY socket option. This however, is not always possible because:

1) The application may not have been coded to set this value
2) The priority of application traffic is often a site-specific administrative decision rather than an application defined one.

This cgroup allows an administrator to assign a process to a group which defines the priority of egress traffic on a given interface. Network priority groups can be created by first mounting the cgroup filesystem:

```
# mount -t cgroup -onet_prio none /sys/fs/cgroup/net_prio
```

With the above step, the initial group acting as the parent accounting group becomes visible at '/sys/fs/cgroup/net_prio'. This group includes all tasks in the system. '/sys/fs/cgroup/net_prio/tasks' lists the tasks in this cgroup.

Each net_prio cgroup contains two files that are subsystem specific

net_prio.prioidx
This file is read-only, and is simply informative. It contains a unique integer value that the kernel uses as an internal representation of this cgroup.

net_prio.ifpriomap
This file contains a map of the priorities assigned to traffic originating from processes in

this group and egressing the system on various interfaces. It contains a list of tuples in the form <ifname priority>. Contents of this file can be modified by echoing a string into the file using the same tuple format. For example:

```
echo "eth0 5" > /sys/fs/cgroups/net_prio/iscsi/net_prio.ifpriomap
```

This command would force any traffic originating from processes belonging to the iscsi net_prio cgroup and egressing on interface eth0 to have the priority of said traffic set to the value 5. The parent accounting group also has a writeable 'net_prio.ifpriomap' file that can be used to set a system default priority.

Priorities are set immediately prior to queueing a frame to the device queueing discipline (qdisc) so priorities will be assigned prior to the hardware queue selection being made.

One usage for the net_prio cgroup is with mqprio qdisc allowing application traffic to be steered to hardware/driver based traffic classes. These mappings can then be managed by administrators or other networking protocols such as DCBX.

A new net_prio cgroup inherits the parent's configuration.

32.13 Process Number Controller

32.13.1 Abstract

The process number controller is used to allow a cgroup hierarchy to stop any new tasks from being fork()'d or clone()'d after a certain limit is reached.

Since it is trivial to hit the task limit without hitting any kmemcg limits in place, PIDs are a fundamental resource. As such, PID exhaustion must be preventable in the scope of a cgroup hierarchy by allowing resource limiting of the number of tasks in a cgroup.

32.13.2 Usage

In order to use the *pids* controller, set the maximum number of tasks in pids.max (this is not available in the root cgroup for obvious reasons). The number of processes currently in the cgroup is given by pids.current.

Organisational operations are not blocked by cgroup policies, so it is possible to have pids.current > pids.max. This can be done by either setting the limit to be smaller than pids.current, or attaching enough processes to the cgroup such that pids.current > pids.max. However, it is not possible to violate a cgroup policy through fork() or clone(). fork() and clone() will return -EAGAIN if the creation of a new process would cause a cgroup policy to be violated.

To set a cgroup to have no limit, set pids.max to ”max”. This is the default for all new cgroups (N.B. that PID limits are hierarchical, so the most stringent limit in the hierarchy is followed).

pids.current tracks all child cgroup hierarchies, so parent/pids.current is a superset of parent/child/pids.current.

The pids.events file contains event counters:

- max: Number of times fork failed because limit was hit.

32.13.3 Example

First, we mount the pids controller:

```
# mkdir -p /sys/fs/cgroup/pids
# mount -t cgroup -o pids none /sys/fs/cgroup/pids
```

Then we create a hierarchy, set limits and attach processes to it:

```
# mkdir -p /sys/fs/cgroup/pids/parent/child
# echo 2 > /sys/fs/cgroup/pids/parent/pids.max
# echo $$ > /sys/fs/cgroup/pids/parent/cgroup.procs
# cat /sys/fs/cgroup/pids/parent/pids.current
2
#
```

It should be noted that attempts to overcome the set limit (2 in this case) will fail:

```
# cat /sys/fs/cgroup/pids/parent/pids.current
2
# ( /bin/echo "Here's some processes for you." | cat )
sh: fork: Resource temporary unavailable
#
```

Even if we migrate to a child cgroup (which doesn't have a set limit), we will not be able to overcome the most stringent limit in the hierarchy (in this case, parent's):

```
# echo $$ > /sys/fs/cgroup/pids/parent/child/cgroup.procs
# cat /sys/fs/cgroup/pids/parent/pids.current
2
# cat /sys/fs/cgroup/pids/parent/child/pids.current
2
# cat /sys/fs/cgroup/pids/parent/child/pids.max
max
# ( /bin/echo "Here's some processes for you." | cat )
sh: fork: Resource temporary unavailable
#
```

We can set a limit that is smaller than pids.current, which will stop any new processes from being forked at all (note that the shell itself counts towards pids.current):

```
# echo 1 > /sys/fs/cgroup/pids/parent/pids.max
# /bin/echo "We can't even spawn a single process now."
sh: fork: Resource temporary unavailable
# echo 0 > /sys/fs/cgroup/pids/parent/pids.max
# /bin/echo "We can't even spawn a single process now."
sh: fork: Resource temporary unavailable
#
```

32.14 RDMA Controller

32.14.1 1. Overview

1-1. What is RDMA controller?

RDMA controller allows user to limit RDMA/IB specific resources that a given set of processes can use. These processes are grouped using RDMA controller.

RDMA controller defines two resources which can be limited for processes of a cgroup.

1-2. Why RDMA controller needed?

Currently user space applications can easily take away all the rdma verb specific resources such as AH, CQ, QP, MR etc. Due to which other applications in other cgroup or kernel space ULPs may not even get chance to allocate any rdma resources. This can lead to service unavailability.

Therefore RDMA controller is needed through which resource consumption of processes can be limited. Through this controller different rdma resources can be accounted.

1-3. How is RDMA controller implemented?

RDMA cgroup allows limit configuration of resources. Rdma cgroup maintains resource accounting per cgroup, per device using resource pool structure. Each such resource pool is limited up to 64 resources in given resource pool by rdma cgroup, which can be extended later if required.

This resource pool object is linked to the cgroup css. Typically there are 0 to 4 resource pool instances per cgroup, per device in most use cases. But nothing limits to have it more. At present hundreds of RDMA devices per single cgroup may not be handled optimally, however there is no known use case or requirement for such configuration either.

Since RDMA resources can be allocated from any process and can be freed by any of the child processes which shares the address space, rdma resources are always owned by the creator cgroup css. This allows process migration from one to other cgroup without major complexity of transferring resource ownership; because such ownership is not really present due to shared nature of rdma resources. Linking resources around css also ensures that cgroups can be deleted after processes migrated. This allow progress migration as well with active resources, even though that is not a primary use case.

Whenever RDMA resource charging occurs, owner rdma cgroup is returned to the caller. Same rdma cgroup should be passed while uncharging the resource. This also allows process migrated with active RDMA resource to charge to new owner cgroup for new resource. It also allows to uncharge resource of a process from previously charged cgroup which is migrated to new cgroup, even though that is not a primary use case.

Resource pool object is created in following situations. (a) User sets the limit and no previous resource pool exist for the device of interest for the cgroup. (b) No resource limits were configured, but IB/RDMA stack tries to charge the resource. So that it correctly uncharge them when applications are running without limits and later on when limits are enforced during uncharging, otherwise usage count will drop to negative.

Resource pool is destroyed if all the resource limits are set to max and it is the last resource getting deallocated.

User should set all the limit to max value if it intents to remove/unconfigure the resource pool for a particular device.

IB stack honors limits enforced by the rdma controller. When application query about maximum resource limits of IB device, it returns minimum of what is configured by user for a given cgroup and what is supported by IB device.

Following resources can be accounted by rdma controller.

hca_handle	Maximum number of HCA Handles
hca_object	Maximum number of HCA Objects

32.14.2 2. Usage Examples

(a) Configure resource limit:

```
echo mlx4_0 hca_handle=2 hca_object=2000 > /sys/fs/cgroup/rdma/1/rdma.max
echo ocrdma1 hca_handle=3 > /sys/fs/cgroup/rdma/2/rdma.max
```

(b) Query resource limit:

```
cat /sys/fs/cgroup/rdma/2/rdma.max
#Output:
mlx4_0 hca_handle=2 hca_object=2000
ocrdma1 hca_handle=3 hca_object=max
```

(c) Query current usage:

```
cat /sys/fs/cgroup/rdma/2/rdma.current
#Output:
mlx4_0 hca_handle=1 hca_object=20
ocrdma1 hca_handle=1 hca_object=23
```

(d) Delete resource limit:

```
echo mlx4_0 hca_handle=max hca_object=max > /sys/fs/cgroup/rdma/1/rdma.max
```

CHAPTER

THIRTYTHREE

CONTROL GROUP V2

Date
October, 2015

Author
Tejun Heo <tj@kernel.org>

This is the authoritative documentation on the design, interface and conventions of cgroup v2. It describes all userland-visible aspects of cgroup including core and specific controller behaviors. All future changes must be reflected in this document. Documentation for v1 is available under *Documentation/admin-guide/cgroup-v1/index.rst*.

33.1 Introduction

33.1.1 Terminology

”cgroup” stands for ”control group” and is never capitalized. The singular form is used to designate the whole feature and also as a qualifier as in ”cgroup controllers”. When explicitly referring to multiple individual control groups, the plural form ”cgroups” is used.

33.1.2 What is cgroup?

cgroup is a mechanism to organize processes hierarchically and distribute system resources along the hierarchy in a controlled and configurable manner.

cgroup is largely composed of two parts - the core and controllers. cgroup core is primarily responsible for hierarchically organizing processes. A cgroup controller is usually responsible for distributing a specific type of system resource along the hierarchy although there are utility controllers which serve purposes other than resource distribution.

cgroups form a tree structure and every process in the system belongs to one and only one cgroup. All threads of a process belong to the same cgroup. On creation, all processes are put in the cgroup that the parent process belongs to at the time. A process can be migrated to another cgroup. Migration of a process doesn't affect already existing descendant processes.

Following certain structural constraints, controllers may be enabled or disabled selectively on a cgroup. All controller behaviors are hierarchical - if a controller is enabled on a cgroup, it affects all processes which belong to the cgroups consisting the inclusive sub-hierarchy of the cgroup. When a controller is enabled on a nested cgroup, it always restricts the resource distribution further. The restrictions set closer to the root in the hierarchy can not be overridden from further away.

33.2 Basic Operations

33.2.1 Mounting

Unlike v1, cgroup v2 has only single hierarchy. The cgroup v2 hierarchy can be mounted with the following mount command:

```
# mount -t cgroup2 none $MOUNT_POINT
```

cgroup2 filesystem has the magic number 0x63677270 (”cgrp”). All controllers which support v2 and are not bound to a v1 hierarchy are automatically bound to the v2 hierarchy and show up at the root. Controllers which are not in active use in the v2 hierarchy can be bound to other hierarchies. This allows mixing v2 hierarchy with the legacy v1 multiple hierarchies in a fully backward compatible way.

A controller can be moved across hierarchies only after the controller is no longer referenced in its current hierarchy. Because per-cgroup controller states are destroyed asynchronously and controllers may have lingering references, a controller may not show up immediately on the v2 hierarchy after the final umount of the previous hierarchy. Similarly, a controller should be fully disabled to be moved out of the unified hierarchy and it may take some time for the disabled controller to become available for other hierarchies; furthermore, due to inter-controller dependencies, other controllers may need to be disabled too.

While useful for development and manual configurations, moving controllers dynamically between the v2 and other hierarchies is strongly discouraged for production use. It is recommended to decide the hierarchies and controller associations before starting using the controllers after system boot.

During transition to v2, system management software might still automount the v1 cgroup filesystem and so hijack all controllers during boot, before manual intervention is possible. To make testing and experimenting easier, the kernel parameter cgroup_no_v1= allows disabling controllers in v1 and make them always available in v2.

cgroup v2 currently supports the following mount options.

nsdelegate
Consider cgroup namespaces as delegation boundaries. This option is system wide and can only be set on mount or modified through remount from the init namespace. The mount option is ignored on non-init namespace mounts. Please refer to the Delegation section for details.

favordynmods
Reduce the latencies of dynamic cgroup modifications such as task migrations and controller on/offs at the cost of making hot path operations such as forks and exits more expensive. The static usage pattern of creating a cgroup, enabling controllers, and then seeding it with CLONE_INTO_CGROUP is not affected by this option.

memory_localevents
Only populate memory.events with data for the current cgroup, and not any subtrees. This is legacy behaviour, the default behaviour without this option is to include subtree counts. This option is system wide and can only be set on mount or modified through remount from the init namespace. The mount option is ignored on non-init namespace mounts.

memory_recursiveprot
Recursively apply memory.min and memory.low protection to entire subtrees, without requiring explicit downward propagation into leaf cgroups. This allows protecting entire subtrees from one another, while retaining free competition within those subtrees. This should have been the default behavior but is a mount-option to avoid regressing setups relying on the original semantics (e.g. specifying bogusly high 'bypass' protection values at higher tree levels).

memory_hugetlb_accounting
Count HugeTLB memory usage towards the cgroup's overall memory usage for the memory controller (for the purpose of statistics reporting and memory protetion). This is a new behavior that could regress existing setups, so it must be explicitly opted in with this mount option.

A few caveats to keep in mind:

- There is no HugeTLB pool management involved in the memory controller. The pre-allocated pool does not belong to anyone. Specifically, when a new HugeTLB folio is allocated to the pool, it is not accounted for from the perspective of the memory controller. It is only charged to a cgroup when it is actually used (for e.g at page fault time). Host memory overcommit management has to consider this when configuring hard limits. In general, HugeTLB pool management should be done via other mechanisms (such as the HugeTLB controller).
- Failure to charge a HugeTLB folio to the memory controller results in SIGBUS. This could happen even if the HugeTLB pool still has pages available (but the cgroup limit is hit and reclaim attempt fails).
- Charging HugeTLB memory towards the memory controller affects memory protection and reclaim dynamics. Any userspace tuning (of low, min limits for e.g) needs to take this into account.
- HugeTLB pages utilized while this option is not selected will not be tracked by the memory controller (even if cgroup v2 is remounted later on).

33.2.2 Organizing Processes and Threads

Processes

Initially, only the root cgroup exists to which all processes belong. A child cgroup can be created by creating a sub-directory:

```
# mkdir $CGROUP_NAME
```

A given cgroup may have multiple child cgroups forming a tree structure. Each cgroup has a read-writable interface file ”cgroup.procs”. When read, it lists the PIDs of all processes which belong to the cgroup one-per-line. The PIDs are not ordered and the same PID may show up more than once if the process got moved to another cgroup and then back or the PID got recycled while reading.

A process can be migrated into a cgroup by writing its PID to the target cgroup's ”cgroup.procs” file. Only one process can be migrated on a single write(2) call. If a process is composed of multiple threads, writing the PID of any thread migrates all threads of the process.

When a process forks a child process, the new process is born into the cgroup that the forking process belongs to at the time of the operation. After exit, a process stays associated with the cgroup that it belonged to at the time of exit until it's reaped; however, a zombie process does not appear in ”cgroup.procs” and thus can't be moved to another cgroup.

A cgroup which doesn't have any children or live processes can be destroyed by removing the directory. Note that a cgroup which doesn't have any children and is associated only with zombie processes is considered empty and can be removed:

```
# rmdir $CGROUP_NAME
```

”/proc/$PID/cgroup” lists a process's cgroup membership. If legacy cgroup is in use in the system, this file may contain multiple lines, one for each hierarchy. The entry for cgroup v2 is always in the format ”0::$PATH”:

```
# cat /proc/842/cgroup
...
0::/test-cgroup/test-cgroup-nested
```

If the process becomes a zombie and the cgroup it was associated with is removed subsequently, ” (deleted)” is appended to the path:

```
# cat /proc/842/cgroup
...
0::/test-cgroup/test-cgroup-nested (deleted)
```

Threads

cgroup v2 supports thread granularity for a subset of controllers to support use cases requiring hierarchical resource distribution across the threads of a group of processes. By default, all threads of a process belong to the same cgroup, which also serves as the resource domain to host resource consumptions which are not specific to a process or thread. The thread mode allows threads to be spread across a subtree while still maintaining the common resource domain for them.

Controllers which support thread mode are called threaded controllers. The ones which don't are called domain controllers.

Marking a cgroup threaded makes it join the resource domain of its parent as a threaded cgroup. The parent may be another threaded cgroup whose resource domain is further up in the hierarchy. The root of a threaded subtree, that is, the nearest ancestor which is not threaded, is called threaded domain or thread root interchangeably and serves as the resource domain for the entire subtree.

Inside a threaded subtree, threads of a process can be put in different cgroups and are not subject to the no internal process constraint - threaded controllers can be enabled on non-leaf cgroups whether they have threads in them or not.

As the threaded domain cgroup hosts all the domain resource consumptions of the subtree, it is considered to have internal resource consumptions whether there are processes in it or not and can't have populated child cgroups which aren't threaded. Because the root cgroup is not subject to no internal process constraint, it can serve both as a threaded domain and a parent to domain cgroups.

The current operation mode or type of the cgroup is shown in the "cgroup.type" file which indicates whether the cgroup is a normal domain, a domain which is serving as the domain of a threaded subtree, or a threaded cgroup.

On creation, a cgroup is always a domain cgroup and can be made threaded by writing "threaded" to the "cgroup.type" file. The operation is single direction:

```
# echo threaded > cgroup.type
```

Once threaded, the cgroup can't be made a domain again. To enable the thread mode, the following conditions must be met.

- As the cgroup will join the parent's resource domain. The parent must either be a valid (threaded) domain or a threaded cgroup.
- When the parent is an unthreaded domain, it must not have any domain controllers enabled or populated domain children. The root is exempt from this requirement.

Topology-wise, a cgroup can be in an invalid state. Please consider the following topology:

```
A (threaded domain) - B (threaded) - C (domain, just created)
```

C is created as a domain but isn't connected to a parent which can host child domains. C can't be used until it is turned into a threaded cgroup. "cgroup.type" file will report "domain (invalid)" in these cases. Operations which fail due to invalid topology use EOPNOTSUPP as the errno.

A domain cgroup is turned into a threaded domain when one of its child cgroup becomes threaded or threaded controllers are enabled in the "cgroup.subtree_control" file while there are processes in the cgroup. A threaded domain reverts to a normal domain when the conditions clear.

When read, "cgroup.threads" contains the list of the thread IDs of all threads in the cgroup. Except that the operations are per-thread instead of per-process, "cgroup.threads" has the same format and behaves the same way as "cgroup.procs". While "cgroup.threads" can be written to in any cgroup, as it can only move threads inside the same threaded domain, its operations are confined inside each threaded subtree.

The threaded domain cgroup serves as the resource domain for the whole subtree, and, while the threads can be scattered across the subtree, all the processes are considered to be in the threaded domain cgroup. "cgroup.procs" in a threaded domain cgroup contains the PIDs of all processes in the subtree and is not readable in the subtree proper. However, "cgroup.procs" can be written to from anywhere in the subtree to migrate all threads of the matching process to the cgroup.

Only threaded controllers can be enabled in a threaded subtree. When a threaded controller is enabled inside a threaded subtree, it only accounts for and controls resource consumptions associated with the threads in the cgroup and its descendants. All consumptions which aren't tied to a specific thread belong to the threaded domain cgroup.

Because a threaded subtree is exempt from no internal process constraint, a threaded controller must be able to handle competition between threads in a non-leaf cgroup and its child cgroups. Each threaded controller defines how such competitions are handled.

Currently, the following controllers are threaded and can be enabled in a threaded cgroup:

```
- cpu
- cpuset
```

```
- perf_event
- pids
```

33.2.3 [Un]populated Notification

Each non-root cgroup has a ”cgroup.events” file which contains ”populated” field indicating whether the cgroup's sub-hierarchy has live processes in it. Its value is 0 if there is no live process in the cgroup and its descendants; otherwise, 1. poll and [id]notify events are triggered when the value changes. This can be used, for example, to start a clean-up operation after all processes of a given sub-hierarchy have exited. The populated state updates and notifications are recursive. Consider the following sub-hierarchy where the numbers in the parentheses represent the numbers of processes in each cgroup:

```
A(4) - B(0) - C(1)
            \ D(0)
```

A, B and C's ”populated” fields would be 1 while D's 0. After the one process in C exits, B and C's ”populated” fields would flip to ”0” and file modified events will be generated on the ”cgroup.events” files of both cgroups.

33.2.4 Controlling Controllers

Enabling and Disabling

Each cgroup has a ”cgroup.controllers” file which lists all controllers available for the cgroup to enable:

```
# cat cgroup.controllers
cpu io memory
```

No controller is enabled by default. Controllers can be enabled and disabled by writing to the ”cgroup.subtree_control” file:

```
# echo "+cpu +memory -io" > cgroup.subtree_control
```

Only controllers which are listed in ”cgroup.controllers” can be enabled. When multiple operations are specified as above, either they all succeed or fail. If multiple operations on the same controller are specified, the last one is effective.

Enabling a controller in a cgroup indicates that the distribution of the target resource across its immediate children will be controlled. Consider the following sub-hierarchy. The enabled controllers are listed in parentheses:

```
A(cpu,memory) - B(memory) - C()
                          \ D()
```

As A has ”cpu” and ”memory” enabled, A will control the distribution of CPU cycles and memory to its children, in this case, B. As B has ”memory” enabled but not ”CPU”, C and D will compete freely on CPU cycles but their division of memory available to B will be controlled.

As a controller regulates the distribution of the target resource to the cgroup's children, enabling it creates the controller's interface files in the child cgroups. In the above example, enabling ”cpu” on B would create the ”cpu.” prefixed controller interface files in C and D. Likewise, disabling ”memory” from B would remove the ”memory.” prefixed controller interface files from C and D. This means that the controller interface files - anything which doesn't start with ”cgroup.” are owned by the parent rather than the cgroup itself.

Top-down Constraint

Resources are distributed top-down and a cgroup can further distribute a resource only if the resource has been distributed to it from the parent. This means that all non-root ”cgroup.subtree_control” files can only contain controllers which are enabled in the parent's ”cgroup.subtree_control” file. A controller can be enabled only if the parent has the controller enabled and a controller can't be disabled if one or more children have it enabled.

No Internal Process Constraint

Non-root cgroups can distribute domain resources to their children only when they don't have any processes of their own. In other words, only domain cgroups which don't contain any processes can have domain controllers enabled in their ”cgroup.subtree_control” files.

This guarantees that, when a domain controller is looking at the part of the hierarchy which has it enabled, processes are always only on the leaves. This rules out situations where child cgroups compete against internal processes of the parent.

The root cgroup is exempt from this restriction. Root contains processes and anonymous resource consumption which can't be associated with any other cgroups and requires special treatment from most controllers. How resource consumption in the root cgroup is governed is up to each controller (for more information on this topic please refer to the Non-normative information section in the Controllers chapter).

Note that the restriction doesn't get in the way if there is no enabled controller in the cgroup's ”cgroup.subtree_control”. This is important as otherwise it wouldn't be possible to create children of a populated cgroup. To control resource distribution of a cgroup, the cgroup must create children and transfer all its processes to the children before enabling controllers in its ”cgroup.subtree_control” file.

33.2.5 Delegation

Model of Delegation

A cgroup can be delegated in two ways. First, to a less privileged user by granting write access of the directory and its ”cgroup.procs”, ”cgroup.threads” and ”cgroup.subtree_control” files to the user. Second, if the ”nsdelegate” mount option is set, automatically to a cgroup namespace on namespace creation.

Because the resource control interface files in a given directory control the distribution of the parent's resources, the delegatee shouldn't be allowed to write to them. For the first method, this is achieved by not granting access to these files. For the second, the kernel rejects writes to all files other than ”cgroup.procs” and ”cgroup.subtree_control” on a namespace root from inside the namespace.

The end results are equivalent for both delegation types. Once delegated, the user can build sub-hierarchy under the directory, organize processes inside it as it sees fit and further distribute the resources it received from the parent. The limits and other settings of all resource controllers are hierarchical and regardless of what happens in the delegated sub-hierarchy, nothing can escape the resource restrictions imposed by the parent.

Currently, cgroup doesn't impose any restrictions on the number of cgroups in or nesting depth of a delegated sub-hierarchy; however, this may be limited explicitly in the future.

Delegation Containment

A delegated sub-hierarchy is contained in the sense that processes can't be moved into or out of the sub-hierarchy by the delegatee.

For delegations to a less privileged user, this is achieved by requiring the following conditions for a process with a non-root euid to migrate a target process into a cgroup by writing its PID to the ”cgroup.procs” file.

- The writer must have write access to the ”cgroup.procs” file.
- The writer must have write access to the ”cgroup.procs” file of the common ancestor of the source and destination cgroups.

The above two constraints ensure that while a delegatee may migrate processes around freely in the delegated sub-hierarchy it can't pull in from or push out to outside the sub-hierarchy.

For an example, let's assume cgroups C0 and C1 have been delegated to user U0 who created C00, C01 under C0 and C10 under C1 as follows and all processes under C0 and C1 belong to U0:

```
~~~~~~~~~~~~~ - C0 - C00
~ cgroup    ~      \ C01
~ hierarchy ~
~~~~~~~~~~~~~ - C1 - C10
```

Let's also say U0 wants to write the PID of a process which is currently in C10 into ”C00/cgroup.procs”. U0 has write access to the file; however, the common ancestor of the source cgroup C10 and the destination cgroup C00 is above the points of delegation and U0 would not have write access to its ”cgroup.procs” files and thus the write will be denied with -EACCES.

For delegations to namespaces, containment is achieved by requiring that both the source and destination cgroups are reachable from the namespace of the process which is attempting the migration. If either is not reachable, the migration is rejected with -ENOENT.

33.2.6 Guidelines

Organize Once and Control

Migrating a process across cgroups is a relatively expensive operation and stateful resources such as memory are not moved together with the process. This is an explicit design decision as there often exist inherent trade-offs between migration and various hot paths in terms of synchronization cost.

As such, migrating processes across cgroups frequently as a means to apply different resource restrictions is discouraged. A workload should be assigned to a cgroup according to the system's logical and resource structure once on start-up. Dynamic adjustments to resource distribution can be made by changing controller configuration through the interface files.

Avoid Name Collisions

Interface files for a cgroup and its children cgroups occupy the same directory and it is possible to create children cgroups which collide with interface files.

All cgroup core interface files are prefixed with ”cgroup.” and each controller's interface files are prefixed with the controller name and a dot. A controller's name is composed of lower case alphabets and '_'s but never begins with an '_' so it can be used as the prefix character for collision avoidance. Also, interface file names won't start or end with terms which are often used in categorizing workloads such as job, service, slice, unit or workload.

cgroup doesn't do anything to prevent name collisions and it's the user's responsibility to avoid them.

33.3 Resource Distribution Models

cgroup controllers implement several resource distribution schemes depending on the resource type and expected use cases. This section describes major schemes in use along with their expected behaviors.

33.3.1 Weights

A parent's resource is distributed by adding up the weights of all active children and giving each the fraction matching the ratio of its weight against the sum. As only children which can make use of the resource at the moment participate in the distribution, this is work-conserving. Due to the dynamic nature, this model is usually used for stateless resources.

All weights are in the range [1, 10000] with the default at 100. This allows symmetric multiplicative biases in both directions at fine enough granularity while staying in the intuitive range.

As long as the weight is in range, all configuration combinations are valid and there is no reason to reject configuration changes or process migrations.

”cpu.weight” proportionally distributes CPU cycles to active children and is an example of this type.

33.3.2 Limits

A child can only consume up to the configured amount of the resource. Limits can be over-committed - the sum of the limits of children can exceed the amount of resource available to the parent.

Limits are in the range [0, max] and defaults to ”max”, which is noop.

As limits can be over-committed, all configuration combinations are valid and there is no reason to reject configuration changes or process migrations.

”io.max” limits the maximum BPS and/or IOPS that a cgroup can consume on an IO device and is an example of this type.

33.3.3 Protections

A cgroup is protected up to the configured amount of the resource as long as the usages of all its ancestors are under their protected levels. Protections can be hard guarantees or best effort soft boundaries. Protections can also be over-committed in which case only up to the amount available to the parent is protected among children.

Protections are in the range [0, max] and defaults to 0, which is noop.

As protections can be over-committed, all configuration combinations are valid and there is no reason to reject configuration changes or process migrations.

”memory.low” implements best-effort memory protection and is an example of this type.

33.3.4 Allocations

A cgroup is exclusively allocated a certain amount of a finite resource. Allocations can't be over-committed - the sum of the allocations of children can not exceed the amount of resource available to the parent.

Allocations are in the range [0, max] and defaults to 0, which is no resource.

As allocations can't be over-committed, some configuration combinations are invalid and should be rejected. Also, if the resource is mandatory for execution of processes, process migrations may be rejected.

”cpu.rt.max” hard-allocates realtime slices and is an example of this type.

33.4 Interface Files

33.4.1 Format

All interface files should be in one of the following formats whenever possible:

```
New-line separated values
(when only one value can be written at once)

      VAL0\n
      VAL1\n
```

```
      ...

Space separated values
(when read-only or multiple values can be written at once)

      VAL0 VAL1 ...\n

Flat keyed

      KEY0 VAL0\n
      KEY1 VAL1\n
      ...

Nested keyed

      KEY0 SUB_KEY0=VAL00 SUB_KEY1=VAL01...
      KEY1 SUB_KEY0=VAL10 SUB_KEY1=VAL11...
      ...
```

For a writable file, the format for writing should generally match reading; however, controllers may allow omitting later fields or implement restricted shortcuts for most common use cases.

For both flat and nested keyed files, only the values for a single key can be written at a time. For nested keyed files, the sub key pairs may be specified in any order and not all pairs have to be specified.

33.4.2 Conventions

- Settings for a single feature should be contained in a single file.
- The root cgroup should be exempt from resource control and thus shouldn't have resource control interface files.
- The default time unit is microseconds. If a different unit is ever used, an explicit unit suffix must be present.
- A parts-per quantity should use a percentage decimal with at least two digit fractional part - e.g. 13.40.
- If a controller implements weight based resource distribution, its interface file should be named "weight" and have the range [1, 10000] with 100 as the default. The values are chosen to allow enough and symmetric bias in both directions while keeping it intuitive (the default is 100%).
- If a controller implements an absolute resource guarantee and/or limit, the interface files should be named "min" and "max" respectively. If a controller implements best effort resource guarantee and/or limit, the interface files should be named "low" and "high" respectively.

  In the above four control files, the special token "max" should be used to represent upward infinity for both reading and writing.
- If a setting has a configurable default value and keyed specific overrides, the default entry should be keyed with "default" and appear as the first entry in the file.

The default value can be updated by writing either ”default $VAL” or ”$VAL”.

When writing to update a specific override, ”default” can be used as the value to indicate removal of the override. Override entries with ”default” as the value must not appear when read.

For example, a setting which is keyed by major:minor device numbers with integer values may look like the following:

```
# cat cgroup-example-interface-file
default 150
8:0 300
```

The default value can be updated by:

```
# echo 125 > cgroup-example-interface-file
```

or:

```
# echo "default 125" > cgroup-example-interface-file
```

An override can be set by:

```
# echo "8:16 170" > cgroup-example-interface-file
```

and cleared by:

```
# echo "8:0 default" > cgroup-example-interface-file
# cat cgroup-example-interface-file
default 125
8:16 170
```

- For events which are not very high frequency, an interface file ”events” should be created which lists event key value pairs. Whenever a notifiable event happens, file modified event should be generated on the file.

33.4.3 Core Interface Files

All cgroup core files are prefixed with ”cgroup.”

cgroup.type

A read-write single value file which exists on non-root cgroups.

When read, it indicates the current type of the cgroup, which can be one of the following values.

- ”domain” : A normal valid domain cgroup.
- ”domain threaded” : A threaded domain cgroup which is serving as the root of a threaded subtree.
- ”domain invalid” : A cgroup which is in an invalid state. It can't be populated or have controllers enabled. It may be allowed to become a threaded cgroup.
- ”threaded” : A threaded cgroup which is a member of a threaded subtree.

A cgroup can be turned into a threaded cgroup by writing "threaded" to this file.

cgroup.procs
A read-write new-line separated values file which exists on all cgroups.

When read, it lists the PIDs of all processes which belong to the cgroup one-per-line. The PIDs are not ordered and the same PID may show up more than once if the process got moved to another cgroup and then back or the PID got recycled while reading.

A PID can be written to migrate the process associated with the PID to the cgroup. The writer should match all of the following conditions.

- It must have write access to the "cgroup.procs" file.
- It must have write access to the "cgroup.procs" file of the common ancestor of the source and destination cgroups.

When delegating a sub-hierarchy, write access to this file should be granted along with the containing directory.

In a threaded cgroup, reading this file fails with EOPNOTSUPP as all the processes belong to the thread root. Writing is supported and moves every thread of the process to the cgroup.

cgroup.threads
A read-write new-line separated values file which exists on all cgroups.

When read, it lists the TIDs of all threads which belong to the cgroup one-per-line. The TIDs are not ordered and the same TID may show up more than once if the thread got moved to another cgroup and then back or the TID got recycled while reading.

A TID can be written to migrate the thread associated with the TID to the cgroup. The writer should match all of the following conditions.

- It must have write access to the "cgroup.threads" file.
- The cgroup that the thread is currently in must be in the same resource domain as the destination cgroup.
- It must have write access to the "cgroup.procs" file of the common ancestor of the source and destination cgroups.

When delegating a sub-hierarchy, write access to this file should be granted along with the containing directory.

cgroup.controllers
A read-only space separated values file which exists on all cgroups.

It shows space separated list of all controllers available to the cgroup. The controllers are not ordered.

cgroup.subtree_control
A read-write space separated values file which exists on all cgroups. Starts out empty.

When read, it shows space separated list of the controllers which are enabled to control resource distribution from the cgroup to its children.

Space separated list of controllers prefixed with '+' or '-' can be written to enable or disable controllers. A controller name prefixed with '+' enables the controller and '-' disables. If a controller appears more than once on the list, the last one is effective. When multiple enable and disable operations are specified, either all succeed or all fail.

cgroup.events
A read-only flat-keyed file which exists on non-root cgroups. The following entries are defined. Unless specified otherwise, a value change in this file generates a file modified event.

populated
1 if the cgroup or its descendants contains any live processes; otherwise, 0.

frozen
1 if the cgroup is frozen; otherwise, 0.

cgroup.max.descendants
A read-write single value files. The default is ”max”.

Maximum allowed number of descent cgroups. If the actual number of descendants is equal or larger, an attempt to create a new cgroup in the hierarchy will fail.

cgroup.max.depth
A read-write single value files. The default is ”max”.

Maximum allowed descent depth below the current cgroup. If the actual descent depth is equal or larger, an attempt to create a new child cgroup will fail.

cgroup.stat
A read-only flat-keyed file with the following entries:

nr_descendants
Total number of visible descendant cgroups.

nr_dying_descendants
Total number of dying descendant cgroups. A cgroup becomes dying after being deleted by a user. The cgroup will remain in dying state for some time undefined time (which can depend on system load) before being completely destroyed.

A process can't enter a dying cgroup under any circumstances, a dying cgroup can't revive.

A dying cgroup can consume system resources not exceeding limits, which were active at the moment of cgroup deletion.

cgroup.freeze
A read-write single value file which exists on non-root cgroups. Allowed values are ”0” and ”1”. The default is ”0”.

Writing ”1” to the file causes freezing of the cgroup and all descendant cgroups. This means that all belonging processes will be stopped and will not run until the cgroup will be explicitly unfrozen. Freezing of the cgroup may take some time; when this action is completed, the ”frozen” value in the cgroup.events control file will be updated to ”1” and the corresponding notification will be issued.

A cgroup can be frozen either by its own settings, or by settings of any ancestor cgroups. If any of ancestor cgroups is frozen, the cgroup will remain frozen.

Processes in the frozen cgroup can be killed by a fatal signal. They also can enter and leave a frozen cgroup: either by an explicit move by a user, or if freezing of the cgroup races with fork(). If a process is moved to a frozen cgroup, it stops. If a process is moved out of a frozen cgroup, it becomes running.

Frozen status of a cgroup doesn't affect any cgroup tree operations: it's possible to delete a frozen (and empty) cgroup, as well as create new sub-cgroups.

cgroup.kill
A write-only single value file which exists in non-root cgroups. The only allowed value is "1".

Writing "1" to the file causes the cgroup and all descendant cgroups to be killed. This means that all processes located in the affected cgroup tree will be killed via SIGKILL.

Killing a cgroup tree will deal with concurrent forks appropriately and is protected against migrations.

In a threaded cgroup, writing this file fails with EOPNOTSUPP as killing cgroups is a process directed operation, i.e. it affects the whole thread-group.

cgroup.pressure
A read-write single value file that allowed values are "0" and "1". The default is "1".

Writing "0" to the file will disable the cgroup PSI accounting. Writing "1" to the file will re-enable the cgroup PSI accounting.

This control attribute is not hierarchical, so disable or enable PSI accounting in a cgroup does not affect PSI accounting in descendants and doesn't need pass enablement via ancestors from root.

The reason this control attribute exists is that PSI accounts stalls for each cgroup separately and aggregates it at each level of the hierarchy. This may cause non-negligible overhead for some workloads when under deep level of the hierarchy, in which case this control attribute can be used to disable PSI accounting in the non-leaf cgroups.

irq.pressure
A read-write nested-keyed file.

Shows pressure stall information for IRQ/SOFTIRQ. See Documentation/accounting/psi.rst for details.

33.5 Controllers

33.5.1 CPU

The ”cpu” controllers regulates distribution of CPU cycles. This controller implements weight and absolute bandwidth limit models for normal scheduling policy and absolute bandwidth allocation model for realtime scheduling policy.

In all the above models, cycles distribution is defined only on a temporal base and it does not account for the frequency at which tasks are executed. The (optional) utilization clamping support allows to hint the schedutil cpufreq governor about the minimum desired frequency which should always be provided by a CPU, as well as the maximum desired frequency, which should not be exceeded by a CPU.

WARNING: cgroup2 doesn't yet support control of realtime processes and the cpu controller can only be enabled when all RT processes are in the root cgroup. Be aware that system management software may already have placed RT processes into nonroot cgroups during the system boot process, and these processes may need to be moved to the root cgroup before the cpu controller can be enabled.

CPU Interface Files

All time durations are in microseconds.

cpu.stat
A read-only flat-keyed file. This file exists whether the controller is enabled or not.

It always reports the following three stats:

- usage_usec
- user_usec
- system_usec

and the following five when the controller is enabled:

- nr_periods
- nr_throttled
- throttled_usec
- nr_bursts
- burst_usec

cpu.weight
A read-write single value file which exists on non-root cgroups. The default is ”100”.

For non idle groups (cpu.idle = 0), the weight is in the range [1, 10000].

If the cgroup has been configured to be SCHED_IDLE (cpu.idle = 1), then the weight will show as a 0.

cpu.weight.nice

A read-write single value file which exists on non-root cgroups. The default is "0".

The nice value is in the range [-20, 19].

This interface file is an alternative interface for "cpu.weight" and allows reading and setting weight using the same values used by nice(2). Because the range is smaller and granularity is coarser for the nice values, the read value is the closest approximation of the current weight.

cpu.max

A read-write two value file which exists on non-root cgroups. The default is "max 100000".

The maximum bandwidth limit. It's in the following format:

```
$MAX $PERIOD
```

which indicates that the group may consume up to $MAX in each $PERIOD duration. "max" for $MAX indicates no limit. If only one number is written, $MAX is updated.

cpu.max.burst

A read-write single value file which exists on non-root cgroups. The default is "0".

The burst in the range [0, $MAX].

cpu.pressure

A read-write nested-keyed file.

Shows pressure stall information for CPU. See Documentation/accounting/psi.rst for details.

cpu.uclamp.min

A read-write single value file which exists on non-root cgroups. The default is "0", i.e. no utilization boosting.

The requested minimum utilization (protection) as a percentage rational number, e.g. 12.34 for 12.34%.

This interface allows reading and setting minimum utilization clamp values similar to the sched_setattr(2). This minimum utilization value is used to clamp the task specific minimum utilization clamp.

The requested minimum utilization (protection) is always capped by the current value for the maximum utilization (limit), i.e. *cpu.uclamp.max*.

cpu.uclamp.max

A read-write single value file which exists on non-root cgroups. The default is "max". i.e. no utilization capping

The requested maximum utilization (limit) as a percentage rational number, e.g. 98.76 for 98.76%.

This interface allows reading and setting maximum utilization clamp values similar to the sched_setattr(2). This maximum utilization value is used to clamp the task specific maximum utilization clamp.

cpu.idle
A read-write single value file which exists on non-root cgroups. The default is 0.

This is the cgroup analog of the per-task SCHED_IDLE sched policy. Setting this value to a 1 will make the scheduling policy of the cgroup SCHED_IDLE. The threads inside the cgroup will retain their own relative priorities, but the cgroup itself will be treated as very low priority relative to its peers.

33.5.2 Memory

The "memory" controller regulates distribution of memory. Memory is stateful and implements both limit and protection models. Due to the intertwining between memory usage and reclaim pressure and the stateful nature of memory, the distribution model is relatively complex.

While not completely water-tight, all major memory usages by a given cgroup are tracked so that the total memory consumption can be accounted and controlled to a reasonable extent. Currently, the following types of memory usages are tracked.

- Userland memory - page cache and anonymous memory.
- Kernel data structures such as dentries and inodes.
- TCP socket buffers.

The above list may expand in the future for better coverage.

Memory Interface Files

All memory amounts are in bytes. If a value which is not aligned to PAGE_SIZE is written, the value may be rounded up to the closest PAGE_SIZE multiple when read back.

memory.current
A read-only single value file which exists on non-root cgroups.

The total amount of memory currently being used by the cgroup and its descendants.

memory.min
A read-write single value file which exists on non-root cgroups. The default is "0".

Hard memory protection. If the memory usage of a cgroup is within its effective min boundary, the cgroup's memory won't be reclaimed under any conditions. If there is no unprotected reclaimable memory available, OOM killer is invoked. Above the effective min boundary (or effective low boundary if it is higher), pages are reclaimed proportionally to the overage, reducing reclaim pressure for smaller overages.

Effective min boundary is limited by memory.min values of all ancestor cgroups. If there is memory.min overcommitment (child cgroup or cgroups are requiring more protected memory than parent will allow), then each child cgroup will get the part of parent's protection proportional to its actual memory usage below memory.min.

Putting more memory than generally available under this protection is discouraged and may lead to constant OOMs.

If a memory cgroup is not populated with processes, its memory.min is ignored.

memory.low

A read-write single value file which exists on non-root cgroups. The default is "0".

Best-effort memory protection. If the memory usage of a cgroup is within its effective low boundary, the cgroup's memory won't be reclaimed unless there is no reclaimable memory available in unprotected cgroups. Above the effective low boundary (or effective min boundary if it is higher), pages are reclaimed proportionally to the overage, reducing reclaim pressure for smaller overages.

Effective low boundary is limited by memory.low values of all ancestor cgroups. If there is memory.low overcommitment (child cgroup or cgroups are requiring more protected memory than parent will allow), then each child cgroup will get the part of parent's protection proportional to its actual memory usage below memory.low.

Putting more memory than generally available under this protection is discouraged.

memory.high

A read-write single value file which exists on non-root cgroups. The default is "max".

Memory usage throttle limit. If a cgroup's usage goes over the high boundary, the processes of the cgroup are throttled and put under heavy reclaim pressure.

Going over the high limit never invokes the OOM killer and under extreme conditions the limit may be breached. The high limit should be used in scenarios where an external process monitors the limited cgroup to alleviate heavy reclaim pressure.

memory.max

A read-write single value file which exists on non-root cgroups. The default is "max".

Memory usage hard limit. This is the main mechanism to limit memory usage of a cgroup. If a cgroup's memory usage reaches this limit and can't be reduced, the OOM killer is invoked in the cgroup. Under certain circumstances, the usage may go over the limit temporarily.

In default configuration regular 0-order allocations always succeed unless OOM killer chooses current task as a victim.

Some kinds of allocations don't invoke the OOM killer. Caller could retry them differently, return into userspace as -ENOMEM or silently ignore in cases like disk readahead.

memory.reclaim

A write-only nested-keyed file which exists for all cgroups.

This is a simple interface to trigger memory reclaim in the target cgroup.

This file accepts a single key, the number of bytes to reclaim. No nested keys are currently supported.

Example:

```
echo "1G" > memory.reclaim
```

The interface can be later extended with nested keys to configure the reclaim behavior. For example, specify the type of memory to reclaim from (anon, file, ..).

Please note that the kernel can over or under reclaim from the target cgroup. If less bytes are reclaimed than the specified amount, -EAGAIN is returned.

Please note that the proactive reclaim (triggered by this interface) is not meant to indicate memory pressure on the memory cgroup. Therefore socket memory balancing triggered by the memory reclaim normally is not exercised in this case. This means that the networking layer will not adapt based on reclaim induced by memory.reclaim.

memory.peak
A read-only single value file which exists on non-root cgroups.

The max memory usage recorded for the cgroup and its descendants since the creation of the cgroup.

memory.oom.group
A read-write single value file which exists on non-root cgroups. The default value is "0".

Determines whether the cgroup should be treated as an indivisible workload by the OOM killer. If set, all tasks belonging to the cgroup or to its descendants (if the memory cgroup is not a leaf cgroup) are killed together or not at all. This can be used to avoid partial kills to guarantee workload integrity.

Tasks with the OOM protection (oom_score_adj set to -1000) are treated as an exception and are never killed.

If the OOM killer is invoked in a cgroup, it's not going to kill any tasks outside of this cgroup, regardless memory.oom.group values of ancestor cgroups.

memory.events
A read-only flat-keyed file which exists on non-root cgroups. The following entries are defined. Unless specified otherwise, a value change in this file generates a file modified event.

Note that all fields in this file are hierarchical and the file modified event can be generated due to an event down the hierarchy. For the local events at the cgroup level see memory.events.local.

low
The number of times the cgroup is reclaimed due to high memory pressure even though its usage is under the low boundary. This usually indicates that the low boundary is over-committed.

high
The number of times processes of the cgroup are throttled and routed to perform direct memory reclaim because the high memory boundary was exceeded. For a cgroup whose memory usage is capped by the high limit rather than global memory pressure, this event's occurrences are expected.

max
The number of times the cgroup's memory usage was about to go over the max boundary. If direct reclaim fails to bring it down, the cgroup goes to OOM state.

oom
The number of time the cgroup's memory usage was reached the limit and allocation was about to fail.

This event is not raised if the OOM killer is not considered as an option, e.g. for failed high-order allocations or if caller asked to not retry attempts.

oom_kill
The number of processes belonging to this cgroup killed by any kind of OOM killer.

oom_group_kill
The number of times a group OOM has occurred.

memory.events.local
Similar to memory.events but the fields in the file are local to the cgroup i.e. not hierarchical. The file modified event generated on this file reflects only the local events.

memory.stat
A read-only flat-keyed file which exists on non-root cgroups.

This breaks down the cgroup's memory footprint into different types of memory, type-specific details, and other information on the state and past events of the memory management system.

All memory amounts are in bytes.

The entries are ordered to be human readable, and new entries can show up in the middle. Don't rely on items remaining in a fixed position; use the keys to look up specific values!

If the entry has no per-node counter (or not show in the memory.numa_stat). We use 'npn' (non-per-node) as the tag to indicate that it will not show in the memory.numa_stat.

anon
Amount of memory used in anonymous mappings such as brk(), sbrk), and mmap(MAP_ANONYMOUS)

file
Amount of memory used to cache filesystem data, including tmpfs and shared memory.

kernel (npn)
Amount of total kernel memory, including (kernel_stack, pagetables, percpu, vmalloc, slab) in addition to other kernel memory use cases.

kernel_stack
Amount of memory allocated to kernel stacks.

pagetables
Amount of memory allocated for page tables.

sec_pagetables
Amount of memory allocated for secondary page tables, this currently includes KVM mmu allocations on x86 and arm64.

percpu (npn)
Amount of memory used for storing per-cpu kernel data structures.

sock (npn)
Amount of memory used in network transmission buffers

vmalloc (npn)
Amount of memory used for vmap backed memory.

shmem
Amount of cached filesystem data that is swap-backed, such as tmpfs, shm segments, shared anonymous mmap()s

zswap
Amount of memory consumed by the zswap compression backend.

zswapped
Amount of application memory swapped out to zswap.

file_mapped
Amount of cached filesystem data mapped with mmap()

file_dirty
Amount of cached filesystem data that was modified but not yet written back to disk

file_writeback
Amount of cached filesystem data that was modified and is currently being written back to disk

swapcached
Amount of swap cached in memory. The swapcache is accounted against both memory and swap usage.

anon_thp
Amount of memory used in anonymous mappings backed by transparent hugepages

file_thp
Amount of cached filesystem data backed by transparent hugepages

shmem_thp
Amount of shm, tmpfs, shared anonymous mmap()s backed by transparent hugepages

inactive_anon, active_anon, inactive_file, active_file, unevictable
Amount of memory, swap-backed and filesystem-backed, on the internal memory management lists used by the page reclaim algorithm.

As these represent internal list state (eg. shmem pages are on anon memory management lists), inactive_foo + active_foo may not be equal to the value for the foo counter, since the foo counter is type-based, not list-based.

slab_reclaimable
Part of ”slab” that might be reclaimed, such as dentries and inodes.

slab_unreclaimable
Part of ”slab” that cannot be reclaimed on memory pressure.

slab (npn)
Amount of memory used for storing in-kernel data structures.

workingset_refault_anon
Number of refaults of previously evicted anonymous pages.

workingset_refault_file
Number of refaults of previously evicted file pages.

workingset_activate_anon
Number of refaulted anonymous pages that were immediately activated.

workingset_activate_file
Number of refaulted file pages that were immediately activated.

workingset_restore_anon
Number of restored anonymous pages which have been detected as an active workingset before they got reclaimed.

workingset_restore_file
Number of restored file pages which have been detected as an active workingset before they got reclaimed.

workingset_nodereclaim
Number of times a shadow node has been reclaimed

pgscan (npn)
Amount of scanned pages (in an inactive LRU list)

pgsteal (npn)
Amount of reclaimed pages

pgscan_kswapd (npn)
Amount of scanned pages by kswapd (in an inactive LRU list)

pgscan_direct (npn)
Amount of scanned pages directly (in an inactive LRU list)

pgscan_khugepaged (npn)
Amount of scanned pages by khugepaged (in an inactive LRU list)

pgsteal_kswapd (npn)
Amount of reclaimed pages by kswapd

pgsteal_direct (npn)
Amount of reclaimed pages directly

pgsteal_khugepaged (npn)
Amount of reclaimed pages by khugepaged

pgfault (npn)
Total number of page faults incurred

pgmajfault (npn)
Number of major page faults incurred

pgrefill (npn)
Amount of scanned pages (in an active LRU list)

pgactivate (npn)
Amount of pages moved to the active LRU list

pgdeactivate (npn)
Amount of pages moved to the inactive LRU list

pglazyfree (npn)
Amount of pages postponed to be freed under memory pressure

pglazyfreed (npn)
Amount of reclaimed lazyfree pages

thp_fault_alloc (npn)
Number of transparent hugepages which were allocated to satisfy a page fault. This counter is not present when CONFIG_TRANSPARENT_HUGEPAGE is not set.

thp_collapse_alloc (npn)
Number of transparent hugepages which were allocated to allow collapsing an existing range of pages. This counter is not present when CONFIG_TRANSPARENT_HUGEPAGE is not set.

thp_swpout (npn)
Number of transparent hugepages which are swapout in one piece without splitting.

thp_swpout_fallback (npn)
Number of transparent hugepages which were split before swapout. Usually because failed to allocate some continuous swap space for the huge page.

memory.numa_stat
A read-only nested-keyed file which exists on non-root cgroups.

This breaks down the cgroup's memory footprint into different types of memory, type-specific details, and other information per node on the state of the memory management system.

This is useful for providing visibility into the NUMA locality information within an memcg since the pages are allowed to be allocated from any physical node. One of the use case is evaluating application performance by combining this information with the application's CPU allocation.

All memory amounts are in bytes.

The output format of memory.numa_stat is:

```
type N0=<bytes in node 0> N1=<bytes in node 1> ...
```

The entries are ordered to be human readable, and new entries can show up in the middle. Don't rely on items remaining in a fixed position; use the keys to look up specific values!

The entries can refer to the memory.stat.

memory.swap.current
A read-only single value file which exists on non-root cgroups.

The total amount of swap currently being used by the cgroup and its descendants.

memory.swap.high
A read-write single value file which exists on non-root cgroups. The default is "max".

Swap usage throttle limit. If a cgroup's swap usage exceeds this limit, all its further allocations will be throttled to allow userspace to implement custom out-of-memory procedures.

This limit marks a point of no return for the cgroup. It is NOT designed to manage the amount of swapping a workload does during regular operation. Compare to memory.swap.max, which prohibits swapping past a set amount, but lets the cgroup continue unimpeded as long as other memory can be reclaimed.

Healthy workloads are not expected to reach this limit.

memory.swap.peak
A read-only single value file which exists on non-root cgroups.

The max swap usage recorded for the cgroup and its descendants since the creation of the cgroup.

memory.swap.max
A read-write single value file which exists on non-root cgroups. The default is "max".

Swap usage hard limit. If a cgroup's swap usage reaches this limit, anonymous memory of the cgroup will not be swapped out.

memory.swap.events
A read-only flat-keyed file which exists on non-root cgroups. The following entries are defined. Unless specified otherwise, a value change in this file generates a file modified event.

high
The number of times the cgroup's swap usage was over the high threshold.

max
The number of times the cgroup's swap usage was about to go over the max boundary and swap allocation failed.

fail
The number of times swap allocation failed either because of running out of swap system-wide or max limit.

When reduced under the current usage, the existing swap entries are reclaimed gradually and the swap usage may stay higher than the limit for an extended period of time. This reduces the impact on the workload and memory management.

memory.zswap.current
A read-only single value file which exists on non-root cgroups.

The total amount of memory consumed by the zswap compression backend.

memory.zswap.max
A read-write single value file which exists on non-root cgroups. The default is "max".

Zswap usage hard limit. If a cgroup's zswap pool reaches this limit, it will refuse to take any more stores before existing entries fault back in or are written out to disk.

memory.zswap.writeback
A read-write single value file. The default value is "1". The initial value of the root cgroup is 1, and when a new cgroup is created, it inherits the current value of its parent.

When this is set to 0, all swapping attempts to swapping devices are disabled. This included both zswap writebacks, and swapping due to zswap store failures. If the zswap store failures are recurring (for e.g if the pages are incompressible), users can observe reclaim inefficiency after disabling writeback (because the same pages might be rejected again and again).

Note that this is subtly different from setting memory.swap.max to 0, as it still allows for pages to be written to the zswap pool.

memory.pressure
A read-only nested-keyed file.

Shows pressure stall information for memory. See Documentation/accounting/psi.rst for details.

Usage Guidelines

"memory.high" is the main mechanism to control memory usage. Over-committing on high limit (sum of high limits > available memory) and letting global memory pressure to distribute memory according to usage is a viable strategy.

Because breach of the high limit doesn't trigger the OOM killer but throttles the offending cgroup, a management agent has ample opportunities to monitor and take appropriate actions such as granting more memory or terminating the workload.

Determining whether a cgroup has enough memory is not trivial as memory usage doesn't indicate whether the workload can benefit from more memory. For example, a workload which writes data received from network to a file can use all available memory but can also operate as performant with a small amount of memory. A measure of memory pressure - how much the workload is being impacted due to lack of memory - is necessary to determine whether a workload needs more memory; unfortunately, memory pressure monitoring mechanism isn't implemented yet.

Memory Ownership

A memory area is charged to the cgroup which instantiated it and stays charged to the cgroup until the area is released. Migrating a process to a different cgroup doesn't move the memory usages that it instantiated while in the previous cgroup to the new cgroup.

A memory area may be used by processes belonging to different cgroups. To which cgroup the area will be charged is in-deterministic; however, over time, the memory area is likely to end up in a cgroup which has enough memory allowance to avoid high reclaim pressure.

If a cgroup sweeps a considerable amount of memory which is expected to be accessed repeatedly by other cgroups, it may make sense to use POSIX_FADV_DONTNEED to relinquish the ownership of memory areas belonging to the affected files to ensure correct memory ownership.

33.5.3 IO

The "io" controller regulates the distribution of IO resources. This controller implements both weight based and absolute bandwidth or IOPS limit distribution; however, weight based distribution is available only if cfq-iosched is in use and neither scheme is available for blk-mq devices.

IO Interface Files

io.stat

A read-only nested-keyed file.

Lines are keyed by $MAJ:$MIN device numbers and not ordered. The following nested keys are defined.

rbytes	Bytes read
wbytes	Bytes written
rios	Number of read IOs
wios	Number of write IOs
dbytes	Bytes discarded
dios	Number of discard IOs

An example read output follows:

```
8:16 rbytes=1459200 wbytes=314773504 rios=192 wios=353 dbytes=0
↪dios=0
8:0 rbytes=90430464 wbytes=299008000 rios=8950 wios=1252
↪dbytes=50331648 dios=3021
```

io.cost.qos

A read-write nested-keyed file which exists only on the root cgroup.

This file configures the Quality of Service of the IO cost model based controller (CONFIG_BLK_CGROUP_IOCOST) which currently implements "io.weight" proportional control. Lines are keyed by $MAJ:$MIN device numbers and not ordered. The line for a given device is populated on the first write for the device on "io.cost.qos" or "io.cost.model". The following nested keys are defined.

enable	Weight-based control enable
ctrl	”auto” or ”user”
rpct	Read latency percentile [0, 100]
rlat	Read latency threshold
wpct	Write latency percentile [0, 100]
wlat	Write latency threshold
min	Minimum scaling percentage [1, 10000]
max	Maximum scaling percentage [1, 10000]

The controller is disabled by default and can be enabled by setting ”enable” to 1. ”rpct” and ”wpct” parameters default to zero and the controller uses internal device saturation state to adjust the overall IO rate between ”min” and ”max”.

When a better control quality is needed, latency QoS parameters can be configured. For example:

```
8:16 enable=1 ctrl=auto rpct=95.00 rlat=75000 wpct=95.00␣
↪wlat=150000 min=50.00 max=150.0
```

shows that on sdb, the controller is enabled, will consider the device saturated if the 95th percentile of read completion latencies is above 75ms or write 150ms, and adjust the overall IO issue rate between 50% and 150% accordingly.

The lower the saturation point, the better the latency QoS at the cost of aggregate bandwidth. The narrower the allowed adjustment range between ”min” and ”max”, the more conformant to the cost model the IO behavior. Note that the IO issue base rate may be far off from 100% and setting ”min” and ”max” blindly can lead to a significant loss of device capacity or control quality. ”min” and ”max” are useful for regulating devices which show wide temporary behavior changes - e.g. a ssd which accepts writes at the line speed for a while and then completely stalls for multiple seconds.

When ”ctrl” is ”auto”, the parameters are controlled by the kernel and may change automatically. Setting ”ctrl” to ”user” or setting any of the percentile and latency parameters puts it into ”user” mode and disables the automatic changes. The automatic mode can be restored by setting ”ctrl” to ”auto”.

io.cost.model

A read-write nested-keyed file which exists only on the root cgroup.

This file configures the cost model of the IO cost model based controller (CONFIG_BLK_CGROUP_IOCOST) which currently implements ”io.weight” proportional control. Lines are keyed by $MAJ:$MIN device numbers and not ordered. The line for a given device is populated on the first write for the device on ”io.cost.qos” or ”io.cost.model”. The following nested keys are defined.

ctrl	”auto” or ”user”
model	The cost model in use - ”linear”

When ”ctrl” is ”auto”, the kernel may change all parameters dynamically. When ”ctrl” is set to ”user” or any other parameters are written to, ”ctrl” become ”user” and the automatic changes are disabled.

When ”model” is ”linear”, the following model parameters are defined.

[r|w]bps	The maximum sequential IO throughput
[r|w]seqiops	The maximum 4k sequential IOs per second
[r|w]randiops	The maximum 4k random IOs per second

From the above, the builtin linear model determines the base costs of a sequential and random IO and the cost coefficient for the IO size. While simple, this model can cover most common device classes acceptably.

The IO cost model isn't expected to be accurate in absolute sense and is scaled to the device behavior dynamically.

If needed, tools/cgroup/iocost_coef_gen.py can be used to generate device-specific coefficients.

io.weight

A read-write flat-keyed file which exists on non-root cgroups. The default is ”default 100”.

The first line is the default weight applied to devices without specific override. The rest are overrides keyed by $MAJ:$MIN device numbers and not ordered. The weights are in the range [1, 10000] and specifies the relative amount IO time the cgroup can use in relation to its siblings.

The default weight can be updated by writing either ”default $WEIGHT” or simply ”$WEIGHT”. Overrides can be set by writing ”$MAJ:$MIN $WEIGHT” and unset by writing ”$MAJ:$MIN default”.

An example read output follows:

```
default 100
8:16 200
8:0 50
```

io.max

A read-write nested-keyed file which exists on non-root cgroups.

BPS and IOPS based IO limit. Lines are keyed by $MAJ:$MIN device numbers and not ordered. The following nested keys are defined.

rbps	Max read bytes per second
wbps	Max write bytes per second
riops	Max read IO operations per second
wiops	Max write IO operations per second

When writing, any number of nested key-value pairs can be specified in any order. ”max” can be specified as the value to remove a specific limit. If the same key is specified multiple times, the outcome is undefined.

BPS and IOPS are measured in each IO direction and IOs are delayed if limit is reached. Temporary bursts are allowed.

Setting read limit at 2M BPS and write at 120 IOPS for 8:16:

```
echo "8:16 rbps=2097152 wiops=120" > io.max
```

Reading returns the following:

```
8:16 rbps=2097152 wbps=max riops=max wiops=120
```

Write IOPS limit can be removed by writing the following:

```
echo "8:16 wiops=max" > io.max
```

Reading now returns the following:

```
8:16 rbps=2097152 wbps=max riops=max wiops=max
```

io.pressure
A read-only nested-keyed file.

Shows pressure stall information for IO. See Documentation/accounting/psi.rst for details.

Writeback

Page cache is dirtied through buffered writes and shared mmaps and written asynchronously to the backing filesystem by the writeback mechanism. Writeback sits between the memory and IO domains and regulates the proportion of dirty memory by balancing dirtying and write IOs.

The io controller, in conjunction with the memory controller, implements control of page cache writeback IOs. The memory controller defines the memory domain that dirty memory ratio is calculated and maintained for and the io controller defines the io domain which writes out dirty pages for the memory domain. Both system-wide and per-cgroup dirty memory states are examined and the more restrictive of the two is enforced.

cgroup writeback requires explicit support from the underlying filesystem. Currently, cgroup writeback is implemented on ext2, ext4, btrfs, f2fs, and xfs. On other filesystems, all writeback IOs are attributed to the root cgroup.

There are inherent differences in memory and writeback management which affects how cgroup ownership is tracked. Memory is tracked per page while writeback per inode. For the purpose of writeback, an inode is assigned to a cgroup and all IO requests to write dirty pages from the inode are attributed to that cgroup.

As cgroup ownership for memory is tracked per page, there can be pages which are associated with different cgroups than the one the inode is associated with. These are called foreign pages. The writeback constantly keeps track of foreign pages and, if a particular foreign cgroup becomes the majority over a certain period of time, switches the ownership of the inode to that cgroup.

While this model is enough for most use cases where a given inode is mostly dirtied by a single cgroup even when the main writing cgroup changes over time, use cases where multiple cgroups write to a single inode simultaneously are not supported well. In such circumstances, a significant portion of IOs are likely to be attributed incorrectly. As memory controller assigns page ownership on the first use and doesn't update it until the page is released, even if writeback strictly follows page ownership, multiple cgroups dirtying overlapping areas wouldn't work as expected. It's recommended to avoid such usage patterns.

The sysctl knobs which affect writeback behavior are applied to cgroup writeback as follows.

vm.dirty_background_ratio, vm.dirty_ratio
These ratios apply the same to cgroup writeback with the amount of available memory capped by limits imposed by the memory controller and system-wide clean memory.

vm.dirty_background_bytes, vm.dirty_bytes
For cgroup writeback, this is calculated into ratio against total available memory and applied the same way as vm.dirty[_background]_ratio.

IO Latency

This is a cgroup v2 controller for IO workload protection. You provide a group with a latency target, and if the average latency exceeds that target the controller will throttle any peers that have a lower latency target than the protected workload.

The limits are only applied at the peer level in the hierarchy. This means that in the diagram below, only groups A, B, and C will influence each other, and groups D and F will influence each other. Group G will influence nobody:

```
          [root]
  /          |            \
  A          B            C
 /  \        |
D    F       G
```

So the ideal way to configure this is to set io.latency in groups A, B, and C. Generally you do not want to set a value lower than the latency your device supports. Experiment to find the value that works best for your workload. Start at higher than the expected latency for your device and watch the avg_lat value in io.stat for your workload group to get an idea of the latency you see during normal operation. Use the avg_lat value as a basis for your real setting, setting at 10-15% higher than the value in io.stat.

How IO Latency Throttling Works

io.latency is work conserving; so as long as everybody is meeting their latency target the controller doesn't do anything. Once a group starts missing its target it begins throttling any peer group that has a higher target than itself. This throttling takes 2 forms:

- Queue depth throttling. This is the number of outstanding IO's a group is allowed to have. We will clamp down relatively quickly, starting at no limit and going all the way down to 1 IO at a time.
- Artificial delay induction. There are certain types of IO that cannot be throttled without possibly adversely affecting higher priority groups. This includes swapping and metadata IO. These types of IO are allowed to occur normally, however they are ”charged” to the originating group. If the originating group is being throttled you will see the use_delay and delay fields in io.stat increase. The delay value is how many microseconds that are being added to any process that runs in this group. Because this number can grow quite large if there is a lot of swapping or metadata IO occurring we limit the individual delay events to 1 second at a time.

Once the victimized group starts meeting its latency target again it will start unthrottling any peer groups that were throttled previously. If the victimized group simply stops doing IO the global counter will unthrottle appropriately.

IO Latency Interface Files

io.latency
This takes a similar format as the other controllers.

"MAJOR:MINOR target=<target time in microseconds>"

io.stat
If the controller is enabled you will see extra stats in io.stat in addition to the normal ones.

depth
This is the current queue depth for the group.

avg_lat
This is an exponential moving average with a decay rate of 1/exp bound by the sampling interval. The decay rate interval can be calculated by multiplying the win value in io.stat by the corresponding number of samples based on the win value.

win
The sampling window size in milliseconds. This is the minimum duration of time between evaluation events. Windows only elapse with IO activity. Idle periods extend the most recent window.

IO Priority

A single attribute controls the behavior of the I/O priority cgroup policy, namely the io.prio.class attribute. The following values are accepted for that attribute:

no-change
Do not modify the I/O priority class.

promote-to-rt
For requests that have a non-RT I/O priority class, change it into RT. Also change the priority level of these requests to 4. Do not modify the I/O priority of requests that have priority class RT.

restrict-to-be
For requests that do not have an I/O priority class or that have I/O priority class RT, change it into BE. Also change the priority level of these requests to 0. Do not modify the I/O priority class of requests that have priority class IDLE.

idle
Change the I/O priority class of all requests into IDLE, the lowest I/O priority class.

none-to-rt
Deprecated. Just an alias for promote-to-rt.

The following numerical values are associated with the I/O priority policies:

no-change	0
promote-to-rt	1
restrict-to-be	2
idle	3

The numerical value that corresponds to each I/O priority class is as follows:

IOPRIO_CLASS_NONE	0
IOPRIO_CLASS_RT (real-time)	1
IOPRIO_CLASS_BE (best effort)	2
IOPRIO_CLASS_IDLE	3

The algorithm to set the I/O priority class for a request is as follows:

- If I/O priority class policy is promote-to-rt, change the request I/O priority class to IOPRIO_CLASS_RT and change the request I/O priority level to 4.
- If I/O priority class policy is not promote-to-rt, translate the I/O priority class policy into a number, then change the request I/O priority class into the maximum of the I/O priority class policy number and the numerical I/O priority class.

33.5.4 PID

The process number controller is used to allow a cgroup to stop any new tasks from being fork()'d or clone()'d after a specified limit is reached.

The number of tasks in a cgroup can be exhausted in ways which other controllers cannot prevent, thus warranting its own controller. For example, a fork bomb is likely to exhaust the number of tasks before hitting memory restrictions.

Note that PIDs used in this controller refer to TIDs, process IDs as used by the kernel.

PID Interface Files

pids.max
A read-write single value file which exists on non-root cgroups. The default is "max".

Hard limit of number of processes.

pids.current
A read-only single value file which exists on all cgroups.

The number of processes currently in the cgroup and its descendants.

Organisational operations are not blocked by cgroup policies, so it is possible to have pids.current > pids.max. This can be done by either setting the limit to be smaller than pids.current, or attaching enough processes to the cgroup such that pids.current is larger than pids.max. However, it is not possible to violate a cgroup PID policy through fork() or clone(). These will return -EAGAIN if the creation of a new process would cause a cgroup policy to be violated.

33.5.5 Cpuset

The ”cpuset” controller provides a mechanism for constraining the CPU and memory node placement of tasks to only the resources specified in the cpuset interface files in a task's current cgroup. This is especially valuable on large NUMA systems where placing jobs on properly sized subsets of the systems with careful processor and memory placement to reduce cross-node memory access and contention can improve overall system performance.

The ”cpuset” controller is hierarchical. That means the controller cannot use CPUs or memory nodes not allowed in its parent.

Cpuset Interface Files

cpuset.cpus

A read-write multiple values file which exists on non-root cpuset-enabled cgroups.

It lists the requested CPUs to be used by tasks within this cgroup. The actual list of CPUs to be granted, however, is subjected to constraints imposed by its parent and can differ from the requested CPUs.

The CPU numbers are comma-separated numbers or ranges. For example:

```
# cat cpuset.cpus
0-4,6,8-10
```

An empty value indicates that the cgroup is using the same setting as the nearest cgroup ancestor with a non-empty ”cpuset.cpus” or all the available CPUs if none is found.

The value of ”cpuset.cpus” stays constant until the next update and won't be affected by any CPU hotplug events.

cpuset.cpus.effective

A read-only multiple values file which exists on all cpuset-enabled cgroups.

It lists the onlined CPUs that are actually granted to this cgroup by its parent. These CPUs are allowed to be used by tasks within the current cgroup.

If ”cpuset.cpus” is empty, the ”cpuset.cpus.effective” file shows all the CPUs from the parent cgroup that can be available to be used by this cgroup. Otherwise, it should be a subset of ”cpuset.cpus” unless none of the CPUs listed in ”cpuset.cpus” can be granted. In this case, it will be treated just like an empty ”cpuset.cpus”.

Its value will be affected by CPU hotplug events.

cpuset.mems

A read-write multiple values file which exists on non-root cpuset-enabled cgroups.

It lists the requested memory nodes to be used by tasks within this cgroup. The actual list of memory nodes granted, however, is subjected to constraints imposed by its parent and can differ from the requested memory nodes.

The memory node numbers are comma-separated numbers or ranges. For example:

```
# cat cpuset.mems
0-1,3
```

An empty value indicates that the cgroup is using the same setting as the nearest cgroup ancestor with a non-empty "cpuset.mems" or all the available memory nodes if none is found.

The value of "cpuset.mems" stays constant until the next update and won't be affected by any memory nodes hotplug events.

Setting a non-empty value to "cpuset.mems" causes memory of tasks within the cgroup to be migrated to the designated nodes if they are currently using memory outside of the designated nodes.

There is a cost for this memory migration. The migration may not be complete and some memory pages may be left behind. So it is recommended that "cpuset.mems" should be set properly before spawning new tasks into the cpuset. Even if there is a need to change "cpuset.mems" with active tasks, it shouldn't be done frequently.

cpuset.mems.effective

A read-only multiple values file which exists on all cpuset-enabled cgroups.

It lists the onlined memory nodes that are actually granted to this cgroup by its parent. These memory nodes are allowed to be used by tasks within the current cgroup.

If "cpuset.mems" is empty, it shows all the memory nodes from the parent cgroup that will be available to be used by this cgroup. Otherwise, it should be a subset of "cpuset.mems" unless none of the memory nodes listed in "cpuset.mems" can be granted. In this case, it will be treated just like an empty "cpuset.mems".

Its value will be affected by memory nodes hotplug events.

cpuset.cpus.exclusive

A read-write multiple values file which exists on non-root cpuset-enabled cgroups.

It lists all the exclusive CPUs that are allowed to be used to create a new cpuset partition. Its value is not used unless the cgroup becomes a valid partition root. See the "cpuset.cpus.partition" section below for a description of what a cpuset partition is.

When the cgroup becomes a partition root, the actual exclusive CPUs that are allocated to that partition are listed in "cpuset.cpus.exclusive.effective" which may be different from "cpuset.cpus.exclusive". If "cpuset.cpus.exclusive" has previously been set, "cpuset.cpus.exclusive.effective" is always a subset of it.

Users can manually set it to a value that is different from "cpuset.cpus". The only constraint in setting it is that the list of CPUs must be exclusive with respect to its sibling.

For a parent cgroup, any one of its exclusive CPUs can only be distributed to at most one of its child cgroups. Having an exclusive CPU appearing in two or more of its child cgroups is not allowed (the exclusivity rule). A value that violates the exclusivity rule will be rejected with a write error.

The root cgroup is a partition root and all its available CPUs are in its exclusive CPU set.

cpuset.cpus.exclusive.effective
A read-only multiple values file which exists on all non-root cpuset-enabled cgroups.

This file shows the effective set of exclusive CPUs that can be used to create a partition root. The content of this file will always be a subset of "cpuset.cpus" and its parent's "cpuset.cpus.exclusive.effective" if its parent is not the root cgroup. It will also be a subset of "cpuset.cpus.exclusive" if it is set. If "cpuset.cpus.exclusive" is not set, it is treated to have an implicit value of "cpuset.cpus" in the formation of local partition.

cpuset.cpus.isolated
A read-only and root cgroup only multiple values file.

This file shows the set of all isolated CPUs used in existing isolated partitions. It will be empty if no isolated partition is created.

cpuset.cpus.partition
A read-write single value file which exists on non-root cpuset-enabled cgroups. This flag is owned by the parent cgroup and is not delegatable.

It accepts only the following input values when written to.

"member"	Non-root member of a partition
"root"	Partition root
"isolated"	Partition root without load balancing

A cpuset partition is a collection of cpuset-enabled cgroups with a partition root at the top of the hierarchy and its descendants except those that are separate partition roots themselves and their descendants. A partition has exclusive access to the set of exclusive CPUs allocated to it. Other cgroups outside of that partition cannot use any CPUs in that set.

There are two types of partitions - local and remote. A local partition is one whose parent cgroup is also a valid partition root. A remote partition is one whose parent cgroup is not a valid partition root itself. Writing to "cpuset.cpus.exclusive" is optional for the creation of a local partition as its "cpuset.cpus.exclusive" file will assume an implicit value that is the same as "cpuset.cpus" if it is not set. Writing the proper "cpuset.cpus.exclusive" values down the cgroup hierarchy before the target partition root is mandatory for the creation of a remote partition.

Currently, a remote partition cannot be created under a local partition. All the ancestors of a remote partition root except the root cgroup cannot be a partition root.

The root cgroup is always a partition root and its state cannot be changed. All other non-root cgroups start out as "member".

When set to "root", the current cgroup is the root of a new partition or scheduling domain. The set of exclusive CPUs is determined by the value of its "cpuset.cpus.exclusive.effective".

When set to ”isolated”, the CPUs in that partition will be in an isolated state without any load balancing from the scheduler and excluded from the unbound workqueues. Tasks placed in such a partition with multiple CPUs should be carefully distributed and bound to each of the individual CPUs for optimal performance.

A partition root (”root” or ”isolated”) can be in one of the two possible states - valid or invalid. An invalid partition root is in a degraded state where some state information may be retained, but behaves more like a ”member”.

All possible state transitions among ”member”, ”root” and ”isolated” are allowed.

On read, the ”cpuset.cpus.partition” file can show the following values.

”member”	Non-root member of a partition
”root”	Partition root
”isolated”	Partition root without load balancing
”root invalid (<reason>)”	Invalid partition root
”isolated invalid (<reason>)”	Invalid isolated partition root

In the case of an invalid partition root, a descriptive string on why the partition is invalid is included within parentheses.

For a local partition root to be valid, the following conditions must be met.

1) The parent cgroup is a valid partition root.
2) The ”cpuset.cpus.exclusive.effective” file cannot be empty, though it may contain offline CPUs.
3) The ”cpuset.cpus.effective” cannot be empty unless there is no task associated with this partition.

For a remote partition root to be valid, all the above conditions except the first one must be met.

External events like hotplug or changes to ”cpuset.cpus” or ”cpuset.cpus.exclusive” can cause a valid partition root to become invalid and vice versa. Note that a task cannot be moved to a cgroup with empty ”cpuset.cpus.effective”.

A valid non-root parent partition may distribute out all its CPUs to its child local partitions when there is no task associated with it.

Care must be taken to change a valid partition root to ”member” as all its child local partitions, if present, will become invalid causing disruption to tasks running in those child partitions. These inactivated partitions could be recovered if their parent is switched back to a partition root with a proper value in ”cpuset.cpus” or ”cpuset.cpus.exclusive”.

Poll and inotify events are triggered whenever the state of ”cpuset.cpus.partition” changes. That includes changes caused by write to ”cpuset.cpus.partition”, cpu hotplug or other changes that modify the validity status of the partition. This will allow user space agents to monitor unexpected changes to ”cpuset.cpus.partition” without the need to do continuous polling.

A user can pre-configure certain CPUs to an isolated state with load balancing disabled at boot time with the "isolcpus" kernel boot command line option. If those CPUs are to be put into a partition, they have to be used in an isolated partition.

33.5.6 Device controller

Device controller manages access to device files. It includes both creation of new device files (using mknod), and access to the existing device files.

Cgroup v2 device controller has no interface files and is implemented on top of cgroup BPF. To control access to device files, a user may create bpf programs of type BPF_PROG_TYPE_CGROUP_DEVICE and attach them to cgroups with BPF_CGROUP_DEVICE flag. On an attempt to access a device file, corresponding BPF programs will be executed, and depending on the return value the attempt will succeed or fail with -EPERM.

A BPF_PROG_TYPE_CGROUP_DEVICE program takes a pointer to the bpf_cgroup_dev_ctx structure, which describes the device access attempt: access type (mknod/read/write) and device (type, major and minor numbers). If the program returns 0, the attempt fails with -EPERM, otherwise it succeeds.

An example of BPF_PROG_TYPE_CGROUP_DEVICE program may be found in tools/testing/selftests/bpf/progs/dev_cgroup.c in the kernel source tree.

33.5.7 RDMA

The "rdma" controller regulates the distribution and accounting of RDMA resources.

RDMA Interface Files

rdma.max

A readwrite nested-keyed file that exists for all the cgroups except root that describes current configured resource limit for a RDMA/IB device.

Lines are keyed by device name and are not ordered. Each line contains space separated resource name and its configured limit that can be distributed.

The following nested keys are defined.

hca_handle	Maximum number of HCA Handles
hca_object	Maximum number of HCA Objects

An example for mlx4 and ocrdma device follows:

```
mlx4_0 hca_handle=2 hca_object=2000
ocrdma1 hca_handle=3 hca_object=max
```

rdma.current

A read-only file that describes current resource usage. It exists for all the cgroup except root.

An example for mlx4 and ocrdma device follows:

```
mlx4_0 hca_handle=1 hca_object=20
ocrdma1 hca_handle=1 hca_object=23
```

33.5.8 HugeTLB

The HugeTLB controller allows to limit the HugeTLB usage per control group and enforces the controller limit during page fault.

HugeTLB Interface Files

hugetlb.<hugepagesize>.current
Show current usage for "hugepagesize" hugetlb. It exists for all the cgroup except root.

hugetlb.<hugepagesize>.max
Set/show the hard limit of "hugepagesize" hugetlb usage. The default value is "max". It exists for all the cgroup except root.

hugetlb.<hugepagesize>.events
A read-only flat-keyed file which exists on non-root cgroups.

max
The number of allocation failure due to HugeTLB limit

hugetlb.<hugepagesize>.events.local
Similar to hugetlb.<hugepagesize>.events but the fields in the file are local to the cgroup i.e. not hierarchical. The file modified event generated on this file reflects only the local events.

hugetlb.<hugepagesize>.numa_stat
Similar to memory.numa_stat, it shows the numa information of the hugetlb pages of <hugepagesize> in this cgroup. Only active in use hugetlb pages are included. The per-node values are in bytes.

33.5.9 Misc

The Miscellaneous cgroup provides the resource limiting and tracking mechanism for the scalar resources which cannot be abstracted like the other cgroup resources. Controller is enabled by the CONFIG_CGROUP_MISC config option.

A resource can be added to the controller via enum misc_res_type{} in the include/linux/misc_cgroup.h file and the corresponding name via misc_res_name[] in the kernel/cgroup/misc.c file. Provider of the resource must set its capacity prior to using the resource by calling misc_cg_set_capacity().

Once a capacity is set then the resource usage can be updated using charge and uncharge APIs. All of the APIs to interact with misc controller are in include/linux/misc_cgroup.h.

Misc Interface Files

Miscellaneous controller provides 3 interface files. If two misc resources (res_a and res_b) are registered then:

misc.capacity
A read-only flat-keyed file shown only in the root cgroup. It shows miscellaneous scalar resources available on the platform along with their quantities:

```
$ cat misc.capacity
res_a 50
res_b 10
```

misc.current
A read-only flat-keyed file shown in the all cgroups. It shows the current usage of the resources in the cgroup and its children.:

```
$ cat misc.current
res_a 3
res_b 0
```

misc.max
A read-write flat-keyed file shown in the non root cgroups. Allowed maximum usage of the resources in the cgroup and its children.:

```
$ cat misc.max
res_a max
res_b 4
```

Limit can be set by:

```
# echo res_a 1 > misc.max
```

Limit can be set to max by:

```
# echo res_a max > misc.max
```

Limits can be set higher than the capacity value in the misc.capacity file.

misc.events
A read-only flat-keyed file which exists on non-root cgroups. The following entries are defined. Unless specified otherwise, a value change in this file generates a file modified event. All fields in this file are hierarchical.

max
The number of times the cgroup's resource usage was about to go over the max boundary.

Migration and Ownership

A miscellaneous scalar resource is charged to the cgroup in which it is used first, and stays charged to that cgroup until that resource is freed. Migrating a process to a different cgroup does not move the charge to the destination cgroup where the process has moved.

33.5.10 Others

perf_event

perf_event controller, if not mounted on a legacy hierarchy, is automatically enabled on the v2 hierarchy so that perf events can always be filtered by cgroup v2 path. The controller can still be moved to a legacy hierarchy after v2 hierarchy is populated.

33.5.11 Non-normative information

This section contains information that isn't considered to be a part of the stable kernel API and so is subject to change.

CPU controller root cgroup process behaviour

When distributing CPU cycles in the root cgroup each thread in this cgroup is treated as if it was hosted in a separate child cgroup of the root cgroup. This child cgroup weight is dependent on its thread nice level.

For details of this mapping see sched_prio_to_weight array in kernel/sched/core.c file (values from this array should be scaled appropriately so the neutral - nice 0 - value is 100 instead of 1024).

IO controller root cgroup process behaviour

Root cgroup processes are hosted in an implicit leaf child node. When distributing IO resources this implicit child node is taken into account as if it was a normal child cgroup of the root cgroup with a weight value of 200.

33.6 Namespace

33.6.1 Basics

cgroup namespace provides a mechanism to virtualize the view of the "/proc/$PID/cgroup" file and cgroup mounts. The CLONE_NEWCGROUP clone flag can be used with clone(2) and unshare(2) to create a new cgroup namespace. The process running inside the cgroup namespace will have its "/proc/$PID/cgroup" output restricted to cgroupns root. The cgroupns root is the cgroup of the process at the time of creation of the cgroup namespace.

Without cgroup namespace, the "/proc/$PID/cgroup" file shows the complete path of the cgroup of a process. In a container setup where a set of cgroups and namespaces are intended to

isolate processes the "/proc/$PID/cgroup" file may leak potential system level information to the isolated processes. For example:

```
# cat /proc/self/cgroup
0::/batchjobs/container_id1
```

The path '/batchjobs/container_id1' can be considered as system-data and undesirable to expose to the isolated processes. cgroup namespace can be used to restrict visibility of this path. For example, before creating a cgroup namespace, one would see:

```
# ls -l /proc/self/ns/cgroup
lrwxrwxrwx 1 root root 0 2014-07-15 10:37 /proc/self/ns/cgroup ->␣
↪cgroup:[4026531835]
# cat /proc/self/cgroup
0::/batchjobs/container_id1
```

After unsharing a new namespace, the view changes:

```
# ls -l /proc/self/ns/cgroup
lrwxrwxrwx 1 root root 0 2014-07-15 10:35 /proc/self/ns/cgroup ->␣
↪cgroup:[4026532183]
# cat /proc/self/cgroup
0::/
```

When some thread from a multi-threaded process unshares its cgroup namespace, the new cgroupns gets applied to the entire process (all the threads). This is natural for the v2 hierarchy; however, for the legacy hierarchies, this may be unexpected.

A cgroup namespace is alive as long as there are processes inside or mounts pinning it. When the last usage goes away, the cgroup namespace is destroyed. The cgroupns root and the actual cgroups remain.

33.6.2 The Root and Views

The 'cgroupns root' for a cgroup namespace is the cgroup in which the process calling unshare(2) is running. For example, if a process in /batchjobs/container_id1 cgroup calls unshare, cgroup /batchjobs/container_id1 becomes the cgroupns root. For the init_cgroup_ns, this is the real root ('/') cgroup.

The cgroupns root cgroup does not change even if the namespace creator process later moves to a different cgroup:

```
# ~/unshare -c # unshare cgroupns in some cgroup
# cat /proc/self/cgroup
0::/
# mkdir sub_cgrp_1
# echo 0 > sub_cgrp_1/cgroup.procs
# cat /proc/self/cgroup
0::/sub_cgrp_1
```

Each process gets its namespace-specific view of "/proc/$PID/cgroup"

Processes running inside the cgroup namespace will be able to see cgroup paths (in /proc/self/cgroup) only inside their root cgroup. From within an unshared cgroupns:

```
# sleep 100000 &
[1] 7353
# echo 7353 > sub_cgrp_1/cgroup.procs
# cat /proc/7353/cgroup
0::/sub_cgrp_1
```

From the initial cgroup namespace, the real cgroup path will be visible:

```
$ cat /proc/7353/cgroup
0::/batchjobs/container_id1/sub_cgrp_1
```

From a sibling cgroup namespace (that is, a namespace rooted at a different cgroup), the cgroup path relative to its own cgroup namespace root will be shown. For instance, if PID 7353's cgroup namespace root is at '/batchjobs/container_id2', then it will see:

```
# cat /proc/7353/cgroup
0::/../container_id2/sub_cgrp_1
```

Note that the relative path always starts with '/' to indicate that its relative to the cgroup namespace root of the caller.

33.6.3 Migration and setns(2)

Processes inside a cgroup namespace can move into and out of the namespace root if they have proper access to external cgroups. For example, from inside a namespace with cgroupns root at /batchjobs/container_id1, and assuming that the global hierarchy is still accessible inside cgroupns:

```
# cat /proc/7353/cgroup
0::/sub_cgrp_1
# echo 7353 > batchjobs/container_id2/cgroup.procs
# cat /proc/7353/cgroup
0::/../container_id2
```

Note that this kind of setup is not encouraged. A task inside cgroup namespace should only be exposed to its own cgroupns hierarchy.

setns(2) to another cgroup namespace is allowed when:

(a) the process has CAP_SYS_ADMIN against its current user namespace

(b) the process has CAP_SYS_ADMIN against the target cgroup namespace's userns

No implicit cgroup changes happen with attaching to another cgroup namespace. It is expected that the someone moves the attaching process under the target cgroup namespace root.

33.6.4 Interaction with Other Namespaces

Namespace specific cgroup hierarchy can be mounted by a process running inside a non-init cgroup namespace:

```
# mount -t cgroup2 none $MOUNT_POINT
```

This will mount the unified cgroup hierarchy with cgroupns root as the filesystem root. The process needs CAP_SYS_ADMIN against its user and mount namespaces.

The virtualization of /proc/self/cgroup file combined with restricting the view of cgroup hierarchy by namespace-private cgroupfs mount provides a properly isolated cgroup view inside the container.

33.7 Information on Kernel Programming

This section contains kernel programming information in the areas where interacting with cgroup is necessary. cgroup core and controllers are not covered.

33.7.1 Filesystem Support for Writeback

A filesystem can support cgroup writeback by updating address_space_operations->writepage[s]() to annotate bio's using the following two functions.

wbc_init_bio(@wbc, @bio)
Should be called for each bio carrying writeback data and associates the bio with the inode's owner cgroup and the corresponding request queue. This must be called after a queue (device) has been associated with the bio and before submission.

wbc_account_cgroup_owner(@wbc, @page, @bytes)
Should be called for each data segment being written out. While this function doesn't care exactly when it's called during the writeback session, it's the easiest and most natural to call it as data segments are added to a bio.

With writeback bio's annotated, cgroup support can be enabled per super_block by setting SB_I_CGROUPWB in ->s_iflags. This allows for selective disabling of cgroup writeback support which is helpful when certain filesystem features, e.g. journaled data mode, are incompatible.

wbc_init_bio() binds the specified bio to its cgroup. Depending on the configuration, the bio may be executed at a lower priority and if the writeback session is holding shared resources, e.g. a journal entry, may lead to priority inversion. There is no one easy solution for the problem. Filesystems can try to work around specific problem cases by skipping wbc_init_bio() and using bio_associate_blkg() directly.

33.8 Deprecated v1 Core Features

- Multiple hierarchies including named ones are not supported.
- All v1 mount options are not supported.
- The ”tasks” file is removed and ”cgroup.procs” is not sorted.
- ”cgroup.clone_children” is removed.
- /proc/cgroups is meaningless for v2. Use ”cgroup.controllers” file at the root instead.

33.9 Issues with v1 and Rationales for v2

33.9.1 Multiple Hierarchies

cgroup v1 allowed an arbitrary number of hierarchies and each hierarchy could host any number of controllers. While this seemed to provide a high level of flexibility, it wasn't useful in practice.

For example, as there is only one instance of each controller, utility type controllers such as freezer which can be useful in all hierarchies could only be used in one. The issue is exacerbated by the fact that controllers couldn't be moved to another hierarchy once hierarchies were populated. Another issue was that all controllers bound to a hierarchy were forced to have exactly the same view of the hierarchy. It wasn't possible to vary the granularity depending on the specific controller.

In practice, these issues heavily limited which controllers could be put on the same hierarchy and most configurations resorted to putting each controller on its own hierarchy. Only closely related ones, such as the cpu and cpuacct controllers, made sense to be put on the same hierarchy. This often meant that userland ended up managing multiple similar hierarchies repeating the same steps on each hierarchy whenever a hierarchy management operation was necessary.

Furthermore, support for multiple hierarchies came at a steep cost. It greatly complicated cgroup core implementation but more importantly the support for multiple hierarchies restricted how cgroup could be used in general and what controllers was able to do.

There was no limit on how many hierarchies there might be, which meant that a thread's cgroup membership couldn't be described in finite length. The key might contain any number of entries and was unlimited in length, which made it highly awkward to manipulate and led to addition of controllers which existed only to identify membership, which in turn exacerbated the original problem of proliferating number of hierarchies.

Also, as a controller couldn't have any expectation regarding the topologies of hierarchies other controllers might be on, each controller had to assume that all other controllers were attached to completely orthogonal hierarchies. This made it impossible, or at least very cumbersome, for controllers to cooperate with each other.

In most use cases, putting controllers on hierarchies which are completely orthogonal to each other isn't necessary. What usually is called for is the ability to have differing levels of granularity depending on the specific controller. In other words, hierarchy may be collapsed from leaf towards root when viewed from specific controllers. For example, a given configuration might not care about how memory is distributed beyond a certain level while still wanting to control how CPU cycles are distributed.

33.9.2 Thread Granularity

cgroup v1 allowed threads of a process to belong to different cgroups. This didn't make sense for some controllers and those controllers ended up implementing different ways to ignore such situations but much more importantly it blurred the line between API exposed to individual applications and system management interface.

Generally, in-process knowledge is available only to the process itself; thus, unlike service-level organization of processes, categorizing threads of a process requires active participation from the application which owns the target process.

cgroup v1 had an ambiguously defined delegation model which got abused in combination with thread granularity. cgroups were delegated to individual applications so that they can create and manage their own sub-hierarchies and control resource distributions along them. This effectively raised cgroup to the status of a syscall-like API exposed to lay programs.

First of all, cgroup has a fundamentally inadequate interface to be exposed this way. For a process to access its own knobs, it has to extract the path on the target hierarchy from /proc/self/cgroup, construct the path by appending the name of the knob to the path, open and then read and/or write to it. This is not only extremely clunky and unusual but also inherently racy. There is no conventional way to define transaction across the required steps and nothing can guarantee that the process would actually be operating on its own sub-hierarchy.

cgroup controllers implemented a number of knobs which would never be accepted as public APIs because they were just adding control knobs to system-management pseudo filesystem. cgroup ended up with interface knobs which were not properly abstracted or refined and directly revealed kernel internal details. These knobs got exposed to individual applications through the ill-defined delegation mechanism effectively abusing cgroup as a shortcut to implementing public APIs without going through the required scrutiny.

This was painful for both userland and kernel. Userland ended up with misbehaving and poorly abstracted interfaces and kernel exposing and locked into constructs inadvertently.

33.9.3 Competition Between Inner Nodes and Threads

cgroup v1 allowed threads to be in any cgroups which created an interesting problem where threads belonging to a parent cgroup and its children cgroups competed for resources. This was nasty as two different types of entities competed and there was no obvious way to settle it. Different controllers did different things.

The cpu controller considered threads and cgroups as equivalents and mapped nice levels to cgroup weights. This worked for some cases but fell flat when children wanted to be allocated specific ratios of CPU cycles and the number of internal threads fluctuated - the ratios constantly changed as the number of competing entities fluctuated. There also were other issues. The mapping from nice level to weight wasn't obvious or universal, and there were various other knobs which simply weren't available for threads.

The io controller implicitly created a hidden leaf node for each cgroup to host the threads. The hidden leaf had its own copies of all the knobs with `leaf_` prefixed. While this allowed equivalent control over internal threads, it was with serious drawbacks. It always added an extra layer of nesting which wouldn't be necessary otherwise, made the interface messy and significantly complicated the implementation.

The memory controller didn't have a way to control what happened between internal tasks and child cgroups and the behavior was not clearly defined. There were attempts to add ad-

hoc behaviors and knobs to tailor the behavior to specific workloads which would have led to problems extremely difficult to resolve in the long term.

Multiple controllers struggled with internal tasks and came up with different ways to deal with it; unfortunately, all the approaches were severely flawed and, furthermore, the widely different behaviors made cgroup as a whole highly inconsistent.

This clearly is a problem which needs to be addressed from cgroup core in a uniform way.

33.9.4 Other Interface Issues

cgroup v1 grew without oversight and developed a large number of idiosyncrasies and inconsistencies. One issue on the cgroup core side was how an empty cgroup was notified - a userland helper binary was forked and executed for each event. The event delivery wasn't recursive or delegatable. The limitations of the mechanism also led to in-kernel event delivery filtering mechanism further complicating the interface.

Controller interfaces were problematic too. An extreme example is controllers completely ignoring hierarchical organization and treating all cgroups as if they were all located directly under the root cgroup. Some controllers exposed a large amount of inconsistent implementation details to userland.

There also was no consistency across controllers. When a new cgroup was created, some controllers defaulted to not imposing extra restrictions while others disallowed any resource usage until explicitly configured. Configuration knobs for the same type of control used widely differing naming schemes and formats. Statistics and information knobs were named arbitrarily and used different formats and units even in the same controller.

cgroup v2 establishes common conventions where appropriate and updates controllers so that they expose minimal and consistent interfaces.

33.9.5 Controller Issues and Remedies

Memory

The original lower boundary, the soft limit, is defined as a limit that is per default unset. As a result, the set of cgroups that global reclaim prefers is opt-in, rather than opt-out. The costs for optimizing these mostly negative lookups are so high that the implementation, despite its enormous size, does not even provide the basic desirable behavior. First off, the soft limit has no hierarchical meaning. All configured groups are organized in a global rbtree and treated like equal peers, regardless where they are located in the hierarchy. This makes subtree delegation impossible. Second, the soft limit reclaim pass is so aggressive that it not just introduces high allocation latencies into the system, but also impacts system performance due to overreclaim, to the point where the feature becomes self-defeating.

The memory.low boundary on the other hand is a top-down allocated reserve. A cgroup enjoys reclaim protection when it's within its effective low, which makes delegation of subtrees possible. It also enjoys having reclaim pressure proportional to its overage when above its effective low.

The original high boundary, the hard limit, is defined as a strict limit that can not budge, even if the OOM killer has to be called. But this generally goes against the goal of making the most out of the available memory. The memory consumption of workloads varies during runtime, and

that requires users to overcommit. But doing that with a strict upper limit requires either a fairly accurate prediction of the working set size or adding slack to the limit. Since working set size estimation is hard and error prone, and getting it wrong results in OOM kills, most users tend to err on the side of a looser limit and end up wasting precious resources.

The memory.high boundary on the other hand can be set much more conservatively. When hit, it throttles allocations by forcing them into direct reclaim to work off the excess, but it never invokes the OOM killer. As a result, a high boundary that is chosen too aggressively will not terminate the processes, but instead it will lead to gradual performance degradation. The user can monitor this and make corrections until the minimal memory footprint that still gives acceptable performance is found.

In extreme cases, with many concurrent allocations and a complete breakdown of reclaim progress within the group, the high boundary can be exceeded. But even then it's mostly better to satisfy the allocation from the slack available in other groups or the rest of the system than killing the group. Otherwise, memory.max is there to limit this type of spillover and ultimately contain buggy or even malicious applications.

Setting the original memory.limit_in_bytes below the current usage was subject to a race condition, where concurrent charges could cause the limit setting to fail. memory.max on the other hand will first set the limit to prevent new charges, and then reclaim and OOM kill until the new limit is met - or the task writing to memory.max is killed.

The combined memory+swap accounting and limiting is replaced by real control over swap space.

The main argument for a combined memory+swap facility in the original cgroup design was that global or parental pressure would always be able to swap all anonymous memory of a child group, regardless of the child's own (possibly untrusted) configuration. However, untrusted groups can sabotage swapping by other means - such as referencing its anonymous memory in a tight loop - and an admin can not assume full swappability when overcommitting untrusted jobs.

For trusted jobs, on the other hand, a combined counter is not an intuitive userspace interface, and it flies in the face of the idea that cgroup controllers should account and limit specific physical resources. Swap space is a resource like all others in the system, and that's why unified hierarchy allows distributing it separately.

CHAPTER

THIRTYFOUR

CIFS

34.1 Introduction

This is the client VFS module for the SMB3 NAS protocol as well as for older dialects such as the Common Internet File System (CIFS) protocol which was the successor to the Server Message Block (SMB) protocol, the native file sharing mechanism for most early PC operating systems. New and improved versions of CIFS are now called SMB2 and SMB3. Use of SMB3 (and later, including SMB3.1.1 the most current dialect) is strongly preferred over using older dialects like CIFS due to security reasons. All modern dialects, including the most recent, SMB3.1.1, are supported by the CIFS VFS module. The SMB3 protocol is implemented and supported by all major file servers such as Windows (including Windows 2019 Server), as well as by Samba (which provides excellent CIFS/SMB2/SMB3 server support and tools for Linux and many other operating systems). Apple systems also support SMB3 well, as do most Network Attached Storage vendors, so this network filesystem client can mount to a wide variety of systems. It also supports mounting to the cloud (for example Microsoft Azure), including the necessary security features.

The intent of this module is to provide the most advanced network file system function for SMB3 compliant servers, including advanced security features, excellent parallelized high performance i/o, better POSIX compliance, secure per-user session establishment, encryption, high performance safe distributed caching (leases/oplocks), optional packet signing, large files, Unicode support and other internationalization improvements. Since both Samba server and this filesystem client support the CIFS Unix extensions, and the Linux client also suppors SMB3 POSIX extensions, the combination can provide a reasonable alternative to other network and cluster file systems for fileserving in some Linux to Linux environments, not just in Linux to Windows (or Linux to Mac) environments.

This filesystem has a mount utility (mount.cifs) and various user space tools (including smbinfo and setcifsacl) that can be obtained from

https://git.samba.org/?p=cifs-utils.git

or

git://git.samba.org/cifs-utils.git

mount.cifs should be installed in the directory with the other mount helpers.

For more information on the module see the project wiki page at

https://wiki.samba.org/index.php/LinuxCIFS

and

https://wiki.samba.org/index.php/LinuxCIFS_utils

34.2 Usage

This module supports the SMB3 family of advanced network protocols (as well as older dialects, originally called "CIFS" or SMB1).

The CIFS VFS module for Linux supports many advanced network filesystem features such as hierarchical DFS like namespace, hardlinks, locking and more. It was designed to comply with the SNIA CIFS Technical Reference (which supersedes the 1992 X/Open SMB Standard) as well as to perform best practice practical interoperability with Windows 2000, Windows XP, Samba and equivalent servers. This code was developed in participation with the Protocol Freedom Information Foundation. CIFS and now SMB3 has now become a defacto standard for interoperating between Macs and Windows and major NAS appliances.

Please see MS-SMB2 (for detailed SMB2/SMB3/SMB3.1.1 protocol specification) or https://samba.org/samba/PFIF/ for more details.

For questions or bug reports please contact:

smfrench@gmail.com

See the project page at: https://wiki.samba.org/index.php/LinuxCIFS_utils

34.2.1 Build instructions

For Linux:

1) Download the kernel (e.g. from https://www.kernel.org) and change directory into the top of the kernel directory tree (e.g. /usr/src/linux-2.5.73)
2) make menuconfig (or make xconfig)
3) select cifs from within the network filesystem choices
4) save and exit
5) make

34.2.2 Installation instructions

If you have built the CIFS vfs as module (successfully) simply type `make modules_install` (or if you prefer, manually copy the file to the modules directory e.g. /lib/modules/6.3.0-060300-generic/kernel/fs/smb/client/cifs.ko).

If you have built the CIFS vfs into the kernel itself, follow the instructions for your distribution on how to install a new kernel (usually you would simply type `make install`).

If you do not have the utility mount.cifs (in the Samba 4.x source tree and on the CIFS VFS web site) copy it to the same directory in which mount helpers reside (usually /sbin). Although the helper software is not required, mount.cifs is recommended. Most distros include a `cifs-utils` package that includes this utility so it is recommended to install this.

Note that running the Winbind pam/nss module (logon service) on all of your Linux clients is useful in mapping Uids and Gids consistently across the domain to the proper network user. The mount.cifs mount helper can be found at cifs-utils.git on git.samba.org

If cifs is built as a module, then the size and number of network buffers and maximum number of simultaneous requests to one server can be configured. Changing these from their defaults is not recommended. By executing modinfo:

```
modinfo <path to cifs.ko>
```

on kernel/fs/smb/client/cifs.ko the list of configuration changes that can be made at module initialization time (by running insmod cifs.ko) can be seen.

34.2.3 Recommendations

To improve security the SMB2.1 dialect or later (usually will get SMB3.1.1) is now the new default. To use old dialects (e.g. to mount Windows XP) use "vers=1.0" on mount (or vers=2.0 for Windows Vista). Note that the CIFS (vers=1.0) is much older and less secure than the default dialect SMB3 which includes many advanced security features such as downgrade attack detection and encrypted shares and stronger signing and authentication algorithms. There are additional mount options that may be helpful for SMB3 to get improved POSIX behavior (NB: can use vers=3 to force SMB3 or later, never 2.1):

`mfsymlinks` and either `cifsacl` or `modefromsid` (usually with `idsfromsid`)

34.2.4 Allowing User Mounts

To permit users to mount and unmount over directories they own is possible with the cifs vfs. A way to enable such mounting is to mark the mount.cifs utility as suid (e.g. `chmod +s /sbin/mount.cifs`). To enable users to umount shares they mount requires

1) mount.cifs version 1.4 or later
2) an entry for the share in /etc/fstab indicating that a user may unmount it e.g.:

```
//server/usersharename  /mnt/username cifs user 0 0
```

Note that when the mount.cifs utility is run suid (allowing user mounts), in order to reduce risks, the `nosuid` mount flag is passed in on mount to disallow execution of an suid program mounted on the remote target. When mount is executed as root, nosuid is not passed in by default, and execution of suid programs on the remote target would be enabled by default. This can be changed, as with nfs and other filesystems, by simply specifying `nosuid` among the mount options. For user mounts though to be able to pass the suid flag to mount requires rebuilding mount.cifs with the following flag: CIFS_ALLOW_USR_SUID

There is a corresponding manual page for cifs mounting in the Samba 3.0 and later source tree in docs/manpages/mount.cifs.8

34.2.5 Allowing User Unmounts

To permit users to unmount directories that they have user mounted (see above), the utility umount.cifs may be used. It may be invoked directly, or if umount.cifs is placed in /sbin, umount can invoke the cifs umount helper (at least for most versions of the umount utility) for umount of cifs mounts, unless umount is invoked with -i (which will avoid invoking a umount helper). As with mount.cifs, to enable user unmounts umount.cifs must be marked as suid (e.g. `chmod +s /sbin/umount.cifs`) or equivalent (some distributions allow adding entries to a file to the /etc/permissions file to achieve the equivalent suid effect). For this utility to succeed the target path must be a cifs mount, and the uid of the current user must match the uid of the user who mounted the resource.

Also note that the customary way of allowing user mounts and unmounts is (instead of using mount.cifs and unmount.cifs as suid) to add a line to the file /etc/fstab for each //server/share you wish to mount, but this can become unwieldy when potential mount targets include many or unpredictable UNC names.

34.2.6 Samba Considerations

Most current servers support SMB2.1 and SMB3 which are more secure, but there are useful protocol extensions for the older less secure CIFS dialect, so to get the maximum benefit if mounting using the older dialect (CIFS/SMB1), we recommend using a server that supports the SNIA CIFS Unix Extensions standard (e.g. almost any version of Samba ie version 2.2.5 or later) but the CIFS vfs works fine with a wide variety of CIFS servers. Note that uid, gid and file permissions will display default values if you do not have a server that supports the Unix extensions for CIFS (such as Samba 2.2.5 or later). To enable the Unix CIFS Extensions in the Samba server, add the line:

```
unix extensions = yes
```

to your smb.conf file on the server. Note that the following smb.conf settings are also useful (on the Samba server) when the majority of clients are Unix or Linux:

```
case sensitive = yes
delete readonly = yes
ea support = yes
```

Note that server ea support is required for supporting xattrs from the Linux cifs client, and that EA support is present in later versions of Samba (e.g. 3.0.6 and later (also EA support works in all versions of Windows, at least to shares on NTFS filesystems). Extended Attribute (xattr) support is an optional feature of most Linux filesystems which may require enabling via make menuconfig. Client support for extended attributes (user xattr) can be disabled on a per-mount basis by specifying `nouser_xattr` on mount.

The CIFS client can get and set POSIX ACLs (getfacl, setfacl) to Samba servers version 3.10 and later. Setting POSIX ACLs requires enabling both XATTR and then POSIX support in the CIFS configuration options when building the cifs module. POSIX ACL support can be disabled on a per mount basic by specifying `noacl` on mount.

Some administrators may want to change Samba's smb.conf `map archive` and `create mask` parameters from the default. Unless the create mask is changed newly created files can end up with an unnecessarily restrictive default mode, which may not be what you want, although if the CIFS Unix extensions are enabled on the server and client, subsequent setattr calls (e.g. chmod)

can fix the mode. Note that creating special devices (mknod) remotely may require specifying a mkdev function to Samba if you are not using Samba 3.0.6 or later. For more information on these see the manual pages (`man smb.conf`) on the Samba server system. Note that the cifs vfs, unlike the smbfs vfs, does not read the smb.conf on the client system (the few optional settings are passed in on mount via -o parameters instead). Note that Samba 2.2.7 or later includes a fix that allows the CIFS VFS to delete open files (required for strict POSIX compliance). Windows Servers already supported this feature. Samba server does not allow symlinks that refer to files outside of the share, so in Samba versions prior to 3.0.6, most symlinks to files with absolute paths (ie beginning with slash) such as:

```
ln -s /mnt/foo bar
```

would be forbidden. Samba 3.0.6 server or later includes the ability to create such symlinks safely by converting unsafe symlinks (ie symlinks to server files that are outside of the share) to a samba specific format on the server that is ignored by local server applications and non-cifs clients and that will not be traversed by the Samba server). This is opaque to the Linux client application using the cifs vfs. Absolute symlinks will work to Samba 3.0.5 or later, but only for remote clients using the CIFS Unix extensions, and will be invisible to Windows clients and typically will not affect local applications running on the same server as Samba.

34.2.7 Use instructions

Once the CIFS VFS support is built into the kernel or installed as a module (cifs.ko), you can use mount syntax like the following to access Samba or Mac or Windows servers:

```
mount -t cifs //9.53.216.11/e$ /mnt -o username=myname,password=mypassword
```

Before -o the option -v may be specified to make the mount.cifs mount helper display the mount steps more verbosely. After -o the following commonly used cifs vfs specific options are supported:

```
username=<username>
password=<password>
domain=<domain name>
```

Other cifs mount options are described below. Use of TCP names (in addition to ip addresses) is available if the mount helper (mount.cifs) is installed. If you do not trust the server to which are mounted, or if you do not have cifs signing enabled (and the physical network is insecure), consider use of the standard mount options `noexec` and `nosuid` to reduce the risk of running an altered binary on your local system (downloaded from a hostile server or altered by a hostile router).

Although mounting using format corresponding to the CIFS URL specification is not possible in mount.cifs yet, it is possible to use an alternate format for the server and sharename (which is somewhat similar to NFS style mount syntax) instead of the more widely used UNC format (i.e. \servershare):

```
mount -t cifs tcp_name_of_server:share_name /mnt -o user=myname,pass=mypasswd
```

When using the mount helper mount.cifs, passwords may be specified via alternate mechanisms, instead of specifying it after -o using the normal `pass=` syntax on the command line: 1) By

including it in a credential file. Specify credentials=filename as one of the mount options. Credential files contain two lines:

```
username=someuser
password=your_password
```

2) By specifying the password in the PASSWD environment variable (similarly the user name can be taken from the USER environment variable).
3) By specifying the password in a file by name via PASSWD_FILE
4) By specifying the password in a file by file descriptor via PASSWD_FD

If no password is provided, mount.cifs will prompt for password entry

34.2.8 Restrictions

Servers must support either ”pure-TCP” (port 445 TCP/IP CIFS connections) or RFC 1001/1002 support for ”Netbios-Over-TCP/IP.” This is not likely to be a problem as most servers support this.

Valid filenames differ between Windows and Linux. Windows typically restricts filenames which contain certain reserved characters (e.g.the character : which is used to delimit the beginning of a stream name by Windows), while Linux allows a slightly wider set of valid characters in filenames. Windows servers can remap such characters when an explicit mapping is specified in the Server's registry. Samba starting with version 3.10 will allow such filenames (ie those which contain valid Linux characters, which normally would be forbidden for Windows/CIFS semantics) as long as the server is configured for Unix Extensions (and the client has not disabled /proc/fs/cifs/LinuxExtensionsEnabled). In addition the mount option `mapposix` can be used on CIFS (vers=1.0) to force the mapping of illegal Windows/NTFS/SMB characters to a remap range (this mount parameter is the default for SMB3). This remap (`mapposix`) range is also compatible with Mac (and ”Services for Mac” on some older Windows).

34.2.9 CIFS VFS Mount Options

A partial list of the supported mount options follows:

username
The user name to use when trying to establish the CIFS session.

password
The user password. If the mount helper is installed, the user will be prompted for password if not supplied.

ip
The ip address of the target server

unc
The target server Universal Network Name (export) to mount.

domain
Set the SMB/CIFS workgroup name prepended to the username during CIFS session establishment

forceuid
Set the default uid for inodes to the uid passed in on mount. For mounts to servers which do support the CIFS Unix extensions, such as a properly configured Samba server, the server provides the uid, gid and mode so this parameter should not be specified unless the server and clients uid and gid numbering differ. If the server and client are in the same domain (e.g. running winbind or nss_ldap) and the server supports the Unix Extensions then the uid and gid can be retrieved from the server (and uid and gid would not have to be specified on the mount. For servers which do not support the CIFS Unix extensions, the default uid (and gid) returned on lookup of existing files will be the uid (gid) of the person who executed the mount (root, except when mount.cifs is configured setuid for user mounts) unless the `uid=` (gid) mount option is specified. Also note that permission checks (authorization checks) on accesses to a file occur at the server, but there are cases in which an administrator may want to restrict at the client as well. For those servers which do not report a uid/gid owner (such as Windows), permissions can also be checked at the client, and a crude form of client side permission checking can be enabled by specifying file_mode and dir_mode on the client. (default)

forcegid
(similar to above but for the groupid instead of uid) (default)

noforceuid
Fill in file owner information (uid) by requesting it from the server if possible. With this option, the value given in the uid= option (on mount) will only be used if the server can not support returning uids on inodes.

noforcegid
(similar to above but for the group owner, gid, instead of uid)

uid
Set the default uid for inodes, and indicate to the cifs kernel driver which local user mounted. If the server supports the unix extensions the default uid is not used to fill in the owner fields of inodes (files) unless the `forceuid` parameter is specified.

gid
Set the default gid for inodes (similar to above).

file_mode
If CIFS Unix extensions are not supported by the server this overrides the default mode for file inodes.

fsc
Enable local disk caching using FS-Cache (off by default). This option could be useful to improve performance on a slow link, heavily loaded server and/or network where reading from the disk is faster than reading from the server (over the network). This could also impact scalability positively as the number of calls to the server are reduced. However, local caching is not suitable for all workloads for e.g. read-once type workloads. So, you need to consider carefully your workload/scenario before using this option. Currently, local disk caching is functional for CIFS files opened as read-only.

dir_mode
If CIFS Unix extensions are not supported by the server this overrides the default

mode for directory inodes.

port
attempt to contact the server on this tcp port, before trying the usual ports (port 445, then 139).

iocharset
Codepage used to convert local path names to and from Unicode. Unicode is used by default for network path names if the server supports it. If iocharset is not specified then the nls_default specified during the local client kernel build will be used. If server does not support Unicode, this parameter is unused.

rsize
default read size (usually 16K). The client currently can not use rsize larger than CIFSMaxBufSize. CIFSMaxBufSize defaults to 16K and may be changed (from 8K to the maximum kmalloc size allowed by your kernel) at module install time for cifs.ko. Setting CIFSMaxBufSize to a very large value will cause cifs to use more memory and may reduce performance in some cases. To use rsize greater than 127K (the original cifs protocol maximum) also requires that the server support a new Unix Capability flag (for very large read) which some newer servers (e.g. Samba 3.0.26 or later) do. rsize can be set from a minimum of 2048 to a maximum of 130048 (127K or CIFSMaxBufSize, whichever is smaller)

wsize
default write size (default 57344) maximum wsize currently allowed by CIFS is 57344 (fourteen 4096 byte pages)

actimeo=n
attribute cache timeout in seconds (default 1 second). After this timeout, the cifs client requests fresh attribute information from the server. This option allows to tune the attribute cache timeout to suit the workload needs. Shorter timeouts mean better the cache coherency, but increased number of calls to the server. Longer timeouts mean reduced number of calls to the server at the expense of less stricter cache coherency checks (i.e. incorrect attribute cache for a short period of time).

rw
mount the network share read-write (note that the server may still consider the share read-only)

ro
mount network share read-only

version
used to distinguish different versions of the mount helper utility (not typically needed)

sep
if first mount option (after the -o), overrides the comma as the separator between the mount parameters. e.g.:

```
-o user=myname,password=mypassword,domain=mydom
```

could be passed instead with period as the separator by:

```
-o sep=.user=myname.password=mypassword.domain=mydom
```

this might be useful when comma is contained within username or password or domain. This option is less important when the cifs mount helper cifs.mount (version 1.1 or later) is used.

nosuid
Do not allow remote executables with the suid bit program to be executed. This is only meaningful for mounts to servers such as Samba which support the CIFS Unix Extensions. If you do not trust the servers in your network (your mount targets) it is recommended that you specify this option for greater security.

exec
Permit execution of binaries on the mount.

noexec
Do not permit execution of binaries on the mount.

dev
Recognize block devices on the remote mount.

nodev
Do not recognize devices on the remote mount.

suid
Allow remote files on this mountpoint with suid enabled to be executed (default for mounts when executed as root, nosuid is default for user mounts).

credentials
Although ignored by the cifs kernel component, it is used by the mount helper, mount.cifs. When mount.cifs is installed it opens and reads the credential file specified in order to obtain the userid and password arguments which are passed to the cifs vfs.

guest
Although ignored by the kernel component, the mount.cifs mount helper will not prompt the user for a password if guest is specified on the mount options. If no password is specified a null password will be used.

perm
Client does permission checks (vfs_permission check of uid and gid of the file against the mode and desired operation), Note that this is in addition to the normal ACL check on the target machine done by the server software. Client permission checking is enabled by default.

noperm
Client does not do permission checks. This can expose files on this mount to access by other users on the local client system. It is typically only needed when the server supports the CIFS Unix Extensions but the UIDs/GIDs on the client and server system do not match closely enough to allow access by the user doing the mount, but it may be useful with non CIFS Unix Extension mounts for cases in which the default mode is specified on the mount but is not to be enforced on the client (e.g. perhaps when MultiUserMount is enabled) Note that this does not affect the normal ACL check on the target machine done by the server software (of the server ACL against the user name provided at mount time).

serverino
Use server's inode numbers instead of generating automatically incrementing inode numbers on the client. Although this will make it easier to spot hardlinked files (as they will have the same inode numbers) and inode numbers may be persistent, note that the server does not guarantee that the inode numbers are unique if multiple server side mounts are exported under a single share (since inode numbers on the servers might not be unique if multiple filesystems are mounted under the same shared higher level directory). Note that some older (e.g. pre-Windows 2000) do not support returning UniqueIDs or the CIFS Unix Extensions equivalent and for those this mount option will have no effect. Exporting cifs mounts under nfsd requires this mount option on the cifs mount. This is now the default if server supports the required network operation.

noserverino
Client generates inode numbers (rather than using the actual one from the server). These inode numbers will vary after unmount or reboot which can confuse some applications, but not all server filesystems support unique inode numbers.

setuids
If the CIFS Unix extensions are negotiated with the server the client will attempt to set the effective uid and gid of the local process on newly created files, directories, and devices (create, mkdir, mknod). If the CIFS Unix Extensions are not negotiated, for newly created files and directories instead of using the default uid and gid specified on the mount, cache the new file's uid and gid locally which means that the uid for the file can change when the inode is reloaded (or the user remounts the share).

nosetuids
The client will not attempt to set the uid and gid on on newly created files, directories, and devices (create, mkdir, mknod) which will result in the server setting the uid and gid to the default (usually the server uid of the user who mounted the share). Letting the server (rather than the client) set the uid and gid is the default. If the CIFS Unix Extensions are not negotiated then the uid and gid for new files will appear to be the uid (gid) of the mounter or the uid (gid) parameter specified on the mount.

netbiosname
When mounting to servers via port 139, specifies the RFC1001 source name to use to represent the client netbios machine name when doing the RFC1001 netbios session initialize.

direct
Do not do inode data caching on files opened on this mount. This precludes mmapping files on this mount. In some cases with fast networks and little or no caching benefits on the client (e.g. when the application is doing large sequential reads bigger than page size without rereading the same data) this can provide better performance than the default behavior which caches reads (readahead) and writes (writebehind) through the local Linux client pagecache if oplock (caching token) is granted and held. Note that direct allows write operations larger than page size to be sent to the server.

strictcache
Use for switching on strict cache mode. In this mode the client read from the

cache all the time it has Oplock Level II, otherwise - read from the server. All written data are stored in the cache, but if the client doesn't have Exclusive Oplock, it writes the data to the server.

rwpidforward
Forward pid of a process who opened a file to any read or write operation on that file. This prevent applications like WINE from failing on read and write if we use mandatory brlock style.

acl
Allow setfacl and getfacl to manage posix ACLs if server supports them. (default)

noacl
Do not allow setfacl and getfacl calls on this mount

user_xattr
Allow getting and setting user xattrs (those attributes whose name begins with `user.` or `os2.`) as OS/2 EAs (extended attributes) to the server. This allows support of the setfattr and getfattr utilities. (default)

nouser_xattr
Do not allow getfattr/setfattr to get/set/list xattrs

mapchars
Translate six of the seven reserved characters (not backslash):

```
*?<>|:
```

to the remap range (above 0xF000), which also allows the CIFS client to recognize files created with such characters by Windows's POSIX emulation. This can also be useful when mounting to most versions of Samba (which also forbids creating and opening files whose names contain any of these seven characters). This has no effect if the server does not support Unicode on the wire.

nomapchars
Do not translate any of these seven characters (default).

nocase
Request case insensitive path name matching (case sensitive is the default if the server supports it). (mount option `ignorecase` is identical to `nocase`)

posixpaths
If CIFS Unix extensions are supported, attempt to negotiate posix path name support which allows certain characters forbidden in typical CIFS filenames, without requiring remapping. (default)

noposixpaths
If CIFS Unix extensions are supported, do not request posix path name support (this may cause servers to reject creatingfile with certain reserved characters).

nounix
Disable the CIFS Unix Extensions for this mount (tree connection). This is rarely needed, but it may be useful in order to turn off multiple settings all at once (ie posix acls, posix locks, posix paths, symlink support and retrieving uids/gids/mode from the server) or to work around a bug in server which implement the Unix Extensions.

nobrl
Do not send byte range lock requests to the server. This is necessary for certain applications that break with cifs style mandatory byte range locks (and most cifs servers do not yet support requesting advisory byte range locks).

forcemandatorylock
Even if the server supports posix (advisory) byte range locking, send only mandatory lock requests. For some (presumably rare) applications, originally coded for DOS/Windows, which require Windows style mandatory byte range locking, they may be able to take advantage of this option, forcing the cifs client to only send mandatory locks even if the cifs server would support posix advisory locks. `forcemand` is accepted as a shorter form of this mount option.

nostrictsync
If this mount option is set, when an application does an fsync call then the cifs client does not send an SMB Flush to the server (to force the server to write all dirty data for this file immediately to disk), although cifs still sends all dirty (cached) file data to the server and waits for the server to respond to the write. Since SMB Flush can be very slow, and some servers may be reliable enough (to risk delaying slightly flushing the data to disk on the server), turning on this option may be useful to improve performance for applications that fsync too much, at a small risk of server crash. If this mount option is not set, by default cifs will send an SMB flush request (and wait for a response) on every fsync call.

nodfs
Disable DFS (global name space support) even if the server claims to support it. This can help work around a problem with parsing of DFS paths with Samba server versions 3.0.24 and 3.0.25.

remount
remount the share (often used to change from ro to rw mounts or vice versa)

cifsacl
Report mode bits (e.g. on stat) based on the Windows ACL for the file. (EXPERIMENTAL)

servern
Specify the server 's netbios name (RFC1001 name) to use when attempting to setup a session to the server. This is needed for mounting to some older servers (such as OS/2 or Windows 98 and Windows ME) since they do not support a default server name. A server name can be up to 15 characters long and is usually uppercased.

sfu
When the CIFS Unix Extensions are not negotiated, attempt to create device files and fifos in a format compatible with Services for Unix (SFU). In addition retrieve bits 10-12 of the mode via the SETFILEBITS extended attribute (as SFU does). In the future the bottom 9 bits of the mode also will be emulated using queries of the security descriptor (ACL).

mfsymlinks
Enable support for Minshall+French symlinks (see http://wiki.samba.org/index.php/UNIX_Extensions#Minshall.2BFrench_symlinks) This option is ignored when specified together with the 'sfu' option. Minshall+French symlinks are used even if the server supports the CIFS Unix Extensions.

sign
Must use packet signing (helps avoid unwanted data modification by intermediate systems in the route). Note that signing does not work with lanman or plaintext authentication.

seal
Must seal (encrypt) all data on this mounted share before sending on the network. Requires support for Unix Extensions. Note that this differs from the sign mount option in that it causes encryption of data sent over this mounted share but other shares mounted to the same server are unaffected.

locallease
This option is rarely needed. Fcntl F_SETLEASE is used by some applications such as Samba and NFSv4 server to check to see whether a file is cacheable. CIFS has no way to explicitly request a lease, but can check whether a file is cacheable (oplocked). Unfortunately, even if a file is not oplocked, it could still be cacheable (ie cifs client could grant fcntl leases if no other local processes are using the file) for cases for example such as when the server does not support oplocks and the user is sure that the only updates to the file will be from this client. Specifying this mount option will allow the cifs client to check for leases (only) locally for files which are not oplocked instead of denying leases in that case. (EXPERIMENTAL)

sec
Security mode. Allowed values are:

none
attempt to connection as a null user (no name)

krb5
Use Kerberos version 5 authentication

krb5i
Use Kerberos authentication and packet signing

ntlm
Use NTLM password hashing (default)

ntlmi
Use NTLM password hashing with signing (if /proc/fs/cifs/PacketSigningEnabled on or if server requires signing also can be the default)

ntlmv2
Use NTLMv2 password hashing

ntlmv2i
Use NTLMv2 password hashing with packet signing

lanman
(if configured in kernel config) use older lanman hash

hard
Retry file operations if server is not responding

soft
Limit retries to unresponsive servers (usually only one retry) before returning an error. (default)

The mount.cifs mount helper also accepts a few mount options before -o including:

-S	take password from stdin (equivalent to setting the environment variable `PASSWD_FD=0`
-V	print mount.cifs version
-?	display simple usage information

With most 2.6 kernel versions of modutils, the version of the cifs kernel module can be displayed via modinfo.

34.2.10 Misc /proc/fs/cifs Flags and Debug Info

Informational pseudo-files:

DebugData	Displays information about active CIFS sessions and shares, features enabled as well as the cifs.ko version.
Stats	Lists summary resource usage information as well as per share statistics.
open_files	List all the open file handles on all active SMB sessions.
mount_params	List of all mount parameters available for the module

Configuration pseudo-files:

SecurityFlags	Flags which control security negotiation and also packet signing. Authentication (may/must) flags (e.g. for NTLM and/or NTLMv2) may be combined with the signing flags. Specifying two different password hashing mechanisms (as "must use") on the other hand does not make much sense. Default flags are:
	`0x07007`
	(NTLM, NTLMv2 and packet signing allowed). The maximum allowable flags if you want to allow mounts to servers using weaker password hashes is 0x37037 (lanman, plaintext, ntlm, ntlmv2, signing allowed). Some SecurityFlags require the corresponding menuconfig options to be enabled. Enabling plaintext authentication currently requires also enabling lanman authentication in the security flags because the cifs module only supports sending laintext passwords using the older lanman dialect form of the session setup SMB. (e.g. for authentication using plain text passwords, set the SecurityFlags to 0x30030):
	`may use packet signing 0x00001`
	`must use packet signing 0x01001`
	`may use NTLM (most common password hash) 0x00002`
	`must use NTLM 0x02002`
	`may use NTLMv2 0x00004`
	`must use NTLMv2 0x04004`
	`may use Kerberos security 0x00008`
	`must use Kerberos 0x08008`
	`may use lanman (weak) password hash 0x00010`
	`must use lanman password hash 0x10010`
	`may use plaintext passwords 0x00020`
	`must use plaintext passwords 0x20020`
	`(reserved for future packet encryption) 0x00040`

cifsFYI	If set to non-zero value, additional debug information will be logged to the system error log. This field contains three flags controlling different classes of debugging entries. The maximum value it can be set to

These experimental features and tracing can be enabled by changing flags in /proc/fs/cifs (after the cifs module has been installed or built into the kernel, e.g. insmod cifs). To enable a feature set it to 1 e.g. to enable tracing to the kernel message log type:

```
echo 7 > /proc/fs/cifs/cifsFYI
```

cifsFYI functions as a bit mask. Setting it to 1 enables additional kernel logging of various informational messages. 2 enables logging of non-zero SMB return codes while 4 enables logging of requests that take longer than one second to complete (except for byte range lock requests). Setting it to 4 requires CONFIG_CIFS_STATS2 to be set in kernel configuration (.config). Setting it to seven enables all three. Finally, tracing the start of smb requests and responses can be enabled via:

```
echo 1 > /proc/fs/cifs/traceSMB
```

Per share (per client mount) statistics are available in /proc/fs/cifs/Stats. Additional information is available if CONFIG_CIFS_STATS2 is enabled in the kernel configuration (.config). The statistics returned include counters which represent the number of attempted and failed (ie non-zero return code from the server) SMB3 (or cifs) requests grouped by request type (read, write, close etc.). Also recorded is the total bytes read and bytes written to the server for that share. Note that due to client caching effects this can be less than the number of bytes read and written by the application running on the client. Statistics can be reset to zero by `echo 0 > /proc/fs/cifs/Stats` which may be useful if comparing performance of two different scenarios.

Also note that `cat /proc/fs/cifs/DebugData` will display information about the active sessions and the shares that are mounted.

Enabling Kerberos (extended security) works but requires version 1.2 or later of the helper program cifs.upcall to be present and to be configured in the /etc/request-key.conf file. The cifs.upcall helper program is from the Samba project(https://www.samba.org). NTLM and NTLMv2 and LANMAN support do not require this helper. Note that NTLMv2 security (which does not require the cifs.upcall helper program), instead of using Kerberos, is sufficient for some use cases.

DFS support allows transparent redirection to shares in an MS-DFS name space. In addition, DFS support for target shares which are specified as UNC names which begin with host names (rather than IP addresses) requires a user space helper (such as cifs.upcall) to be present in order to translate host names to ip address, and the user space helper must also be configured in the file /etc/request-key.conf. Samba, Windows servers and many NAS appliances support DFS as a way of constructing a global name space to ease network configuration and improve reliability.

To use cifs Kerberos and DFS support, the Linux keyutils package should be installed and something like the following lines should be added to the /etc/request-key.conf file:

```
create cifs.spnego * * /usr/local/sbin/cifs.upcall %k
create dns_resolver * * /usr/local/sbin/cifs.upcall %k
```

34.2.11 CIFS kernel module parameters

These module parameters can be specified or modified either during the time of module loading or during the runtime by using the interface:

```
/sys/module/cifs/parameters/<param>
```

i.e.:

```
echo "value" > /sys/module/cifs/parameters/<param>
```

More detailed descriptions of the available module parameters and their values can be seen by doing:

modinfo cifs (or modinfo smb3)

1. enable_oplocks	Enable or disable oplocks. Oplocks are enabled by default. [Y/y/1]. To disable use any of [N/n/0].

34.3 TODO

As of 6.7 kernel. See https://wiki.samba.org/index.php/LinuxCIFSKernel for list of features added by release

34.3.1 A Partial List of Missing Features

Contributions are welcome. There are plenty of opportunities for visible, important contributions to this module. Here is a partial list of the known problems and missing features:

a) SMB3 (and SMB3.1.1) missing optional features: multichannel performance optimizations, algorithmic channel selection, directory leases optimizations, support for faster packet signing (GMAC), support for compression over the network, T10 copy offload ie "ODX" (copy chunk, and "Duplicate Extents" ioctl are currently the only two server side copy mechanisms supported)

b) Better optimized compounding and error handling for sparse file support, perhaps addition of new optional SMB3.1.1 fsctls to make collapse range and insert range more atomic

c) Support for SMB3.1.1 over QUIC (and perhaps other socket based protocols like SCTP)

d) quota support (needs minor kernel change since quota calls otherwise won't make it to network filesystems or deviceless filesystems).

e) Additional use cases can be optimized to use "compounding" (e.g. open/query/close and open/setinfo/close) to reduce the number of roundtrips to the server and improve performance. Various cases (stat, statfs, create, unlink, mkdir, xattrs) already have been improved by using compounding but more can be done. In addition we could significantly reduce redundant opens by using deferred close (with handle caching leases) and better using reference counters on file handles.

f) Finish inotify support so kde and gnome file list windows will autorefresh (partially complete by Asser). Needs minor kernel vfs change to support removing D_NOTIFY on a file.

g) Add GUI tool to configure /proc/fs/cifs settings and for display of the CIFS statistics (started)

h) implement support for security and trusted categories of xattrs (requires minor protocol extension) to enable better support for SELINUX

i) Add support for tree connect contexts (see MS-SMB2) a new SMB3.1.1 protocol feature (may be especially useful for virtualization).

j) Create UID mapping facility so server UIDs can be mapped on a per mount or a per server basis to client UIDs or nobody if no mapping exists. Also better integration with winbind for resolving SID owners

k) Add tools to take advantage of more smb3 specific ioctls and features (passthrough ioctl/fsctl is now implemented in cifs.ko to allow sending various SMB3 fsctls and query info and set info calls directly from user space) Add tools to make setting various non-POSIX metadata attributes easier from tools (e.g. extending what was done in smb-info tool).

l) encrypted file support (currently the attribute showing the file is encrypted on the server is reported, but changing the attribute is not supported).

m) improved stats gathering tools (perhaps integration with nfsometer?) to extend and make easier to use what is currently in /proc/fs/cifs/Stats

n) Add support for claims based ACLs (”DAC”)

o) mount helper GUI (to simplify the various configuration options on mount)

p) Expand support for witness protocol to allow for notification of share move, and server network adapter changes. Currently only notifications by the witness protocol for server move is supported by the Linux client.

q) Allow mount.cifs to be more verbose in reporting errors with dialect or unsupported feature errors. This would now be easier due to the implementation of the new mount API.

r) updating cifs documentation, and user guide.

s) Addressing bugs found by running a broader set of xfstests in standard file system xfstest suite.

t) split cifs and smb3 support into separate modules so legacy (and less secure) CIFS dialect can be disabled in environments that don't need it and simplify the code.

v) Additional testing of POSIX Extensions for SMB3.1.1

w) Support for the Mac SMB3.1.1 extensions to improve interop with Apple servers

x) Support for additional authentication options (e.g. IAKERB, peer-to-peer Kerberos, SCRAM and others supported by existing servers)

y) Improved tracing, more eBPF trace points, better scripts for performance analysis

34.3.2 Known Bugs

See https://bugzilla.samba.org - search on product "CifsVFS" for current bug list. Also check http://bugzilla.kernel.org (Product = File System, Component = CIFS) and xfstest results e.g. https://wiki.samba.org/index.php/Xfstest-results-smb3

34.3.3 Misc testing to do

1) check out max path names and max path name components against various server types. Try nested symlinks (8 deep). Return max path name in stat -f information
2) Improve xfstest's cifs/smb3 enablement and adapt xfstests where needed to test cifs/smb3 better
3) Additional performance testing and optimization using iozone and similar - there are some easy changes that can be done to parallelize sequential writes, and when signing is disabled to request larger read sizes (larger than negotiated size) and send larger write sizes to modern servers.
4) More exhaustively test against less common servers
5) Continue to extend the smb3 "buildbot" which does automated xfstesting against Windows, Samba and Azure currently - to add additional tests and to allow the buildbot to execute the tests faster. The URL for the buildbot is: http://smb3-test-rhel-75.southcentralus.cloudapp.azure.com
6) Address various coverity warnings (most are not bugs per-se, but the more warnings are addressed, the easier it is to spot real problems that static analyzers will point out in the future).

34.4 Changes

See https://wiki.samba.org/index.php/LinuxCIFSKernel for summary information about fixes/improvements to CIFS/SMB2/SMB3 support (changes to cifs.ko module) by kernel version (and cifs internal module version). This may be easier to read than parsing the output of "git log fs/smb/client" by release.

34.5 Authors

34.5.1 Original Author

Steve French (smfrench@gmail.com, sfrench@samba.org)

The author wishes to express his appreciation and thanks to: Andrew Tridgell (Samba team) for his early suggestions about SMB/CIFS VFS improvements. Thanks to IBM for allowing me time and test resources to pursue this project, to Jim McDonough from IBM (and the Samba Team) for his help, to the IBM Linux JFS team for explaining many esoteric Linux filesystem features. Jeremy Allison of the Samba team has done invaluable work in adding the server side of the original CIFS Unix extensions and reviewing and implementing portions of the newer CIFS POSIX extensions into the Samba 3 file server. Thank Dave Boutcher of IBM Rochester (author of the OS/400 smb/cifs filesystem client) for proving years ago that very good smb/cifs

clients could be done on Unix-like operating systems. Volker Lendecke, Andrew Tridgell, Urban Widmark, John Newbigin and others for their work on the Linux smbfs module. Thanks to the other members of the Storage Network Industry Association CIFS Technical Workgroup for their work specifying this highly complex protocol and finally thanks to the Samba team for their technical advice and encouragement.

34.5.2 Patch Contributors

- Zwane Mwaikambo
- Andi Kleen
- Amrut Joshi
- Shobhit Dayal
- Sergey Vlasov
- Richard Hughes
- Yury Umanets
- Mark Hamzy (for some of the early cifs IPv6 work)
- Domen Puncer
- Jesper Juhl (in particular for lots of whitespace/formatting cleanup)
- Vince Negri and Dave Stahl (for finding an important caching bug)
- Adrian Bunk (kcalloc cleanups)
- Miklos Szeredi
- Kazeon team for various fixes especially for 2.4 version.
- Asser Ferno (Change Notify support)
- Shaggy (Dave Kleikamp) for innumerable small fs suggestions and some good cleanup
- Gunter Kukkukk (testing and suggestions for support of old servers)
- Igor Mammedov (DFS support)
- Jeff Layton (many, many fixes, as well as great work on the cifs Kerberos code)
- Scott Lovenberg
- Pavel Shilovsky (for great work adding SMB2 support, and various SMB3 features)
- Aurelien Aptel (for DFS SMB3 work and some key bug fixes)
- Ronnie Sahlberg (for SMB3 xattr work, bug fixes, and lots of great work on compounding)
- Shirish Pargaonkar (for many ACL patches over the years)
- Sachin Prabhu (many bug fixes, including for reconnect, copy offload and security)
- Paulo Alcantara (for some excellent work in DFS, and in booting from SMB3)
- Long Li (some great work on RDMA, SMB Direct)

34.5.3 Test case and Bug Report contributors

Thanks to those in the community who have submitted detailed bug reports and debug of problems they have found: Jochen Dolze, David Blaine, Rene Scharfe, Martin Josefsson, Alexander Wild, Anthony Liguori, Lars Muller, Urban Widmark, Massimiliano Ferrero, Howard Owen, Olaf Kirch, Kieron Briggs, Nick Millington and others. Also special mention to the Stanford Checker (SWAT) which pointed out many minor bugs in error paths. Valuable suggestions also have come from Al Viro and Dave Miller.

And thanks to the IBM LTC and Power test teams and SuSE and Citrix and RedHat testers for finding multiple bugs during excellent stress test runs.

CHAPTER

THIRTYFIVE

CLEARING WARN_ONCE

WARN_ONCE / WARN_ON_ONCE / printk_once only emit a message once.

echo 1 > /sys/kernel/debug/clear_warn_once

clears the state and allows the warnings to print once again. This can be useful after test suite runs to reproduce problems.

CHAPTER

THIRTYSIX

CPU LOAD

Linux exports various bits of information via `/proc/stat` and `/proc/uptime` that userland tools, such as top(1), use to calculate the average time system spent in a particular state, for example:

```
$ iostat
Linux 2.6.18.3-exp (linmac)     02/20/2007

avg-cpu:  %user   %nice %system %iowait  %steal   %idle
          10.01    0.00    2.92    5.44    0.00   81.63

...
```

Here the system thinks that over the default sampling period the system spent 10.01% of the time doing work in user space, 2.92% in the kernel, and was overall 81.63% of the time idle.

In most cases the `/proc/stat` information reflects the reality quite closely, however due to the nature of how/when the kernel collects this data sometimes it can not be trusted at all.

So how is this information collected? Whenever timer interrupt is signalled the kernel looks what kind of task was running at this moment and increments the counter that corresponds to this tasks kind/state. The problem with this is that the system could have switched between various states multiple times between two timer interrupts yet the counter is incremented only for the last state.

36.1 Example

If we imagine the system with one task that periodically burns cycles in the following manner:

```
 time line between two timer interrupts
|--------------------------------------|
 ^                                     ^
 |_ something begins working           |
                                       |_ something goes to sleep
                                      (only to be awaken quite soon)
```

In the above situation the system will be 0% loaded according to the `/proc/stat` (since the timer interrupt will always happen when the system is executing the idle handler), but in reality the load is closer to 99%.

One can imagine many more situations where this behavior of the kernel will lead to quite erratic information inside `/proc/stat`:

```
/* gcc -o hog smallhog.c */
#include <time.h>
#include <limits.h>
#include <signal.h>
#include <sys/time.h>
#define HIST 10

static volatile sig_atomic_t stop;

static void sighandler(int signr)
{
        (void) signr;
        stop = 1;
}

static unsigned long hog (unsigned long niters)
{
        stop = 0;
        while (!stop && --niters);
        return niters;
}

int main (void)
{
        int i;
        struct itimerval it = {
                .it_interval = { .tv_sec = 0, .tv_usec = 1 },
                .it_value    = { .tv_sec = 0, .tv_usec = 1 } };
        sigset_t set;
        unsigned long v[HIST];
        double tmp = 0.0;
        unsigned long n;
        signal(SIGALRM, &sighandler);
        setitimer(ITIMER_REAL, &it, NULL);

        hog (ULONG_MAX);
        for (i = 0; i < HIST; ++i) v[i] = ULONG_MAX - hog(ULONG_MAX);
        for (i = 0; i < HIST; ++i) tmp += v[i];
        tmp /= HIST;
        n = tmp - (tmp / 3.0);

        sigemptyset(&set);
        sigaddset(&set, SIGALRM);

        for (;;) {
                hog(n);
                sigwait(&set, &i);
        }
        return 0;
}
```

THIRTYSEVEN

HOW CPU TOPOLOGY INFO IS EXPORTED VIA SYSFS

CPU topology info is exported via sysfs. Items (attributes) are similar to /proc/cpuinfo output of some architectures. They reside in /sys/devices/system/cpu/cpuX/topology/. Please refer to the ABI file: Documentation/ABI/stable/sysfs-devices-system-cpu.

Architecture-neutral, drivers/base/topology.c, exports these attributes. However the die, cluster, book, and drawer hierarchy related sysfs files will only be created if an architecture provides the related macros as described below.

For an architecture to support this feature, it must define some of these macros in include/asm-XXX/topology.h:

```
#define topology_physical_package_id(cpu)
#define topology_die_id(cpu)
#define topology_cluster_id(cpu)
#define topology_core_id(cpu)
#define topology_book_id(cpu)
#define topology_drawer_id(cpu)
#define topology_sibling_cpumask(cpu)
#define topology_core_cpumask(cpu)
#define topology_cluster_cpumask(cpu)
#define topology_die_cpumask(cpu)
#define topology_book_cpumask(cpu)
#define topology_drawer_cpumask(cpu)
```

The type of `**_id macros` is int. The type of `**_cpumask macros` is `(const) struct cpumask *`. The latter correspond with appropriate `**_siblings` sysfs attributes (except for topology_sibling_cpumask() which corresponds with thread_siblings).

To be consistent on all architectures, include/linux/topology.h provides default definitions for any of the above macros that are not defined by include/asm-XXX/topology.h:

1) topology_physical_package_id: -1
2) topology_die_id: -1
3) topology_cluster_id: -1
4) topology_core_id: 0
5) topology_book_id: -1
6) topology_drawer_id: -1
7) topology_sibling_cpumask: just the given CPU

8) topology_core_cpumask: just the given CPU
9) topology_cluster_cpumask: just the given CPU
10) topology_die_cpumask: just the given CPU
11) topology_book_cpumask: just the given CPU
12) topology_drawer_cpumask: just the given CPU

Additionally, CPU topology information is provided under /sys/devices/system/cpu and includes these files. The internal source for the output is in brackets ("[]").

kernel_max:	the maximum CPU index allowed by the kernel configuration. [NR_CPUS-1]
offline:	CPUs that are not online because they have been HOTPLUGGED off or exceed the limit of CPUs allowed by the kernel configuration (kernel_max above). [~cpu_online_mask + cpus >= NR_CPUS]
online:	CPUs that are online and being scheduled [cpu_online_mask]
possible:	CPUs that have been allocated resources and can be brought online if they are present. [cpu_possible_mask]
present:	CPUs that have been identified as being present in the system. [cpu_present_mask]

The format for the above output is compatible with cpulist_parse() [see <linux/cpumask.h>]. Some examples follow.

In this example, there are 64 CPUs in the system but cpus 32-63 exceed the kernel max which is limited to 0..31 by the NR_CPUS config option being 32. Note also that CPUs 2 and 4-31 are not online but could be brought online as they are both present and possible:

```
kernel_max: 31
   offline: 2,4-31,32-63
    online: 0-1,3
  possible: 0-31
   present: 0-31
```

In this example, the NR_CPUS config option is 128, but the kernel was started with possible_cpus=144. There are 4 CPUs in the system and cpu2 was manually taken offline (and is the only CPU that can be brought online.):

```
kernel_max: 127
   offline: 2,4-127,128-143
    online: 0-1,3
  possible: 0-127
   present: 0-3
```

See Documentation/core-api/cpu_hotplug.rst for the possible_cpus=NUM kernel start parameter as well as more information on the various cpumasks.

DELL REMOTE BIOS UPDATE DRIVER (DELL_RBU)

38.1 Purpose

Document demonstrating the use of the Dell Remote BIOS Update driver for updating BIOS images on Dell servers and desktops.

38.2 Scope

This document discusses the functionality of the rbu driver only. It does not cover the support needed from applications to enable the BIOS to update itself with the image downloaded in to the memory.

38.3 Overview

This driver works with Dell OpenManage or Dell Update Packages for updating the BIOS on Dell servers (starting from servers sold since 1999), desktops and notebooks (starting from those sold in 2005).

Please go to http://support.dell.com register and you can find info on OpenManage and Dell Update packages (DUP).

Libsmbios can also be used to update BIOS on Dell systems go to https://linux.dell.com/libsmbios/ for details.

Dell_RBU driver supports BIOS update using the monolithic image and packetized image methods. In case of monolithic the driver allocates a contiguous chunk of physical pages having the BIOS image. In case of packetized the app using the driver breaks the image in to packets of fixed sizes and the driver would place each packet in contiguous physical memory. The driver also maintains a link list of packets for reading them back.

If the dell_rbu driver is unloaded all the allocated memory is freed.

The rbu driver needs to have an application (as mentioned above) which will inform the BIOS to enable the update in the next system reboot.

The user should not unload the rbu driver after downloading the BIOS image or updating.

The driver load creates the following directories under the /sys file system:

```
/sys/class/firmware/dell_rbu/loading
/sys/class/firmware/dell_rbu/data
/sys/devices/platform/dell_rbu/image_type
/sys/devices/platform/dell_rbu/data
/sys/devices/platform/dell_rbu/packet_size
```

The driver supports two types of update mechanism; monolithic and packetized. These update mechanism depends upon the BIOS currently running on the system. Most of the Dell systems support a monolithic update where the BIOS image is copied to a single contiguous block of physical memory.

In case of packet mechanism the single memory can be broken in smaller chunks of contiguous memory and the BIOS image is scattered in these packets.

By default the driver uses monolithic memory for the update type. This can be changed to packets during the driver load time by specifying the load parameter image_type=packet. This can also be changed later as below:

```
echo packet > /sys/devices/platform/dell_rbu/image_type
```

In packet update mode the packet size has to be given before any packets can be downloaded. It is done as below:

```
echo XXXX > /sys/devices/platform/dell_rbu/packet_size
```

In the packet update mechanism, the user needs to create a new file having packets of data arranged back to back. It can be done as follows: The user creates packets header, gets the chunk of the BIOS image and places it next to the packetheader; now, the packetheader + BIOS image chunk added together should match the specified packet_size. This makes one packet, the user needs to create more such packets out of the entire BIOS image file and then arrange all these packets back to back in to one single file.

This file is then copied to /sys/class/firmware/dell_rbu/data. Once this file gets to the driver, the driver extracts packet_size data from the file and spreads it across the physical memory in contiguous packet_sized space.

This method makes sure that all the packets get to the driver in a single operation.

In monolithic update the user simply get the BIOS image (.hdr file) and copies to the data file as is without any change to the BIOS image itself.

Do the steps below to download the BIOS image.

1) echo 1 > /sys/class/firmware/dell_rbu/loading
2) cp bios_image.hdr /sys/class/firmware/dell_rbu/data
3) echo 0 > /sys/class/firmware/dell_rbu/loading

The /sys/class/firmware/dell_rbu/ entries will remain till the following is done.

```
echo -1 > /sys/class/firmware/dell_rbu/loading
```

Until this step is completed the driver cannot be unloaded.

Also echoing either mono, packet or init in to image_type will free up the memory allocated by the driver.

If a user by accident executes steps 1 and 3 above without executing step 2; it will make the /sys/class/firmware/dell_rbu/ entries disappear.

The entries can be recreated by doing the following:

```
echo init > /sys/devices/platform/dell_rbu/image_type
```

Note: echoing init in image_type does not change its original value.

Also the driver provides /sys/devices/platform/dell_rbu/data readonly file to read back the image downloaded.

Note: After updating the BIOS image a user mode application needs to execute code which sends the BIOS update request to the BIOS. So on the next reboot the BIOS knows about the new image downloaded and it updates itself. Also don't unload the rbu driver if the image has to be updated.

THIRTYNINE

DEVICE MAPPER

39.1 Guidance for writing policies

Try to keep transactionality out of it. The core is careful to avoid asking about anything that is migrating. This is a pain, but makes it easier to write the policies.

Mappings are loaded into the policy at construction time.

Every bio that is mapped by the target is referred to the policy. The policy can return a simple HIT or MISS or issue a migration.

Currently there's no way for the policy to issue background work, e.g. to start writing back dirty blocks that are going to be evicted soon.

Because we map bios, rather than requests it's easy for the policy to get fooled by many small bios. For this reason the core target issues periodic ticks to the policy. It's suggested that the policy doesn't update states (eg, hit counts) for a block more than once for each tick. The core ticks by watching bios complete, and so trying to see when the io scheduler has let the ios run.

39.1.1 Overview of supplied cache replacement policies

multiqueue (mq)

This policy is now an alias for smq (see below).

The following tunables are accepted, but have no effect:

```
'sequential_threshold <#nr_sequential_ios>'
'random_threshold <#nr_random_ios>'
'read_promote_adjustment <value>'
'write_promote_adjustment <value>'
'discard_promote_adjustment <value>'
```

Stochastic multiqueue (smq)

This policy is the default.

The stochastic multi-queue (smq) policy addresses some of the problems with the multiqueue (mq) policy.

The smq policy (vs mq) offers the promise of less memory utilization, improved performance and increased adaptability in the face of changing workloads. smq also does not have any cumbersome tuning knobs.

Users may switch from ”mq” to ”smq” simply by appropriately reloading a DM table that is using the cache target. Doing so will cause all of the mq policy's hints to be dropped. Also, performance of the cache may degrade slightly until smq recalculates the origin device's hotspots that should be cached.

Memory usage

The mq policy used a lot of memory; 88 bytes per cache block on a 64 bit machine.

smq uses 28bit indexes to implement its data structures rather than pointers. It avoids storing an explicit hit count for each block. It has a 'hotspot' queue, rather than a pre-cache, which uses a quarter of the entries (each hotspot block covers a larger area than a single cache block).

All this means smq uses ~25bytes per cache block. Still a lot of memory, but a substantial improvement nonetheless.

Level balancing

mq placed entries in different levels of the multiqueue structures based on their hit count (~ln(hit count)). This meant the bottom levels generally had the most entries, and the top ones had very few. Having unbalanced levels like this reduced the efficacy of the multiqueue.

smq does not maintain a hit count, instead it swaps hit entries with the least recently used entry from the level above. The overall ordering being a side effect of this stochastic process. With this scheme we can decide how many entries occupy each multiqueue level, resulting in better promotion/demotion decisions.

Adaptability: The mq policy maintained a hit count for each cache block. For a different block to get promoted to the cache its hit count has to exceed the lowest currently in the cache. This meant it could take a long time for the cache to adapt between varying IO patterns.

smq doesn't maintain hit counts, so a lot of this problem just goes away. In addition it tracks performance of the hotspot queue, which is used to decide which blocks to promote. If the hotspot queue is performing badly then it starts moving entries more quickly between levels. This lets it adapt to new IO patterns very quickly.

Performance

Testing smq shows substantially better performance than mq.

cleaner

The cleaner writes back all dirty blocks in a cache to decommission it.

39.1.2 Examples

The syntax for a table is:

```
cache <metadata dev> <cache dev> <origin dev> <block size>
<#feature_args> [<feature arg>]*
<policy> <#policy_args> [<policy arg>]*
```

The syntax to send a message using the dmsetup command is:

```
dmsetup message <mapped device> 0 sequential_threshold 1024
dmsetup message <mapped device> 0 random_threshold 8
```

Using dmsetup:

```
dmsetup create blah --table "0 268435456 cache /dev/sdb /dev/sdc \
    /dev/sdd 512 0 mq 4 sequential_threshold 1024 random_threshold 8"
creates a 128GB large mapped device named 'blah' with the
sequential threshold set to 1024 and the random_threshold set to 8.
```

39.2 Cache

39.2.1 Introduction

dm-cache is a device mapper target written by Joe Thornber, Heinz Mauelshagen, and Mike Snitzer.

It aims to improve performance of a block device (eg, a spindle) by dynamically migrating some of its data to a faster, smaller device (eg, an SSD).

This device-mapper solution allows us to insert this caching at different levels of the dm stack, for instance above the data device for a thin-provisioning pool. Caching solutions that are integrated more closely with the virtual memory system should give better performance.

The target reuses the metadata library used in the thin-provisioning library.

The decision as to what data to migrate and when is left to a plug-in policy module. Several of these have been written as we experiment, and we hope other people will contribute others for specific io scenarios (eg. a vm image server).

39.2.2 Glossary

Migration
Movement of the primary copy of a logical block from one device to the other.

Promotion
Migration from slow device to fast device.

Demotion
Migration from fast device to slow device.

The origin device always contains a copy of the logical block, which may be out of date or kept in sync with the copy on the cache device (depending on policy).

39.2.3 Design

Sub-devices

The target is constructed by passing three devices to it (along with other parameters detailed later):

1. An origin device - the big, slow one.
2. A cache device - the small, fast one.
3. A small metadata device - records which blocks are in the cache, which are dirty, and extra hints for use by the policy object. This information could be put on the cache device, but having it separate allows the volume manager to configure it differently, e.g. as a mirror for extra robustness. This metadata device may only be used by a single cache device.

Fixed block size

The origin is divided up into blocks of a fixed size. This block size is configurable when you first create the cache. Typically we've been using block sizes of 256KB - 1024KB. The block size must be between 64 sectors (32KB) and 2097152 sectors (1GB) and a multiple of 64 sectors (32KB).

Having a fixed block size simplifies the target a lot. But it is something of a compromise. For instance, a small part of a block may be getting hit a lot, yet the whole block will be promoted to the cache. So large block sizes are bad because they waste cache space. And small block sizes are bad because they increase the amount of metadata (both in core and on disk).

Cache operating modes

The cache has three operating modes: writeback, writethrough and passthrough.

If writeback, the default, is selected then a write to a block that is cached will go only to the cache and the block will be marked dirty in the metadata.

If writethrough is selected then a write to a cached block will not complete until it has hit both the origin and cache devices. Clean blocks should remain clean.

If passthrough is selected, useful when the cache contents are not known to be coherent with the origin device, then all reads are served from the origin device (all reads miss the cache) and all

writes are forwarded to the origin device; additionally, write hits cause cache block invalidates. To enable passthrough mode the cache must be clean. Passthrough mode allows a cache device to be activated without having to worry about coherency. Coherency that exists is maintained, although the cache will gradually cool as writes take place. If the coherency of the cache can later be verified, or established through use of the ”invalidate_cblocks” message, the cache device can be transitioned to writethrough or writeback mode while still warm. Otherwise, the cache contents can be discarded prior to transitioning to the desired operating mode.

A simple cleaner policy is provided, which will clean (write back) all dirty blocks in a cache. Useful for decommissioning a cache or when shrinking a cache. Shrinking the cache's fast device requires all cache blocks, in the area of the cache being removed, to be clean. If the area being removed from the cache still contains dirty blocks the resize will fail. Care must be taken to never reduce the volume used for the cache's fast device until the cache is clean. This is of particular importance if writeback mode is used. Writethrough and passthrough modes already maintain a clean cache. Future support to partially clean the cache, above a specified threshold, will allow for keeping the cache warm and in writeback mode during resize.

Migration throttling

Migrating data between the origin and cache device uses bandwidth. The user can set a throttle to prevent more than a certain amount of migration occurring at any one time. Currently we're not taking any account of normal io traffic going to the devices. More work needs doing here to avoid migrating during those peak io moments.

For the time being, a message ”migration_threshold <#sectors>” can be used to set the maximum number of sectors being migrated, the default being 2048 sectors (1MB).

Updating on-disk metadata

On-disk metadata is committed every time a FLUSH or FUA bio is written. If no such requests are made then commits will occur every second. This means the cache behaves like a physical disk that has a volatile write cache. If power is lost you may lose some recent writes. The metadata should always be consistent in spite of any crash.

The 'dirty' state for a cache block changes far too frequently for us to keep updating it on the fly. So we treat it as a hint. In normal operation it will be written when the dm device is suspended. If the system crashes all cache blocks will be assumed dirty when restarted.

Per-block policy hints

Policy plug-ins can store a chunk of data per cache block. It's up to the policy how big this chunk is, but it should be kept small. Like the dirty flags this data is lost if there's a crash so a safe fallback value should always be possible.

Policy hints affect performance, not correctness.

Policy messaging

Policies will have different tunables, specific to each one, so we need a generic way of getting and setting these. Device-mapper messages are used. Refer to cache-policies.txt.

Discard bitset resolution

We can avoid copying data during migration if we know the block has been discarded. A prime example of this is when mkfs discards the whole block device. We store a bitset tracking the discard state of blocks. However, we allow this bitset to have a different block size from the cache blocks. This is because we need to track the discard state for all of the origin device (compare with the dirty bitset which is just for the smaller cache device).

39.2.4 Target interface

Constructor

```
cache <metadata dev> <cache dev> <origin dev> <block size>
      <#feature args> [<feature arg>]*
      <policy> <#policy args> [policy args]*
```

metadata dev	fast device holding the persistent metadata
cache dev	fast device holding cached data blocks
origin dev	slow device holding original data blocks
block size	cache unit size in sectors
#feature args	number of feature arguments passed
feature args	writethrough or passthrough (The default is writeback.)
policy	the replacement policy to use
#policy args	an even number of arguments corresponding to key/value pairs passed to the policy
policy args	key/value pairs passed to the policy E.g. 'sequential_threshold 1024' See cache-policies.txt for details.

Optional feature arguments are:

writethrough	write through caching that prohibits cache block content from being different from origin block content. Without this argument, the default behaviour is to write back cache block contents later for performance reasons, so they may differ from the corresponding origin blocks.
passthrough	a degraded mode useful for various cache coherency situations (e.g., rolling back snapshots of underlying storage). Reads and writes always go to the origin. If a write goes to a cached origin block, then the cache block is invalidated. To enable passthrough mode the cache must be clean.
metadata2	use version 2 of the metadata. This stores the dirty bits in a separate btree, which improves speed of shutting down the cache.
no_discard_passdown	disable passing down discards from the cache to the origin's data device.

A policy called 'default' is always registered. This is an alias for the policy we currently think is giving best all round performance.

As the default policy could vary between kernels, if you are relying on the characteristics of a specific policy, always request it by name.

Status

```
<metadata block size> <#used metadata blocks>/<#total metadata blocks>
<cache block size> <#used cache blocks>/<#total cache blocks>
<#read hits> <#read misses> <#write hits> <#write misses>
<#demotions> <#promotions> <#dirty> <#features> <features>*
<#core args> <core args>* <policy name> <#policy args> <policy args>*
<cache metadata mode>
```

metadata block size	Fixed block size for each metadata block in sectors
#used metadata blocks	Number of metadata blocks used
#total metadata blocks	Total number of metadata blocks
cache block size	Configurable block size for the cache device in sectors
#used cache blocks	Number of blocks resident in the cache
#total cache blocks	Total number of cache blocks
#read hits	Number of times a READ bio has been mapped to the cache
#read misses	Number of times a READ bio has been mapped to the origin
#write hits	Number of times a WRITE bio has been mapped to the cache
#write misses	Number of times a WRITE bio has been mapped to the origin
#demotions	Number of times a block has been removed from the cache
#promotions	Number of times a block has been moved to the cache
#dirty	Number of blocks in the cache that differ from the origin
#feature args	Number of feature args to follow
feature args	'writethrough' (optional)
#core args	Number of core arguments (must be even)
core args	Key/value pairs for tuning the core e.g. migration_threshold
policy name	Name of the policy
#policy args	Number of policy arguments to follow (must be even)
policy args	Key/value pairs e.g. sequential_threshold
cache metadata mode	ro if read-only, rw if read-write In serious cases where even a read-only mode is deemed unsafe no further I/O will be permitted and the status will just contain the string 'Fail'. The userspace recovery tools should then be used.
needs_check	'needs_check' if set, '-' if not set A metadata operation has failed, resulting in the needs_check flag being set in the metadata's superblock. The metadata device must be deactivated and checked/repaired before the cache can be made fully operational again. '-' indicates needs_check is not set.

Messages

Policies will have different tunables, specific to each one, so we need a generic way of getting and setting these. Device-mapper messages are used. (A sysfs interface would also be possible.)

The message format is:

```
<key> <value>
```

E.g.:

```
dmsetup message my_cache 0 sequential_threshold 1024
```

Invalidation is removing an entry from the cache without writing it back. Cache blocks can be invalidated via the invalidate_cblocks message, which takes an arbitrary number of cblock ranges. Each cblock range's end value is "one past the end", meaning 5-10 expresses a range of values from 5 to 9. Each cblock must be expressed as a decimal value, in the future a variant message that takes cblock ranges expressed in hexadecimal may be needed to better support efficient invalidation of larger caches. The cache must be in passthrough mode when invalidate_cblocks is used:

```
invalidate_cblocks [<cblock>|<cblock begin>-<cblock end>]*
```

E.g.:

```
dmsetup message my_cache 0 invalidate_cblocks 2345 3456-4567 5678-6789
```

39.2.5 Examples

The test suite can be found here:

https://github.com/jthornber/device-mapper-test-suite

```
dmsetup create my_cache --table '0 41943040 cache /dev/mapper/metadata \
        /dev/mapper/ssd /dev/mapper/origin 512 1 writeback default 0'
dmsetup create my_cache --table '0 41943040 cache /dev/mapper/metadata \
        /dev/mapper/ssd /dev/mapper/origin 1024 1 writeback \
        mq 4 sequential_threshold 1024 random_threshold 8'
```

39.3 dm-delay

Device-Mapper's ”delay” target delays reads and/or writes and maps them to different devices.

Parameters:

```
<device> <offset> <delay> [<write_device> <write_offset> <write_delay>
                           [<flush_device> <flush_offset> <flush_delay>]]
```

With separate write parameters, the first set is only used for reads. Offsets are specified in sectors. Delays are specified in milliseconds.

39.3.1 Example scripts

```
#!/bin/sh
# Create device delaying rw operation for 500ms
echo "0 `blockdev --getsz $1` delay $1 0 500" | dmsetup create delayed
```

```
#!/bin/sh
# Create device delaying only write operation for 500ms and
# splitting reads and writes to different devices $1 $2
echo "0 `blockdev --getsz $1` delay $1 0 0 $2 0 500" | dmsetup create delayed
```

39.4 dm-clone

39.4.1 Introduction

dm-clone is a device mapper target which produces a one-to-one copy of an existing, read-only source device into a writable destination device: It presents a virtual block device which makes all data appear immediately, and redirects reads and writes accordingly.

The main use case of dm-clone is to clone a potentially remote, high-latency, read-only, archival-type block device into a writable, fast, primary-type device for fast, low-latency I/O. The cloned device is visible/mountable immediately and the copy of the source device to the destination device happens in the background, in parallel with user I/O.

For example, one could restore an application backup from a read-only copy, accessible through a network storage protocol (NBD, Fibre Channel, iSCSI, AoE, etc.), into a local SSD or NVMe device, and start using the device immediately, without waiting for the restore to complete.

When the cloning completes, the dm-clone table can be removed altogether and be replaced, e.g., by a linear table, mapping directly to the destination device.

The dm-clone target reuses the metadata library used by the thin-provisioning target.

39.4.2 Glossary

Hydration
: The process of filling a region of the destination device with data from the same region of the source device, i.e., copying the region from the source to the destination device.

Once a region gets hydrated we redirect all I/O regarding it to the destination device.

39.4.3 Design

Sub-devices

The target is constructed by passing three devices to it (along with other parameters detailed later):

1. A source device - the read-only device that gets cloned and source of the hydration.
2. A destination device - the destination of the hydration, which will become a clone of the source device.
3. A small metadata device - it records which regions are already valid in the destination device, i.e., which regions have already been hydrated, or have been written to directly, via user I/O.

The size of the destination device must be at least equal to the size of the source device.

Regions

dm-clone divides the source and destination devices in fixed sized regions. Regions are the unit of hydration, i.e., the minimum amount of data copied from the source to the destination device.

The region size is configurable when you first create the dm-clone device. The recommended region size is the same as the file system block size, which usually is 4KB. The region size must be between 8 sectors (4KB) and 2097152 sectors (1GB) and a power of two.

Reads and writes from/to hydrated regions are serviced from the destination device.

A read to a not yet hydrated region is serviced directly from the source device.

A write to a not yet hydrated region will be delayed until the corresponding region has been hydrated and the hydration of the region starts immediately.

Note that a write request with size equal to region size will skip copying of the corresponding region from the source device and overwrite the region of the destination device directly.

Discards

dm-clone interprets a discard request to a range that hasn't been hydrated yet as a hint to skip hydration of the regions covered by the request, i.e., it skips copying the region's data from the source to the destination device, and only updates its metadata.

If the destination device supports discards, then by default dm-clone will pass down discard requests to it.

Background Hydration

dm-clone copies continuously from the source to the destination device, until all of the device has been copied.

Copying data from the source to the destination device uses bandwidth. The user can set a throttle to prevent more than a certain amount of copying occurring at any one time. Moreover, dm-clone takes into account user I/O traffic going to the devices and pauses the background hydration when there is I/O in-flight.

A message *hydration_threshold <#regions>* can be used to set the maximum number of regions being copied, the default being 1 region.

dm-clone employs dm-kcopyd for copying portions of the source device to the destination device. By default, we issue copy requests of size equal to the region size. A message *hydration_batch_size <#regions>* can be used to tune the size of these copy requests. Increasing the hydration batch size results in dm-clone trying to batch together contiguous regions, so we copy the data in batches of this many regions.

When the hydration of the destination device finishes, a dm event will be sent to user space.

Updating on-disk metadata

On-disk metadata is committed every time a FLUSH or FUA bio is written. If no such requests are made then commits will occur every second. This means the dm-clone device behaves like a physical disk that has a volatile write cache. If power is lost you may lose some recent writes. The metadata should always be consistent in spite of any crash.

39.4.4 Target Interface

Constructor

```
clone <metadata dev> <destination dev> <source dev> <region␣
↪size>
     [<#feature args> [<feature arg>]* [<#core args> [<core␣
↪arg>]*]]
```

metadata dev	Fast device holding the persistent metadata
destination dev	The destination device, where the source will be cloned
source dev	Read only device containing the data that gets cloned
region size	The size of a region in sectors
#feature args	Number of feature arguments passed
feature args	no_hydration or no_discard_passdown
#core args	An even number of arguments corresponding to key/value pairs passed to dm-clone
core args	Key/value pairs passed to dm-clone, e.g. *hydration_threshold 256*

Optional feature arguments are:

no_hydration	Create a dm-clone instance with background hydration disabled
no_discard_passdown	Disable passing down discards to the destination device

Optional core arguments are:

hydration_threshold <#regions>	Maximum number of regions being copied from the source to the destination device at any one time, during background hydration.
hydration_batch_size <#regions>	During background hydration, try to batch together contiguous regions, so we copy data from the source to the destination device in batches of this many regions.

Status

```
<metadata block size> <#used metadata blocks>/<#total metadata␣
↪blocks>
<region size> <#hydrated regions>/<#total regions> <#hydrating␣
↪regions>
<#feature args> <feature args>* <#core args> <core args>*
<clone metadata mode>
```

metadata block size	Fixed block size for each metadata block in sectors
#used metadata blocks	Number of metadata blocks used
#total metadata blocks	Total number of metadata blocks
region size	Configurable region size for the device in sectors
#hydrated regions	Number of regions that have finished hydrating
#total regions	Total number of regions to hydrate
#hydrating regions	Number of regions currently hydrating
#feature args	Number of feature arguments to follow
feature args	Feature arguments, e.g. *no_hydration*
#core args	Even number of core arguments to follow
core args	Key/value pairs for tuning the core, e.g. *hydration_threshold 256*
clone metadata mode	ro if read-only, rw if read-write In serious cases where even a read-only mode is deemed unsafe no further I/O will be permitted and the status will just contain the string 'Fail'. If the metadata mode changes, a dm event will be sent to user space.

Messages

disable_hydration
Disable the background hydration of the destination device.

enable_hydration
Enable the background hydration of the destination device.

hydration_threshold <#regions>
Set background hydration threshold.

hydration_batch_size <#regions>
Set background hydration batch size.

39.4.5 Examples

Clone a device containing a file system

1. Create the dm-clone device.

```
dmsetup create clone --table "0 1048576000 clone $metadata_dev $dest_dev \
  $source_dev 8 1 no_hydration"
```

2. Mount the device and trim the file system. dm-clone interprets the discards sent by the file system and it will not hydrate the unused space.

```
mount /dev/mapper/clone /mnt/cloned-fs
fstrim /mnt/cloned-fs
```

3. Enable background hydration of the destination device.

```
dmsetup message clone 0 enable_hydration
```

4. When the hydration finishes, we can replace the dm-clone table with a linear table.

```
dmsetup suspend clone
dmsetup load clone --table "0 1048576000 linear $dest_dev 0"
dmsetup resume clone
```

   The metadata device is no longer needed and can be safely discarded or reused for other purposes.

39.4.6 Known issues

1. We redirect reads, to not-yet-hydrated regions, to the source device. If reading the source device has high latency and the user repeatedly reads from the same regions, this behaviour could degrade performance. We should use these reads as hints to hydrate the relevant regions sooner. Currently, we rely on the page cache to cache these regions, so we hopefully don't end up reading them multiple times from the source device.
2. Release in-core resources, i.e., the bitmaps tracking which regions are hydrated, after the hydration has finished.
3. During background hydration, if we fail to read the source or write to the destination device, we print an error message, but the hydration process continues indefinitely, until it succeeds. We should stop the background hydration after a number of failures and emit a dm event for user space to notice.

39.4.7 Why not...?

We explored the following alternatives before implementing dm-clone:

1. Use dm-cache with cache size equal to the source device and implement a new cloning policy:
   - The resulting cache device is not a one-to-one mirror of the source device and thus we cannot remove the cache device once cloning completes.
   - dm-cache writes to the source device, which violates our requirement that the source device must be treated as read-only.
   - Caching is semantically different from cloning.
2. Use dm-snapshot with a COW device equal to the source device:
   - dm-snapshot stores its metadata in the COW device, so the resulting device is not a one-to-one mirror of the source device.
   - No background copying mechanism.
   - dm-snapshot needs to commit its metadata whenever a pending exception completes, to ensure snapshot consistency. In the case of cloning, we don't need to be so strict and can rely on committing metadata every time a FLUSH or FUA bio is written, or periodically, like dm-thin and dm-cache do. This improves the performance significantly.
3. Use dm-mirror: The mirror target has a background copying/mirroring mechanism, but it writes to all mirrors, thus violating our requirement that the source device must be treated as read-only.
4. Use dm-thin's external snapshot functionality. This approach is the most promising among all alternatives, as the thinly-provisioned volume is a one-to-one mirror of the source device and handles reads and writes to un-provisioned/not-yet-cloned areas the same way as dm-clone does.

   Still:

   - There is no background copying mechanism, though one could be implemented.
   - Most importantly, we want to support arbitrary block devices as the destination of the cloning process and not restrict ourselves to thinly-provisioned volumes. Thin-provisioning has an inherent metadata overhead, for maintaining the thin volume mappings, which significantly degrades performance.

   Moreover, cloning a device shouldn't force the use of thin-provisioning. On the other hand, if we wish to use thin provisioning, we can just use a thin LV as dm-clone's destination device.

39.5 dm-crypt

Device-Mapper's ”crypt” target provides transparent encryption of block devices using the kernel crypto API.

For a more detailed description of supported parameters see: https://gitlab.com/cryptsetup/cryptsetup/wikis/DMCrypt

Parameters:

```
<cipher> <key> <iv_offset> <device path> \
<offset> [<#opt_params> <opt_params>]
```

<cipher>

Encryption cipher, encryption mode and Initial Vector (IV) generator.

The cipher specifications format is:

```
cipher[:keycount]-chainmode-ivmode[:ivopts]
```

Examples:

```
aes-cbc-essiv:sha256
aes-xts-plain64
serpent-xts-plain64
```

Cipher format also supports direct specification with kernel crypt API format (selected by capi: prefix). The IV specification is the same as for the first format type. This format is mainly used for specification of authenticated modes.

The crypto API cipher specifications format is:

```
capi:cipher_api_spec-ivmode[:ivopts]
```

Examples:

```
capi:cbc(aes)-essiv:sha256
capi:xts(aes)-plain64
```

Examples of authenticated modes:

```
capi:gcm(aes)-random
capi:authenc(hmac(sha256),xts(aes))-random
capi:rfc7539(chacha20,poly1305)-random
```

The /proc/crypto contains a list of currently loaded crypto modes.

<key>

Key used for encryption. It is encoded either as a hexadecimal number or it can be passed as <key_string> prefixed with single colon character (':') for keys residing in kernel keyring service. You can only use key sizes that are valid for the selected cipher in combination with the selected iv mode. Note that for some iv modes the key string can contain additional keys (for example IV seed) so the key contains more parts concatenated into a single string.

<key_string>
The kernel keyring key is identified by string in following format: <key_size>:<key_type>:<key_description>.

<key_size>
The encryption key size in bytes. The kernel key payload size must match the value passed in <key_size>.

<key_type>
Either 'logon', 'user', 'encrypted' or 'trusted' kernel key type.

<key_description>
The kernel keyring key description crypt target should look for when loading key of <key_type>.

<keycount>
Multi-key compatibility mode. You can define <keycount> keys and then sectors are encrypted according to their offsets (sector 0 uses key0; sector 1 uses key1 etc.). <keycount> must be a power of two.

<iv_offset>
The IV offset is a sector count that is added to the sector number before creating the IV.

<device path>
This is the device that is going to be used as backend and contains the encrypted data. You can specify it as a path like /dev/xxx or a device number <major>:<minor>.

<offset>
Starting sector within the device where the encrypted data begins.

<#opt_params>
Number of optional parameters. If there are no optional parameters, the optional parameters section can be skipped or #opt_params can be zero. Otherwise #opt_params is the number of following arguments.

Example of optional parameters section:
3 allow_discards same_cpu_crypt submit_from_crypt_cpus

allow_discards
Block discard requests (a.k.a. TRIM) are passed through the crypt device. The default is to ignore discard requests.

WARNING: Assess the specific security risks carefully before enabling this option. For example, allowing discards on encrypted devices may lead to the leak of information about the ciphertext device (filesystem type, used space etc.) if the discarded blocks can be located easily on the device later.

same_cpu_crypt
Perform encryption using the same cpu that IO was submitted on. The default is to use an unbound workqueue so that encryption work is automatically balanced between available CPUs.

submit_from_crypt_cpus
Disable offloading writes to a separate thread after encryption. There are some situations where offloading write bios from the encryption threads to a single thread degrades performance significantly. The default is to offload write bios to the same thread because it benefits CFQ to have writes submitted using the same context.

no_read_workqueue
Bypass dm-crypt internal workqueue and process read requests synchronously.

no_write_workqueue
Bypass dm-crypt internal workqueue and process write requests synchronously. This option is automatically enabled for host-managed zoned block devices (e.g. host-managed SMR hard-disks).

integrity:<bytes>:<type>
The device requires additional <bytes> metadata per-sector stored in per-bio integrity structure. This metadata must by provided by underlying dm-integrity target.

The <type> can be "none" if metadata is used only for persistent IV.

For Authenticated Encryption with Additional Data (AEAD) the <type> is "aead". An AEAD mode additionally calculates and verifies integrity for the encrypted device. The additional space is then used for storing authentication tag (and persistent IV if needed).

sector_size:<bytes>
Use <bytes> as the encryption unit instead of 512 bytes sectors. This option can be in range 512 - 4096 bytes and must be power of two. Virtual device will announce this size as a minimal IO and logical sector.

iv_large_sectors
IV generators will use sector number counted in <sector_size> units instead of default 512 bytes sectors.

For example, if <sector_size> is 4096 bytes, plain64 IV for the second sector will be 8 (without flag) and 1 if iv_large_sectors is present. The <iv_offset> must be multiple of <sector_size> (in 512 bytes units) if this flag is specified.

39.5.1 Example scripts

LUKS (Linux Unified Key Setup) is now the preferred way to set up disk encryption with dm-crypt using the 'cryptsetup' utility, see https://gitlab.com/cryptsetup/cryptsetup

```
#!/bin/sh
# Create a crypt device using dmsetup
dmsetup create crypt1 --table "0 `blockdev --getsz $1` crypt aes-cbc-
↪essiv:sha256 babebabebabebabebabebabebabebabe 0 $1 0"
```

```
#!/bin/sh
# Create a crypt device using dmsetup when encryption key is stored in keyring␣
↪service
dmsetup create crypt2 --table "0 `blockdev --getsize $1` crypt aes-cbc-
↪essiv:sha256 :32:logon:my_prefix:my_key 0 $1 0"
```

```
#!/bin/sh
# Create a crypt device using cryptsetup and LUKS header with default cipher
cryptsetup luksFormat $1
cryptsetup luksOpen $1 crypt1
```

39.6 dm-dust

This target emulates the behavior of bad sectors at arbitrary locations, and the ability to enable the emulation of the failures at an arbitrary time.

This target behaves similarly to a linear target. At a given time, the user can send a message to the target to start failing read requests on specific blocks (to emulate the behavior of a hard disk drive with bad sectors).

When the failure behavior is enabled (i.e.: when the output of "dmsetup status" displays "fail_read_on_bad_block"), reads of blocks in the "bad block list" will fail with EIO ("Input/output error").

Writes of blocks in the "bad block list will result in the following:

1. Remove the block from the "bad block list".
2. Successfully complete the write.

This emulates the "remapped sector" behavior of a drive with bad sectors.

Normally, a drive that is encountering bad sectors will most likely encounter more bad sectors, at an unknown time or location. With dm-dust, the user can use the "addbadblock" and "removebadblock" messages to add arbitrary bad blocks at new locations, and the "enable" and "disable" messages to modulate the state of whether the configured "bad blocks" will be treated as bad, or bypassed. This allows the pre-writing of test data and metadata prior to simulating a "failure" event where bad sectors start to appear.

39.6.1 Table parameters

<device_path> <offset> <blksz>

Mandatory parameters:

<device_path>:
Path to the block device.

<offset>:
Offset to data area from start of device_path

<blksz>:
Block size in bytes

(minimum 512, maximum 1073741824, must be a power of 2)

39.6.2 Usage instructions

First, find the size (in 512-byte sectors) of the device to be used:

```
$ sudo blockdev --getsz /dev/vdb1
33552384
```

Create the dm-dust device: (For a device with a block size of 512 bytes)

```
$ sudo dmsetup create dust1 --table '0 33552384 dust /dev/vdb1 0 512'
```

(For a device with a block size of 4096 bytes)

```
$ sudo dmsetup create dust1 --table '0 33552384 dust /dev/vdb1 0 4096'
```

Check the status of the read behavior (”bypass” indicates that all I/O will be passed through to the underlying device; ”verbose” indicates that bad block additions, removals, and remaps will be verbosely logged):

```
$ sudo dmsetup status dust1
0 33552384 dust 252:17 bypass verbose

$ sudo dd if=/dev/mapper/dust1 of=/dev/null bs=512 count=128 iflag=direct
128+0 records in
128+0 records out

$ sudo dd if=/dev/zero of=/dev/mapper/dust1 bs=512 count=128 oflag=direct
128+0 records in
128+0 records out
```

39.6.3 Adding and removing bad blocks

At any time (i.e.: whether the device has the ”bad block” emulation enabled or disabled), bad blocks may be added or removed from the device via the ”addbadblock” and ”removebadblock” messages:

```
$ sudo dmsetup message dust1 0 addbadblock 60
kernel: device-mapper: dust: badblock added at block 60

$ sudo dmsetup message dust1 0 addbadblock 67
kernel: device-mapper: dust: badblock added at block 67

$ sudo dmsetup message dust1 0 addbadblock 72
kernel: device-mapper: dust: badblock added at block 72
```

These bad blocks will be stored in the ”bad block list”. While the device is in ”bypass” mode, reads and writes will succeed:

```
$ sudo dmsetup status dust1
0 33552384 dust 252:17 bypass
```

39.6.4 Enabling block read failures

To enable the ”fail read on bad block” behavior, send the ”enable” message:

```
$ sudo dmsetup message dust1 0 enable
kernel: device-mapper: dust: enabling read failures on bad sectors

$ sudo dmsetup status dust1
0 33552384 dust 252:17 fail_read_on_bad_block
```

With the device in ”fail read on bad block” mode, attempting to read a block will encounter an ”Input/output error”:

```
$ sudo dd if=/dev/mapper/dust1 of=/dev/null bs=512 count=1 skip=67 iflag=direct
dd: error reading '/dev/mapper/dust1': Input/output error
0+0 records in
0+0 records out
0 bytes copied, 0.00040651 s, 0.0 kB/s
```

...and writing to the bad blocks will remove the blocks from the list, therefore emulating the ”remap” behavior of hard disk drives:

```
$ sudo dd if=/dev/zero of=/dev/mapper/dust1 bs=512 count=128 oflag=direct
128+0 records in
128+0 records out

kernel: device-mapper: dust: block 60 removed from badblocklist by write
kernel: device-mapper: dust: block 67 removed from badblocklist by write
kernel: device-mapper: dust: block 72 removed from badblocklist by write
kernel: device-mapper: dust: block 87 removed from badblocklist by write
```

39.6.5 Bad block add/remove error handling

Attempting to add a bad block that already exists in the list will result in an ”Invalid argument” error, as well as a helpful message:

```
$ sudo dmsetup message dust1 0 addbadblock 88
device-mapper: message ioctl on dust1  failed: Invalid argument
kernel: device-mapper: dust: block 88 already in badblocklist
```

Attempting to remove a bad block that doesn't exist in the list will result in an ”Invalid argument” error, as well as a helpful message:

```
$ sudo dmsetup message dust1 0 removebadblock 87
device-mapper: message ioctl on dust1  failed: Invalid argument
kernel: device-mapper: dust: block 87 not found in badblocklist
```

39.6.6 Counting the number of bad blocks in the bad block list

To count the number of bad blocks configured in the device, run the following message command:

```
$ sudo dmsetup message dust1 0 countbadblocks
```

A message will print with the number of bad blocks currently configured on the device:

```
countbadblocks: 895 badblock(s) found
```

39.6.7 Querying for specific bad blocks

To find out if a specific block is in the bad block list, run the following message command:

```
$ sudo dmsetup message dust1 0 queryblock 72
```

The following message will print if the block is in the list:

```
dust_query_block: block 72 found in badblocklist
```

The following message will print if the block is not in the list:

```
dust_query_block: block 72 not found in badblocklist
```

The ”queryblock” message command will work in both the ”enabled” and ”disabled” modes, allowing the verification of whether a block will be treated as ”bad” without having to issue I/O to the device, or having to ”enable” the bad block emulation.

39.6.8 Clearing the bad block list

To clear the bad block list (without needing to individually run a ”removebadblock” message command for every block), run the following message command:

```
$ sudo dmsetup message dust1 0 clearbadblocks
```

After clearing the bad block list, the following message will appear:

```
dust_clear_badblocks: badblocks cleared
```

If there were no bad blocks to clear, the following message will appear:

```
dust_clear_badblocks: no badblocks found
```

39.6.9 Listing the bad block list

To list all bad blocks in the bad block list (using an example device with blocks 1 and 2 in the bad block list), run the following message command:

```
$ sudo dmsetup message dust1 0 listbadblocks
1
2
```

If there are no bad blocks in the bad block list, the command will execute with no output:

```
$ sudo dmsetup message dust1 0 listbadblocks
```

39.6.10 Message commands list

Below is a list of the messages that can be sent to a dust device:

Operations on blocks (requires a <blknum> argument):

```
addbadblock <blknum>
queryblock <blknum>
removebadblock <blknum>
```

...where <blknum> is a block number within range of the device (corresponding to the block size of the device.)

Single argument message commands:

```
countbadblocks
clearbadblocks
listbadblocks
disable
enable
quiet
```

39.6.11 Device removal

When finished, remove the device via the "dmsetup remove" command:

```
$ sudo dmsetup remove dust1
```

39.6.12 Quiet mode

On test runs with many bad blocks, it may be desirable to avoid excessive logging (from bad blocks added, removed, or "remapped"). This can be done by enabling "quiet mode" via the following message:

```
$ sudo dmsetup message dust1 0 quiet
```

This will suppress log messages from add / remove / removed by write operations. Log messages from "countbadblocks" or "queryblock" message commands will still print in quiet mode.

The status of quiet mode can be seen by running "dmsetup status":

```
$ sudo dmsetup status dust1
0 33552384 dust 252:17 fail_read_on_bad_block quiet
```

To disable quiet mode, send the "quiet" message again:

```
$ sudo dmsetup message dust1 0 quiet

$ sudo dmsetup status dust1
0 33552384 dust 252:17 fail_read_on_bad_block verbose
```

(The presence of "verbose" indicates normal logging.)

39.6.13 ”Why not...?”

scsi_debug has a ”medium error” mode that can fail reads on one specified sector (sector 0x1234, hardcoded in the source code), but it uses RAM for the persistent storage, which drastically decreases the potential device size.

dm-flakey fails all I/O from all block locations at a specified time frequency, and not a given point in time.

When a bad sector occurs on a hard disk drive, reads to that sector are failed by the device, usually resulting in an error code of EIO (”I/O error”) or ENODATA (”No data available”). However, a write to the sector may succeed, and result in the sector becoming readable after the device controller no longer experiences errors reading the sector (or after a reallocation of the sector). However, there may be bad sectors that occur on the device in the future, in a different, unpredictable location.

This target seeks to provide a device that can exhibit the behavior of a bad sector at a known sector location, at a known time, based on a large storage device (at least tens of gigabytes, not occupying system memory).

39.7 dm-ebs

This target is similar to the linear target except that it emulates a smaller logical block size on a device with a larger logical block size. Its main purpose is to provide emulation of 512 byte sectors on devices that do not provide this emulation (i.e. 4K native disks).

Supported emulated logical block sizes 512, 1024, 2048 and 4096.

Underlying block size can be set to > 4K to test buffering larger units.

39.7.1 Table parameters

<dev path> <offset> <emulated sectors> [<underlying sectors>]

Mandatory parameters:

<dev path>:
Full pathname to the underlying block-device, or a ”major:minor” device-number.

<offset>:
Starting sector within the device; has to be a multiple of <emulated sectors>.

<emulated sectors>:
Number of sectors defining the logical block size to be emulated; 1, 2, 4, 8 sectors of 512 bytes supported.

Optional parameter:

<underlying sectors>:
Number of sectors defining the logical block size of <dev path>. 2^N supported, e.g. 8 = emulate 8 sectors of 512 bytes = 4KiB. If not provided, the logical block size of <dev path> will be used.

Examples:

Emulate 1 sector = 512 bytes logical block size on /dev/sda starting at offset 1024 sectors with underlying devices block size automatically set:

ebs /dev/sda 1024 1

Emulate 2 sector = 1KiB logical block size on /dev/sda starting at offset 128 sectors, enforce 2KiB underlying device block size. This presumes 2KiB logical blocksize on /dev/sda or less to work:

ebs /dev/sda 128 2 4

39.8 dm-flakey

This target is the same as the linear target except that it exhibits unreliable behaviour periodically. It's been found useful in simulating failing devices for testing purposes.

Starting from the time the table is loaded, the device is available for <up interval> seconds, then exhibits unreliable behaviour for <down interval> seconds, and then this cycle repeats.

Also, consider using this in combination with the dm-delay target too, which can delay reads and writes and/or send them to different underlying devices.

39.8.1 Table parameters

```
<dev path> <offset> <up interval> <down interval> \
  [<num_features> [<feature arguments>]]
```

Mandatory parameters:

<dev path>:
Full pathname to the underlying block-device, or a ”major:minor” device-number.

<offset>:
Starting sector within the device.

<up interval>:
Number of seconds device is available.

<down interval>:
Number of seconds device returns errors.

Optional feature parameters:

If no feature parameters are present, during the periods of unreliability, all I/O returns errors.

error_reads:
All read I/O is failed with an error signalled. Write I/O is handled correctly.

drop_writes:
All write I/O is silently ignored. Read I/O is handled correctly.

error_writes:
All write I/O is failed with an error signalled. Read I/O is handled correctly.

corrupt_bio_byte <Nth_byte> <direction> <value> <flags>:

During <down interval>, replace <Nth_byte> of the data of each matching bio with <value>.

<Nth_byte>:
The offset of the byte to replace. Counting starts at 1, to replace the first byte.

<direction>:
Either 'r' to corrupt reads or 'w' to corrupt writes. 'w' is incompatible with drop_writes.

<value>:
The value (from 0-255) to write.

<flags>:
Perform the replacement only if bio->bi_opf has all the selected flags set.

random_read_corrupt <probability>
During <down interval>, replace random byte in a read bio with a random value. probability is an integer between 0 and 1000000000 meaning 0% to 100% probability of corruption.

random_write_corrupt <probability>
During <down interval>, replace random byte in a write bio with a random value. probability is an integer between 0 and 1000000000 meaning 0% to 100% probability of corruption.

Examples:

Replaces the 32nd byte of READ bios with the value 1:

```
corrupt_bio_byte 32 r 1 0
```

Replaces the 224th byte of REQ_META (=32) bios with the value 0:

```
corrupt_bio_byte 224 w 0 32
```

39.9 dm-ima

For a given system, various external services/infrastructure tools (including the attestation service) interact with it - both during the setup and during rest of the system run-time. They share sensitive data and/or execute critical workload on that system. The external services may want to verify the current run-time state of the relevant kernel subsystems before fully trusting the system with business-critical data/workload.

Device mapper plays a critical role on a given system by providing various important functionalities to the block devices using various target types like crypt, verity, integrity etc. Each of these target types' functionalities can be configured with various attributes. The attributes chosen to configure these target types can significantly impact the security profile of the block device, and in-turn, of the system itself. For instance, the type of encryption algorithm and the key size determines the strength of encryption for a given block device.

Therefore, verifying the current state of various block devices as well as their various target attributes is crucial for external services before fully trusting the system with business-critical data/workload.

IMA kernel subsystem provides the necessary functionality for device mapper to measure the state and configuration of various block devices -

- by device mapper itself, from within the kernel,
- in a tamper resistant way,
- and re-measured - triggered on state/configuration change.

39.9.1 Setting the IMA Policy:

For IMA to measure the data on a given system, the IMA policy on the system needs to be updated to have following line, and the system needs to be restarted for the measurements to take effect.

```
/etc/ima/ima-policy
   measure func=CRITICAL_DATA label=device-mapper template=ima-buf
```

The measurements will be reflected in the IMA logs, which are located at:

```
/sys/kernel/security/integrity/ima/ascii_runtime_measurements
/sys/kernel/security/integrity/ima/binary_runtime_measurements
```

Then IMA ASCII measurement log has the following format:

```
<PCR> <TEMPLATE_DATA_DIGEST> <TEMPLATE_NAME> <TEMPLATE_DATA>

PCR := Platform Configuration Register, in which the values are registered.
      This is applicable if TPM chip is in use.

TEMPLATE_DATA_DIGEST := Template data digest of the IMA record.
TEMPLATE_NAME := Template name that registered the integrity value (e.g. ima-
↪buf).

TEMPLATE_DATA := <ALG> ":" <EVENT_DIGEST> <EVENT_NAME> <EVENT_DATA>
                 It contains data for the specific event to be measured,
                 in a given template data format.

ALG := Algorithm to compute event digest
EVENT_DIGEST := Digest of the event data
EVENT_NAME := Description of the event (e.g. 'dm_table_load').
EVENT_DATA := The event data to be measured.
```

NOTE #1:
The DM target data measured by IMA subsystem can alternatively be queried from userspace by setting DM_IMA_MEASUREMENT_FLAG with DM_TABLE_STATUS_CMD.

NOTE #2:
The Kernel configuration CONFIG_IMA_DISABLE_HTABLE allows measurement of duplicate records.
To support recording duplicate IMA events in the IMA log, the Kernel needs to be configured with CONFIG_IMA_DISABLE_HTABLE=y.

39.9.2 Supported Device States:

Following device state changes will trigger IMA measurements:

1. Table load
2. Device resume
3. Device remove
4. Table clear
5. Device rename

1. Table load:

When a new table is loaded in a device's inactive table slot, the device information and target specific details from the targets in the table are measured.

The IMA measurement log has the following format for 'dm_table_load':

```
EVENT_NAME := "dm_table_load"
EVENT_DATA := <dm_version_str> ";" <device_metadata> ";" <table_load_data>

dm_version_str := "dm_version=" <N> "." <N> "." <N>
                 Same as Device Mapper driver version.
device_metadata := <device_name> "," <device_uuid> "," <device_major> ","
↪<device_minor> ","
                  <minor_count> "," <num_device_targets> ";"

device_name := "name=" <dm-device-name>
device_uuid := "uuid=" <dm-device-uuid>
device_major := "major=" <N>
device_minor := "minor=" <N>
minor_count := "minor_count=" <N>
num_device_targets := "num_targets=" <N>
dm-device-name := Name of the device. If it contains special characters like '\
↪', ',', ';',
                  they are prefixed with '\'.
dm-device-uuid := UUID of the device. If it contains special characters like '\
↪', ',', ';',
                  they are prefixed with '\'.
```

```
table_load_data := <target_data>
                   Represents the data (as name=value pairs) from various␣
↪targets in the table,
                   which is being loaded into the DM device's inactive table␣
↪slot.
target_data := <target_data_row> | <target_data><target_data_row>

target_data_row := <target_index> "," <target_begin> "," <target_len> ","
↪<target_name> ","
                   <target_version> "," <target_attributes> ";"
target_index := "target_index=" <N>
                Represents nth target in the table (from 0 to N-1 targets␣
↪specified in <num_device_targets>)
                If all the data for N targets doesn't fit in the given buffer -
↪ then the data that fits
                in the buffer (say from target 0 to x) is measured in a given␣
↪IMA event.
                The remaining data from targets x+1 to N-1 is measured in the␣
↪subsequent IMA events,
                with the same format as that of 'dm_table_load'
                i.e. <dm_version_str> ";" <device_metadata> ";" <table_load_
↪data>.

target_begin := "target_begin=" <N>
target_len := "target_len=" <N>
target_name := Name of the target. 'linear', 'crypt', 'integrity' etc.
               The targets that are supported for IMA measurements are␣
↪documented below in the
               'Supported targets' section.
target_version := "target_version=" <N> "." <N> "." <N>
target_attributes := Data containing comma separated list of name=value pairs␣
↪of target specific attributes.

For instance, if a linear device is created with the following table entries,
 # dmsetup create linear1
 0 2 linear /dev/loop0 512
 2 2 linear /dev/loop0 512
 4 2 linear /dev/loop0 512
 6 2 linear /dev/loop0 512

Then IMA ASCII measurement log will have the following entry:
(converted from ASCII to text for readability)

10 a8c5ff755561c7a28146389d1514c318592af49a ima-buf␣
↪sha256:4d73481ecce5eadba8ab084640d85bb9ca899af4d0a122989252a76efadc5b72
dm_table_load
dm_version=4.45.0;
name=linear1,uuid=,major=253,minor=0,minor_count=1,num_targets=4;
target_index=0,target_begin=0,target_len=2,target_name=linear,target_version=1.
↪4.0,device_name=7:0,start=512;
```

```
target_index=1,target_begin=2,target_len=2,target_name=linear,target_version=1.
↪4.0,device_name=7:0,start=512;
target_index=2,target_begin=4,target_len=2,target_name=linear,target_version=1.
↪4.0,device_name=7:0,start=512;
target_index=3,target_begin=6,target_len=2,target_name=linear,target_version=1.
↪4.0,device_name=7:0,start=512;
```

2. Device resume:

When a suspended device is resumed, the device information and the hash of the data from previous load of an active table are measured.

The IMA measurement log has the following format for 'dm_device_resume':

```
EVENT_NAME := "dm_device_resume"
EVENT_DATA := <dm_version_str> ";" <device_metadata> ";" <active_table_hash> ";
↪" <current_device_capacity> ";"

dm_version_str := As described in the 'Table load' section above.
device_metadata := As described in the 'Table load' section above.
active_table_hash := "active_table_hash=" <table_hash_alg> ":" <table_hash>
                     Rerpresents the hash of the IMA data being measured for␣
↪the
                     active table for the device.
table_hash_alg := Algorithm used to compute the hash.
table_hash := Hash of the (<dm_version_str> ";" <device_metadata> ";" <table_
↪load_data> ";")
              as described in the 'dm_table_load' above.
              Note: If the table_load data spans across multiple IMA 'dm_table_
↪load'
              events for a given device, the hash is computed combining all␣
↪the event data
              i.e. (<dm_version_str> ";" <device_metadata> ";" <table_load_
↪data> ";")
              across all those events.
current_device_capacity := "current_device_capacity=" <N>

For instance, if a linear device is resumed with the following command,
#dmsetup resume linear1

then IMA ASCII measurement log will have an entry with:
(converted from ASCII to text for readability)

10 56c00cc062ffc24ccd9ac2d67d194af3282b934e ima-buf␣
↪sha256:e7d12c03b958b4e0e53e7363a06376be88d98a1ac191fdbd3baf5e4b77f329b6
dm_device_resume
dm_version=4.45.0;
name=linear1,uuid=,major=253,minor=0,minor_count=1,num_targets=4;

↪hash=sha256:4d73481ecce5eadba8ab084640d85bb9ca899af4d0a122989252a76efadc5b72;
↪current_device_capacity=8;
```

3. Device remove:

When a device is removed, the device information and a sha256 hash of the data from an active and inactive table are measured.

The IMA measurement log has the following format for 'dm_device_remove':

```
EVENT_NAME := "dm_device_remove"
EVENT_DATA := <dm_version_str> ";" <device_active_metadata> ";" <device_
↪inactive_metadata> ";"
              <active_table_hash> "," <inactive_table_hash> "," <remove_all> ";
↪" <current_device_capacity> ";"

dm_version_str := As described in the 'Table load' section above.
device_active_metadata := Device metadata that reflects the currently loaded␣
↪active table.
                          The format is same as 'device_metadata' described in␣
↪the 'Table load' section above.
device_inactive_metadata := Device metadata that reflects the inactive table.
                            The format is same as 'device_metadata' described␣
↪in the 'Table load' section above.
active_table_hash := Hash of the currently loaded active table.
                     The format is same as 'active_table_hash' described in␣
↪the 'Device resume' section above.
inactive_table_hash :=  Hash of the inactive table.
                        The format is same as 'active_table_hash' described in␣
↪the 'Device resume' section above.
remove_all := "remove_all=" <yes_no>
yes_no := "y" | "n"
current_device_capacity := "current_device_capacity=" <N>

For instance, if a linear device is removed with the following command,
 #dmsetup remove l1

then IMA ASCII measurement log will have the following entry:
(converted from ASCII to text for readability)

10 790e830a3a7a31590824ac0642b3b31c2d0e8b38 ima-buf␣
↪sha256:ab9f3c959367a8f5d4403d6ce9c3627dadfa8f9f0e7ec7899299782388de3840

↪remove_all=n;
```

```
current_device_capacity=2048;
```

4. Table clear:

When an inactive table is cleared from the device, the device information and a sha256 hash of the data from an inactive table are measured.

The IMA measurement log has the following format for 'dm_table_clear':

```
EVENT_NAME := "dm_table_clear"
EVENT_DATA := <dm_version_str> ";" <device_inactive_metadata> ";" <inactive_
↪table_hash> ";" <current_device_capacity> ";"

dm_version_str := As described in the 'Table load' section above.
device_inactive_metadata := Device metadata that was captured during the load␣
↪time inactive table being cleared.
                            The format is same as 'device_metadata' described␣
↪in the 'Table load' section above.
inactive_table_hash := Hash of the inactive table being cleared from the␣
↪device.
                       The format is same as 'active_table_hash' described in␣
↪the 'Device resume' section above.
current_device_capacity := "current_device_capacity=" <N>

For instance, if a linear device's inactive table is cleared,
 #dmsetup clear l1

then IMA ASCII measurement log will have an entry with:
(converted from ASCII to text for readability)

↪current_device_capacity=1024;
```

5. Device rename:

When an device's NAME or UUID is changed, the device information and the new NAME and UUID are measured.

The IMA measurement log has the following format for 'dm_device_rename':

```
EVENT_NAME := "dm_device_rename"
EVENT_DATA := <dm_version_str> ";" <device_active_metadata> ";" <new_device_
↪name> "," <new_device_uuid> ";" <current_device_capacity> ";"
```

```
dm_version_str := As described in the 'Table load' section above.
device_active_metadata := Device metadata that reflects the currently loaded␣
↪active table.
                          The format is same as 'device_metadata' described in␣
↪the 'Table load' section above.
new_device_name := "new_name=" <dm-device-name>
dm-device-name := Same as <dm-device-name> described in 'Table load' section␣
↪above
new_device_uuid := "new_uuid=" <dm-device-uuid>

current_device_capacity=1024;
```

39.9.3 Supported targets:

Following targets are supported to measure their data using IMA:

1. cache
2. crypt
3. integrity
4. linear
5. mirror
6. multipath
7. raid
8. snapshot
9. striped
10. verity

1. cache

The 'target_attributes' (described as part of EVENT_DATA in 'Table load' section above) has the following data format for 'cache' target.

```
target_attributes := <target_name> "," <target_version> "," <metadata_mode> ",
↪" <cache_metadata_device> ","
                     <cache_device> "," <cache_origin_device> ","
↪<writethrough> "," <writeback> ","
                     <passthrough> "," <no_discard_passdown> ";"

target_name := "target_name=cache"
target_version := "target_version=" <N> "." <N> "." <N>
metadata_mode := "metadata_mode=" <cache_metadata_mode>
cache_metadata_mode := "fail" | "ro" | "rw"
cache_device := "cache_device=" <cache_device_name_string>
cache_origin_device := "cache_origin_device=" <cache_origin_device_string>
writethrough := "writethrough=" <yes_no>
writeback := "writeback=" <yes_no>
passthrough := "passthrough=" <yes_no>
no_discard_passdown := "no_discard_passdown=" <yes_no>
yes_no := "y" | "n"

E.g.
When a 'cache' target is loaded, then IMA ASCII measurement log will have an␣
↪entry
similar to the following, depicting what 'cache' attributes are measured in␣
↪EVENT_DATA
for 'dm_table_load' event.
(converted from ASCII to text for readability)

dm_version=4.45.0;name=cache1,uuid=cache_uuid,major=253,minor=2,minor_count=1,
↪num_targets=1;
```

```
target_index=0,target_begin=0,target_len=28672,target_name=cache,target_
↪version=2.2.0,metadata_mode=rw,
cache_metadata_device=253:4,cache_device=253:3,cache_origin_device=253:5,
↪writethrough=y,writeback=n,
passthrough=n,metadata2=y,no_discard_passdown=n;
```

2. crypt

The 'target_attributes' (described as part of EVENT_DATA in 'Table load' section above) has the following data format for 'crypt' target.

```
target_attributes := <target_name> "," <target_version> "," <allow_discards> ",
↪" <same_cpu_crypt> ","
                     <submit_from_crypt_cpus> "," <no_read_workqueue> "," <no_
↪write_workqueue> ","
                     <iv_large_sectors> "," <iv_large_sectors> "," [<integrity_
↪tag_size> ","] [<cipher_auth> ","]
                     [<sector_size> ","] [<cipher_string> ","] <key_size> ","
↪<key_parts> ","
                     <key_extra_size> "," <key_mac_size> ";"

target_name := "target_name=crypt"
target_version := "target_version=" <N> "." <N> "." <N>
allow_discards := "allow_discards=" <yes_no>
same_cpu_crypt := "same_cpu_crypt=" <yes_no>
submit_from_crypt_cpus := "submit_from_crypt_cpus=" <yes_no>
no_read_workqueue := "no_read_workqueue=" <yes_no>
no_write_workqueue := "no_write_workqueue=" <yes_no>
iv_large_sectors := "iv_large_sectors=" <yes_no>
integrity_tag_size := "integrity_tag_size=" <N>
cipher_auth := "cipher_auth=" <string>
sector_size := "sector_size="  <N>
cipher_string := "cipher_string="
key_size := "key_size="  <N>
key_parts := "key_parts="  <N>
key_extra_size := "key_extra_size="  <N>
key_mac_size := "key_mac_size="  <N>
yes_no := "y" | "n"

E.g.
When a 'crypt' target is loaded, then IMA ASCII measurement log will have an␣
↪entry
similar to the following, depicting what 'crypt' attributes are measured in␣
↪EVENT_DATA
for 'dm_table_load' event.
(converted from ASCII to text for readability)

dm_version=4.45.0;
name=crypt1,uuid=crypt_uuid1,major=253,minor=0,minor_count=1,num_targets=1;
target_index=0,target_begin=0,target_len=1953125,target_name=crypt,target_
↪version=1.23.0,
```

```
allow_discards=y,same_cpu=n,submit_from_crypt_cpus=n,no_read_workqueue=n,no_
↪write_workqueue=n,
iv_large_sectors=n,cipher_string=aes-xts-plain64,key_size=32,key_parts=1,key_
↪extra_size=0,key_mac_size=0;
```

3. integrity

The 'target_attributes' (described as part of EVENT_DATA in 'Table load' section above) has the following data format for 'integrity' target.

```
target_attributes := <target_name> "," <target_version> "," <dev_name> ","
↪<start>
                     <tag_size> "," <mode> "," [<meta_device> ","] [<block_
↪size> ","] <recalculate> ","
                     <allow_discards> "," <fix_padding> "," <fix_hmac> ","
↪<legacy_recalculate> ","
                     <journal_sectors> "," <interleave_sectors> "," <buffer_
↪sectors> ";"

target_name := "target_name=integrity"
target_version := "target_version=" <N> "." <N> "." <N>
dev_name := "dev_name=" <device_name_str>
start := "start=" <N>
tag_size := "tag_size=" <N>
mode := "mode=" <integrity_mode_str>
integrity_mode_str := "J" | "B" | "D" | "R"
meta_device := "meta_device=" <meta_device_str>
block_size := "block_size=" <N>
recalculate := "recalculate=" <yes_no>
allow_discards := "allow_discards=" <yes_no>
fix_padding := "fix_padding=" <yes_no>
fix_hmac := "fix_hmac=" <yes_no>
legacy_recalculate := "legacy_recalculate=" <yes_no>
journal_sectors := "journal_sectors=" <N>
interleave_sectors := "interleave_sectors=" <N>
buffer_sectors := "buffer_sectors=" <N>
yes_no := "y" | "n"

E.g.
When a 'integrity' target is loaded, then IMA ASCII measurement log will have␣
↪an entry
similar to the following, depicting what 'integrity' attributes are measured␣
↪in EVENT_DATA
for 'dm_table_load' event.
(converted from ASCII to text for readability)

dm_version=4.45.0;
name=integrity1,uuid=,major=253,minor=1,minor_count=1,num_targets=1;
target_index=0,target_begin=0,target_len=7856,target_name=integrity,target_
↪version=1.10.0,
```

```
dev_name=253:0,start=0,tag_size=32,mode=J,recalculate=n,allow_discards=n,fix_
↪padding=n,
fix_hmac=n,legacy_recalculate=n,journal_sectors=88,interleave_sectors=32768,
↪buffer_sectors=128;
```

4. linear

The 'target_attributes' (described as part of EVENT_DATA in 'Table load' section above) has the following data format for 'linear' target.

```
target_attributes := <target_name> "," <target_version> "," <device_name> <,>
↪<start> ";"

target_name := "target_name=linear"
target_version := "target_version=" <N> "." <N> "." <N>
device_name := "device_name=" <linear_device_name_str>
start := "start=" <N>

E.g.
When a 'linear' target is loaded, then IMA ASCII measurement log will have an␣
↪entry
similar to the following, depicting what 'linear' attributes are measured in␣
↪EVENT_DATA
for 'dm_table_load' event.
(converted from ASCII to text for readability)

dm_version=4.45.0;
name=linear1,uuid=linear_uuid1,major=253,minor=2,minor_count=1,num_targets=1;
target_index=0,target_begin=0,target_len=28672,target_name=linear,target_
↪version=1.4.0,
device_name=253:1,start=2048;
```

5. mirror

The 'target_attributes' (described as part of EVENT_DATA in 'Table load' section above) has the following data format for 'mirror' target.

```
target_attributes := <target_name> "," <target_version> "," <nr_mirrors> ","
                     <mirror_device_data> "," <handle_errors> "," <keep_log> ",
↪" <log_type_status> ";"

target_name := "target_name=mirror"
target_version := "target_version=" <N> "." <N> "." <N>
nr_mirrors := "nr_mirrors=" <NR>
mirror_device_data := <mirror_device_row> | <mirror_device_data><mirror_device_
↪row>
                      mirror_device_row is repeated <NR> times - for <NR>␣
↪described in <nr_mirrors>.
mirror_device_row := <mirror_device_name> "," <mirror_device_status>
```

```
mirror_device_name := "mirror_device_" <X> "=" <mirror_device_name_str>
                      where <X> ranges from 0 to (<NR> -1) - for <NR>␣
↪described in <nr_mirrors>.
mirror_device_status := "mirror_device_" <X> "_status=" <mirror_device_status_
↪char>
                       where <X> ranges from 0 to (<NR> -1) - for <NR>␣
↪described in <nr_mirrors>.
mirror_device_status_char := "A" | "F" | "D" | "S" | "R" | "U"
handle_errors := "handle_errors=" <yes_no>
keep_log := "keep_log=" <yes_no>
log_type_status := "log_type_status=" <log_type_status_str>
yes_no := "y" | "n"

E.g.
When a 'mirror' target is loaded, then IMA ASCII measurement log will have an␣
↪entry
similar to the following, depicting what 'mirror' attributes are measured in␣
↪EVENT_DATA
for 'dm_table_load' event.
(converted from ASCII to text for readability)

dm_version=4.45.0;
name=mirror1,uuid=mirror_uuid1,major=253,minor=6,minor_count=1,num_targets=1;
target_index=0,target_begin=0,target_len=2048,target_name=mirror,target_
↪version=1.14.0,nr_mirrors=2,
   mirror_device_0=253:4,mirror_device_0_status=A,
   mirror_device_1=253:5,mirror_device_1_status=A,
handle_errors=y,keep_log=n,log_type_status=;
```

6. multipath

The 'target_attributes' (described as part of EVENT_DATA in 'Table load' section above) has the following data format for 'multipath' target.

```
target_attributes := <target_name> "," <target_version> "," <nr_priority_
↪groups>
                     ["," <pg_state> "," <priority_groups> "," <priority_group_
↪paths>] ";"

target_name := "target_name=multipath"
target_version := "target_version=" <N> "." <N> "." <N>
nr_priority_groups := "nr_priority_groups=" <NPG>
priority_groups := <priority_groups_row>|<priority_groups_row><priority_groups>
priority_groups_row := "pg_state_" <X> "=" <pg_state_str> "," "nr_pgpaths_" <X>
↪  "=" <NPGP> ","
                       "path_selector_name_" <X> "=" <string> "," <priority_
↪group_paths>
                       where <X> ranges from 0 to (<NPG> -1) - for <NPG>␣
↪described in <nr_priority_groups>.
pg_state_str := "E" | "A" | "D"
```

```
<priority_group_paths> := <priority_group_paths_row> | <priority_group_paths_
↪row><priority_group_paths>
priority_group_paths_row := "path_name_" <X> "_" <Y> "=" <string> "," "is_
↪active_" <X> "_" <Y> "=" <is_active_str>
                            "fail_count_" <X> "_" <Y> "=" <N> "," "path_
↪selector_status_" <X> "_" <Y> "=" <path_selector_status_str>
                            where <X> ranges from 0 to (<NPG> -1) - for <NPG>␣
↪described in <nr_priority_groups>,
                            and <Y> ranges from 0 to (<NPGP> -1) - for <NPGP>␣
↪described in <priority_groups_row>.
is_active_str := "A" | "F"

E.g.
When a 'multipath' target is loaded, then IMA ASCII measurement log will have␣
↪an entry
similar to the following, depicting what 'multipath' attributes are measured␣
↪in EVENT_DATA
for 'dm_table_load' event.
(converted from ASCII to text for readability)

dm_version=4.45.0;
name=mp,uuid=,major=253,minor=0,minor_count=1,num_targets=1;
target_index=0,target_begin=0,target_len=2097152,target_name=multipath,target_
↪version=1.14.0,nr_priority_groups=2,
   pg_state_0=E,nr_pgpaths_0=2,path_selector_name_0=queue-length,

   raid_device_3_status=A;
```

8. snapshot

The 'target_attributes' (described as part of EVENT_DATA in 'Table load' section above) has the following data format for 'snapshot' target.

```
target_attributes := <target_name> "," <target_version> "," <snap_origin_name>
↪","
                     <snap_cow_name> "," <snap_valid> "," <snap_merge_failed>
↪"," <snapshot_overflowed> ";"

target_name := "target_name=snapshot"
target_version := "target_version=" <N> "." <N> "." <N>
snap_origin_name := "snap_origin_name=" <string>
snap_cow_name := "snap_cow_name=" <string>
snap_valid := "snap_valid=" <yes_no>
snap_merge_failed := "snap_merge_failed=" <yes_no>
snapshot_overflowed := "snapshot_overflowed=" <yes_no>
yes_no := "y" | "n"
```

```
E.g.
When a 'snapshot' target is loaded, then IMA ASCII measurement log will have␣
↪an entry
similar to the following, depicting what 'snapshot' attributes are measured in␣
↪EVENT_DATA
for 'dm_table_load' event.
(converted from ASCII to text for readability)

dm_version=4.45.0;
name=snap1,uuid=snap_uuid1,major=253,minor=13,minor_count=1,num_targets=1;
target_index=0,target_begin=0,target_len=4096,target_name=snapshot,target_
↪version=1.16.0,
snap_origin_name=253:11,snap_cow_name=253:12,snap_valid=y,snap_merge_failed=n,
↪snapshot_overflowed=n;
```

9. striped

The 'target_attributes' (described as part of EVENT_DATA in 'Table load' section above) has the following data format for 'striped' target.

```
target_attributes := <target_name> "," <target_version> "," <stripes> ","
↪<chunk_size> ","
                     <stripe_data> ";"

target_name := "target_name=striped"
target_version := "target_version=" <N> "." <N> "." <N>
stripes := "stripes=" <NS>
chunk_size := "chunk_size=" <N>
stripe_data := <stripe_data_row>|<stripe_data><stripe_data_row>
stripe_data_row := <stripe_device_name> "," <stripe_physical_start> ","
↪<stripe_status>
stripe_device_name := "stripe_" <X> "_device_name=" <stripe_device_name_str>
                      where <X> ranges from 0 to (<NS> -1) - for <NS>␣
↪described in <stripes>.
stripe_physical_start := "stripe_" <X> "_physical_start=" <N>
                          where <X> ranges from 0 to (<NS> -1) - for <NS>␣
↪described in <stripes>.
stripe_status := "stripe_" <X> "_status=" <stripe_status_str>
                 where <X> ranges from 0 to (<NS> -1) - for <NS> described in
↪<stripes>.
stripe_status_str := "D" | "A"

E.g.
When a 'striped' target is loaded, then IMA ASCII measurement log will have an␣
↪entry
similar to the following, depicting what 'striped' attributes are measured in␣
↪EVENT_DATA
for 'dm_table_load' event.
(converted from ASCII to text for readability)
```

```
dm_version=4.45.0;
name=striped1,uuid=striped_uuid1,major=253,minor=5,minor_count=1,num_targets=1;
target_index=0,target_begin=0,target_len=640,target_name=striped,target_
↪version=1.6.0,stripes=2,chunk_size=64,
   stripe_0_device_name=253:0,stripe_0_physical_start=2048,stripe_0_status=A,
   stripe_1_device_name=253:3,stripe_1_physical_start=2048,stripe_1_status=A;
```

10. verity

The 'target_attributes' (described as part of EVENT_DATA in 'Table load' section above) has the following data format for 'verity' target.

```
target_attributes := <target_name> "," <target_version> "," <hash_failed> ","
↪<verity_version> ","
                     <data_device_name> "," <hash_device_name> "," <verity_
↪algorithm> "," <root_digest> ","
                     <salt> "," <ignore_zero_blocks> "," <check_at_most_once> [
↪"," <root_hash_sig_key_desc>]
                     ["," <verity_mode>] ";"

target_name := "target_name=verity"
target_version := "target_version=" <N> "." <N> "." <N>
hash_failed := "hash_failed=" <hash_failed_str>
hash_failed_str := "C" | "V"
verity_version := "verity_version=" <verity_version_str>
data_device_name := "data_device_name=" <data_device_name_str>
hash_device_name := "hash_device_name=" <hash_device_name_str>
verity_algorithm := "verity_algorithm=" <verity_algorithm_str>
root_digest := "root_digest=" <root_digest_str>
salt := "salt=" <salt_str>
salt_str := "-" <verity_salt_str>
ignore_zero_blocks := "ignore_zero_blocks=" <yes_no>
check_at_most_once := "check_at_most_once=" <yes_no>
root_hash_sig_key_desc := "root_hash_sig_key_desc="
verity_mode := "verity_mode=" <verity_mode_str>
verity_mode_str := "ignore_corruption" | "restart_on_corruption" | "panic_on_
↪corruption" | "invalid"
yes_no := "y" | "n"

E.g.
When a 'verity' target is loaded, then IMA ASCII measurement log will have an␣
↪entry
similar to the following, depicting what 'verity' attributes are measured in␣
↪EVENT_DATA
for 'dm_table_load' event.
(converted from ASCII to text for readability)

dm_version=4.45.0;
name=test-verity,uuid=,major=253,minor=2,minor_count=1,num_targets=1;
target_index=0,target_begin=0,target_len=1953120,target_name=verity,target_
↪version=1.8.0,hash_failed=V,
```

```
verity_version=1,data_device_name=253:1,hash_device_name=253:0,verity_
↪algorithm=sha256,
root_digest=29cb87e60ce7b12b443ba6008266f3e41e93e403d7f298f8e3f316b29ff89c5e,
salt=e48da609055204e89ae53b655ca2216dd983cf3cb829f34f63a297d106d53e2d,
ignore_zero_blocks=n,check_at_most_once=n;
```

39.10 Early creation of mapped devices

It is possible to configure a device-mapper device to act as the root device for your system in two ways.

The first is to build an initial ramdisk which boots to a minimal userspace which configures the device, then pivot_root(8) in to it.

The second is to create one or more device-mappers using the module parameter "dm-mod.create=" through the kernel boot command line argument.

The format is specified as a string of data separated by commas and optionally semi-colons, where:

- a comma is used to separate fields like name, uuid, flags and table (specifies one device)
- a semi-colon is used to separate devices.

So the format will look like this:

```
dm-mod.create=<name>,<uuid>,<minor>,<flags>,<table>[,<table>+][;<name>,<uuid>,
↪<minor>,<flags>,<table>[,<table>+]+]
```

Where:

```
<name>          ::= The device name.
<uuid>          ::= xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxx | ""
<minor>         ::= The device minor number | ""
<flags>         ::= "ro" | "rw"
<table>         ::= <start_sector> <num_sectors> <target_type> <target_args>
<target_type>   ::= "verity" | "linear" | ... (see list below)
```

The dm line should be equivalent to the one used by the dmsetup tool with the *--concise* argument.

39.10.1 Target types

Not all target types are available as there are serious risks in allowing activation of certain DM targets without first using userspace tools to check the validity of associated metadata.

cache	constrained, userspace should verify cache device
crypt	allowed
delay	allowed
era	constrained, userspace should verify metadata device
flakey	constrained, meant for test
linear	allowed
log-writes	constrained, userspace should verify metadata device
mirror	constrained, userspace should verify main/mirror device
raid	constrained, userspace should verify metadata device
snapshot	constrained, userspace should verify src/dst device
snapshot-origin	allowed
snapshot-merge	constrained, userspace should verify src/dst device
striped	allowed
switch	constrained, userspace should verify dev path
thin	constrained, requires dm target message from userspace
thin-pool	constrained, requires dm target message from userspace
verity	allowed
writecache	constrained, userspace should verify cache device
zero	constrained, not meant for rootfs

If the target is not listed above, it is constrained by default (not tested).

39.10.2 Examples

An example of booting to a linear array made up of user-mode linux block devices:

```
dm-mod.create="lroot,,,rw, 0 4096 linear 98:16 0, 4096 4096 linear 98:32 0"␣
↪root=/dev/dm-0
```

This will boot to a rw dm-linear target of 8192 sectors split across two block devices identified by their major:minor numbers. After boot, udev will rename this target to /dev/mapper/lroot (depending on the rules). No uuid was assigned.

An example of multiple device-mappers, with the dm-mod.create="..." contents is shown here split on multiple lines for readability:

```
dm-linear,,1,rw,
  0 32768 linear 8:1 0,
  32768 1024000 linear 8:2 0;
dm-verity,,3,ro,
  0 1638400 verity 1 /dev/sdc1 /dev/sdc2 4096 4096 204800 1 sha256
  ac87db56303c9c1da433d7209b5a6ef3e4779df141200cbd7c157dcb8dd89c42
  5ebfe87f7df3235b80a117ebc4078e44f55045487ad4a96581d1adb564615b51
```

Other examples (per target):

"crypt":

```
dm-crypt,,8,ro,
  0 1048576 crypt aes-xts-plain64
```

```
  babebabebabebab
```

The dm-integrity target can be used with the dm-crypt target - in this situation the dm-crypt target creates the integrity data and passes them to the dm-integrity target via bio_integrity_payload attached to the bio. In this mode, the dm-crypt and dm-integrity targets provide authenticated disk encryption - if the attacker modifies the encrypted device, an I/O error is returned instead of random data.

The dm-integrity target can also be used as a standalone target, in this mode it calculates and verifies the integrity tag internally. In this mode, the dm-integrity target can be used to detect silent data corruption on the disk or in the I/O path.

There's an alternate mode of operation where dm-integrity uses a bitmap instead of a journal. If a bit in the bitmap is 1, the corresponding region's data and integrity tags are not synchronized - if the machine crashes, the unsynchronized regions will be recalculated. The bitmap mode is faster than the journal mode, because we don't have to write the data twice, but it is also less reliable, because if data corruption happens when the machine crashes, it may not be detected.

When loading the target for the first time, the kernel driver will format the device. But it will only format the device if the superblock contains zeroes. If the superblock is neither valid nor zeroed, the dm-integrity target can't be loaded.

Accesses to the on-disk metadata area containing checksums (aka tags) are buffered using dm-bufio. When an access to any given metadata area occurs, each unique metadata area gets its own buffer(s). The buffer size is capped at the size of the metadata area, but may be smaller, thereby requiring multiple buffers to represent the full metadata area. A smaller buffer size will produce a smaller resulting read/write operation to the metadata area for small reads/writes. The metadata is still read even in a full write to the data covered by a single buffer.

To use the target for the first time:

1. overwrite the superblock with zeroes
2. load the dm-integrity target with one-sector size, the kernel driver will format the device
3. unload the dm-integrity target
4. read the ”provided_data_sectors” value from the superblock
5. load the dm-integrity target with the target size ”provided_data_sectors”
6. if you want to use dm-integrity with dm-crypt, load the dm-crypt target with the size ”provided_data_sectors”

Target arguments:

1. the underlying block device
2. the number of reserved sector at the beginning of the device - the dm-integrity won't read of write these sectors
3. the size of the integrity tag (if ”-” is used, the size is taken from the internal-hash algorithm)
4. mode:

   D - direct writes (without journal)
   in this mode, journaling is not used and data sectors and integrity tags are written separately. In case of crash, it is possible that the data and integrity tag doesn't match.

   J - journaled writes
   data and integrity tags are written to the journal and atomicity is guaranteed.

In case of crash, either both data and tag or none of them are written. The journaled mode degrades write throughput twice because the data have to be written twice.

B - bitmap mode - data and metadata are written without any synchronization, the driver maintains a bitmap of dirty regions where data and metadata don't match. This mode can only be used with internal hash.

R - recovery mode - in this mode, journal is not replayed, checksums are not checked and writes to the device are not allowed. This mode is useful for data recovery if the device cannot be activated in any of the other standard modes.

5. the number of additional arguments

Additional arguments:

journal_sectors:number
The size of journal, this argument is used only if formatting the device. If the device is already formatted, the value from the superblock is used.

interleave_sectors:number (default 32768)
The number of interleaved sectors. This values is rounded down to a power of two. If the device is already formatted, the value from the superblock is used.

meta_device:device
Don't interleave the data and metadata on the device. Use a separate device for metadata.

buffer_sectors:number (default 128)
The number of sectors in one metadata buffer. The value is rounded down to a power of two.

journal_watermark:number (default 50)
The journal watermark in percents. When the size of the journal exceeds this watermark, the thread that flushes the journal will be started.

commit_time:number (default 10000)
Commit time in milliseconds. When this time passes, the journal is written. The journal is also written immediately if the FLUSH request is received.

internal_hash:algorithm(:key) (the key is optional)
Use internal hash or crc. When this argument is used, the dm-integrity target won't accept integrity tags from the upper target, but it will automatically generate and verify the integrity tags.

You can use a crc algorithm (such as crc32), then integrity target will protect the data against accidental corruption. You can also use a hmac algorithm (for example "hmac(sha256):0123456789abcdef"), in this mode it will provide cryptographic authentication of the data without encryption.

When this argument is not used, the integrity tags are accepted from an upper layer target, such as dm-crypt. The upper layer target should check the validity of the integrity tags.

recalculate
Recalculate the integrity tags automatically. It is only valid when using internal hash.

journal_crypt:algorithm(:key) (the key is optional)
Encrypt the journal using given algorithm to make sure that the attacker can't read the

journal. You can use a block cipher here (such as "cbc(aes)") or a stream cipher (for example "chacha20" or "ctr(aes)").

The journal contains history of last writes to the block device, an attacker reading the journal could see the last sector numbers that were written. From the sector numbers, the attacker can infer the size of files that were written. To protect against this situation, you can encrypt the journal.

journal_mac:algorithm(:key) (the key is optional)
Protect sector numbers in the journal from accidental or malicious modification. To protect against accidental modification, use a crc algorithm, to protect against malicious modification, use a hmac algorithm with a key.

This option is not needed when using internal-hash because in this mode, the integrity of journal entries is checked when replaying the journal. Thus, modified sector number would be detected at this stage.

block_size:number (default 512)
The size of a data block in bytes. The larger the block size the less overhead there is for per-block integrity metadata. Supported values are 512, 1024, 2048 and 4096 bytes.

sectors_per_bit:number
In the bitmap mode, this parameter specifies the number of 512-byte sectors that corresponds to one bitmap bit.

bitmap_flush_interval:number
The bitmap flush interval in milliseconds. The metadata buffers are synchronized when this interval expires.

allow_discards
Allow block discard requests (a.k.a. TRIM) for the integrity device. Discards are only allowed to devices using internal hash.

fix_padding
Use a smaller padding of the tag area that is more space-efficient. If this option is not present, large padding is used - that is for compatibility with older kernels.

fix_hmac
Improve security of internal_hash and journal_mac:

- the section number is mixed to the mac, so that an attacker can't copy sectors from one journal section to another journal section
- the superblock is protected by journal_mac
- a 16-byte salt stored in the superblock is mixed to the mac, so that the attacker can't detect that two disks have the same hmac key and also to disallow the attacker to move sectors from one disk to another

legacy_recalculate
Allow recalculating of volumes with HMAC keys. This is disabled by default for security reasons - an attacker could modify the volume, set recalc_sector to zero, and the kernel would not detect the modification.

The journal mode (D/J), buffer_sectors, journal_watermark, commit_time and allow_discards can be changed when reloading the target (load an inactive table and swap the tables with suspend and resume). The other arguments should not be changed when reloading the target because the layout of disk data depend on them and the reloaded target would be non-functional.

For example, on a device using the default interleave_sectors of 32768, a block_size of 512, and an internal_hash of crc32c with a tag size of 4 bytes, it will take 128 KiB of tags to track a full data area, requiring 256 sectors of metadata per data area. With the default buffer_sectors of 128, that means there will be 2 buffers per metadata area, or 2 buffers per 16 MiB of data.

Status line:

1. the number of integrity mismatches
2. provided data sectors - that is the number of sectors that the user could use
3. the current recalculating position (or '-' if we didn't recalculate)

The layout of the formatted block device:

- **reserved sectors**
  (they are not used by this target, they can be used for storing LUKS metadata or for other purpose), the size of the reserved area is specified in the target arguments
- **superblock (4kiB)**
  - magic string - identifies that the device was formatted
  - version
  - log2(interleave sectors)
  - integrity tag size
  - the number of journal sections
  - provided data sectors - the number of sectors that this target provides (i.e. the size of the device minus the size of all metadata and padding). The user of this target should not send bios that access data beyond the ”provided data sectors” limit.
  - **flags**

    SB_FLAG_HAVE_JOURNAL_MAC

    * a flag is set if journal_mac is used

    SB_FLAG_RECALCULATING

    * recalculating is in progress

    SB_FLAG_DIRTY_BITMAP

    * journal area contains the bitmap of dirty blocks
  - log2(sectors per block)
  - a position where recalculating finished
- **journal**
  The journal is divided into sections, each section contains:
  - metadata area (4kiB), it contains journal entries
    * every journal entry contains:
      · logical sector (specifies where the data and tag should be written)
      · last 8 bytes of data

        - integrity tag (the size is specified in the superblock)
      - every metadata sector ends with
        - mac (8-bytes), all the macs in 8 metadata sectors form a 64-byte value. It is used to store hmac of sector numbers in the journal section, to protect against a possibility that the attacker tampers with sector numbers in the journal.
        - commit id
    - data area (the size is variable; it depends on how many journal entries fit into the metadata area)
      - every sector in the data area contains:
        - data (504 bytes of data, the last 8 bytes are stored in the journal entry)
        - commit id

    To test if the whole journal section was written correctly, every 512-byte sector of the journal ends with 8-byte commit id. If the commit id matches on all sectors in a journal section, then it is assumed that the section was written correctly. If the commit id doesn't match, the section was written partially and it should not be replayed.

- **one or more runs of interleaved tags and data.**
  Each run contains:
  - tag area - it contains integrity tags. There is one tag for each sector in the data area. The size of this area is always 4KiB or greater.
  - data area - it contains data sectors. The number of data sectors in one run must be a power of two. log2 of this value is stored in the superblock.

39.12 dm-io

Dm-io provides synchronous and asynchronous I/O services. There are three types of I/O services available, and each type has a sync and an async version.

The user must set up an io_region structure to describe the desired location of the I/O. Each io_region indicates a block-device along with the starting sector and size of the region:

```
struct io_region {
   struct block_device *bdev;
   sector_t sector;
   sector_t count;
};
```

Dm-io can read from one io_region or write to one or more io_regions. Writes to multiple regions are specified by an array of io_region structures.

The first I/O service type takes a list of memory pages as the data buffer for the I/O, along with an offset into the first page:

```
struct page_list {
   struct page_list *next;
   struct page *page;
```

```
};

int dm_io_sync(unsigned int num_regions, struct io_region *where, int rw,
               struct page_list *pl, unsigned int offset,
               unsigned long *error_bits);
int dm_io_async(unsigned int num_regions, struct io_region *where, int rw,
                struct page_list *pl, unsigned int offset,
                io_notify_fn fn, void *context);
```

The second I/O service type takes an array of bio vectors as the data buffer for the I/O. This service can be handy if the caller has a pre-assembled bio, but wants to direct different portions of the bio to different devices:

```
int dm_io_sync_bvec(unsigned int num_regions, struct io_region *where,
                    int rw, struct bio_vec *bvec,
                    unsigned long *error_bits);
int dm_io_async_bvec(unsigned int num_regions, struct io_region *where,
                     int rw, struct bio_vec *bvec,
                     io_notify_fn fn, void *context);
```

The third I/O service type takes a pointer to a vmalloc'd memory buffer as the data buffer for the I/O. This service can be handy if the caller needs to do I/O to a large region but doesn't want to allocate a large number of individual memory pages:

```
int dm_io_sync_vm(unsigned int num_regions, struct io_region *where, int rw,
                  void *data, unsigned long *error_bits);
int dm_io_async_vm(unsigned int num_regions, struct io_region *where, int rw,
                   void *data, io_notify_fn fn, void *context);
```

Callers of the asynchronous I/O services must include the name of a completion callback routine and a pointer to some context data for the I/O:

```
typedef void (*io_notify_fn)(unsigned long error, void *context);
```

The ”error” parameter in this callback, as well as the **error* parameter in all of the synchronous versions, is a bitset (instead of a simple error value). In the case of an write-I/O to multiple regions, this bitset allows dm-io to indicate success or failure on each individual region.

Before using any of the dm-io services, the user should call dm_io_get() and specify the number of pages they expect to perform I/O on concurrently. Dm-io will attempt to resize its mempool to make sure enough pages are always available in order to avoid unnecessary waiting while performing I/O.

When the user is finished using the dm-io services, they should call dm_io_put() and specify the same number of pages that were given on the dm_io_get() call.

39.13 Device-Mapper Logging

The device-mapper logging code is used by some of the device-mapper RAID targets to track regions of the disk that are not consistent. A region (or portion of the address space) of the disk may be inconsistent because a RAID stripe is currently being operated on or a machine died while the region was being altered. In the case of mirrors, a region would be considered dirty/inconsistent while you are writing to it because the writes need to be replicated for all the legs of the mirror and may not reach the legs at the same time. Once all writes are complete, the region is considered clean again.

There is a generic logging interface that the device-mapper RAID implementations use to perform logging operations (see dm_dirty_log_type in include/linux/dm-dirty-log.h). Various different logging implementations are available and provide different capabilities. The list includes:

Type	Files
disk	drivers/md/dm-log.c
core	drivers/md/dm-log.c
userspace	drivers/md/dm-log-userspace* include/linux/dm-log-userspace.h

39.13.1 The ”disk” log type

This log implementation commits the log state to disk. This way, the logging state survives reboots/crashes.

39.13.2 The ”core” log type

This log implementation keeps the log state in memory. The log state will not survive a reboot or crash, but there may be a small boost in performance. This method can also be used if no storage device is available for storing log state.

39.13.3 The ”userspace” log type

This log type simply provides a way to export the log API to userspace, so log implementations can be done there. This is done by forwarding most logging requests to userspace, where a daemon receives and processes the request.

The structure used for communication between kernel and userspace are located in include/linux/dm-log-userspace.h. Due to the frequency, diversity, and 2-way communication nature of the exchanges between kernel and userspace, 'connector' is used as the interface for communication.

There are currently two userspace log implementations that leverage this framework - ”clustered-disk” and ”clustered-core”. These implementations provide a cluster-coherent log for shared-storage. Device-mapper mirroring can be used in a shared-storage environment when the cluster log implementations are employed.

39.14 dm-queue-length

dm-queue-length is a path selector module for device-mapper targets, which selects a path with the least number of in-flight I/Os. The path selector name is 'queue-length'.

Table parameters for each path: [<repeat_count>]

```
<repeat_count>: The number of I/Os to dispatch using the selected
                path before switching to the next path.
                If not given, internal default is used. To check
                the default value, see the activated table.
```

Status for each path: <status> <fail-count> <in-flight>

```
<status>: 'A' if the path is active, 'F' if the path is failed.
<fail-count>: The number of path failures.
<in-flight>: The number of in-flight I/Os on the path.
```

39.14.1 Algorithm

dm-queue-length increments/decrements 'in-flight' when an I/O is dispatched/completed respectively. dm-queue-length selects a path with the minimum 'in-flight'.

39.14.2 Examples

In case that 2 paths (sda and sdb) are used with repeat_count == 128.

```
# echo "0 10 multipath 0 0 1 1 queue-length 0 2 1 8:0 128 8:16 128" \
  dmsetup create test
#
# dmsetup table
test: 0 10 multipath 0 0 1 1 queue-length 0 2 1 8:0 128 8:16 128
#
# dmsetup status
test: 0 10 multipath 2 0 0 0 1 1 E 0 2 1 8:0 A 0 0 8:16 A 0 0
```

39.15 dm-raid

The device-mapper RAID (dm-raid) target provides a bridge from DM to MD. It allows the MD RAID drivers to be accessed using a device-mapper interface.

39.15.1 Mapping Table Interface

The target is named ”raid” and it accepts the following parameters:

```
<raid_type> <#raid_params> <raid_params> \
  <#raid_devs> <metadata_dev0> <dev0> [.. <metadata_devN> <devN>]
```

<raid_type>:

raid0	RAID0 striping (no resilience)
raid1	RAID1 mirroring
raid4	RAID4 with dedicated last parity disk
raid5_n	RAID5 with dedicated last parity disk supporting takeover Same as raid4 • Transitory layout
raid5_la	RAID5 left asymmetric • rotating parity 0 with data continuation
raid5_ra	RAID5 right asymmetric • rotating parity N with data continuation
raid5_ls	RAID5 left symmetric • rotating parity 0 with data restart
raid5_rs	RAID5 right symmetric • rotating parity N with data restart
raid6_zr	RAID6 zero restart • rotating parity zero (left-to-right) with data restart
raid6_nr	RAID6 N restart • rotating parity N (right-to-left) with data restart
raid6_nc	RAID6 N continue • rotating parity N (right-to-left) with data continuation
raid6_n_6	RAID6 with dedicate parity disks • parity and Q-syndrome on the last 2 disks; layout for takeover from/to raid4/raid5_n
raid6_la_6	Same as ”raid_la” plus dedicated last Q-syndrome disk • layout for takeover from raid5_la from/to raid6
raid6_ra_6	Same as ”raid5_ra” dedicated last Q-syndrome disk • layout for takeover from raid5_ra from/to raid6
raid6_ls_6	Same as ”raid5_ls” dedicated last Q-syndrome disk • layout for takeover from raid5_ls from/to raid6
raid6_rs_6	Same as ”raid5_rs” dedicated last Q-syndrome disk • layout for takeover from raid5_rs

Reference: Chapter 4 of https://www.snia.org/sites/default/files/SNIA_DDF_Technical_Position_v2.0.pdf

<#raid_params>: The number of parameters that follow.

<raid_params> consists of

Mandatory parameters:

<chunk_size>:
Chunk size in sectors. This parameter is often known as ”stripe size”. It is the only mandatory parameter and is placed first.

followed by optional parameters (in any order):

[sync|nosync]
Force or prevent RAID initialization.

[rebuild <idx>]
Rebuild drive number 'idx' (first drive is 0).

[daemon_sleep <ms>]
Interval between runs of the bitmap daemon that clear bits. A longer interval means less bitmap I/O but resyncing after a failure is likely to take longer.

[min_recovery_rate <kB/sec/disk>]
Throttle RAID initialization

[max_recovery_rate <kB/sec/disk>]
Throttle RAID initialization

[write_mostly <idx>]
Mark drive index 'idx' write-mostly.

[max_write_behind <sectors>]
See '--write-behind=' (man mdadm)

[stripe_cache <sectors>]
Stripe cache size (RAID 4/5/6 only)

[region_size <sectors>]
The region_size multiplied by the number of regions is the logical size of the array. The bitmap records the device synchronisation state for each region.

[raid10_copies <# copies>], [raid10_format <near|far|offset>]
These two options are used to alter the default layout of a RAID10 configuration. The number of copies is can be specified, but the default is 2. There are also three variations to how the copies are laid down - the default is ”near”. Near copies are what most people think of with respect to mirroring. If these options are left unspecified, or 'raid10_copies 2' and/or 'raid10_format near' are given, then the layouts for 2, 3 and 4 devices are:

2 drives	3 drives	4 drives
A1 A1	A1 A1 A2	A1 A1 A2 A2
A2 A2	A2 A3 A3	A3 A3 A4 A4
A3 A3	A4 A4 A5	A5 A5 A6 A6
A4 A4	A5 A6 A6	A7 A7 A8 A8

The 2-device layout is equivalent 2-way RAID1. The 4-device layout is what a traditional RAID10 would look like. The 3-device layout is what might be called a 'RAID1E - Integrated Adjacent Stripe Mirroring'.

If 'raid10_copies 2' and 'raid10_format far', then the layouts for 2, 3 and 4 devices are:

2 drives	3 drives	4 drives
A1 A2	A1 A2 A3	A1 A2 A3 A4
A3 A4	A4 A5 A6	A5 A6 A7 A8
A5 A6	A7 A8 A9	A9 A10 A11 A12
A2 A1	A3 A1 A2	A2 A1 A4 A3
A4 A3	A6 A4 A5	A6 A5 A8 A7
A6 A5	A9 A7 A8	A10 A9 A12 A11

If 'raid10_copies 2' and 'raid10_format offset', then the layouts for 2, 3 and 4 devices are:

2 drives	3 drives	4 drives
A1 A2	A1 A2 A3	A1 A2 A3 A4
A2 A1	A3 A1 A2	A2 A1 A4 A3
A3 A4	A4 A5 A6	A5 A6 A7 A8
A4 A3	A6 A4 A5	A6 A5 A8 A7
A5 A6	A7 A8 A9	A9 A10 A11 A12
A6 A5	A9 A7 A8	A10 A9 A12 A11

Here we see layouts closely akin to 'RAID1E - Integrated Offset Stripe Mirroring'.

[delta_disks <N>]
The delta_disks option value (-251 < N < +251) triggers device removal (negative value) or device addition (positive value) to any reshape supporting raid levels 4/5/6 and 10. RAID levels 4/5/6 allow for addition of devices (metadata and data device tuple), raid10_near and raid10_offset only allow for device addition. raid10_far does not support any reshaping at all. A minimum of devices have to be kept to enforce resilience, which is 3 devices for raid4/5 and 4 devices for raid6.

[data_offset <sectors>]
This option value defines the offset into each data device where the data starts. This is used to provide out-of-place reshaping space to avoid writing over data while changing the layout of stripes, hence an interruption/crash may happen at any time without the risk of losing data. E.g. when adding devices to an existing raid set during forward reshaping, the out-of-place space will be allocated at the beginning of each raid device. The kernel raid4/5/6/10 MD personalities supporting such device addition will read the data from the existing first stripes (those with smaller number of stripes) starting at data_offset to fill up a new stripe with the larger number of stripes, calculate

the redundancy blocks (CRC/Q-syndrome) and write that new stripe to offset 0. Same will be applied to all N-1 other new stripes. This out-of-place scheme is used to change the RAID type (i.e. the allocation algorithm) as well, e.g. changing from raid5_ls to raid5_n.

[journal_dev <dev>]
This option adds a journal device to raid4/5/6 raid sets and uses it to close the 'write hole' caused by the non-atomic updates to the component devices which can cause data loss during recovery. The journal device is used as writethrough thus causing writes to be throttled versus non-journaled raid4/5/6 sets. Takeover/reshape is not possible with a raid4/5/6 journal device; it has to be deconfigured before requesting these.

[journal_mode <mode>]
This option sets the caching mode on journaled raid4/5/6 raid sets (see 'journal_dev <dev>' above) to 'writethrough' or 'writeback'. If 'writeback' is selected the journal device has to be resilient and must not suffer from the 'write hole' problem itself (e.g. use raid1 or raid10) to avoid a single point of failure.

<#raid_devs>: The number of devices composing the array.
Each device consists of two entries. The first is the device containing the metadata (if any); the second is the one containing the data. A Maximum of 64 metadata/data device entries are supported up to target version 1.8.0. 1.9.0 supports up to 253 which is enforced by the used MD kernel runtime.

If a drive has failed or is missing at creation time, a '-' can be given for both the metadata and data drives for a given position.

39.15.2 Example Tables

```
# RAID4 - 4 data drives, 1 parity (no metadata devices)
# No metadata devices specified to hold superblock/bitmap info
# Chunk size of 1MiB
# (Lines separated for easy reading)

0 1960893648 raid \
        raid4 1 2048 \
        5 - 8:17 - 8:33 - 8:49 - 8:65 - 8:81

# RAID4 - 4 data drives, 1 parity (with metadata devices)
# Chunk size of 1MiB, force RAID initialization,
#       min recovery rate at 20 kiB/sec/disk

0 1960893648 raid \
        raid4 4 2048 sync min_recovery_rate 20 \
        5 8:17 8:18 8:33 8:34 8:49 8:50 8:65 8:66 8:81 8:82
```

39.15.3 Status Output

'dmsetup table' displays the table used to construct the mapping. The optional parameters are always printed in the order listed above with ”sync” or ”nosync” always output ahead of the other arguments, regardless of the order used when originally loading the table. Arguments that can be repeated are ordered by value.

'dmsetup status' yields information on the state and health of the array. The output is as follows (normally a single line, but expanded here for clarity):

```
1: <s> <l> raid \
2:      <raid_type> <#devices> <health_chars> \
3:      <sync_ratio> <sync_action> <mismatch_cnt>
```

Line 1 is the standard output produced by device-mapper.

Line 2 & 3 are produced by the raid target and are best explained by example:

```
0 1960893648 raid raid4 5 AAAAA 2/490221568 init 0
```

Here we can see the RAID type is raid4, there are 5 devices - all of which are 'A'live, and the array is 2/490221568 complete with its initial recovery. Here is a fuller description of the individual fields:

<raid_type>	Same as the <raid_type> used to create the array.
<health_chars>	One char for each device, indicating: • 'A' = alive and in-sync • 'a' = alive but not in-sync • 'D' = dead/failed.
<sync_ratio>	The ratio indicating how much of the array has undergone the process described by 'sync_action'. If the 'sync_action' is ”check” or ”repair”, then the process of ”resync” or ”recover” can be considered complete.
<sync_action>	One of the following possible states: **idle** • No synchronization action is being performed. **frozen** • The current action has been halted. **resync** • Array is undergoing its initial synchronization or is resynchronizing after an unclean shutdown (possibly aided by a bitmap). **recover** • A device in the array is being rebuilt or replaced. **check** • A user-initiated full check of the array is being performed. All blocks are read and checked for consistency. The number of discrepancies found are recorded in <mismatch_cnt>. No changes are made to the array by this action. **repair** • The same as ”check”, but discrepancies are corrected. **reshape** • The array is undergoing a reshape.
<mismatch_cnt>	The number of discrepancies found between mirror copies in RAID1/10 or wrong parity values found in RAID4/5/6. This value is valid only after a ”check” of the array is performed. A healthy array has a 'mismatch_cnt' of 0.
<data_offset>	The current data offset to the start of the user data on each component device of the raid set (see the respective raid parameter to support out-of-place reshaping).
<journal_char>	'A' = active in the raid journal device

39.15.4 Message Interface

The dm-raid target will accept certain actions through the 'message' interface. ('man dmsetup' for more information on the message interface.) These actions include:

”idle”	Halt the current sync action.
”frozen”	Freeze the current sync action.
”resync”	Initiate/continue a resync.
”recover”	Initiate/continue a recover process.
”check”	Initiate a check (i.e. a ”scrub”) of the array.
”repair”	Initiate a repair of the array.

39.15.5 Discard Support

The implementation of discard support among hardware vendors varies. When a block is discarded, some storage devices will return zeroes when the block is read. These devices set the 'discard_zeroes_data' attribute. Other devices will return random data. Confusingly, some devices that advertise 'discard_zeroes_data' will not reliably return zeroes when discarded blocks are read! Since RAID 4/5/6 uses blocks from a number of devices to calculate parity blocks and (for performance reasons) relies on 'discard_zeroes_data' being reliable, it is important that the devices be consistent. Blocks may be discarded in the middle of a RAID 4/5/6 stripe and if subsequent read results are not consistent, the parity blocks may be calculated differently at any time; making the parity blocks useless for redundancy. It is important to understand how your hardware behaves with discards if you are going to enable discards with RAID 4/5/6.

Since the behavior of storage devices is unreliable in this respect, even when reporting 'discard_zeroes_data', by default RAID 4/5/6 discard support is disabled -- this ensures data integrity at the expense of losing some performance.

Storage devices that properly support 'discard_zeroes_data' are increasingly whitelisted in the kernel and can thus be trusted.

For trusted devices, the following dm-raid module parameter can be set to safely enable discard support for RAID 4/5/6:

> 'devices_handle_discards_safely'

39.15.6 Version History

```
1.0.0  Initial version.  Support for RAID 4/5/6
1.1.0  Added support for RAID 1
1.2.0  Handle creation of arrays that contain failed devices.
1.3.0  Added support for RAID 10
1.3.1  Allow device replacement/rebuild for RAID 10
1.3.2  Fix/improve redundancy checking for RAID10
1.4.0  Non-functional change.  Removes arg from mapping function.
1.4.1  RAID10 fix redundancy validation checks (commit 55ebbb5).
1.4.2  Add RAID10 "far" and "offset" algorithm support.
1.5.0  Add message interface to allow manipulation of the sync_action.
       New status (STATUSTYPE_INFO) fields: sync_action and mismatch_cnt.
1.5.1  Add ability to restore transiently failed devices on resume.
```

```
1.5.2  'mismatch_cnt' is zero unless [last_]sync_action is "check".
1.6.0  Add discard support (and devices_handle_discard_safely module param).
1.7.0  Add support for MD RAID0 mappings.
1.8.0  Explicitly check for compatible flags in the superblock metadata
       and reject to start the raid set if any are set by a newer
       target version, thus avoiding data corruption on a raid set
       with a reshape in progress.
1.9.0  Add support for RAID level takeover/reshape/region size
       and set size reduction.
1.9.1  Fix activation of existing RAID 4/10 mapped devices
1.9.2  Don't emit '- -' on the status table line in case the constructor
       fails reading a superblock. Correctly emit 'maj:min1 maj:min2' and
       'D' on the status line.  If '- -' is passed into the constructor, emit
       '- -' on the table line and '-' as the status line health character.
1.10.0 Add support for raid4/5/6 journal device
1.10.1 Fix data corruption on reshape request
1.11.0 Fix table line argument order
       (wrong raid10_copies/raid10_format sequence)
1.11.1 Add raid4/5/6 journal write-back support via journal_mode option
1.12.1 Fix for MD deadlock between mddev_suspend() and md_write_start()␣
↪available
1.13.0 Fix dev_health status at end of "recover" (was 'a', now 'A')
1.13.1 Fix deadlock caused by early md_stop_writes().  Also fix size an
       state races.
1.13.2 Fix raid redundancy validation and avoid keeping raid set frozen
1.14.0 Fix reshape race on small devices.  Fix stripe adding reshape
       deadlock/potential data corruption.  Update superblock when
       specific devices are requested via rebuild.  Fix RAID leg
       rebuild errors.
1.15.0 Fix size extensions not being synchronized in case of new MD bitmap
       pages allocated;  also fix those not occurring after previous reductions
1.15.1 Fix argument count and arguments for rebuild/write_mostly/journal_
↪(dev|mode)
       on the status line.
```

39.16 dm-service-time

dm-service-time is a path selector module for device-mapper targets, which selects a path with the shortest estimated service time for the incoming I/O.

The service time for each path is estimated by dividing the total size of in-flight I/Os on a path with the performance value of the path. The performance value is a relative throughput value among all paths in a path-group, and it can be specified as a table argument.

The path selector name is 'service-time'.

Table parameters for each path:

[<repeat_count> [<relative_throughput>]]

<repeat_count>:

The number of I/Os to dispatch using the selected path before switching to the next path. If not given, internal default is used. To check the default value, see the activated table.

<relative_throughput>:
The relative throughput value of the path among all paths in the path-group. The valid range is 0-100. If not given, minimum value '1' is used. If '0' is given, the path isn't selected while other paths having a positive value are available.

Status for each path:

<status> <fail-count> <in-flight-size> <relative_throughput>

<status>:
'A' if the path is active, 'F' if the path is failed.

<fail-count>:
The number of path failures.

<in-flight-size>:
The size of in-flight I/Os on the path.

<relative_throughput>:
The relative throughput value of the path among all paths in the path-group.

39.16.1 Algorithm

dm-service-time adds the I/O size to 'in-flight-size' when the I/O is dispatched and subtracts when completed. Basically, dm-service-time selects a path having minimum service time which is calculated by:

```
('in-flight-size' + 'size-of-incoming-io') / 'relative_throughput'
```

However, some optimizations below are used to reduce the calculation as much as possible.

1. If the paths have the same 'relative_throughput', skip the division and just compare the 'in-flight-size'.
2. If the paths have the same 'in-flight-size', skip the division and just compare the 'relative_throughput'.
3. If some paths have non-zero 'relative_throughput' and others have zero 'relative_throughput', ignore those paths with zero 'relative_throughput'.

If such optimizations can't be applied, calculate service time, and compare service time. If calculated service time is equal, the path having maximum 'relative_throughput' may be better. So compare 'relative_throughput' then.

39.16.2 Examples

In case that 2 paths (sda and sdb) are used with repeat_count == 128 and sda has an average throughput 1GB/s and sdb has 4GB/s, 'relative_throughput' value may be '1' for sda and '4' for sdb:

```
# echo "0 10 multipath 0 0 1 1 service-time 0 2 2 8:0 128 1 8:16 128 4" \
  dmsetup create test
#
# dmsetup table
test: 0 10 multipath 0 0 1 1 service-time 0 2 2 8:0 128 1 8:16 128 4
#
# dmsetup status
test: 0 10 multipath 2 0 0 0 1 1 E 0 2 2 8:0 A 0 0 1 8:16 A 0 0 4
```

Or '2' for sda and '8' for sdb would be also true:

```
# echo "0 10 multipath 0 0 1 1 service-time 0 2 2 8:0 128 2 8:16 128 8" \
  dmsetup create test
#
# dmsetup table
test: 0 10 multipath 0 0 1 1 service-time 0 2 2 8:0 128 2 8:16 128 8
#
# dmsetup status
test: 0 10 multipath 2 0 0 0 1 1 E 0 2 2 8:0 A 0 0 2 8:16 A 0 0 8
```

39.17 device-mapper uevent

The device-mapper uevent code adds the capability to device-mapper to create and send kobject uevents (uevents). Previously device-mapper events were only available through the ioctl interface. The advantage of the uevents interface is the event contains environment attributes providing increased context for the event avoiding the need to query the state of the device-mapper device after the event is received.

There are two functions currently for device-mapper events. The first function listed creates the event and the second function sends the event(s):

```
void dm_path_uevent(enum dm_uevent_type event_type, struct dm_target *ti,
                    const char *path, unsigned nr_valid_paths)

void dm_send_uevents(struct list_head *events, struct kobject *kobj)
```

The variables added to the uevent environment are:

39.17.1 Variable Name: DM_TARGET

Uevent Action(s)
KOBJ_CHANGE

Type
string

Description
Value
Name of device-mapper target that generated the event.

39.17.2 Variable Name: DM_ACTION

Uevent Action(s)
KOBJ_CHANGE

Type
string

Description
Value
Device-mapper specific action that caused the uevent action. PATH_FAILED - A path has failed; PATH_REINSTATED - A path has been reinstated.

39.17.3 Variable Name: DM_SEQNUM

Uevent Action(s)
KOBJ_CHANGE

Type
unsigned integer

Description
A sequence number for this specific device-mapper device.

Value
Valid unsigned integer range.

39.17.4 Variable Name: DM_PATH

Uevent Action(s)
KOBJ_CHANGE

Type
string

Description
Major and minor number of the path device pertaining to this event.

Value
Path name in the form of ”Major:Minor”

39.17.5 Variable Name: DM_NR_VALID_PATHS

Uevent Action(s)
KOBJ_CHANGE

Type
unsigned integer

Description
Value
Valid unsigned integer range.

39.17.6 Variable Name: DM_NAME

Uevent Action(s)
KOBJ_CHANGE

Type
string

Description
Name of the device-mapper device.

Value
Name

39.17.7 Variable Name: DM_UUID

Uevent Action(s)
KOBJ_CHANGE

Type
string

Description
UUID of the device-mapper device.

Value
UUID. (Empty string if there isn't one.)

An example of the uevents generated as captured by udevmonitor is shown below

1.) Path failure:

```
UEVENT[1192521009.711215] change@/block/dm-3
ACTION=change
DEVPATH=/block/dm-3
SUBSYSTEM=block
DM_TARGET=multipath
DM_ACTION=PATH_FAILED
DM_SEQNUM=1
DM_PATH=8:32
DM_NR_VALID_PATHS=0
DM_NAME=mpath2
DM_UUID=mpath-35333333000002328
```

```
MINOR=3
MAJOR=253
SEQNUM=1130
```

2.) Path reinstate:

```
UEVENT[1192521132.989927] change@/block/dm-3
ACTION=change
DEVPATH=/block/dm-3
SUBSYSTEM=block
DM_TARGET=multipath
DM_ACTION=PATH_REINSTATED
DM_SEQNUM=2
DM_PATH=8:32
DM_NR_VALID_PATHS=1
DM_NAME=mpath2
DM_UUID=mpath-35333333000002328
MINOR=3
MAJOR=253
SEQNUM=1131
```

39.18 dm-zoned

The dm-zoned device mapper target exposes a zoned block device (ZBC and ZAC compliant devices) as a regular block device without any write pattern constraints. In effect, it implements a drive-managed zoned block device which hides from the user (a file system or an application doing raw block device accesses) the sequential write constraints of host-managed zoned block devices and can mitigate the potential device-side performance degradation due to excessive random writes on host-aware zoned block devices.

For a more detailed description of the zoned block device models and their constraints see (for SCSI devices):

https://www.t10.org/drafts.htm#ZBC_Family

and (for ATA devices):

http://www.t13.org/Documents/UploadedDocuments/docs2015/di537r05-Zoned_Device_ATA_Command_Set_ZAC.pdf

The dm-zoned implementation is simple and minimizes system overhead (CPU and memory usage as well as storage capacity loss). For a 10TB host-managed disk with 256 MB zones, dm-zoned memory usage per disk instance is at most 4.5 MB and as little as 5 zones will be used internally for storing metadata and performing reclaim operations.

dm-zoned target devices are formatted and checked using the dmzadm utility available at:

https://github.com/hgst/dm-zoned-tools

39.18.1 Algorithm

dm-zoned implements an on-disk buffering scheme to handle non-sequential write accesses to the sequential zones of a zoned block device. Conventional zones are used for caching as well as for storing internal metadata. It can also use a regular block device together with the zoned block device; in that case the regular block device will be split logically in zones with the same size as the zoned block device. These zones will be placed in front of the zones from the zoned block device and will be handled just like conventional zones.

The zones of the device(s) are separated into 2 types:

1) Metadata zones: these are conventional zones used to store metadata. Metadata zones are not reported as usable capacity to the user.

2) Data zones: all remaining zones, the vast majority of which will be sequential zones used exclusively to store user data. The conventional zones of the device may be used also for buffering user random writes. Data in these zones may be directly mapped to the conventional zone, but later moved to a sequential zone so that the conventional zone can be reused for buffering incoming random writes.

dm-zoned exposes a logical device with a sector size of 4096 bytes, irrespective of the physical sector size of the backend zoned block device being used. This allows reducing the amount of metadata needed to manage valid blocks (blocks written).

The on-disk metadata format is as follows:

1) The first block of the first conventional zone found contains the super block which describes the on disk amount and position of metadata blocks.

2) Following the super block, a set of blocks is used to describe the mapping of the logical device blocks. The mapping is done per chunk of blocks, with the chunk size equal to the zoned block device size. The mapping table is indexed by chunk number and each mapping entry indicates the zone number of the device storing the chunk of data. Each mapping entry may also indicate if the zone number of a conventional zone used to buffer random modification to the data zone.

3) A set of blocks used to store bitmaps indicating the validity of blocks in the data zones follows the mapping table. A valid block is defined as a block that was written and not discarded. For a buffered data chunk, a block is always valid only in the data zone mapping the chunk or in the buffer zone of the chunk.

For a logical chunk mapped to a conventional zone, all write operations are processed by directly writing to the zone. If the mapping zone is a sequential zone, the write operation is processed directly only if the write offset within the logical chunk is equal to the write pointer offset within of the sequential data zone (i.e. the write operation is aligned on the zone write pointer). Otherwise, write operations are processed indirectly using a buffer zone. In that case, an unused conventional zone is allocated and assigned to the chunk being accessed. Writing a block to the buffer zone of a chunk will automatically invalidate the same block in the sequential zone mapping the chunk. If all blocks of the sequential zone become invalid, the zone is freed and the chunk buffer zone becomes the primary zone mapping the chunk, resulting in native random write performance similar to a regular block device.

Read operations are processed according to the block validity information provided by the bitmaps. Valid blocks are read either from the sequential zone mapping a chunk, or if the chunk is buffered, from the buffer zone assigned. If the accessed chunk has no mapping, or the accessed blocks are invalid, the read buffer is zeroed and the read operation terminated.

After some time, the limited number of conventional zones available may be exhausted (all used to map chunks or buffer sequential zones) and unaligned writes to unbuffered chunks become impossible. To avoid this situation, a reclaim process regularly scans used conventional zones and tries to reclaim the least recently used zones by copying the valid blocks of the buffer zone to a free sequential zone. Once the copy completes, the chunk mapping is updated to point to the sequential zone and the buffer zone freed for reuse.

39.18.2 Metadata Protection

To protect metadata against corruption in case of sudden power loss or system crash, 2 sets of metadata zones are used. One set, the primary set, is used as the main metadata region, while the secondary set is used as a staging area. Modified metadata is first written to the secondary set and validated by updating the super block in the secondary set, a generation counter is used to indicate that this set contains the newest metadata. Once this operation completes, in place of metadata block updates can be done in the primary metadata set. This ensures that one of the set is always consistent (all modifications committed or none at all). Flush operations are used as a commit point. Upon reception of a flush request, metadata modification activity is temporarily blocked (for both incoming BIO processing and reclaim process) and all dirty metadata blocks are staged and updated. Normal operation is then resumed. Flushing metadata thus only temporarily delays write and discard requests. Read requests can be processed concurrently while metadata flush is being executed.

If a regular device is used in conjunction with the zoned block device, a third set of metadata (without the zone bitmaps) is written to the start of the zoned block device. This metadata has a generation counter of '0' and will never be updated during normal operation; it just serves for identification purposes. The first and second copy of the metadata are located at the start of the regular block device.

39.18.3 Usage

A zoned block device must first be formatted using the dmzadm tool. This will analyze the device zone configuration, determine where to place the metadata sets on the device and initialize the metadata sets.

Ex:

```
dmzadm --format /dev/sdxx
```

If two drives are to be used, both devices must be specified, with the regular block device as the first device.

Ex:

```
dmzadm --format /dev/sdxx /dev/sdyy
```

Formatted device(s) can be started with the dmzadm utility, too.:

Ex:

```
dmzadm --start /dev/sdxx /dev/sdyy
```

Information about the internal layout and current usage of the zones can be obtained with the 'status' callback from dmsetup:

Ex:

```
dmsetup status /dev/dm-X
```

will return a line

> 0 <size> zoned <nr_zones> zones <nr_unmap_rnd>/<nr_rnd> random <nr_unmap_seq>/<nr_seq> sequential

where <nr_zones> is the total number of zones, <nr_unmap_rnd> is the number of unmapped (ie free) random zones, <nr_rnd> the total number of zones, <nr_unmap_seq> the number of unmapped sequential zones, and <nr_seq> the total number of sequential zones.

Normally the reclaim process will be started once there are less than 50 percent free random zones. In order to start the reclaim process manually even before reaching this threshold the 'dmsetup message' function can be used:

Ex:

```
dmsetup message /dev/dm-X 0 reclaim
```

will start the reclaim process and random zones will be moved to sequential zones.

39.19 dm-era

39.19.1 Introduction

dm-era is a target that behaves similar to the linear target. In addition it keeps track of which blocks were written within a user defined period of time called an 'era'. Each era target instance maintains the current era as a monotonically increasing 32-bit counter.

Use cases include tracking changed blocks for backup software, and partially invalidating the contents of a cache to restore cache coherency after rolling back a vendor snapshot.

39.19.2 Constructor

era <metadata dev> <origin dev> <block size>

metadata dev	fast device holding the persistent metadata
origin dev	device holding data blocks that may change
block size	block size of origin data device, granularity that is tracked by the target

39.19.3 Messages

None of the dm messages take any arguments.

checkpoint

Possibly move to a new era. You shouldn't assume the era has incremented. After sending this message, you should check the current era via the status line.

take_metadata_snap

Create a clone of the metadata, to allow a userland process to read it.

drop_metadata_snap

Drop the metadata snapshot.

39.19.4 Status

<metadata block size> <#used metadata blocks>/<#total metadata blocks> <current era> <held metadata root | '-'>

metadata block size	Fixed block size for each metadata block in sectors
#used metadata blocks	Number of metadata blocks used
#total metadata blocks	Total number of metadata blocks
current era	The current era
held metadata root	The location, in blocks, of the metadata root that has been 'held' for userspace read access. '-' indicates there is no held root

39.19.5 Detailed use case

The scenario of invalidating a cache when rolling back a vendor snapshot was the primary use case when developing this target:

Taking a vendor snapshot

- Send a checkpoint message to the era target
- Make a note of the current era in its status line
- Take vendor snapshot (the era and snapshot should be forever associated now).

Rolling back to an vendor snapshot

- Cache enters passthrough mode (see: dm-cache's docs in cache.txt)
- Rollback vendor storage
- Take metadata snapshot
- Ascertain which blocks have been written since the snapshot was taken by checking each block's era
- Invalidate those blocks in the caching software
- Cache returns to writeback/writethrough mode

39.19.6 Memory usage

The target uses a bitset to record writes in the current era. It also has a spare bitset ready for switching over to a new era. Other than that it uses a few 4k blocks for updating metadata:

```
(4 * nr_blocks) bytes + buffers
```

39.19.7 Resilience

Metadata is updated on disk before a write to a previously unwritten block is performed. As such dm-era should not be effected by a hard crash such as power failure.

39.19.8 Userland tools

Userland tools are found in the increasingly poorly named thin-provisioning-tools project:

https://github.com/jthornber/thin-provisioning-tools

39.20 kcopyd

Kcopyd provides the ability to copy a range of sectors from one block-device to one or more other block-devices, with an asynchronous completion notification. It is used by dm-snapshot and dm-mirror.

Users of kcopyd must first create a client and indicate how many memory pages to set aside for their copy jobs. This is done with a call to kcopyd_client_create():

```
int kcopyd_client_create(unsigned int num_pages,
                         struct kcopyd_client **result);
```

To start a copy job, the user must set up io_region structures to describe the source and destinations of the copy. Each io_region indicates a block-device along with the starting sector and size of the region. The source of the copy is given as one io_region structure, and the destinations of the copy are given as an array of io_region structures:

```
struct io_region {
   struct block_device *bdev;
   sector_t sector;
   sector_t count;
};
```

To start the copy, the user calls kcopyd_copy(), passing in the client pointer, pointers to the source and destination io_regions, the name of a completion callback routine, and a pointer to some context data for the copy:

```
int kcopyd_copy(struct kcopyd_client *kc, struct io_region *from,
                unsigned int num_dests, struct io_region *dests,
                unsigned int flags, kcopyd_notify_fn fn, void *context);

typedef void (*kcopyd_notify_fn)(int read_err, unsigned int write_err,
                                 void *context);
```

When the copy completes, kcopyd will call the user's completion routine, passing back the user's context pointer. It will also indicate if a read or write error occurred during the copy.

When a user is done with all their copy jobs, they should call kcopyd_client_destroy() to delete the kcopyd client, which will release the associated memory pages:

```
void kcopyd_client_destroy(struct kcopyd_client *kc);
```

39.21 dm-linear

Device-Mapper's ”linear” target maps a linear range of the Device-Mapper device onto a linear range of another device. This is the basic building block of logical volume managers.

Parameters: <dev path> <offset>

<dev path>:
Full pathname to the underlying block-device, or a ”major:minor” device-number.

<offset>:
Starting sector within the device.

39.21.1 Example scripts

```
#!/bin/sh
# Create an identity mapping for a device
echo "0 `blockdev --getsz $1` linear $1 0" | dmsetup create identity
```

```
#!/bin/sh
# Join 2 devices together
size1=`blockdev --getsz $1`
size2=`blockdev --getsz $2`
echo "0 $size1 linear $1 0
$size1 $size2 linear $2 0" | dmsetup create joined
```

```
#!/usr/bin/perl -w
# Split a device into 4M chunks and then join them together in reverse order.

my $name = "reverse";
my $extent_size = 4 * 1024 * 2;
my $dev = $ARGV[0];
my $table = "";
my $count = 0;

if (!defined($dev)) {
        die("Please specify a device.\n");
}

my $dev_size = `blockdev --getsz $dev`;
my $extents = int($dev_size / $extent_size) -
              (($dev_size % $extent_size) ? 1 : 0);

while ($extents > 0) {
        my $this_start = $count * $extent_size;
        $extents--;
        $count++;
        my $this_offset = $extents * $extent_size;

        $table .= "$this_start $extent_size linear $dev $this_offset\n";
}

`echo \"$table\" | dmsetup create $name`;
```

39.22 dm-log-writes

This target takes 2 devices, one to pass all IO to normally, and one to log all of the write operations to. This is intended for file system developers wishing to verify the integrity of metadata or data as the file system is written to. There is a log_write_entry written for every WRITE request and the target is able to take arbitrary data from userspace to insert into the log. The data that is in the WRITE requests is copied into the log to make the replay happen exactly as it happened originally.

39.22.1 Log Ordering

We log things in order of completion once we are sure the write is no longer in cache. This means that normal WRITE requests are not actually logged until the next REQ_PREFLUSH request. This is to make it easier for userspace to replay the log in a way that correlates to what is on disk and not what is in cache, to make it easier to detect improper waiting/flushing.

This works by attaching all WRITE requests to a list once the write completes. Once we see a REQ_PREFLUSH request we splice this list onto the request and once the FLUSH request completes we log all of the WRITEs and then the FLUSH. Only completed WRITEs, at the time the REQ_PREFLUSH is issued, are added in order to simulate the worst case scenario with regard to power failures. Consider the following example (W means write, C means complete):

W1,W2,W3,C3,C2,Wflush,C1,Cflush

The log would show the following:

W3,W2,flush,W1....

Again this is to simulate what is actually on disk, this allows us to detect cases where a power failure at a particular point in time would create an inconsistent file system.

Any REQ_FUA requests bypass this flushing mechanism and are logged as soon as they complete as those requests will obviously bypass the device cache.

Any REQ_OP_DISCARD requests are treated like WRITE requests. Otherwise we would have all the DISCARD requests, and then the WRITE requests and then the FLUSH request. Consider the following example:

WRITE block 1, DISCARD block 1, FLUSH

If we logged DISCARD when it completed, the replay would look like this:

DISCARD 1, WRITE 1, FLUSH

which isn't quite what happened and wouldn't be caught during the log replay.

39.22.2 Target interface

i) Constructor

log-writes <dev_path> <log_dev_path>

dev_path	Device that all of the IO will go to normally.
log_dev_path	Device where the log entries are written to.

ii) Status

<#logged entries> <highest allocated sector>

#logged entries	Number of logged entries
highest allocated sector	Highest allocated sector

iii) Messages

mark <description>

You can use a dmsetup message to set an arbitrary mark in a log. For example say you want to fsck a file system after every write, but first you need to replay up to the mkfs to make sure we're fsck'ing something reasonable, you would do something like this:

```
mkfs.btrfs -f /dev/mapper/log
dmsetup message log 0 mark mkfs
<run test>
```

This would allow you to replay the log up to the mkfs mark and then replay from that point on doing the fsck check in the interval that you want.

Every log has a mark at the end labeled ”dm-log-writes-end”.

39.22.3 Userspace component

There is a userspace tool that will replay the log for you in various ways. It can be found here: https://github.com/josefbacik/log-writes

39.22.4 Example usage

Say you want to test fsync on your file system. You would do something like this:

```
TABLE="0 $(blockdev --getsz /dev/sdb) log-writes /dev/sdb /dev/sdc"
dmsetup create log --table "$TABLE"
mkfs.btrfs -f /dev/mapper/log
dmsetup message log 0 mark mkfs

mount /dev/mapper/log /mnt/btrfs-test
<some test that does fsync at the end>
dmsetup message log 0 mark fsync
md5sum /mnt/btrfs-test/foo
umount /mnt/btrfs-test

dmsetup remove log
replay-log --log /dev/sdc --replay /dev/sdb --end-mark fsync
mount /dev/sdb /mnt/btrfs-test
md5sum /mnt/btrfs-test/foo
<verify md5sum's are correct>

Another option is to do a complicated file system operation and verify the file
system is consistent during the entire operation.  You could do this with:

TABLE="0 $(blockdev --getsz /dev/sdb) log-writes /dev/sdb /dev/sdc"
dmsetup create log --table "$TABLE"
mkfs.btrfs -f /dev/mapper/log
dmsetup message log 0 mark mkfs

mount /dev/mapper/log /mnt/btrfs-test
<fsstress to dirty the fs>
btrfs filesystem balance /mnt/btrfs-test
umount /mnt/btrfs-test
dmsetup remove log

replay-log --log /dev/sdc --replay /dev/sdb --end-mark mkfs
btrfsck /dev/sdb
replay-log --log /dev/sdc --replay /dev/sdb --start-mark mkfs \
      --fsck "btrfsck /dev/sdb" --check fua
```

And that will replay the log until it sees a FUA request, run the fsck command and if the fsck passes it will replay to the next FUA, until it is completed or the fsck command exists abnormally.

39.23 Persistent data

39.23.1 Introduction

The more-sophisticated device-mapper targets require complex metadata that is managed in kernel. In late 2010 we were seeing that various different targets were rolling their own data structures, for example:

- Mikulas Patocka's multisnap implementation
- Heinz Mauelshagen's thin provisioning target
- Another btree-based caching target posted to dm-devel
- Another multi-snapshot target based on a design of Daniel Phillips

Maintaining these data structures takes a lot of work, so if possible we'd like to reduce the number.

The persistent-data library is an attempt to provide a re-usable framework for people who want to store metadata in device-mapper targets. It's currently used by the thin-provisioning target and an upcoming hierarchical storage target.

39.23.2 Overview

The main documentation is in the header files which can all be found under drivers/md/persistent-data.

The block manager

dm-block-manager.[hc]

This provides access to the data on disk in fixed sized-blocks. There is a read/write locking interface to prevent concurrent accesses, and keep data that is being used in the cache.

Clients of persistent-data are unlikely to use this directly.

The transaction manager

dm-transaction-manager.[hc]

This restricts access to blocks and enforces copy-on-write semantics. The only way you can get hold of a writable block through the transaction manager is by shadowing an existing block (ie. doing copy-on-write) or allocating a fresh one. Shadowing is elided within the same transaction so performance is reasonable. The commit method ensures that all data is flushed before it writes the superblock. On power failure your metadata will be as it was when last committed.

The Space Maps

dm-space-map.h dm-space-map-metadata.[hc] dm-space-map-disk.[hc]

On-disk data structures that keep track of reference counts of blocks. Also acts as the allocator of new blocks. Currently two implementations: a simpler one for managing blocks on a different device (eg. thinly-provisioned data blocks); and one for managing the metadata space. The latter is complicated by the need to store its own data within the space it's managing.

The data structures

dm-btree.[hc] dm-btree-remove.c dm-btree-spine.c dm-btree-internal.h

Currently there is only one data structure, a hierarchical btree. There are plans to add more. For example, something with an array-like interface would see a lot of use.

The btree is 'hierarchical' in that you can define it to be composed of nested btrees, and take multiple keys. For example, the thin-provisioning target uses a btree with two levels of nesting. The first maps a device id to a mapping tree, and that in turn maps a virtual block to a physical block.

Values stored in the btrees can have arbitrary size. Keys are always 64bits, although nesting allows you to use multiple keys.

39.24 Device-mapper snapshot support

Device-mapper allows you, without massive data copying:

- To create snapshots of any block device i.e. mountable, saved states of the block device which are also writable without interfering with the original content;
- To create device ”forks”, i.e. multiple different versions of the same data stream.
- To merge a snapshot of a block device back into the snapshot's origin device.

In the first two cases, dm copies only the chunks of data that get changed and uses a separate copy-on-write (COW) block device for storage.

For snapshot merge the contents of the COW storage are merged back into the origin device.

There are three dm targets available: snapshot, snapshot-origin, and snapshot-merge.

- snapshot-origin <origin>

which will normally have one or more snapshots based on it. Reads will be mapped directly to the backing device. For each write, the original data will be saved in the <COW device> of each snapshot to keep its visible content unchanged, at least until the <COW device> fills up.

- snapshot <origin> <COW device> <persistent?> <chunksize> [<# feature args> [<arg>]*]

A snapshot of the <origin> block device is created. Changed chunks of <chunksize> sectors will be stored on the <COW device>. Writes will only go to the <COW device>. Reads will come from the <COW device> or from <origin> for unchanged data. <COW device> will often be smaller than the origin and if it fills up the snapshot will become useless and be disabled,

returning errors. So it is important to monitor the amount of free space and expand the <COW device> before it fills up.

<persistent?> is P (Persistent) or N (Not persistent - will not survive after reboot). O (Overflow) can be added as a persistent store option to allow userspace to advertise its support for seeing "Overflow" in the snapshot status. So supported store types are "P", "PO" and "N".

The difference between persistent and transient is with transient snapshots less metadata must be saved on disk - they can be kept in memory by the kernel.

When loading or unloading the snapshot target, the corresponding snapshot-origin or snapshot-merge target must be suspended. A failure to suspend the origin target could result in data corruption.

Optional features:

> discard_zeroes_cow - a discard issued to the snapshot device that maps to entire chunks to will zero the corresponding exception(s) in the snapshot's exception store.
>
> discard_passdown_origin - a discard to the snapshot device is passed down to the snapshot-origin's underlying device. This doesn't cause copy-out to the snapshot exception store because the snapshot-origin target is bypassed.
>
> The discard_passdown_origin feature depends on the discard_zeroes_cow feature being enabled.

- snapshot-merge <origin> <COW device> <persistent> <chunksize> [<# feature args> [<arg>]*]

takes the same table arguments as the snapshot target except it only works with persistent snapshots. This target assumes the role of the "snapshot-origin" target and must not be loaded if the "snapshot-origin" is still present for <origin>.

Creates a merging snapshot that takes control of the changed chunks stored in the <COW device> of an existing snapshot, through a handover procedure, and merges these chunks back into the <origin>. Once merging has started (in the background) the <origin> may be opened and the merge will continue while I/O is flowing to it. Changes to the <origin> are deferred until the merging snapshot's corresponding chunk(s) have been merged. Once merging has started the snapshot device, associated with the "snapshot" target, will return -EIO when accessed.

39.24.1 How snapshot is used by LVM2

When you create the first LVM2 snapshot of a volume, four dm devices are used:

1) a device containing the original mapping table of the source volume;
2) a device used as the <COW device>;
3) a "snapshot" device, combining #1 and #2, which is the visible snapshot volume;
4) the "original" volume (which uses the device number used by the original source volume), whose table is replaced by a "snapshot-origin" mapping from device #1.

A fixed naming scheme is used, so with the following commands:

```
lvcreate -L 1G -n base volumeGroup
lvcreate -L 100M --snapshot -n snap volumeGroup/base
```

we'll have this situation (with volumes in above order):

```
# dmsetup table|grep volumeGroup

volumeGroup-base-real: 0 2097152 linear 8:19 384
volumeGroup-snap-cow: 0 204800 linear 8:19 2097536
volumeGroup-snap: 0 2097152 snapshot 254:11 254:12 P 16
volumeGroup-base: 0 2097152 snapshot-origin 254:11

# ls -lL /dev/mapper/volumeGroup-*
brw-------  1 root root 254, 11 29 ago 18:15 /dev/mapper/volumeGroup-base-real
brw-------  1 root root 254, 12 29 ago 18:15 /dev/mapper/volumeGroup-snap-cow
brw-------  1 root root 254, 13 29 ago 18:15 /dev/mapper/volumeGroup-snap
brw-------  1 root root 254, 10 29 ago 18:14 /dev/mapper/volumeGroup-base
```

39.24.2 How snapshot-merge is used by LVM2

A merging snapshot assumes the role of the ”snapshot-origin” while merging. As such the ”snapshot-origin” is replaced with ”snapshot-merge”. The ”-real” device is not changed and the ”-cow” device is renamed to <origin name>-cow to aid LVM2's cleanup of the merging snapshot after it completes. The ”snapshot” that hands over its COW device to the ”snapshot-merge” is deactivated (unless using lvchange --refresh); but if it is left active it will simply return I/O errors.

A snapshot will merge into its origin with the following command:

```
lvconvert --merge volumeGroup/snap
```

we'll now have this situation:

```
# dmsetup table|grep volumeGroup

volumeGroup-base-real: 0 2097152 linear 8:19 384
volumeGroup-base-cow: 0 204800 linear 8:19 2097536
volumeGroup-base: 0 2097152 snapshot-merge 254:11 254:12 P 16

# ls -lL /dev/mapper/volumeGroup-*
brw-------  1 root root 254, 11 29 ago 18:15 /dev/mapper/volumeGroup-base-real
brw-------  1 root root 254, 12 29 ago 18:16 /dev/mapper/volumeGroup-base-cow
brw-------  1 root root 254, 10 29 ago 18:16 /dev/mapper/volumeGroup-base
```

39.24.3 How to determine when a merging is complete

The snapshot-merge and snapshot status lines end with:

<sectors_allocated>/<total_sectors> <metadata_sectors>

Both <sectors_allocated> and <total_sectors> include both data and metadata. During merging, the number of sectors allocated gets smaller and smaller. Merging has finished when the number of sectors holding data is zero, in other words <sectors_allocated> == <metadata_sectors>.

Here is a practical example (using a hybrid of lvm and dmsetup commands):

```
# lvs
  LV      VG          Attr   LSize Origin  Snap%  Move Log Copy%  Convert
  base    volumeGroup owi-a- 4.00g
  snap    volumeGroup swi-a- 1.00g base  18.97

# dmsetup status volumeGroup-snap
0 8388608 snapshot 397896/2097152 1560
                                  ^^^^ metadata sectors

# lvconvert --merge -b volumeGroup/snap
  Merging of volume snap started.

# lvs volumeGroup/snap
  LV      VG          Attr   LSize Origin  Snap%  Move Log Copy%  Convert
  base    volumeGroup Owi-a- 4.00g          17.23

# dmsetup status volumeGroup-base
0 8388608 snapshot-merge 281688/2097152 1104

# dmsetup status volumeGroup-base
0 8388608 snapshot-merge 180480/2097152 712

# dmsetup status volumeGroup-base
0 8388608 snapshot-merge 16/2097152 16
```

Merging has finished.

```
# lvs
  LV      VG          Attr   LSize Origin  Snap%  Move Log Copy%  Convert
  base    volumeGroup owi-a- 4.00g
```

39.25 DM statistics

Device Mapper supports the collection of I/O statistics on user-defined regions of a DM device. If no regions are defined no statistics are collected so there isn't any performance impact. Only bio-based DM devices are currently supported.

Each user-defined region specifies a starting sector, length and step. Individual statistics will be collected for each step-sized area within the range specified.

The I/O statistics counters for each step-sized area of a region are in the same format as */sys/block/*/stat* or */proc/diskstats* (see: *I/O statistics fields*). But two extra counters (12 and 13) are provided: total time spent reading and writing. When the histogram argument is used, the 14th parameter is reported that represents the histogram of latencies. All these counters may be accessed by sending the @stats_print message to the appropriate DM device via dmsetup.

The reported times are in milliseconds and the granularity depends on the kernel ticks. When the option precise_timestamps is used, the reported times are in nanoseconds.

Each region has a corresponding unique identifier, which we call a region_id, that is assigned

when the region is created. The region_id must be supplied when querying statistics about the region, deleting the region, etc. Unique region_ids enable multiple userspace programs to request and process statistics for the same DM device without stepping on each other's data.

The creation of DM statistics will allocate memory via kmalloc or fallback to using vmalloc space. At most, 1/4 of the overall system memory may be allocated by DM statistics. The admin can see how much memory is used by reading:

/sys/module/dm_mod/parameters/stats_current_allocated_bytes

39.25.1 Messages

@stats_create <range> <step> [<number_of_optional_arguments> <optional_arguments>...] [<program_id> [<aux_data>]]

Create a new region and return the region_id.

<range>

"-"
whole device

"<start_sector>+<length>"
a range of <length> 512-byte sectors starting with <start_sector>.

<step>

"<area_size>"
the range is subdivided into areas each containing <area_size> sectors.

"/<number_of_areas>"
the range is subdivided into the specified number of areas.

<number_of_optional_arguments>
The number of optional arguments

<optional_arguments>
The following optional arguments are supported:

precise_timestamps
use precise timer with nanosecond resolution instead of the "jiffies" variable. When this argument is used, the resulting times are in nanoseconds instead of milliseconds. Precise timestamps are a little bit slower to obtain than jiffies-based timestamps.

histogram:n1,n2,n3,n4,...
collect histogram of latencies. The numbers n1, n2, etc are times that represent the boundaries of the histogram. If precise_timestamps is not used, the times are in milliseconds, otherwise they are in nanoseconds. For each range, the kernel will report the number of requests that completed within this range. For example, if we use "histogram:10,20,30", the kernel will report four numbers a:b:c:d. a is the number of requests that took 0-10 ms to complete, b is the number of requests that took 10-20 ms to complete, c is the number of requests that took 20-30 ms to complete and d is the number of requests that took more than 30 ms to complete.

<program_id>
An optional parameter. A name that uniquely identifies the userspace owner

of the range. This groups ranges together so that userspace programs can identify the ranges they created and ignore those created by others. The kernel returns this string back in the output of @stats_list message, but it doesn't use it for anything else. If we omit the number of optional arguments, program id must not be a number, otherwise it would be interpreted as the number of optional arguments.

<aux_data>
An optional parameter. A word that provides auxiliary data that is useful to the client program that created the range. The kernel returns this string back in the output of @stats_list message, but it doesn't use this value for anything.

@stats_delete <region_id>
Delete the region with the specified id.

<region_id>
region_id returned from @stats_create

@stats_clear <region_id>
Clear all the counters except the in-flight i/o counters.

<region_id>
region_id returned from @stats_create

@stats_list [<program_id>]
List all regions registered with @stats_create.

<program_id>
An optional parameter. If this parameter is specified, only matching regions are returned. If it is not specified, all regions are returned.

Output format:

<region_id>: <start_sector>+<length> <step> <program_id> <aux_data>
precise_timestamps histogram:n1,n2,n3,...

The strings ”precise_timestamps” and ”histogram” are printed only if they were specified when creating the region.

@stats_print <region_id> [<starting_line> <number_of_lines>]
Print counters for each step-sized area of a region.

<region_id>
region_id returned from @stats_create

<starting_line>
The index of the starting line in the output. If omitted, all lines are returned.

<number_of_lines>
The number of lines to include in the output. If omitted, all lines are returned.

Output format for each step-sized area of a region:

<start_sector>+<length>
counters

The first 11 counters have the same meaning as */sys/block/*/stat or /proc/diskstats*.

Please refer to *I/O statistics fields* for details.

1. the number of reads completed
2. the number of reads merged
3. the number of sectors read
4. the number of milliseconds spent reading
5. the number of writes completed
6. the number of writes merged
7. the number of sectors written
8. the number of milliseconds spent writing
9. the number of I/Os currently in progress
10. the number of milliseconds spent doing I/Os
11. the weighted number of milliseconds spent doing I/Os

Additional counters:

12. the total time spent reading in milliseconds
13. the total time spent writing in milliseconds

@stats_print_clear <region_id> [<starting_line> <number_of_lines>]
Atomically print and then clear all the counters except the in-flight i/o counters. Useful when the client consuming the statistics does not want to lose any statistics (those updated between printing and clearing).

<region_id>
region_id returned from @stats_create

<starting_line>
The index of the starting line in the output. If omitted, all lines are printed and then cleared.

<number_of_lines>
The number of lines to process. If omitted, all lines are printed and then cleared.

@stats_set_aux <region_id> <aux_data>
Store auxiliary data aux_data for the specified region.

<region_id>
region_id returned from @stats_create

<aux_data>
The string that identifies data which is useful to the client program that created the range. The kernel returns this string back in the output of @stats_list message, but it doesn't use this value for anything.

39.25.2 Examples

Subdivide the DM device 'vol' into 100 pieces and start collecting statistics on them:

```
dmsetup message vol 0 @stats_create - /100
```

Set the auxiliary data string to ”foo bar baz” (the escape for each space must also be escaped, otherwise the shell will consume them):

```
dmsetup message vol 0 @stats_set_aux 0 foo\\ bar\\ baz
```

List the statistics:

```
dmsetup message vol 0 @stats_list
```

Print the statistics:

```
dmsetup message vol 0 @stats_print 0
```

Delete the statistics:

```
dmsetup message vol 0 @stats_delete 0
```

39.26 dm-stripe

Device-Mapper's ”striped” target is used to create a striped (i.e. RAID-0) device across one or more underlying devices. Data is written in ”chunks”, with consecutive chunks rotating among the underlying devices. This can potentially provide improved I/O throughput by utilizing several physical devices in parallel.

Parameters: <num devs> <chunk size> [<dev path> <offset>]+

<num devs>:
Number of underlying devices.

<chunk size>:
Size of each chunk of data. Must be at least as large as the system's PAGE_SIZE.

<dev path>:
Full pathname to the underlying block-device, or a ”major:minor” device-number.

<offset>:
Starting sector within the device.

One or more underlying devices can be specified. The striped device size must be a multiple of the chunk size multiplied by the number of underlying devices.

39.26.1 Example scripts

```
#!/usr/bin/perl -w
# Create a striped device across any number of underlying devices. The device
# will be called "stripe_dev" and have a chunk-size of 128k.

my $chunk_size = 128 * 2;
my $dev_name = "stripe_dev";
my $num_devs = @ARGV;
my @devs = @ARGV;
my ($min_dev_size, $stripe_dev_size, $i);

if (!$num_devs) {
        die("Specify at least one device\n");
}

$min_dev_size = `blockdev --getsz $devs[0]`;
for ($i = 1; $i < $num_devs; $i++) {
        my $this_size = `blockdev --getsz $devs[$i]`;
        $min_dev_size = ($min_dev_size < $this_size) ?
                        $min_dev_size : $this_size;
}

$stripe_dev_size = $min_dev_size * $num_devs;
$stripe_dev_size -= $stripe_dev_size % ($chunk_size * $num_devs);

$table = "0 $stripe_dev_size striped $num_devs $chunk_size";
for ($i = 0; $i < $num_devs; $i++) {
        $table .= " $devs[$i] 0";
}

`echo $table | dmsetup create $dev_name`;
```

39.27 dm-switch

The device-mapper switch target creates a device that supports an arbitrary mapping of fixed-size regions of I/O across a fixed set of paths. The path used for any specific region can be switched dynamically by sending the target a message.

It maps I/O to underlying block devices efficiently when there is a large number of fixed-sized address regions but there is no simple pattern that would allow for a compact representation of the mapping such as dm-stripe.

39.27.1 Background

Dell EqualLogic and some other iSCSI storage arrays use a distributed frameless architecture. In this architecture, the storage group consists of a number of distinct storage arrays (”members”) each having independent controllers, disk storage and network adapters. When a LUN is created it is spread across multiple members. The details of the spreading are hidden from initiators connected to this storage system. The storage group exposes a single target discovery portal, no matter how many members are being used. When iSCSI sessions are created, each session is connected to an eth port on a single member. Data to a LUN can be sent on any iSCSI session, and if the blocks being accessed are stored on another member the I/O will be forwarded as required. This forwarding is invisible to the initiator. The storage layout is also dynamic, and the blocks stored on disk may be moved from member to member as needed to balance the load.

This architecture simplifies the management and configuration of both the storage group and initiators. In a multipathing configuration, it is possible to set up multiple iSCSI sessions to use multiple network interfaces on both the host and target to take advantage of the increased network bandwidth. An initiator could use a simple round robin algorithm to send I/O across all paths and let the storage array members forward it as necessary, but there is a performance advantage to sending data directly to the correct member.

A device-mapper table already lets you map different regions of a device onto different targets. However in this architecture the LUN is spread with an address region size on the order of 10s of MBs, which means the resulting table could have more than a million entries and consume far too much memory.

Using this device-mapper switch target we can now build a two-layer device hierarchy:

> Upper Tier - Determine which array member the I/O should be sent to. Lower Tier - Load balance amongst paths to a particular member.

The lower tier consists of a single dm multipath device for each member. Each of these multipath devices contains the set of paths directly to the array member in one priority group, and leverages existing path selectors to load balance amongst these paths. We also build a non-preferred priority group containing paths to other array members for failover reasons.

The upper tier consists of a single dm-switch device. This device uses a bitmap to look up the location of the I/O and choose the appropriate lower tier device to route the I/O. By using a bitmap we are able to use 4 bits for each address range in a 16 member group (which is very large for us). This is a much denser representation than the dm table b-tree can achieve.

Construction Parameters

<num_paths> <region_size> <num_optional_args> [<optional_args>...] [<dev_path> <offset>]+

<num_paths>
The number of paths across which to distribute the I/O.

<region_size>
The number of 512-byte sectors in a region. Each region can be redirected to any of the available paths.

<num_optional_args>
The number of optional arguments. Currently, no optional arguments are

supported and so this must be zero.

<dev_path>
The block device that represents a specific path to the device.

<offset>
The offset of the start of data on the specific <dev_path> (in units of 512-byte sectors). This number is added to the sector number when forwarding the request to the specific path. Typically it is zero.

Messages

set_region_mappings <index>:<path_nr> [<index>]:<path_nr> [<index>]:<path_nr>...

Modify the region table by specifying which regions are redirected to which paths.

<index>
The region number (region size was specified in constructor parameters). If index is omitted, the next region (previous index + 1) is used. Expressed in hexadecimal (WITHOUT any prefix like 0x).

<path_nr>
The path number in the range 0 ... (<num_paths> - 1). Expressed in hexadecimal (WITHOUT any prefix like 0x).

R<n>,<m>
This parameter allows repetitive patterns to be loaded quickly. <n> and <m> are hexadecimal numbers. The last <n> mappings are repeated in the next <m> slots.

Status

No status line is reported.

Example

Assume that you have volumes vg1/switch0 vg1/switch1 vg1/switch2 with the same size.

Create a switch device with 64kB region size:

```
dmsetup create switch --table "0 `blockdev --getsz /dev/vg1/switch0`
    switch 3 128 0 /dev/vg1/switch0 0 /dev/vg1/switch1 0 /dev/vg1/switch2 0"
```

Set mappings for the first 7 entries to point to devices switch0, switch1, switch2, switch0, switch1, switch2, switch1:

```
dmsetup message switch 0 set_region_mappings 0:0 :1 :2 :0 :1 :2 :1
```

Set repetitive mapping. This command:

```
dmsetup message switch 0 set_region_mappings 1000:1 :2 R2,10
```

is equivalent to:

```
dmsetup message switch 0 set_region_mappings 1000:1 :2 :1 :2 :1 :2 :1 :2 \
    :1 :2 :1 :2 :1 :2 :1 :2 :1 :2
```

39.28 Thin provisioning

39.28.1 Introduction

This document describes a collection of device-mapper targets that between them implement thin-provisioning and snapshots.

The main highlight of this implementation, compared to the previous implementation of snapshots, is that it allows many virtual devices to be stored on the same data volume. This simplifies administration and allows the sharing of data between volumes, thus reducing disk usage.

Another significant feature is support for an arbitrary depth of recursive snapshots (snapshots of snapshots of snapshots ...). The previous implementation of snapshots did this by chaining together lookup tables, and so performance was O(depth). This new implementation uses a single data structure to avoid this degradation with depth. Fragmentation may still be an issue, however, in some scenarios.

Metadata is stored on a separate device from data, giving the administrator some freedom, for example to:

- Improve metadata resilience by storing metadata on a mirrored volume but data on a non-mirrored one.
- Improve performance by storing the metadata on SSD.

39.28.2 Status

These targets are considered safe for production use. But different use cases will have different performance characteristics, for example due to fragmentation of the data volume.

If you find this software is not performing as expected please mail dm-devel@redhat.com with details and we'll try our best to improve things for you.

Userspace tools for checking and repairing the metadata have been fully developed and are available as 'thin_check' and 'thin_repair'. The name of the package that provides these utilities varies by distribution (on a Red Hat distribution it is named 'device-mapper-persistent-data').

39.28.3 Cookbook

This section describes some quick recipes for using thin provisioning. They use the dmsetup program to control the device-mapper driver directly. End users will be advised to use a higher-level volume manager such as LVM2 once support has been added.

Pool device

The pool device ties together the metadata volume and the data volume. It maps I/O linearly to the data volume and updates the metadata via two mechanisms:

- Function calls from the thin targets
- Device-mapper 'messages' from userspace which control the creation of new virtual devices amongst other things.

Setting up a fresh pool device

Setting up a pool device requires a valid metadata device, and a data device. If you do not have an existing metadata device you can make one by zeroing the first 4k to indicate empty metadata.

dd if=/dev/zero of=$metadata_dev bs=4096 count=1

The amount of metadata you need will vary according to how many blocks are shared between thin devices (i.e. through snapshots). If you have less sharing than average you'll need a larger-than-average metadata device.

As a guide, we suggest you calculate the number of bytes to use in the metadata device as 48 * $data_dev_size / $data_block_size but round it up to 2MB if the answer is smaller. If you're creating large numbers of snapshots which are recording large amounts of change, you may find you need to increase this.

The largest size supported is 16GB: If the device is larger, a warning will be issued and the excess space will not be used.

Reloading a pool table

You may reload a pool's table, indeed this is how the pool is resized if it runs out of space. (N.B. While specifying a different metadata device when reloading is not forbidden at the moment, things will go wrong if it does not route I/O to exactly the same on-disk location as previously.)

Using an existing pool device

```
dmsetup create pool \
    --table "0 20971520 thin-pool $metadata_dev $data_dev \
             $data_block_size $low_water_mark"
```

$data_block_size gives the smallest unit of disk space that can be allocated at a time expressed in units of 512-byte sectors. $data_block_size must be between 128 (64KB) and 2097152 (1GB) and a multiple of 128 (64KB). $data_block_size cannot be changed after the thin-pool is created. People primarily interested in thin provisioning may want to use a value such as 1024 (512KB). People doing lots of snapshotting may want a smaller value such as 128 (64KB). If you are not zeroing newly-allocated data, a larger $data_block_size in the region of 256000 (128MB) is suggested.

$low_water_mark is expressed in blocks of size $data_block_size. If free space on the data device drops below this level then a dm event will be triggered which a userspace daemon should catch allowing it to extend the pool device. Only one such event will be sent.

No special event is triggered if a just resumed device's free space is below the low water mark. However, resuming a device always triggers an event; a userspace daemon should verify that free space exceeds the low water mark when handling this event.

A low water mark for the metadata device is maintained in the kernel and will trigger a dm event if free space on the metadata device drops below it.

Updating on-disk metadata

On-disk metadata is committed every time a FLUSH or FUA bio is written. If no such requests are made then commits will occur every second. This means the thin-provisioning target behaves like a physical disk that has a volatile write cache. If power is lost you may lose some recent writes. The metadata should always be consistent in spite of any crash.

If data space is exhausted the pool will either error or queue IO according to the configuration (see: error_if_no_space). If metadata space is exhausted or a metadata operation fails: the pool will error IO until the pool is taken offline and repair is performed to 1) fix any potential inconsistencies and 2) clear the flag that imposes repair. Once the pool's metadata device is repaired it may be resized, which will allow the pool to return to normal operation. Note that if a pool is flagged as needing repair, the pool's data and metadata devices cannot be resized until repair is performed. It should also be noted that when the pool's metadata space is exhausted the current metadata transaction is aborted. Given that the pool will cache IO whose completion may have already been acknowledged to upper IO layers (e.g. filesystem) it is strongly suggested that consistency checks (e.g. fsck) be performed on those layers when repair of the pool is required.

Thin provisioning

i) Creating a new thinly-provisioned volume.

   To create a new thinly- provisioned volume you must send a message to an active pool device, /dev/mapper/pool in this example:

```
dmsetup message /dev/mapper/pool 0 "create_thin 0"
```

   Here '0' is an identifier for the volume, a 24-bit number. It's up to the caller to allocate and manage these identifiers. If the identifier is already in use, the message will fail with -EEXIST.

ii) Using a thinly-provisioned volume.

   Thinly-provisioned volumes are activated using the 'thin' target:

```
dmsetup create thin --table "0 2097152 thin /dev/mapper/pool 0"
```

   The last parameter is the identifier for the thinp device.

Internal snapshots

i) Creating an internal snapshot.

Snapshots are created with another message to the pool.

N.B. If the origin device that you wish to snapshot is active, you must suspend it before creating the snapshot to avoid corruption. This is NOT enforced at the moment, so please be careful!

```
dmsetup suspend /dev/mapper/thin
dmsetup message /dev/mapper/pool 0 "create_snap 1 0"
dmsetup resume /dev/mapper/thin
```

Here '1' is the identifier for the volume, a 24-bit number. '0' is the identifier for the origin device.

ii) Using an internal snapshot.

Once created, the user doesn't have to worry about any connection between the origin and the snapshot. Indeed the snapshot is no different from any other thinly-provisioned device and can be snapshotted itself via the same method. It's perfectly legal to have only one of them active, and there's no ordering requirement on activating or removing them both. (This differs from conventional device-mapper snapshots.)

Activate it exactly the same way as any other thinly-provisioned volume:

```
dmsetup create snap --table "0 2097152 thin /dev/mapper/pool 1"
```

External snapshots

You can use an external **read only** device as an origin for a thinly-provisioned volume. Any read to an unprovisioned area of the thin device will be passed through to the origin. Writes trigger the allocation of new blocks as usual.

One use case for this is VM hosts that want to run guests on thinly-provisioned volumes but have the base image on another device (possibly shared between many VMs).

You must not write to the origin device if you use this technique! Of course, you may write to the thin device and take internal snapshots of the thin volume.

i) Creating a snapshot of an external device

This is the same as creating a thin device. You don't mention the origin at this stage.

```
dmsetup message /dev/mapper/pool 0 "create_thin 0"
```

ii) Using a snapshot of an external device.

Append an extra parameter to the thin target specifying the origin:

```
dmsetup create snap --table "0 2097152 thin /dev/mapper/pool 0 /dev/
↪image"
```

N.B. All descendants (internal snapshots) of this snapshot require the same extra origin parameter.

Deactivation

All devices using a pool must be deactivated before the pool itself can be.

```
dmsetup remove thin
dmsetup remove snap
dmsetup remove pool
```

39.28.4 Reference

'thin-pool' target

i) Constructor

```
thin-pool <metadata dev> <data dev> <data block size (sectors)> \
          <low water mark (blocks)> [<number of feature args> [<arg>
↪]*]
```

Optional feature arguments:

skip_block_zeroing:
Skip the zeroing of newly-provisioned blocks.

ignore_discard:
Disable discard support.

no_discard_passdown:
Don't pass discards down to the underlying data device, but just remove the mapping.

read_only:
Don't allow any changes to be made to the pool metadata. This mode is only available after the thin-pool has been created and first used in full read/write mode. It cannot be specified on initial thin-pool creation.

error_if_no_space:
Error IOs, instead of queueing, if no space.

Data block size must be between 64KB (128 sectors) and 1GB (2097152 sectors) inclusive.

ii) Status

```
<transaction id> <used metadata blocks>/<total metadata blocks>
<used data blocks>/<total data blocks> <held metadata root>
ro|rw|out_of_data_space [no_]discard_passdown [error|queue]_if_no_space
needs_check|- metadata_low_watermark
```

transaction id:
A 64-bit number used by userspace to help synchronise with metadata from volume managers.

used data blocks / total data blocks
If the number of free blocks drops below the pool's low water mark a dm event will be sent to userspace. This event is edge-triggered and it will occur only once after each

resume so volume manager writers should register for the event and then check the target's status.

held metadata root:
The location, in blocks, of the metadata root that has been 'held' for userspace read access. '-' indicates there is no held root.

discard_passdown|no_discard_passdown
Whether or not discards are actually being passed down to the underlying device. When this is enabled when loading the table, it can get disabled if the underlying device doesn't support it.

ro|rw|out_of_data_space
If the pool encounters certain types of device failures it will drop into a read-only metadata mode in which no changes to the pool metadata (like allocating new blocks) are permitted.

In serious cases where even a read-only mode is deemed unsafe no further I/O will be permitted and the status will just contain the string 'Fail'. The userspace recovery tools should then be used.

error_if_no_space|queue_if_no_space
If the pool runs out of data or metadata space, the pool will either queue or error the IO destined to the data device. The default is to queue the IO until more space is added or the 'no_space_timeout' expires. The 'no_space_timeout' dm-thin-pool module parameter can be used to change this timeout -- it defaults to 60 seconds but may be disabled using a value of 0.

needs_check
A metadata operation has failed, resulting in the needs_check flag being set in the metadata's superblock. The metadata device must be deactivated and checked/repaired before the thin-pool can be made fully operational again. '-' indicates needs_check is not set.

metadata_low_watermark:
Value of metadata low watermark in blocks. The kernel sets this value internally but userspace needs to know this value to determine if an event was caused by crossing this threshold.

iii) Messages

create_thin <dev id>
Create a new thinly-provisioned device. <dev id> is an arbitrary unique 24-bit identifier chosen by the caller.

create_snap <dev id> <origin id>
Create a new snapshot of another thinly-provisioned device. <dev id> is an arbitrary unique 24-bit identifier chosen by the caller. <origin id> is the identifier of the thinly-provisioned device of which the new device will be a snapshot.

delete <dev id>
Deletes a thin device. Irreversible.

set_transaction_id <current id> <new id>
Userland volume managers, such as LVM, need a way to synchronise their external metadata with the internal metadata of the pool target. The thin-pool target

offers to store an arbitrary 64-bit transaction id and return it on the target's status line. To avoid races you must provide what you think the current transaction id is when you change it with this compare-and-swap message.

reserve_metadata_snap
Reserve a copy of the data mapping btree for use by userland. This allows userland to inspect the mappings as they were when this message was executed. Use the pool's status command to get the root block associated with the metadata snapshot.

release_metadata_snap
Release a previously reserved copy of the data mapping btree.

'thin' target

i) Constructor

```
thin <pool dev> <dev id> [<external origin dev>]
```

pool dev:
the thin-pool device, e.g. /dev/mapper/my_pool or 253:0

dev id:
the internal device identifier of the device to be activated.

external origin dev:
an optional block device outside the pool to be treated as a read-only snapshot origin: reads to unprovisioned areas of the thin target will be mapped to this device.

The pool doesn't store any size against the thin devices. If you load a thin target that is smaller than you've been using previously, then you'll have no access to blocks mapped beyond the end. If you load a target that is bigger than before, then extra blocks will be provisioned as and when needed.

ii) Status

<nr mapped sectors> <highest mapped sector>
If the pool has encountered device errors and failed, the status will just contain the string 'Fail'. The userspace recovery tools should then be used.

In the case where <nr mapped sectors> is 0, there is no highest mapped sector and the value of <highest mapped sector> is unspecified.

39.29 Device-mapper ”unstriped” target

39.29.1 Introduction

The device-mapper ”unstriped” target provides a transparent mechanism to unstripe a device-mapper ”striped” target to access the underlying disks without having to touch the true backing block-device. It can also be used to unstripe a hardware RAID-0 to access backing disks.

Parameters: <number of stripes> <chunk size> <stripe #> <dev_path> <offset>

<number of stripes>
The number of stripes in the RAID 0.

<chunk size>
The amount of 512B sectors in the chunk striping.

<dev_path>
The block device you wish to unstripe.

<stripe #>
The stripe number within the device that corresponds to physical drive you wish to unstripe. This must be 0 indexed.

39.29.2 Why use this module?

An example of undoing an existing dm-stripe

This small bash script will setup 4 loop devices and use the existing striped target to combine the 4 devices into one. It then will use the unstriped target on top of the striped device to access the individual backing loop devices. We write data to the newly exposed unstriped devices and verify the data written matches the correct underlying device on the striped array:

```
#!/bin/bash

MEMBER_SIZE=$((128 * 1024 * 1024))
NUM=4
SEQ_END=$(($(NUM)-1))
CHUNK=256
BS=4096

RAID_SIZE=$(($(MEMBER_SIZE)*$(NUM)/512))
DM_PARMS="0 $(RAID_SIZE) striped $(NUM) $(CHUNK)"
COUNT=$(($(MEMBER_SIZE) / $(BS)))

for i in $(seq 0 $(SEQ_END)); do
  dd if=/dev/zero of=member-$(i) bs=$(MEMBER_SIZE) count=1 oflag=direct
  losetup /dev/loop$(i) member-$(i)
  DM_PARMS+=" /dev/loop$(i) 0"
done

echo $DM_PARMS | dmsetup create raid0
for i in $(seq 0 $(SEQ_END)); do
  echo "0 1 unstriped $(NUM) $(CHUNK) $(i) /dev/mapper/raid0 0" | dmsetup␣
↪create set-$(i)
done;

for i in $(seq 0 $(SEQ_END)); do
  dd if=/dev/urandom of=/dev/mapper/set-$(i) bs=$(BS) count=$(COUNT)␣
↪oflag=direct
  diff /dev/mapper/set-$(i) member-$(i)
done;
```

```
for i in $(seq 0 ${SEQ_END}); do
  dmsetup remove set-${i}
done

dmsetup remove raid0

for i in $(seq 0 ${SEQ_END}); do
  losetup -d /dev/loop${i}
  rm -f member-${i}
done
```

Another example

Intel NVMe drives contain two cores on the physical device. Each core of the drive has segregated access to its LBA range. The current LBA model has a RAID 0 128k chunk on each core, resulting in a 256k stripe across the two cores:

```
 Core 0:       Core 1:

___________   ___________
| LBA 512|    | LBA 768|
| LBA 0  |    | LBA 256|
----------    ----------
```

The purpose of this unstriping is to provide better QoS in noisy neighbor environments. When two partitions are created on the aggregate drive without this unstriping, reads on one partition can affect writes on another partition. This is because the partitions are striped across the two cores. When we unstripe this hardware RAID 0 and make partitions on each new exposed device the two partitions are now physically separated.

With the dm-unstriped target we're able to segregate an fio script that has read and write jobs that are independent of each other. Compared to when we run the test on a combined drive with partitions, we were able to get a 92% reduction in read latency using this device mapper target.

39.29.3 Example dmsetup usage

unstriped on top of Intel NVMe device that has 2 cores

```
dmsetup create nvmset0 --table '0 512 unstriped 2 256 0 /dev/nvme0n1 0'
dmsetup create nvmset1 --table '0 512 unstriped 2 256 1 /dev/nvme0n1 0'
```

There will now be two devices that expose Intel NVMe core 0 and 1 respectively:

```
/dev/mapper/nvmset0
/dev/mapper/nvmset1
```

unstriped on top of striped with 4 drives using 128K chunk size

```
dmsetup create raid_disk0 --table '0 512 unstriped 4 256 0 /dev/mapper/striped␣
↪0'
dmsetup create raid_disk1 --table '0 512 unstriped 4 256 1 /dev/mapper/striped␣
↪0'
dmsetup create raid_disk2 --table '0 512 unstriped 4 256 2 /dev/mapper/striped␣
↪0'
dmsetup create raid_disk3 --table '0 512 unstriped 4 256 3 /dev/mapper/striped␣
↪0'
```

39.30 dm-verity

Device-Mapper's "verity" target provides transparent integrity checking of block devices using a cryptographic digest provided by the kernel crypto API. This target is read-only.

39.30.1 Construction Parameters

```
<version> <dev> <hash_dev>
<data_block_size> <hash_block_size>
<num_data_blocks> <hash_start_block>
<algorithm> <digest> <salt>
[<#opt_params> <opt_params>]
```

<version>
This is the type of the on-disk hash format.

0 is the original format used in the Chromium OS.
The salt is appended when hashing, digests are stored continuously and the rest of the block is padded with zeroes.

1 is the current format that should be used for new devices.
The salt is prepended when hashing and each digest is padded with zeroes to the power of two.

<dev>
This is the device containing data, the integrity of which needs to be checked. It may be specified as a path, like /dev/sdaX, or a device number, <major>:<minor>.

<hash_dev>
This is the device that supplies the hash tree data. It may be specified similarly to the device path and may be the same device. If the same device is used, the hash_start should be outside the configured dm-verity device.

<data_block_size>
The block size on a data device in bytes. Each block corresponds to one digest on the hash device.

<hash_block_size>
The size of a hash block in bytes.

<num_data_blocks>
The number of data blocks on the data device. Additional blocks are inaccessible. You can place hashes to the same partition as data, in this case hashes are placed after <num_data_blocks>.

<hash_start_block>
This is the offset, in <hash_block_size>-blocks, from the start of hash_dev to the root block of the hash tree.

<algorithm>
The cryptographic hash algorithm used for this device. This should be the name of the algorithm, like "sha1".

<digest>
The hexadecimal encoding of the cryptographic hash of the root hash block and the salt. This hash should be trusted as there is no other authenticity beyond this point.

<salt>
The hexadecimal encoding of the salt value.

<#opt_params>
Number of optional parameters. If there are no optional parameters, the optional parameters section can be skipped or #opt_params can be zero. Otherwise #opt_params is the number of following arguments.

Example of optional parameters section:
1 ignore_corruption

ignore_corruption
Log corrupted blocks, but allow read operations to proceed normally.

restart_on_corruption
Restart the system when a corrupted block is discovered. This option is not compatible with ignore_corruption and requires user space support to avoid restart loops.

panic_on_corruption
Panic the device when a corrupted block is discovered. This option is not compatible with ignore_corruption and restart_on_corruption.

ignore_zero_blocks
Do not verify blocks that are expected to contain zeroes and always return zeroes instead. This may be useful if the partition contains unused blocks that are not guaranteed to contain zeroes.

use_fec_from_device <fec_dev>
Use forward error correction (FEC) to recover from corruption if hash verification fails. Use encoding data from the specified device. This may be the same device where data and hash blocks reside, in which case fec_start must be outside data and hash areas.

If the encoding data covers additional metadata, it must be accessible on the hash device after the hash blocks.

Note: block sizes for data and hash devices must match. Also, if the verity <dev> is encrypted the <fec_dev> should be too.

fec_roots <num>
Number of generator roots. This equals to the number of parity bytes in the encoding data. For example, in RS(M, N) encoding, the number of roots is M-N.

fec_blocks <num>
The number of encoding data blocks on the FEC device. The block size for the FEC device is <data_block_size>.

fec_start <offset>
This is the offset, in <data_block_size> blocks, from the start of the FEC device to the beginning of the encoding data.

check_at_most_once
Verify data blocks only the first time they are read from the data device, rather than every time. This reduces the overhead of dm-verity so that it can be used on systems that are memory and/or CPU constrained. However, it provides a reduced level of security because only offline tampering of the data device's content will be detected, not online tampering.

Hash blocks are still verified each time they are read from the hash device, since verification of hash blocks is less performance critical than data blocks, and a hash block will not be verified any more after all the data blocks it covers have been verified anyway.

root_hash_sig_key_desc <key_description>
This is the description of the USER_KEY that the kernel will lookup to get the pkcs7 signature of the roothash. The pkcs7 signature is used to validate the root hash during the creation of the device mapper block device. Verification of roothash depends on the config DM_VERITY_VERIFY_ROOTHASH_SIG being set in the kernel. The signatures are checked against the builtin trusted keyring by default, or the secondary trusted keyring if DM_VERITY_VERIFY_ROOTHASH_SIG_SECONDARY_KEYRING is set. The secondary trusted keyring includes by default the builtin trusted keyring, and it can also gain new certificates at run time if they are signed by a certificate already in the secondary trusted keyring.

try_verify_in_tasklet
If verity hashes are in cache, verify data blocks in kernel tasklet instead of workqueue. This option can reduce IO latency.

39.30.2 Theory of operation

dm-verity is meant to be set up as part of a verified boot path. This may be anything ranging from a boot using tboot or trustedgrub to just booting from a known-good device (like a USB drive or CD).

When a dm-verity device is configured, it is expected that the caller has been authenticated in some way (cryptographic signatures, etc). After instantiation, all hashes will be verified on-demand during disk access. If they cannot be verified up to the root node of the tree, the root hash, then the I/O will fail. This should detect tampering with any data on the device and the hash data.

Cryptographic hashes are used to assert the integrity of the device on a per-block basis. This allows for a lightweight hash computation on first read into the page cache. Block hashes are stored linearly, aligned to the nearest block size.

If forward error correction (FEC) support is enabled any recovery of corrupted data will be verified using the cryptographic hash of the corresponding data. This is why combining error correction with integrity checking is essential.

Hash Tree

Each node in the tree is a cryptographic hash. If it is a leaf node, the hash of some data block on disk is calculated. If it is an intermediary node, the hash of a number of child nodes is calculated.

Each entry in the tree is a collection of neighboring nodes that fit in one block. The number is determined based on block_size and the size of the selected cryptographic digest algorithm. The hashes are linearly-ordered in this entry and any unaligned trailing space is ignored but included when calculating the parent node.

The tree looks something like:

alg = sha256, num_blocks = 32768, block_size = 4096

```
                            [   root    ]
                           /    . . .    \
                [entry_0]                 [entry_1]
              /  . . .  \                  . . .   \
    [entry_0_0]   . . .  [entry_0_127]    . . . .  [entry_1_127]
      / ... \             /   . . .  \             /           \
blk_0 ... blk_127  blk_16256   blk_16383      blk_32640 . . . blk_32767
```

39.30.3 On-disk format

The verity kernel code does not read the verity metadata on-disk header. It only reads the hash blocks which directly follow the header. It is expected that a user-space tool will verify the integrity of the verity header.

Alternatively, the header can be omitted and the dmsetup parameters can be passed via the kernel command-line in a rooted chain of trust where the command-line is verified.

Directly following the header (and with sector number padded to the next hash block boundary) are the hash blocks which are stored a depth at a time (starting from the root), sorted in order of increasing index.

The full specification of kernel parameters and on-disk metadata format is available at the cryptsetup project's wiki page

https://gitlab.com/cryptsetup/cryptsetup/wikis/DMVerity

39.30.4 Status

V (for Valid) is returned if every check performed so far was valid. If any check failed, C (for Corruption) is returned.

39.30.5 Example

Set up a device:

```
# dmsetup create vroot --readonly --table \
  "0 2097152 verity 1 /dev/sda1 /dev/sda2 4096 4096 262144 1 sha256 "\
  "4392712ba01368efdf14b05c76f9e4df0d53664630b5d48632ed17a137f39076 "\
  "1234000000000000000000000000000000000000000000000000000000000000"
```

A command line tool veritysetup is available to compute or verify the hash tree or activate the kernel device. This is available from the cryptsetup upstream repository https://gitlab.com/cryptsetup/cryptsetup/ (as a libcryptsetup extension).

Create hash on the device:

```
# veritysetup format /dev/sda1 /dev/sda2
...
Root hash: 4392712ba01368efdf14b05c76f9e4df0d53664630b5d48632ed17a137f39076
```

Activate the device:

```
# veritysetup create vroot /dev/sda1 /dev/sda2 \
  4392712ba01368efdf14b05c76f9e4df0d53664630b5d48632ed17a137f39076
```

39.31 Writecache target

The writecache target caches writes on persistent memory or on SSD. It doesn't cache reads because reads are supposed to be cached in page cache in normal RAM.

When the device is constructed, the first sector should be zeroed or the first sector should contain valid superblock from previous invocation.

Constructor parameters:

1. **type of the cache device - "p" or "s"**
   - p - persistent memory
   - s - SSD
2. the underlying device that will be cached
3. the cache device
4. block size (4096 is recommended; the maximum block size is the page size)
5. the number of optional parameters (the parameters with an argument count as two)

   start_sector n (default: 0)
   offset from the start of cache device in 512-byte sectors

   high_watermark n (default: 50)
   start writeback when the number of used blocks reach this watermark

   low_watermark x (default: 45)
   stop writeback when the number of used blocks drops below this watermark

writeback_jobs n (default: unlimited)
limit the number of blocks that are in flight during writeback. Setting this value reduces writeback throughput, but it may improve latency of read requests

autocommit_blocks n (default: 64 for pmem, 65536 for ssd)
when the application writes this amount of blocks without issuing the FLUSH request, the blocks are automatically committed

autocommit_time ms (default: 1000)
autocommit time in milliseconds. The data is automatically committed if this time passes and no FLUSH request is received

fua (by default on)
applicable only to persistent memory - use the FUA flag when writing data from persistent memory back to the underlying device

nofua
applicable only to persistent memory - don't use the FUA flag when writing back data and send the FLUSH request afterwards

- some underlying devices perform better with fua, some with nofua. The user should test it

cleaner
when this option is activated (either in the constructor arguments or by a message), the cache will not promote new writes (however, writes to already cached blocks are promoted, to avoid data corruption due to misordered writes) and it will gradually writeback any cached data. The userspace can then monitor the cleaning process with ”dmsetup status”. When the number of cached blocks drops to zero, userspace can unload the dm-writecache target and replace it with dm-linear or other targets.

max_age n
specifies the maximum age of a block in milliseconds. If a block is stored in the cache for too long, it will be written to the underlying device and cleaned up.

metadata_only
only metadata is promoted to the cache. This option improves performance for heavier REQ_META workloads.

pause_writeback n (default: 3000)
pause writeback if there was some write I/O redirected to the origin volume in the last n milliseconds

Status:

1. error indicator - 0 if there was no error, otherwise error number
2. the number of blocks
3. the number of free blocks
4. the number of blocks under writeback
5. the number of read blocks
6. the number of read blocks that hit the cache

7. the number of write blocks
8. the number of write blocks that hit uncommitted block
9. the number of write blocks that hit committed block
10. the number of write blocks that bypass the cache
11. the number of write blocks that are allocated in the cache
12. the number of write requests that are blocked on the freelist
13. the number of flush requests
14. the number of discarded blocks

Messages:

flush
Flush the cache device. The message returns successfully if the cache device was flushed without an error

flush_on_suspend
Flush the cache device on next suspend. Use this message when you are going to remove the cache device. The proper sequence for removing the cache device is:

1. send the ”flush_on_suspend” message
2. load an inactive table with a linear target that maps to the underlying device
3. suspend the device
4. ask for status and verify that there are no errors
5. resume the device, so that it will use the linear target
6. the cache device is now inactive and it can be deleted

cleaner
See above ”cleaner” constructor documentation.

clear_stats
Clear the statistics that are reported on the status line

39.32 dm-zero

Device-Mapper's ”zero” target provides a block-device that always returns zero'd data on reads and silently drops writes. This is similar behavior to /dev/zero, but as a block-device instead of a character-device.

Dm-zero has no target-specific parameters.

One very interesting use of dm-zero is for creating ”sparse” devices in conjunction with dm-snapshot. A sparse device reports a device-size larger than the amount of actual storage space available for that device. A user can write data anywhere within the sparse device and read it back like a normal device. Reads to previously unwritten areas will return a zero'd buffer. When enough data has been written to fill up the actual storage space, the sparse device is deactivated. This can be very useful for testing device and filesystem limitations.

To create a sparse device, start by creating a dm-zero device that's the desired size of the sparse device. For this example, we'll assume a 10TB sparse device:

```
TEN_TERABYTES=`expr 10 \* 1024 \* 1024 \* 1024 \* 2`   # 10 TB in sectors
echo "0 $TEN_TERABYTES zero" | dmsetup create zero1
```

Then create a snapshot of the zero device, using any available block-device as the COW device. The size of the COW device will determine the amount of real space available to the sparse device. For this example, we'll assume /dev/sdb1 is an available 10GB partition:

```
echo "0 $TEN_TERABYTES snapshot /dev/mapper/zero1 /dev/sdb1 p 128" | \
   dmsetup create sparse1
```

This will create a 10TB sparse device called /dev/mapper/sparse1 that has 10GB of actual storage space available. If more than 10GB of data is written to this device, it will start returning I/O errors.

CHAPTER

FORTY

EDID

In the good old days when graphics parameters were configured explicitly in a file called xorg.conf, even broken hardware could be managed.

Today, with the advent of Kernel Mode Setting, a graphics board is either correctly working because all components follow the standards - or the computer is unusable, because the screen remains dark after booting or it displays the wrong area. Cases when this happens are:

- The graphics board does not recognize the monitor.
- The graphics board is unable to detect any EDID data.
- The graphics board incorrectly forwards EDID data to the driver.
- The monitor sends no or bogus EDID data.
- A KVM sends its own EDID data instead of querying the connected monitor.

Adding the kernel parameter ”nomodeset” helps in most cases, but causes restrictions later on.

As a remedy for such situations, the kernel configuration item CONFIG_DRM_LOAD_EDID_FIRMWARE was introduced. It allows to provide an individually prepared or corrected EDID data set in the /lib/firmware directory from where it is loaded via the firmware interface. The code (see drivers/gpu/drm/drm_edid_load.c) contains built-in data sets for commonly used screen resolutions (800x600, 1024x768, 1280x1024, 1600x1200, 1680x1050, 1920x1080) as binary blobs, but the kernel source tree does not contain code to create these data. In order to elucidate the origin of the built-in binary EDID blobs and to facilitate the creation of individual data for a specific misbehaving monitor, commented sources and a Makefile environment are given here.

To create binary EDID and C source code files from the existing data material, simply type ”make” in tools/edid/.

If you want to create your own EDID file, copy the file 1024x768.S, replace the settings with your own data and add a new target to the Makefile. Please note that the EDID data structure expects the timing values in a different way as compared to the standard X11 format.

X11:

HTimings:
hdisp hsyncstart hsyncend htotal

VTimings:
vdisp vsyncstart vsyncend vtotal

EDID:

```
#define XPIX hdisp
#define XBLANK htotal-hdisp
#define XOFFSET hsyncstart-hdisp
#define XPULSE hsyncend-hsyncstart

#define YPIX vdisp
#define YBLANK vtotal-vdisp
#define YOFFSET vsyncstart-vdisp
#define YPULSE vsyncend-vsyncstart
```

CHAPTER

FORTYONE

THE EFI BOOT STUB

On the x86 and ARM platforms, a kernel zImage/bzImage can masquerade as a PE/COFF image, thereby convincing EFI firmware loaders to load it as an EFI executable. The code that modifies the bzImage header, along with the EFI-specific entry point that the firmware loader jumps to are collectively known as the "EFI boot stub", and live in arch/x86/boot/header.S and drivers/firmware/efi/libstub/x86-stub.c, respectively. For ARM the EFI stub is implemented in arch/arm/boot/compressed/efi-header.S and drivers/firmware/efi/libstub/arm32-stub.c. EFI stub code that is shared between architectures is in drivers/firmware/efi/libstub.

For arm64, there is no compressed kernel support, so the Image itself masquerades as a PE/COFF image and the EFI stub is linked into the kernel. The arm64 EFI stub lives in drivers/firmware/efi/libstub/arm64.c and drivers/firmware/efi/libstub/arm64-stub.c.

By using the EFI boot stub it's possible to boot a Linux kernel without the use of a conventional EFI boot loader, such as grub or elilo. Since the EFI boot stub performs the jobs of a boot loader, in a certain sense it *IS* the boot loader.

The EFI boot stub is enabled with the CONFIG_EFI_STUB kernel option.

41.1 How to install bzImage.efi

The bzImage located in arch/x86/boot/bzImage must be copied to the EFI System Partition (ESP) and renamed with the extension ".efi". Without the extension the EFI firmware loader will refuse to execute it. It's not possible to execute bzImage.efi from the usual Linux file systems because EFI firmware doesn't have support for them. For ARM the arch/arm/boot/zImage should be copied to the system partition, and it may not need to be renamed. Similarly for arm64, arch/arm64/boot/Image should be copied but not necessarily renamed.

41.2 Passing kernel parameters from the EFI shell

Arguments to the kernel can be passed after bzImage.efi, e.g.:

```
fs0:> bzImage.efi console=ttyS0 root=/dev/sda4
```

41.3 The ”initrd=” option

Like most boot loaders, the EFI stub allows the user to specify multiple initrd files using the ”initrd=” option. This is the only EFI stub-specific command line parameter, everything else is passed to the kernel when it boots.

The path to the initrd file must be an absolute path from the beginning of the ESP, relative path names do not work. Also, the path is an EFI-style path and directory elements must be separated with backslashes (). For example, given the following directory layout:

```
fs0:>
      Kernels\
                        bzImage.efi
                        initrd-large.img

      Ramdisks\
                        initrd-small.img
                        initrd-medium.img
```

to boot with the initrd-large.img file if the current working directory is fs0:Kernels, the following command must be used:

```
fs0:\Kernels> bzImage.efi initrd=\Kernels\initrd-large.img
```

Notice how bzImage.efi can be specified with a relative path. That's because the image we're executing is interpreted by the EFI shell, which understands relative paths, whereas the rest of the command line is passed to bzImage.efi.

41.4 The ”dtb=” option

For the ARM and arm64 architectures, a device tree must be provided to the kernel. Normally firmware shall supply the device tree via the EFI CONFIGURATION TABLE. However, the ”dtb=” command line option can be used to override the firmware supplied device tree, or to supply one when firmware is unable to.

Please note: Firmware adds runtime configuration information to the device tree before booting the kernel. If dtb= is used to override the device tree, then any runtime data provided by firmware will be lost. The dtb= option should only be used either as a debug tool, or as a last resort when a device tree is not provided in the EFI CONFIGURATION TABLE.

”dtb=” is processed in the same manner as the ”initrd=” option that is described above.

CHAPTER

FORTYTWO

EXT4 GENERAL INFORMATION

Ext4 is an advanced level of the ext3 filesystem which incorporates scalability and reliability enhancements for supporting large filesystems (64 bit) in keeping with increasing disk capacities and state-of-the-art feature requirements.

Mailing list: linux-ext4@vger.kernel.org Web site: http://ext4.wiki.kernel.org

42.1 Quick usage instructions

Note: More extensive information for getting started with ext4 can be found at the ext4 wiki site at the URL: http://ext4.wiki.kernel.org/index.php/Ext4_Howto

- The latest version of e2fsprogs can be found at:

  https://www.kernel.org/pub/linux/kernel/people/tytso/e2fsprogs/

  or

  http://sourceforge.net/project/showfiles.php?group_id=2406

  or grab the latest git repository from:

  https://git.kernel.org/pub/scm/fs/ext2/e2fsprogs.git

- Create a new filesystem using the ext4 filesystem type:

  ```
  # mke2fs -t ext4 /dev/hda1
  ```

  Or to configure an existing ext3 filesystem to support extents:

  ```
  # tune2fs -O extents /dev/hda1
  ```

  If the filesystem was created with 128 byte inodes, it can be converted to use 256 byte for greater efficiency via:

  ```
  # tune2fs -I 256 /dev/hda1
  ```

- Mounting:

  ```
  # mount -t ext4 /dev/hda1 /wherever
  ```

- When comparing performance with other filesystems, it's always important to try multiple workloads; very often a subtle change in a workload parameter can completely change the ranking of which filesystems do well compared to others. When comparing versus ext3, note that ext4 enables write barriers by default, while ext3 does not enable write barriers by default. So it is useful to use explicitly specify whether barriers are enabled or not when via the '-o barriers=[0|1]'

mount option for both ext3 and ext4 filesystems for a fair comparison. When tuning ext3 for best benchmark numbers, it is often worthwhile to try changing the data journaling mode; '-o data=writeback' can be faster for some workloads. (Note however that running mounted with data=writeback can potentially leave stale data exposed in recently written files in case of an unclean shutdown, which could be a security exposure in some situations.) Configuring the filesystem with a large journal can also be helpful for metadata-intensive workloads.

42.2 Features

42.2.1 Currently Available

- ability to use filesystems > 16TB (e2fsprogs support not available yet)
- extent format reduces metadata overhead (RAM, IO for access, transactions)
- extent format more robust in face of on-disk corruption due to magics,
- internal redundancy in tree
- improved file allocation (multi-block alloc)
- lift 32000 subdirectory limit imposed by i_links_count[1]
- nsec timestamps for mtime, atime, ctime, create time
- inode version field on disk (NFSv4, Lustre)
- reduced e2fsck time via uninit_bg feature
- journal checksumming for robustness, performance
- persistent file preallocation (e.g for streaming media, databases)
- ability to pack bitmaps and inode tables into larger virtual groups via the flex_bg feature
- large file support
- inode allocation using large virtual block groups via flex_bg
- delayed allocation
- large block (up to pagesize) support
- efficient new ordered mode in JBD2 and ext4 (avoid using buffer head to force the ordering)
- Case-insensitive file name lookups
- file-based encryption support (fscrypt)
- file-based verity support (fsverity)

[1] Filesystems with a block size of 1k may see a limit imposed by the directory hash tree having a maximum depth of two.

42.3 case-insensitive file name lookups

The case-insensitive file name lookup feature is supported on a per-directory basis, allowing the user to mix case-insensitive and case-sensitive directories in the same filesystem. It is enabled by flipping the +F inode attribute of an empty directory. The case-insensitive string match operation is only defined when we know how text in encoded in a byte sequence. For that reason, in order to enable case-insensitive directories, the filesystem must have the casefold feature, which stores the filesystem-wide encoding model used. By default, the charset adopted is the latest version of Unicode (12.1.0, by the time of this writing), encoded in the UTF-8 form. The comparison algorithm is implemented by normalizing the strings to the Canonical decomposition form, as defined by Unicode, followed by a byte per byte comparison.

The case-awareness is name-preserving on the disk, meaning that the file name provided by userspace is a byte-per-byte match to what is actually written in the disk. The Unicode normalization format used by the kernel is thus an internal representation, and not exposed to the userspace nor to the disk, with the important exception of disk hashes, used on large case-insensitive directories with DX feature. On DX directories, the hash must be calculated using the casefolded version of the filename, meaning that the normalization format used actually has an impact on where the directory entry is stored.

When we change from viewing filenames as opaque byte sequences to seeing them as encoded strings we need to address what happens when a program tries to create a file with an invalid name. The Unicode subsystem within the kernel leaves the decision of what to do in this case to the filesystem, which select its preferred behavior by enabling/disabling the strict mode. When Ext4 encounters one of those strings and the filesystem did not require strict mode, it falls back to considering the entire string as an opaque byte sequence, which still allows the user to operate on that file, but the case-insensitive lookups won't work.

42.4 Options

When mounting an ext4 filesystem, the following option are accepted: (*) == default

ro
Mount filesystem read only. Note that ext4 will replay the journal (and thus write to the partition) even when mounted ”read only”. The mount options ”ro,noload” can be used to prevent writes to the filesystem.

journal_checksum
Enable checksumming of the journal transactions. This will allow the recovery code in e2fsck and the kernel to detect corruption in the kernel. It is a compatible change and will be ignored by older kernels.

journal_async_commit
Commit block can be written to disk without waiting for descriptor blocks. If enabled older kernels cannot mount the device. This will enable 'journal_checksum' internally.

journal_path=path, journal_dev=devnum
When the external journal device's major/minor numbers have changed, these options allow the user to specify the new journal location. The journal device is identified through either its new major/minor numbers encoded in devnum, or via a path to the device.

norecovery, noload
Don't load the journal on mounting. Note that if the filesystem was not unmounted cleanly, skipping the journal replay will lead to the filesystem containing inconsistencies that can lead to any number of problems.

data=journal
All data are committed into the journal prior to being written into the main file system. Enabling this mode will disable delayed allocation and O_DIRECT support.

data=ordered (*)
All data are forced directly out to the main file system prior to its metadata being committed to the journal.

data=writeback
Data ordering is not preserved, data may be written into the main file system after its metadata has been committed to the journal.

commit=nrsec (*)
This setting limits the maximum age of the running transaction to 'nrsec' seconds. The default value is 5 seconds. This means that if you lose your power, you will lose as much as the latest 5 seconds of metadata changes (your filesystem will not be damaged though, thanks to the journaling). This default value (or any low value) will hurt performance, but it's good for data-safety. Setting it to 0 will have the same effect as leaving it at the default (5 seconds). Setting it to very large values will improve performance. Note that due to delayed allocation even older data can be lost on power failure since writeback of those data begins only after time set in /proc/sys/vm/dirty_expire_centisecs.

barrier=<0|1(*)>, barrier(*), nobarrier
This enables/disables the use of write barriers in the jbd code. barrier=0 disables, barrier=1 enables. This also requires an IO stack which can support barriers, and if jbd gets an error on a barrier write, it will disable again with a warning. Write barriers enforce proper on-disk ordering of journal commits, making volatile disk write caches safe to use, at some performance penalty. If your disks are battery-backed in one way or another, disabling barriers may safely improve performance. The mount options ”barrier” and ”nobarrier” can also be used to enable or disable barriers, for consistency with other ext4 mount options.

inode_readahead_blks=n
This tuning parameter controls the maximum number of inode table blocks that ext4's inode table readahead algorithm will pre-read into the buffer cache. The default value is 32 blocks.

nouser_xattr
Disables Extended User Attributes. See the attr(5) manual page for more information about extended attributes.

noacl
This option disables POSIX Access Control List support. If ACL support is enabled in the kernel configuration (CONFIG_EXT4_FS_POSIX_ACL), ACL is enabled by default on mount. See the acl(5) manual page for more information about acl.

bsddf (*)
Make 'df' act like BSD.

minixdf
Make 'df' act like Minix.

debug
Extra debugging information is sent to syslog.

abort
Simulate the effects of calling ext4_abort() for debugging purposes. This is normally used while remounting a filesystem which is already mounted.

errors=remount-ro
Remount the filesystem read-only on an error.

errors=continue
Keep going on a filesystem error.

errors=panic
Panic and halt the machine if an error occurs. (These mount options override the errors behavior specified in the superblock, which can be configured using tune2fs)

data_err=ignore(*)
Just print an error message if an error occurs in a file data buffer in ordered mode.

data_err=abort
Abort the journal if an error occurs in a file data buffer in ordered mode.

grpid | bsdgroups
New objects have the group ID of their parent.

nogrpid (*) | sysvgroups
New objects have the group ID of their creator.

resgid=n
The group ID which may use the reserved blocks.

resuid=n
The user ID which may use the reserved blocks.

sb=
Use alternate superblock at this location.

quota, noquota, grpquota, usrquota
These options are ignored by the filesystem. They are used only by quota tools to recognize volumes where quota should be turned on. See documentation in the quota-tools package for more details (http://sourceforge.net/projects/linuxquota).

jqfmt=<quota type>, usrjquota=<file>, grpjquota=<file>
These options tell filesystem details about quota so that quota information can be properly updated during journal replay. They replace the above quota options. See documentation in the quota-tools package for more details (http://sourceforge.net/projects/linuxquota).

stripe=n
Number of filesystem blocks that mballoc will try to use for allocation size and alignment. For RAID5/6 systems this should be the number of data disks * RAID chunk size in file system blocks.

delalloc (*)
Defer block allocation until just before ext4 writes out the block(s) in question. This allows ext4 to better allocation decisions more efficiently.

nodelalloc
Disable delayed allocation. Blocks are allocated when the data is copied from userspace to the page cache, either via the write(2) system call or when an mmap'ed page which was previously unallocated is written for the first time.

max_batch_time=usec
Maximum amount of time ext4 should wait for additional filesystem operations to be batch together with a synchronous write operation. Since a synchronous write operation is going to force a commit and then a wait for the I/O complete, it doesn't cost much, and can be a huge throughput win, we wait for a small amount of time to see if any other transactions can piggyback on the synchronous write. The algorithm used is designed to automatically tune for the speed of the disk, by measuring the amount of time (on average) that it takes to finish committing a transaction. Call this time the ”commit time”. If the time that the transaction has been running is less than the commit time, ext4 will try sleeping for the commit time to see if other operations will join the transaction. The commit time is capped by the max_batch_time, which defaults to 15000us (15ms). This optimization can be turned off entirely by setting max_batch_time to 0.

min_batch_time=usec
This parameter sets the commit time (as described above) to be at least min_batch_time. It defaults to zero microseconds. Increasing this parameter may improve the throughput of multi-threaded, synchronous workloads on very fast disks, at the cost of increasing latency.

journal_ioprio=prio
The I/O priority (from 0 to 7, where 0 is the highest priority) which should be used for I/O operations submitted by kjournald2 during a commit operation. This defaults to 3, which is a slightly higher priority than the default I/O priority.

auto_da_alloc(*), noauto_da_alloc
Many broken applications don't use fsync() when replacing existing files via patterns such as fd = open(”foo.new”)/write(fd,..)/close(fd)/ rename(”foo.new”, ”foo”), or worse yet, fd = open(”foo”, O_TRUNC)/write(fd,..)/close(fd). If auto_da_alloc is enabled, ext4 will detect the replace-via-rename and replace-via-truncate patterns and force that any delayed allocation blocks are allocated such that at the next journal commit, in the default data=ordered mode, the data blocks of the new file are forced to disk before the rename() operation is committed. This provides roughly the same level of guarantees as ext3, and avoids the ”zero-length” problem that can happen when a system crashes before the delayed allocation blocks are forced to disk.

noinit_itable
Do not initialize any uninitialized inode table blocks in the background. This feature may be used by installation CD's so that the install process can complete as quickly as possible; the inode table initialization process would then be deferred until the next time the file system is unmounted.

init_itable=n
The lazy itable init code will wait n times the number of milliseconds it took to zero out the previous block group's inode table. This minimizes the impact on

the system performance while file system's inode table is being initialized.

discard, nodiscard(*)
Controls whether ext4 should issue discard/TRIM commands to the underlying block device when blocks are freed. This is useful for SSD devices and sparse/thinly-provisioned LUNs, but it is off by default until sufficient testing has been done.

nouid32
Disables 32-bit UIDs and GIDs. This is for interoperability with older kernels which only store and expect 16-bit values.

block_validity(*), noblock_validity
These options enable or disable the in-kernel facility for tracking filesystem metadata blocks within internal data structures. This allows multi- block allocator and other routines to notice bugs or corrupted allocation bitmaps which cause blocks to be allocated which overlap with filesystem metadata blocks.

dioread_lock, dioread_nolock
Controls whether or not ext4 should use the DIO read locking. If the dioread_nolock option is specified ext4 will allocate uninitialized extent before buffer write and convert the extent to initialized after IO completes. This approach allows ext4 code to avoid using inode mutex, which improves scalability on high speed storages. However this does not work with data journaling and dioread_nolock option will be ignored with kernel warning. Note that dioread_nolock code path is only used for extent-based files. Because of the restrictions this options comprises it is off by default (e.g. dioread_lock).

max_dir_size_kb=n
This limits the size of directories so that any attempt to expand them beyond the specified limit in kilobytes will cause an ENOSPC error. This is useful in memory constrained environments, where a very large directory can cause severe performance problems or even provoke the Out Of Memory killer. (For example, if there is only 512mb memory available, a 176mb directory may seriously cramp the system's style.)

i_version
Enable 64-bit inode version support. This option is off by default.

dax
Use direct access (no page cache). See Documentation/filesystems/dax.rst. Note that this option is incompatible with data=journal.

inlinecrypt
When possible, encrypt/decrypt the contents of encrypted files using the blk-crypto framework rather than filesystem-layer encryption. This allows the use of inline encryption hardware. The on-disk format is unaffected. For more details, see Documentation/block/inline-encryption.rst.

42.5 Data Mode

There are 3 different data modes:

- writeback mode

  In data=writeback mode, ext4 does not journal data at all. This mode provides a similar level of journaling as that of XFS, JFS, and ReiserFS in its default mode - metadata journaling. A crash+recovery can cause incorrect data to appear in files which were written shortly before the crash. This mode will typically provide the best ext4 performance.

- ordered mode

  In data=ordered mode, ext4 only officially journals metadata, but it logically groups metadata information related to data changes with the data blocks into a single unit called a transaction. When it's time to write the new metadata out to disk, the associated data blocks are written first. In general, this mode performs slightly slower than writeback but significantly faster than journal mode.

- journal mode

  data=journal mode provides full data and metadata journaling. All new data is written to the journal first, and then to its final location. In the event of a crash, the journal can be replayed, bringing both data and metadata into a consistent state. This mode is the slowest except when data needs to be read from and written to disk at the same time where it outperforms all others modes. Enabling this mode will disable delayed allocation and O_DIRECT support.

42.6 /proc entries

Information about mounted ext4 file systems can be found in /proc/fs/ext4. Each mounted filesystem will have a directory in /proc/fs/ext4 based on its device name (i.e., /proc/fs/ext4/hdc or /proc/fs/ext4/dm-0). The files in each per-device directory are shown in table below.

Files in /proc/fs/ext4/<devname>

mb_groups
: details of multiblock allocator buddy cache of free blocks

42.7 /sys entries

Information about mounted ext4 file systems can be found in /sys/fs/ext4. Each mounted filesystem will have a directory in /sys/fs/ext4 based on its device name (i.e., /sys/fs/ext4/hdc or /sys/fs/ext4/dm-0). The files in each per-device directory are shown in table below.

Files in /sys/fs/ext4/<devname>:

(see also Documentation/ABI/testing/sysfs-fs-ext4)

delayed_allocation_blocks
: This file is read-only and shows the number of blocks that are dirty in the page cache, but which do not have their location in the filesystem allocated yet.

inode_goal
Tuning parameter which (if non-zero) controls the goal inode used by the inode allocator in preference to all other allocation heuristics. This is intended for debugging use only, and should be 0 on production systems.

inode_readahead_blks
Tuning parameter which controls the maximum number of inode table blocks that ext4's inode table readahead algorithm will pre-read into the buffer cache.

lifetime_write_kbytes
This file is read-only and shows the number of kilobytes of data that have been written to this filesystem since it was created.

max_writeback_mb_bump
The maximum number of megabytes the writeback code will try to write out before move on to another inode.

mb_group_prealloc
The multiblock allocator will round up allocation requests to a multiple of this tuning parameter if the stripe size is not set in the ext4 superblock

mb_max_to_scan
The maximum number of extents the multiblock allocator will search to find the best extent.

mb_min_to_scan
The minimum number of extents the multiblock allocator will search to find the best extent.

mb_order2_req
Tuning parameter which controls the minimum size for requests (as a power of 2) where the buddy cache is used.

mb_stats
Controls whether the multiblock allocator should collect statistics, which are shown during the unmount. 1 means to collect statistics, 0 means not to collect statistics.

mb_stream_req
Files which have fewer blocks than this tunable parameter will have their blocks allocated out of a block group specific preallocation pool, so that small files are packed closely together. Each large file will have its blocks allocated out of its own unique preallocation pool.

session_write_kbytes
This file is read-only and shows the number of kilobytes of data that have been written to this filesystem since it was mounted.

reserved_clusters
This is RW file and contains number of reserved clusters in the file system which will be used in the specific situations to avoid costly zeroout, unexpected ENOSPC, or possible data loss. The default is 2% or 4096 clusters, whichever is smaller and this can be changed however it can never exceed number of clusters in the file system. If there is not enough space for the reserved space when mounting the file mount will _not_ fail.

42.8 Ioctls

Ext4 implements various ioctls which can be used by applications to access ext4-specific functionality. An incomplete list of these ioctls is shown in the table below. This list includes truly ext4-specific ioctls (`EXT4_IOC_*`) as well as ioctls that may have been ext4-specific originally but are now supported by some other filesystem(s) too (`FS_IOC_*`).

Table of Ext4 ioctls

FS_IOC_GETFLAGS
Get additional attributes associated with inode. The ioctl argument is an integer bitfield, with bit values described in ext4.h.

FS_IOC_SETFLAGS
Set additional attributes associated with inode. The ioctl argument is an integer bitfield, with bit values described in ext4.h.

EXT4_IOC_GETVERSION, EXT4_IOC_GETVERSION_OLD
Get the inode i_generation number stored for each inode. The i_generation number is normally changed only when new inode is created and it is particularly useful for network filesystems. The '_OLD' version of this ioctl is an alias for FS_IOC_GETVERSION.

EXT4_IOC_SETVERSION, EXT4_IOC_SETVERSION_OLD
Set the inode i_generation number stored for each inode. The '_OLD' version of this ioctl is an alias for FS_IOC_SETVERSION.

EXT4_IOC_GROUP_EXTEND
This ioctl has the same purpose as the resize mount option. It allows to resize filesystem to the end of the last existing block group, further resize has to be done with resize2fs, either online, or offline. The argument points to the unsigned logn number representing the filesystem new block count.

EXT4_IOC_MOVE_EXT
Move the block extents from orig_fd (the one this ioctl is pointing to) to the donor_fd (the one specified in move_extent structure passed as an argument to this ioctl). Then, exchange inode metadata between orig_fd and donor_fd. This is especially useful for online defragmentation, because the allocator has the opportunity to allocate moved blocks better, ideally into one contiguous extent.

EXT4_IOC_GROUP_ADD
Add a new group descriptor to an existing or new group descriptor block. The new group descriptor is described by ext4_new_group_input structure, which is passed as an argument to this ioctl. This is especially useful in conjunction with EXT4_IOC_GROUP_EXTEND, which allows online resize of the filesystem to the end of the last existing block group. Those two ioctls combined is used in userspace online resize tool (e.g. resize2fs).

EXT4_IOC_MIGRATE
This ioctl operates on the filesystem itself. It converts (migrates) ext3 indirect block mapped inode to ext4 extent mapped inode by walking through indirect block mapping of the original inode and converting contiguous block ranges into ext4 extents of the temporary inode. Then, inodes are swapped. This ioctl might help, when migrating from ext3 to ext4 filesystem, however suggestion is to create fresh ext4 filesystem and copy data from the backup. Note, that filesystem

has to support extents for this ioctl to work.

EXT4_IOC_ALLOC_DA_BLKS
Force all of the delay allocated blocks to be allocated to preserve application-expected ext3 behaviour. Note that this will also start triggering a write of the data blocks, but this behaviour may change in the future as it is not necessary and has been done this way only for sake of simplicity.

EXT4_IOC_RESIZE_FS
Resize the filesystem to a new size. The number of blocks of resized filesystem is passed in via 64 bit integer argument. The kernel allocates bitmaps and inode table, the userspace tool thus just passes the new number of blocks.

EXT4_IOC_SWAP_BOOT
Swap i_blocks and associated attributes (like i_blocks, i_size, i_flags, ...) from the specified inode with inode EXT4_BOOT_LOADER_INO (#5). This is typically used to store a boot loader in a secure part of the filesystem, where it can't be changed by a normal user by accident. The data blocks of the previous boot loader will be associated with the given inode.

CHAPTER

FORTYTHREE

FILE SYSTEM MONITORING WITH FANOTIFY

43.1 File system Error Reporting

Fanotify supports the FAN_FS_ERROR event type for file system-wide error reporting. It is meant to be used by file system health monitoring daemons, which listen for these events and take actions (notify sysadmin, start recovery) when a file system problem is detected.

By design, a FAN_FS_ERROR notification exposes sufficient information for a monitoring tool to know a problem in the file system has happened. It doesn't necessarily provide a user space application with semantics to verify an IO operation was successfully executed. That is out of scope for this feature. Instead, it is only meant as a framework for early file system problem detection and reporting recovery tools.

When a file system operation fails, it is common for dozens of kernel errors to cascade after the initial failure, hiding the original failure log, which is usually the most useful debug data to troubleshoot the problem. For this reason, FAN_FS_ERROR tries to report only the first error that occurred for a file system since the last notification, and it simply counts additional errors. This ensures that the most important pieces of information are never lost.

FAN_FS_ERROR requires the fanotify group to be setup with the FAN_REPORT_FID flag.

At the time of this writing, the only file system that emits FAN_FS_ERROR notifications is Ext4.

A FAN_FS_ERROR Notification has the following format:

```
::

   [ Notification Metadata (Mandatory) ]
   [ Generic Error Record  (Mandatory) ]
   [ FID record            (Mandatory) ]
```

The order of records is not guaranteed, and new records might be added in the future. Therefore, applications must not rely on the order and must be prepared to skip over unknown records. Please refer to `samples/fanotify/fs-monitor.c` for an example parser.

43.1.1 Generic error record

The generic error record provides enough information for a file system agnostic tool to learn about a problem in the file system, without providing any additional details about the problem. This record is identified by `struct fanotify_event_info_header.info_type` being set to FAN_EVENT_INFO_TYPE_ERROR.

```
struct fanotify_event_info_error {
     struct fanotify_event_info_header hdr;
    __s32 error;
    __u32 error_count;
};
```

The *error* field identifies the type of error using errno values. *error_count* tracks the number of errors that occurred and were suppressed to preserve the original error information, since the last notification.

43.1.2 FID record

The FID record can be used to uniquely identify the inode that triggered the error through the combination of fsid and file handle. A file system specific application can use that information to attempt a recovery procedure. Errors that are not related to an inode are reported with an empty file handle of type FILEID_INVALID.

CHAPTER

FORTYFOUR

NFS

44.1 NFS Client

44.1.1 The NFS client

The NFS version 2 protocol was first documented in RFC1094 (March 1989). Since then two more major releases of NFS have been published, with NFSv3 being documented in RFC1813 (June 1995), and NFSv4 in RFC3530 (April 2003).

The Linux NFS client currently supports all the above published versions, and work is in progress on adding support for minor version 1 of the NFSv4 protocol.

The purpose of this document is to provide information on some of the special features of the NFS client that can be configured by system administrators.

44.1.2 The nfs4_unique_id parameter

NFSv4 requires clients to identify themselves to servers with a unique string. File open and lock state shared between one client and one server is associated with this identity. To support robust NFSv4 state recovery and transparent state migration, this identity string must not change across client reboots.

Without any other intervention, the Linux client uses a string that contains the local system's node name. System administrators, however, often do not take care to ensure that node names are fully qualified and do not change over the lifetime of a client system. Node names can have other administrative requirements that require particular behavior that does not work well as part of an nfs_client_id4 string.

The nfs.nfs4_unique_id boot parameter specifies a unique string that can be used together with a system's node name when an NFS client identifies itself to a server. Thus, if the system's node name is not unique, its nfs.nfs4_unique_id can help prevent collisions with other clients.

The nfs.nfs4_unique_id string is typically a UUID, though it can contain anything that is believed to be unique across all NFS clients. An nfs4_unique_id string should be chosen when a client system is installed, just as a system's root file system gets a fresh UUID in its label at install time.

The string should remain fixed for the lifetime of the client. It can be changed safely if care is taken that the client shuts down cleanly and all outstanding NFSv4 state has expired, to prevent loss of NFSv4 state.

This string can be stored in an NFS client's grub.conf, or it can be provided via a net boot facility such as PXE. It may also be specified as an nfs.ko module parameter.

This uniquifier string will be the same for all NFS clients running in containers unless it is overridden by a value written to /sys/fs/nfs/net/nfs_client/identifier which will be local to the network namespace of the process which writes.

44.1.3 The DNS resolver

NFSv4 allows for one server to refer the NFS client to data that has been migrated onto another server by means of the special "fs_locations" attribute. See RFC3530 Section 6: Filesystem Migration and Replication and Implementation Guide for Referrals in NFSv4.

The fs_locations information can take the form of either an ip address and a path, or a DNS hostname and a path. The latter requires the NFS client to do a DNS lookup in order to mount the new volume, and hence the need for an upcall to allow userland to provide this service.

Assuming that the user has the 'rpc_pipefs' filesystem mounted in the usual /var/lib/nfs/rpc_pipefs, the upcall consists of the following steps:

(1) The process checks the dns_resolve cache to see if it contains a valid entry. If so, it returns that entry and exits.

(2) If no valid entry exists, the helper script '/sbin/nfs_cache_getent' (may be changed using the 'nfs.cache_getent' kernel boot parameter) is run, with two arguments: - the cache name, "dns_resolve" - the hostname to resolve

(3) After looking up the corresponding ip address, the helper script writes the result into the rpc_pipefs pseudo-file '/var/lib/nfs/rpc_pipefs/cache/dns_resolve/channel' in the following (text) format:

    "<ip address> <hostname> <ttl>n"

    Where <ip address> is in the usual IPv4 (123.456.78.90) or IPv6 (ffee:ddcc:bbaa:9988:7766:5544:3322:1100, ffee::1100, ...) format. <hostname> is identical to the second argument of the helper script, and <ttl> is the 'time to live' of this cache entry (in units of seconds).

    Note: If <ip address> is invalid, say the string "0", then a negative entry is created, which will cause the kernel to treat the hostname as having no valid DNS translation.

44.1.4 A basic sample /sbin/nfs_cache_getent

```
#!/bin/bash
#
ttl=600
#
cut=/usr/bin/cut
getent=/usr/bin/getent
rpc_pipefs=/var/lib/nfs/rpc_pipefs
#
die()
```

```
{
    echo "Usage: $0 cache_name entry_name"
    exit 1
}

[ $# -lt 2 ] && die
cachename="$1"
cache_path=${rpc_pipefs}/cache/${cachename}/channel

case "${cachename}" in
    dns_resolve)
        name="$2"
        result="$(${getent} hosts ${name} | ${cut} -f1 -d\ )"
        [ -z "${result}" ] && result="0"
        ;;
    *)
        die
        ;;
esac
echo "${result} ${name} ${ttl}" >${cache_path}
```

44.2 Mounting the root filesystem via NFS (nfsroot)

Authors

Written 1996 by Gero Kuhlmann <gero@gkminix.han.de>

Updated 1997 by Martin Mares <mj@atrey.karlin.mff.cuni.cz>

Updated 2006 by Nico Schottelius <nico-kernel-nfsroot@schottelius.org>

Updated 2006 by Horms <horms@verge.net.au>

Updated 2018 by Chris Novakovic <chris@chrisn.me.uk>

In order to use a diskless system, such as an X-terminal or printer server for example, it is necessary for the root filesystem to be present on a non-disk device. This may be an initramfs (see Documentation/filesystems/ramfs-rootfs-initramfs.rst), a ramdisk (see *Using the initial RAM disk (initrd)*) or a filesystem mounted via NFS. The following text describes on how to use NFS for the root filesystem. For the rest of this text 'client' means the diskless system, and 'server' means the NFS server.

44.2.1 Enabling nfsroot capabilities

In order to use nfsroot, NFS client support needs to be selected as built-in during configuration. Once this has been selected, the nfsroot option will become available, which should also be selected.

In the networking options, kernel level autoconfiguration can be selected, along with the types of autoconfiguration to support. Selecting all of DHCP, BOOTP and RARP is safe.

44.2.2 Kernel command line

When the kernel has been loaded by a boot loader (see below) it needs to be told what root fs device to use. And in the case of nfsroot, where to find both the server and the name of the directory on the server to mount as root. This can be established using the following kernel command line parameters:

root=/dev/nfs
This is necessary to enable the pseudo-NFS-device. Note that it's not a real device but just a synonym to tell the kernel to use NFS instead of a real device.

nfsroot=[<server-ip>:]<root-dir>[,<nfs-options>]
If the *nfsroot' parameter is NOT given on the command line, the default* `"/tftpboot/%s"`` will be used.

<server-ip> Specifies the IP address of the NFS server.
The default address is determined by the ip parameter (see below). This parameter allows the use of different servers for IP autoconfiguration and NFS.

<root-dir> Name of the directory on the server to mount as root.
If there is a "%s" token in the string, it will be replaced by the ASCII-representation of the client's IP address.

<nfs-options> Standard NFS options. All options are separated by commas.
The following defaults are used:

```
port            = as given by server portmap daemon
rsize           = 4096
wsize           = 4096
timeo           = 7
retrans         = 3
acregmin        = 3
acregmax        = 60
acdirmin        = 30
acdirmax        = 60
flags           = hard, nointr, noposix, cto, ac
```

ip=<client-ip>:<server-ip>:<gw-ip>:<netmask>:<hostname>:<device>:<autoconf>:<dns0-ip>:<dns1-ip>:<ntp0-ip>
This parameter tells the kernel how to configure IP addresses of devices and also how to set up the IP routing table. It was originally called nfsaddrs, but now the boot-time IP configuration works independently of NFS, so it was renamed to ip and the old name remained as an alias for compatibility reasons.

If this parameter is missing from the kernel command line, all fields are assumed to be empty, and the defaults mentioned below apply. In general this means that the kernel tries to configure everything using autoconfiguration.

The <autoconf> parameter can appear alone as the value to the ip parameter (without all the ':' characters before). If the value is "ip=off" or "ip=none", no autoconfiguration will take place, otherwise autoconfiguration will take place. The most common way to use this is "ip=dhcp".

<client-ip> IP address of the client.
Default: Determined using autoconfiguration.

<server-ip> IP address of the NFS server.
If RARP is used to determine the client address and this parameter is NOT empty only replies from the specified server are accepted.

Only required for NFS root. That is autoconfiguration will not be triggered if it is missing and NFS root is not in operation.

Value is exported to /proc/net/pnp with the prefix "bootserver " (see below).

Default: Determined using autoconfiguration. The address of the autoconfiguration server is used.

<gw-ip> IP address of a gateway if the server is on a different subnet.
Default: Determined using autoconfiguration.

<netmask> Netmask for local network interface.
If unspecified the netmask is derived from the client IP address assuming classful addressing.

Default: Determined using autoconfiguration.

<hostname> Name of the client.
If a '.' character is present, anything before the first '.' is used as the client's hostname, and anything after it is used as its NIS domain name. May be supplied by autoconfiguration, but its absence will not trigger autoconfiguration. If specified and DHCP is used, the user-provided hostname (and NIS domain name, if present) will be carried in the DHCP request; this may cause a DNS record to be created or updated for the client.

Default: Client IP address is used in ASCII notation.

<device> Name of network device to use.
Default: If the host only has one device, it is used. Otherwise the device is determined using autoconfiguration. This is done by sending autoconfiguration requests out of all devices, and using the device that received the first reply.

<autoconf> Method to use for autoconfiguration.
In the case of options which specify multiple autoconfiguration protocols, requests are sent using all protocols, and the first one to reply is used.

Only autoconfiguration protocols that have been compiled into the kernel will be used, regardless of the value of this option:

```
off or none: don't use autoconfiguration
              (do static IP assignment instead)
on or any:   use any protocol available in the kernel
             (default)
dhcp:        use DHCP
bootp:       use BOOTP
rarp:        use RARP
both:        use both BOOTP and RARP but not DHCP
             (old option kept for backwards compatibility)
```

if dhcp is used, the client identifier can be used by following format "ip=dhcp,client-id-type,client-id-value"

Default: any

<dns0-ip> IP address of primary nameserver.
Value is exported to /proc/net/pnp with the prefix ”nameserver ” (see below).

Default: None if not using autoconfiguration; determined automatically if using autoconfiguration.

<dns1-ip> IP address of secondary nameserver.
See <dns0-ip>.

<ntp0-ip> IP address of a Network Time Protocol (NTP) server.
Value is exported to /proc/net/ipconfig/ntp_servers, but is otherwise unused (see below).

Default: None if not using autoconfiguration; determined automatically if using autoconfiguration.

After configuration (whether manual or automatic) is complete, two files are created in the following format; lines are omitted if their respective value is empty following configuration:

- /proc/net/pnp:

  #PROTO: <DHCP|BOOTP|RARP|MANUAL> (depending on configuration method) domain <dns-domain> (if autoconfigured, the DNS domain) nameserver <dns0-ip> (primary name server IP) nameserver <dns1-ip> (secondary name server IP) nameserver <dns2-ip> (tertiary name server IP) bootserver <server-ip> (NFS server IP)

- /proc/net/ipconfig/ntp_servers:

  <ntp0-ip> (NTP server IP) <ntp1-ip> (NTP server IP) <ntp2-ip> (NTP server IP)

<dns-domain> and <dns2-ip> (in /proc/net/pnp) and <ntp1-ip> and <ntp2-ip> (in /proc/net/ipconfig/ntp_servers) are requested during autoconfiguration; they cannot be specified as part of the ”ip=” kernel command line parameter.

Because the ”domain” and ”nameserver” options are recognised by DNS resolvers, /etc/resolv.conf is often linked to /proc/net/pnp on systems that use an NFS root filesystem.

Note that the kernel will not synchronise the system time with any NTP servers it discovers; this is the responsibility of a user space process (e.g. an initrd/initramfs script that passes the IP addresses listed in /proc/net/ipconfig/ntp_servers to an NTP client before mounting the real root filesystem if it is on NFS).

nfsrootdebug
This parameter enables debugging messages to appear in the kernel log at boot time so that administrators can verify that the correct NFS mount options, server address, and root path are passed to the NFS client.

rdinit=<executable file>
To specify which file contains the program that starts system initialization, administrators can use this command line parameter. The default value of this parameter is ”/init”. If the specified file exists and the kernel can execute it, root filesystem related kernel command line parameters, including 'nfsroot=', are ignored.

A description of the process of mounting the root file system can be found in Documentation/driver-api/early-userspace/early_userspace_support.rst

44.2.3 Boot Loader

To get the kernel into memory different approaches can be used. They depend on various facilities being available:

- Booting from a floppy using syslinux

  When building kernels, an easy way to create a boot floppy that uses syslinux is to use the zdisk or bzdisk make targets which use zimage and bzimage images respectively. Both targets accept the FDARGS parameter which can be used to set the kernel command line.

  e.g:

  ```
  make bzdisk FDARGS="root=/dev/nfs"
  ```

  Note that the user running this command will need to have access to the floppy drive device, /dev/fd0

  For more information on syslinux, including how to create bootdisks for prebuilt kernels, see https://syslinux.zytor.com/

  Note: Previously it was possible to write a kernel directly to a floppy using dd, configure the boot device using rdev, and boot using the resulting floppy. Linux no longer supports this method of booting.

- Booting from a cdrom using isolinux

  When building kernels, an easy way to create a bootable cdrom that uses isolinux is to use the isoimage target which uses a bzimage image. Like zdisk and bzdisk, this target accepts the FDARGS parameter which can be used to set the kernel command line.

  e.g:

  ```
  make isoimage FDARGS="root=/dev/nfs"
  ```

  The resulting iso image will be arch/<ARCH>/boot/image.iso This can be written to a cdrom using a variety of tools including cdrecord.

  e.g:

  ```
  cdrecord dev=ATAPI:1,0,0 arch/x86/boot/image.iso
  ```

  For more information on isolinux, including how to create bootdisks for prebuilt kernels, see https://syslinux.zytor.com/

- Using LILO

  When using LILO all the necessary command line parameters may be specified using the 'append=' directive in the LILO configuration file.

  However, to use the 'root=' directive you also need to create a dummy root device, which may be removed after LILO is run.

  e.g:

```
mknod /dev/boot255 c 0 255
```

For information on configuring LILO, please refer to its documentation.

- Using GRUB

  When using GRUB, kernel parameter are simply appended after the kernel specification: kernel <kernel> <parameters>

- Using loadlin

  loadlin may be used to boot Linux from a DOS command prompt without requiring a local hard disk to mount as root. This has not been thoroughly tested by the authors of this document, but in general it should be possible configure the kernel command line similarly to the configuration of LILO.

  Please refer to the loadlin documentation for further information.

- Using a boot ROM

  This is probably the most elegant way of booting a diskless client. With a boot ROM the kernel is loaded using the TFTP protocol. The authors of this document are not aware of any no commercial boot ROMs that support booting Linux over the network. However, there are two free implementations of a boot ROM, netboot-nfs and etherboot, both of which are available on sunsite.unc.edu, and both of which contain everything you need to boot a diskless Linux client.

- Using pxelinux

  Pxelinux may be used to boot linux using the PXE boot loader which is present on many modern network cards.

  When using pxelinux, the kernel image is specified using "kernel <relative-path-below /tftpboot>". The nfsroot parameters are passed to the kernel by adding them to the "append" line. It is common to use serial console in conjunction with pxeliunx, see *Linux Serial Console* for more information.

  For more information on isolinux, including how to create bootdisks for prebuilt kernels, see https://syslinux.zytor.com/

44.2.4 Credits

The nfsroot code in the kernel and the RARP support have been written by Gero Kuhlmann <gero@gkminix.han.de>.

The rest of the IP layer autoconfiguration code has been written by Martin Mares <mj@atrey.karlin.mff.cuni.cz>.

In order to write the initial version of nfsroot I would like to thank Jens-Uwe Mager <jum@anubis.han.de> for his help.

44.3 Setting up NFS/RDMA

Author
NetApp and Open Grid Computing (May 29, 2008)

Warning: This document is probably obsolete.

44.3.1 Overview

This document describes how to install and setup the Linux NFS/RDMA client and server software.

The NFS/RDMA client was first included in Linux 2.6.24. The NFS/RDMA server was first included in the following release, Linux 2.6.25.

In our testing, we have obtained excellent performance results (full 10Gbit wire bandwidth at minimal client CPU) under many workloads. The code passes the full Connectathon test suite and operates over both Infiniband and iWARP RDMA adapters.

44.3.2 Getting Help

If you get stuck, you can ask questions on the nfs-rdma-devel@lists.sourceforge.net mailing list.

44.3.3 Installation

These instructions are a step by step guide to building a machine for use with NFS/RDMA.

- Install an RDMA device

  Any device supported by the drivers in drivers/infiniband/hw is acceptable.

  Testing has been performed using several Mellanox-based IB cards, the Ammasso AMS1100 iWARP adapter, and the Chelsio cxgb3 iWARP adapter.

- Install a Linux distribution and tools

  The first kernel release to contain both the NFS/RDMA client and server was Linux 2.6.25 Therefore, a distribution compatible with this and subsequent Linux kernel release should be installed.

  The procedures described in this document have been tested with distributions from Red Hat's Fedora Project (http://fedora.redhat.com/).

- Install nfs-utils-1.1.2 or greater on the client

  An NFS/RDMA mount point can be obtained by using the mount.nfs command in nfs-utils-1.1.2 or greater (nfs-utils-1.1.1 was the first nfs-utils version with support for NFS/RDMA mounts, but for various reasons we recommend using nfs-utils-1.1.2 or greater). To see which version of mount.nfs you are using, type:

  ```
  $ /sbin/mount.nfs -V
  ```

If the version is less than 1.1.2 or the command does not exist, you should install the latest version of nfs-utils.

Download the latest package from: https://www.kernel.org/pub/linux/utils/nfs

Uncompress the package and follow the installation instructions.

If you will not need the idmapper and gssd executables (you do not need these to create an NFS/RDMA enabled mount command), the installation process can be simplified by disabling these features when running configure:

```
$ ./configure --disable-gss --disable-nfsv4
```

To build nfs-utils you will need the tcp_wrappers package installed. For more information on this see the package's README and INSTALL files.

After building the nfs-utils package, there will be a mount.nfs binary in the utils/mount directory. This binary can be used to initiate NFS v2, v3, or v4 mounts. To initiate a v4 mount, the binary must be called mount.nfs4. The standard technique is to create a symlink called mount.nfs4 to mount.nfs.

This mount.nfs binary should be installed at /sbin/mount.nfs as follows:

```
$ sudo cp utils/mount/mount.nfs /sbin/mount.nfs
```

In this location, mount.nfs will be invoked automatically for NFS mounts by the system mount command.

> **Note:** mount.nfs and therefore nfs-utils-1.1.2 or greater is only needed on the NFS client machine. You do not need this specific version of nfs-utils on the server. Furthermore, only the mount.nfs command from nfs-utils-1.1.2 is needed on the client.

- Install a Linux kernel with NFS/RDMA

  The NFS/RDMA client and server are both included in the mainline Linux kernel version 2.6.25 and later. This and other versions of the Linux kernel can be found at: https://www.kernel.org/pub/linux/kernel/

  Download the sources and place them in an appropriate location.

- Configure the RDMA stack

  Make sure your kernel configuration has RDMA support enabled. Under Device Drivers -> InfiniBand support, update the kernel configuration to enable InfiniBand support [NOTE: the option name is misleading. Enabling InfiniBand support is required for all RDMA devices (IB, iWARP, etc.)].

  Enable the appropriate IB HCA support (mlx4, mthca, ehca, ipath, etc.) or iWARP adapter support (amso, cxgb3, etc.).

  If you are using InfiniBand, be sure to enable IP-over-InfiniBand support.

- Configure the NFS client and server

  Your kernel configuration must also have NFS file system support and/or NFS server support enabled. These and other NFS related configuration options can be found under File

Systems -> Network File Systems.

- Build, install, reboot

  The NFS/RDMA code will be enabled automatically if NFS and RDMA are turned on. The NFS/RDMA client and server are configured via the hidden SUNRPC_XPRT_RDMA config option that depends on SUNRPC and INFINIBAND. The value of SUNRPC_XPRT_RDMA will be:

  1. N if either SUNRPC or INFINIBAND are N, in this case the NFS/RDMA client and server will not be built
  2. M if both SUNRPC and INFINIBAND are on (M or Y) and at least one is M, in this case the NFS/RDMA client and server will be built as modules
  3. Y if both SUNRPC and INFINIBAND are Y, in this case the NFS/RDMA client and server will be built into the kernel

  Therefore, if you have followed the steps above and turned no NFS and RDMA, the NFS/RDMA client and server will be built.

  Build a new kernel, install it, boot it.

44.3.4 Check RDMA and NFS Setup

Before configuring the NFS/RDMA software, it is a good idea to test your new kernel to ensure that the kernel is working correctly. In particular, it is a good idea to verify that the RDMA stack is functioning as expected and standard NFS over TCP/IP and/or UDP/IP is working properly.

- Check RDMA Setup

  If you built the RDMA components as modules, load them at this time. For example, if you are using a Mellanox Tavor/Sinai/Arbel card:

```
$ modprobe ib_mthca
$ modprobe ib_ipoib
```

  If you are using InfiniBand, make sure there is a Subnet Manager (SM) running on the network. If your IB switch has an embedded SM, you can use it. Otherwise, you will need to run an SM, such as OpenSM, on one of your end nodes.

  If an SM is running on your network, you should see the following:

```
$ cat /sys/class/infiniband/driverX/ports/1/state
4: ACTIVE
```

  where driverX is mthca0, ipath5, ehca3, etc.

  To further test the InfiniBand software stack, use IPoIB (this assumes you have two IB hosts named host1 and host2):

```
host1$ ip link set dev ib0 up
host1$ ip address add dev ib0 a.b.c.x
host2$ ip link set dev ib0 up
host2$ ip address add dev ib0 a.b.c.y
host1$ ping a.b.c.y
host2$ ping a.b.c.x
```

For other device types, follow the appropriate procedures.

- Check NFS Setup

  For the NFS components enabled above (client and/or server), test their functionality over standard Ethernet using TCP/IP or UDP/IP.

44.3.5 NFS/RDMA Setup

We recommend that you use two machines, one to act as the client and one to act as the server.

One time configuration:

- On the server system, configure the /etc/exports file and start the NFS/RDMA server.

  Exports entries with the following formats have been tested:

```
/vol0   192.168.0.47(fsid=0,rw,async,insecure,no_root_squash)
/vol0   192.168.0.0/255.255.255.0(fsid=0,rw,async,insecure,no_root_squash)
```

  The IP address(es) is(are) the client's IPoIB address for an InfiniBand HCA or the client's iWARP address(es) for an RNIC.

  Note: The ”insecure” option must be used because the NFS/RDMA client does not use a reserved port.

Each time a machine boots:

- Load and configure the RDMA drivers

  For InfiniBand using a Mellanox adapter:

```
$ modprobe ib_mthca
$ modprobe ib_ipoib
$ ip li set dev ib0 up
$ ip addr add dev ib0 a.b.c.d
```

  Note: Please use unique addresses for the client and server!

- Start the NFS server

  If the NFS/RDMA server was built as a module (CONFIG_SUNRPC_XPRT_RDMA=m in kernel config), load the RDMA transport module:

```
$ modprobe svcrdma
```

  Regardless of how the server was built (module or built-in), start the server:

```
$ /etc/init.d/nfs start
```

or

```
$ service nfs start
```

Instruct the server to listen on the RDMA transport:

```
$ echo rdma 20049 > /proc/fs/nfsd/portlist
```

- On the client system

  If the NFS/RDMA client was built as a module (CONFIG_SUNRPC_XPRT_RDMA=m in kernel config), load the RDMA client module:

  ```
  $ modprobe xprtrdma.ko
  ```

  Regardless of how the client was built (module or built-in), use this command to mount the NFS/RDMA server:

  ```
  $ mount -o rdma,port=20049 <IPoIB-server-name-or-address>:/<export> /mnt
  ```

  To verify that the mount is using RDMA, run ”cat /proc/mounts” and check the ”proto” field for the given mount.

  Congratulations! You're using NFS/RDMA!

44.4 Administrative interfaces for nfsd

Note that normally these interfaces are used only by the utilities in nfs-utils.

nfsd is controlled mainly by pseudofiles under the ”nfsd” filesystem, which is normally mounted at /proc/fs/nfsd/.

The server is always started by the first write of a nonzero value to nfsd/threads.

Before doing that, NFSD can be told which sockets to listen on by writing to nfsd/portlist; that write may be:

- an ascii-encoded file descriptor, which should refer to a bound (and listening, for tcp) socket, or
- ”transportname port”, where transportname is currently either ”udp”, ”tcp”, or ”rdma”.

If nfsd is started without doing any of these, then it will create one udp and one tcp listener at port 2049 (see nfsd_init_socks).

On startup, nfsd and lockd grace periods start. nfsd is shut down by a write of 0 to nfsd/threads. All locks and state are thrown away at that point.

Between startup and shutdown, the number of threads may be adjusted up or down by additional writes to nfsd/threads or by writes to nfsd/pool_threads.

For more detail about files under nfsd/ and what they control, see fs/nfsd/nfsctl.c; most of them have detailed comments.

44.4.1 Implementation notes

Note that the rpc server requires the caller to serialize addition and removal of listening sockets, and startup and shutdown of the server. For nfsd this is done using nfsd_mutex.

44.5 NFS ID Mapper

Id mapper is used by NFS to translate user and group ids into names, and to translate user and group names into ids. Part of this translation involves performing an upcall to userspace to request the information. There are two ways NFS could obtain this information: placing a call to /sbin/request-key or by placing a call to the rpc.idmap daemon.

NFS will attempt to call /sbin/request-key first. If this succeeds, the result will be cached using the generic request-key cache. This call should only fail if /etc/request-key.conf is not configured for the id_resolver key type, see the "Configuring" section below if you wish to use the request-key method.

If the call to /sbin/request-key fails (if /etc/request-key.conf is not configured with the id_resolver key type), then the idmapper will ask the legacy rpc.idmap daemon for the id mapping. This result will be stored in a custom NFS idmap cache.

44.5.1 Configuring

The file /etc/request-key.conf will need to be modified so /sbin/request-key can direct the upcall. The following line should be added:

```
#OP TYPE DESCRIPTION CALLOUT INFO PROGRAM ARG1 ARG2 ARG3 ...     #====== =======
=============== =============== ================================           create
id_resolver * * /usr/sbin/nfs.idmap %k %d 600
```

This will direct all id_resolver requests to the program /usr/sbin/nfs.idmap. The last parameter, 600, defines how many seconds into the future the key will expire. This parameter is optional for /usr/sbin/nfs.idmap. When the timeout is not specified, nfs.idmap will default to 600 seconds.

id mapper uses for key descriptions:

```
  uid:  Find the UID for the given user
  gid:  Find the GID for the given group
 user:  Find the user  name for the given UID
group:  Find the group name for the given GID
```

You can handle any of these individually, rather than using the generic upcall program. If you would like to use your own program for a uid lookup then you would edit your request-key.conf so it look similar to this:

```
#OP TYPE DESCRIPTION CALLOUT INFO PROGRAM ARG1 ARG2 ARG3 ...     #====== =======
=============== =============== ================================           create
id_resolver uid:* * /some/other/program %k %d 600   create id_resolver * * /usr/
sbin/nfs.idmap %k %d 600
```

Notice that the new line was added above the line for the generic program. request-key will find the first matching line and corresponding program. In this case, /some/other/program will handle all uid lookups and /usr/sbin/nfs.idmap will handle gid, user, and group lookups.

See Documentation/security/keys/request-key.rst for more information about the request-key function.

44.5.2 nfs.idmap

nfs.idmap is designed to be called by request-key, and should not be run "by hand". This program takes two arguments, a serialized key and a key description. The serialized key is first converted into a key_serial_t, and then passed as an argument to keyctl_instantiate (both are part of keyutils.h).

The actual lookups are performed by functions found in nfsidmap.h. nfs.idmap determines the correct function to call by looking at the first part of the description string. For example, a uid lookup description will appear as "uid:user@domain".

nfs.idmap will return 0 if the key was instantiated, and non-zero otherwise.

44.6 pNFS block layout server user guide

The Linux NFS server now supports the pNFS block layout extension. In this case the NFS server acts as Metadata Server (MDS) for pNFS, which in addition to handling all the metadata access to the NFS export also hands out layouts to the clients to directly access the underlying block devices that are shared with the client.

To use pNFS block layouts with the Linux NFS server the exported file system needs to support the pNFS block layouts (currently just XFS), and the file system must sit on shared storage (typically iSCSI) that is accessible to the clients in addition to the MDS. As of now the file system needs to sit directly on the exported volume, striping or concatenation of volumes on the MDS and clients is not supported yet.

On the server, pNFS block volume support is automatically if the file system support it. On the client make sure the kernel has the CONFIG_PNFS_BLOCK option enabled, the blkmapd daemon from nfs-utils is running, and the file system is mounted using the NFSv4.1 protocol version (mount -o vers=4.1).

If the nfsd server needs to fence a non-responding client it calls /sbin/nfsd-recall-failed with the first argument set to the IP address of the client, and the second argument set to the device node without the /dev prefix for the file system to be fenced. Below is an example file that shows how to translate the device into a serial number from SCSI EVPD 0x80:

```
cat > /sbin/nfsd-recall-failed << EOF
```

```
#!/bin/sh

CLIENT="$1"
DEV="/dev/$2"
EVPD=`sg_inq --page=0x80 ${DEV} | \
        grep "Unit serial number:" | \
        awk -F ': ' '{print $2}'`

echo "fencing client ${CLIENT} serial ${EVPD}" >> /var/log/pnfsd-fence.log
EOF
```

44.7 pNFS SCSI layout server user guide

This document describes support for pNFS SCSI layouts in the Linux NFS server. With pNFS SCSI layouts, the NFS server acts as Metadata Server (MDS) for pNFS, which in addition to handling all the metadata access to the NFS export, also hands out layouts to the clients so that they can directly access the underlying SCSI LUNs that are shared with the client.

To use pNFS SCSI layouts with the Linux NFS server, the exported file system needs to support the pNFS SCSI layouts (currently just XFS), and the file system must sit on a SCSI LUN that is accessible to the clients in addition to the MDS. As of now the file system needs to sit directly on the exported LUN, striping or concatenation of LUNs on the MDS and clients is not supported yet.

On a server built with CONFIG_NFSD_SCSI, the pNFS SCSI volume support is automatically enabled if the file system is exported using the ”pnfs” option and the underlying SCSI device support persistent reservations. On the client make sure the kernel has the CONFIG_PNFS_BLOCK option enabled, and the file system is mounted using the NFSv4.1 protocol version (mount -o vers=4.1).

CHAPTER

FORTYFIVE

GPIO

45.1 GPIO Aggregator

The GPIO Aggregator provides a mechanism to aggregate GPIOs, and expose them as a new gpio_chip. This supports the following use cases.

45.1.1 Aggregating GPIOs using Sysfs

GPIO controllers are exported to userspace using /dev/gpiochip* character devices. Access control to these devices is provided by standard UNIX file system permissions, on an all-or-nothing basis: either a GPIO controller is accessible for a user, or it is not.

The GPIO Aggregator provides access control for a set of one or more GPIOs, by aggregating them into a new gpio_chip, which can be assigned to a group or user using standard UNIX file ownership and permissions. Furthermore, this simplifies and hardens exporting GPIOs to a virtual machine, as the VM can just grab the full GPIO controller, and no longer needs to care about which GPIOs to grab and which not, reducing the attack surface.

Aggregated GPIO controllers are instantiated and destroyed by writing to write-only attribute files in sysfs.

/sys/bus/platform/drivers/gpio-aggregator/

"new_device" ...

Userspace may ask the kernel to instantiate an aggregated GPIO controller by writing a string describing the GPIOs to aggregate to the "new_device" file, using the format

```
[<gpioA>] [<gpiochipB> <offsets>] ...
```

Where:

"<gpioA>" ...

is a GPIO line name,

"<gpiochipB>" ...

is a GPIO chip label, and

"<offsets>" ...

is a comma-separated list of GPIO offsets and/or GPIO offset ranges denoted by dashes.

Example: Instantiate a new GPIO aggregator by aggregating GPIO line 19 of "e6052000.gpio" and GPIO lines 20-21 of "e6050000.gpio" into a new gpio_chip:

```
$ echo 'e6052000.gpio 19 e6050000.gpio 20-21' > new_device
```

"delete_device" ...
Userspace may ask the kernel to destroy an aggregated GPIO controller after use by writing its device name to the "delete_device" file.

Example: Destroy the previously-created aggregated GPIO controller, assumed to be "gpio-aggregator.0":

```
$ echo gpio-aggregator.0 > delete_device
```

45.1.2 Generic GPIO Driver

The GPIO Aggregator can also be used as a generic driver for a simple GPIO-operated device described in DT, without a dedicated in-kernel driver. This is useful in industrial control, and is not unlike e.g. spidev, which allows the user to communicate with an SPI device from userspace.

Binding a device to the GPIO Aggregator is performed either by modifying the gpio-aggregator driver, or by writing to the "driver_override" file in Sysfs.

Example: If "door" is a GPIO-operated device described in DT, using its own compatible value:

```
door {
        compatible = "myvendor,mydoor";

        gpios = <&gpio2 19 GPIO_ACTIVE_HIGH>,
                <&gpio2 20 GPIO_ACTIVE_LOW>;
        gpio-line-names = "open", "lock";
};
```

it can be bound to the GPIO Aggregator by either:

1. Adding its compatible value to `gpio_aggregator_dt_ids[]`,
2. Binding manually using "driver_override":

```
$ echo gpio-aggregator > /sys/bus/platform/devices/door/driver_override
$ echo door > /sys/bus/platform/drivers/gpio-aggregator/bind
```

After that, a new gpiochip "door" has been created:

```
$ gpioinfo door
gpiochip12 - 2 lines:
        line   0:       "open"       unused   input  active-high
        line   1:       "lock"       unused   input  active-high
```

45.2 GPIO Sysfs Interface for Userspace

Warning: THIS ABI IS DEPRECATED, THE ABI DOCUMENTATION HAS BEEN MOVED TO Documentation/ABI/obsolete/sysfs-gpio AND NEW USERSPACE CONSUMERS ARE SUPPOSED TO USE THE CHARACTER DEVICE ABI. THIS OLD SYSFS ABI WILL NOT BE DEVELOPED (NO NEW FEATURES), IT WILL JUST BE MAINTAINED.

Refer to the examples in tools/gpio/* for an introduction to the new character device ABI. Also see the userspace header in include/uapi/linux/gpio.h

45.2.1 The deprecated sysfs ABI

Platforms which use the "gpiolib" implementors framework may choose to configure a sysfs user interface to GPIOs. This is different from the debugfs interface, since it provides control over GPIO direction and value instead of just showing a gpio state summary. Plus, it could be present on production systems without debugging support.

Given appropriate hardware documentation for the system, userspace could know for example that GPIO #23 controls the write protect line used to protect boot loader segments in flash memory. System upgrade procedures may need to temporarily remove that protection, first importing a GPIO, then changing its output state, then updating the code before re-enabling the write protection. In normal use, GPIO #23 would never be touched, and the kernel would have no need to know about it.

Again depending on appropriate hardware documentation, on some systems userspace GPIO can be used to determine system configuration data that standard kernels won't know about. And for some tasks, simple userspace GPIO drivers could be all that the system really needs.

DO NOT ABUSE SYSFS TO CONTROL HARDWARE THAT HAS PROPER KERNEL DRIVERS. PLEASE READ THE DOCUMENT AT Documentation/driver-api/gpio/drivers-on-gpio.rst TO AVOID REINVENTING KERNEL WHEELS IN USERSPACE. I MEAN IT. REALLY.

45.2.2 Paths in Sysfs

There are three kinds of entries in /sys/class/gpio:

- Control interfaces used to get userspace control over GPIOs;
- GPIOs themselves; and
- GPIO controllers ("gpio_chip" instances).

That's in addition to standard files including the "device" symlink.

The control interfaces are write-only:

/sys/class/gpio/

"export" ...
Userspace may ask the kernel to export control of a GPIO to userspace by writing its number to this file.

Example: ”echo 19 > export” will create a ”gpio19” node for GPIO #19, if that's not requested by kernel code.

”unexport” ...
Reverses the effect of exporting to userspace.

Example: ”echo 19 > unexport” will remove a ”gpio19” node exported using the ”export” file.

GPIO signals have paths like /sys/class/gpio/gpio42/ (for GPIO #42) and have the following read/write attributes:

/sys/class/gpio/gpioN/

”direction” ...
reads as either ”in” or ”out”. This value may normally be written. Writing as ”out” defaults to initializing the value as low. To ensure glitch free operation, values ”low” and ”high” may be written to configure the GPIO as an output with that initial value.

Note that this attribute *will not exist* if the kernel doesn't support changing the direction of a GPIO, or it was exported by kernel code that didn't explicitly allow userspace to reconfigure this GPIO's direction.

”value” ...
reads as either 0 (low) or 1 (high). If the GPIO is configured as an output, this value may be written; any nonzero value is treated as high.

If the pin can be configured as interrupt-generating interrupt and if it has been configured to generate interrupts (see the description of ”edge”), you can poll(2) on that file and poll(2) will return whenever the interrupt was triggered. If you use poll(2), set the events POLLPRI and POLLERR. If you use select(2), set the file descriptor in exceptfds. After poll(2) returns, either lseek(2) to the beginning of the sysfs file and read the new value or close the file and re-open it to read the value.

”edge” ...
reads as either ”none”, ”rising”, ”falling”, or ”both”. Write these strings to select the signal edge(s) that will make poll(2) on the ”value” file return.

This file exists only if the pin can be configured as an interrupt generating input pin.

”active_low” ...
reads as either 0 (false) or 1 (true). Write any nonzero value to invert the value attribute both for reading and writing. Existing and subsequent poll(2) support configuration via the edge attribute for ”rising” and ”falling” edges will follow this setting.

GPIO controllers have paths like /sys/class/gpio/gpiochip42/ (for the controller implementing GPIOs starting at #42) and have the following read-only attributes:

/sys/class/gpio/gpiochipN/

”base” ...
same as N, the first GPIO managed by this chip

"label" ...
provided for diagnostics (not always unique)

"ngpio" ...
how many GPIOs this manages (N to N + ngpio - 1)

Board documentation should in most cases cover what GPIOs are used for what purposes. However, those numbers are not always stable; GPIOs on a daughtercard might be different depending on the base board being used, or other cards in the stack. In such cases, you may need to use the gpiochip nodes (possibly in conjunction with schematics) to determine the correct GPIO number to use for a given signal.

45.2.3 Exporting from Kernel code

Kernel code can explicitly manage exports of GPIOs which have already been requested using gpio_request():

```
/* export the GPIO to userspace */
int gpiod_export(struct gpio_desc *desc, bool direction_may_change);

/* reverse gpiod_export() */
void gpiod_unexport(struct gpio_desc *desc);

/* create a sysfs link to an exported GPIO node */
int gpiod_export_link(struct device *dev, const char *name,
              struct gpio_desc *desc);
```

After a kernel driver requests a GPIO, it may only be made available in the sysfs interface by gpiod_export(). The driver can control whether the signal direction may change. This helps drivers prevent userspace code from accidentally clobbering important system state.

This explicit exporting can help with debugging (by making some kinds of experiments easier), or can provide an always-there interface that's suitable for documenting as part of a board support package.

After the GPIO has been exported, gpiod_export_link() allows creating symlinks from elsewhere in sysfs to the GPIO sysfs node. Drivers can use this to provide the interface under their own device in sysfs with a descriptive name.

45.3 GPIO Testing Driver

The GPIO Testing Driver (gpio-mockup) provides a way to create simulated GPIO chips for testing purposes. The lines exposed by these chips can be accessed using the standard GPIO character device interface as well as manipulated using the dedicated debugfs directory structure.

45.3.1 Creating simulated chips using module params

When loading the gpio-mockup driver a number of parameters can be passed to the module.

gpio_mockup_ranges

This parameter takes an argument in the form of an array of integer pairs. Each pair defines the base GPIO number (non-negative integer) and the first number after the last of this chip. If the base GPIO is -1, the gpiolib will assign it automatically. while the following parameter is the number of lines exposed by the chip.

Example: gpio_mockup_ranges=-1,8,-1,16,405,409

The line above creates three chips. The first one will expose 8 lines, the second 16 and the third 4. The base GPIO for the third chip is set to 405 while for two first chips it will be assigned automatically.

gpio_mockup_named_lines

This parameter doesn't take any arguments. It lets the driver know that GPIO lines exposed by it should be named.

The name format is: gpio-mockup-X-Y where X is mockup chip's ID and Y is the line offset.

45.3.2 Manipulating simulated lines

Each mockup chip creates its own subdirectory in /sys/kernel/debug/gpio-mockup/. The directory is named after the chip's label. A symlink is also created, named after the chip's name, which points to the label directory.

Inside each subdirectory, there's a separate attribute for each GPIO line. The name of the attribute represents the line's offset in the chip.

Reading from a line attribute returns the current value. Writing to it (0 or 1) changes the configuration of the simulated pull-up/pull-down resistor (1 - pull-up, 0 - pull-down).

45.4 Configfs GPIO Simulator

The configfs GPIO Simulator (gpio-sim) provides a way to create simulated GPIO chips for testing purposes. The lines exposed by these chips can be accessed using the standard GPIO character device interface as well as manipulated using sysfs attributes.

45.4.1 Creating simulated chips

The gpio-sim module registers a configfs subsystem called `'gpio-sim'`. For details of the configfs filesystem, please refer to the configfs documentation.

The user can create a hierarchy of configfs groups and items as well as modify values of exposed attributes. Once the chip is instantiated, this hierarchy will be translated to appropriate device properties. The general structure is:

Group: `/config/gpio-sim`

This is the top directory of the gpio-sim configfs tree.

Group: `/config/gpio-sim/gpio-device`

Attribute: `/config/gpio-sim/gpio-device/dev_name`

Attribute: `/config/gpio-sim/gpio-device/live`

This is a directory representing a GPIO platform device. The `'dev_name'` attribute is read-only and allows the user-space to read the platform device name (e.g. `'gpio-sim.0'`). The `'live'` attribute allows to trigger the actual creation of the device once it's fully configured. The accepted values are: `'1'` to enable the simulated device and `'0'` to disable and tear it down.

Group: `/config/gpio-sim/gpio-device/gpio-bankX`

Attribute: `/config/gpio-sim/gpio-device/gpio-bankX/chip_name`

Attribute: `/config/gpio-sim/gpio-device/gpio-bankX/num_lines`

This group represents a bank of GPIOs under the top platform device. The `'chip_name'` attribute is read-only and allows the user-space to read the device name of the bank device. The `'num_lines'` attribute allows to specify the number of lines exposed by this bank.

Group: `/config/gpio-sim/gpio-device/gpio-bankX/lineY`

Attribute: `/config/gpio-sim/gpio-device/gpio-bankX/lineY/name`

This group represents a single line at the offset Y. The 'name' attribute allows to set the line name as represented by the 'gpio-line-names' property.

Item: `/config/gpio-sim/gpio-device/gpio-bankX/lineY/hog`

Attribute: `/config/gpio-sim/gpio-device/gpio-bankX/lineY/hog/name`

Attribute: `/config/gpio-sim/gpio-device/gpio-bankX/lineY/hog/direction`

This item makes the gpio-sim module hog the associated line. The `'name'` attribute specifies the in-kernel consumer name to use. The `'direction'` attribute specifies the hog direction and must be one of: `'input'`, `'output-high'` and `'output-low'`.

Inside each bank directory, there's a set of attributes that can be used to configure the new chip. Additionally the user can `mkdir()` subdirectories inside the chip's directory that allow to pass additional configuration for specific lines. The name of those subdirectories must take the form of: `'line<offset>'` (e.g. `'line0'`, `'line20'`, etc.) as the name will be used by the module to assign the config to the specific line at given offset.

Once the confiuration is complete, the `'live'` attribute must be set to 1 in order to instantiate the chip. It can be set back to 0 to destroy the simulated chip. The module will synchronously

wait for the new simulated device to be successfully probed and if this doesn't happen, writing to `'live'` will result in an error.

Simulated GPIO chips can also be defined in device-tree. The compatible string must be: `"gpio-simulator"`. Supported properties are:

`"gpio-sim,label"` - chip label

Other standard GPIO properties (like `"gpio-line-names"`, `"ngpios"` or `"gpio-hog"`) are also supported. Please refer to the GPIO documentation for details.

An example device-tree code defining a GPIO simulator:

```
gpio-sim {
    compatible = "gpio-simulator";

    bank0 {
        gpio-controller;
        #gpio-cells = <2>;
        ngpios = <16>;
        gpio-sim,label = "dt-bank0";
        gpio-line-names = "", "sim-foo", "", "sim-bar";
    };

    bank1 {
        gpio-controller;
        #gpio-cells = <2>;
        ngpios = <8>;
        gpio-sim,label = "dt-bank1";

        line3 {
            gpio-hog;
            gpios = <3 0>;
            output-high;
            line-name = "sim-hog-from-dt";
        };
    };
};
```

45.4.2 Manipulating simulated lines

Each simulated GPIO chip creates a separate sysfs group under its device directory for each exposed line (e.g. `/sys/devices/platform/gpio-sim.X/gpiochipY/`). The name of each group is of the form: `'sim_gpioX'` where X is the offset of the line. Inside each group there are two attributes:

`pull` - allows to read and set the current simulated pull setting for
every line, when writing the value must be one of: `'pull-up'`, `'pull-down'`

`value` - allows to read the current value of the line which may be
different from the pull if the line is being driven from user-space

FORTYSIX

NOTES ON THE CHANGE FROM 16-BIT UIDS TO 32-BIT UIDS

Author
Chris Wing <wingc@umich.edu>

Last updated
January 11, 2000

- kernel code MUST take into account __kernel_uid_t and __kernel_uid32_t when communicating between user and kernel space in an ioctl or data structure.
- kernel code should use uid_t and gid_t in kernel-private structures and code.

What's left to be done for 32-bit UIDs on all Linux architectures:

- Disk quotas have an interesting limitation that is not related to the maximum UID/GID. They are limited by the maximum file size on the underlying filesystem, because quota records are written at offsets corresponding to the UID in question. Further investigation is needed to see if the quota system can cope properly with huge UIDs. If it can deal with 64-bit file offsets on all architectures, this should not be a problem.
- Decide whether or not to keep backwards compatibility with the system accounting file, or if we should break it as the comments suggest (currently, the old 16-bit UID and GID are still written to disk, and part of the former pad space is used to store separate 32-bit UID and GID)
- Need to validate that OS emulation calls the 16-bit UID compatibility syscalls, if the OS being emulated used 16-bit UIDs, or uses the 32-bit UID system calls properly otherwise.

  This affects at least:

  - iBCS on Intel
  - sparc32 emulation on sparc64 (need to support whatever new 32-bit UID system calls are added to sparc32)
- Validate that all filesystems behave properly.

  At present, 32-bit UIDs _should_ work for:

  - ext2
  - ufs
  - isofs
  - nfs
  - coda

  - udf

  Ioctl() fixups have been made for:

  - ncpfs
  - smbfs

  Filesystems with simple fixups to prevent 16-bit UID wraparound:

  - minix
  - sysv
  - qnx4

  Other filesystems have not been checked yet.

- The ncpfs and smpfs filesystems cannot presently use 32-bit UIDs in all ioctl()s. Some new ioctl()s have been added with 32-bit UIDs, but more are needed. (as well as new user<->kernel data structures)
- The ELF core dump format only supports 16-bit UIDs on arm, i386, m68k, sh, and sparc32. Fixing this is probably not that important, but would require adding a new ELF section.
- The ioctl()s used to control the in-kernel NFS server only support 16-bit UIDs on arm, i386, m68k, sh, and sparc32.
- make sure that the UID mapping feature of AX25 networking works properly (it should be safe because it's always used a 32-bit integer to communicate between user and kernel)

CHAPTER

FORTYSEVEN

HARDWARE RANDOM NUMBER GENERATORS

47.1 Introduction

The hw_random framework is software that makes use of a special hardware feature on your CPU or motherboard, a Random Number Generator (RNG). The software has two parts: a core providing the /dev/hwrng character device and its sysfs support, plus a hardware-specific driver that plugs into that core.

To make the most effective use of these mechanisms, you should download the support software as well. Download the latest version of the ”rng-tools” package from:

https://github.com/nhorman/rng-tools

Those tools use /dev/hwrng to fill the kernel entropy pool, which is used internally and exported by the /dev/urandom and /dev/random special files.

47.2 Theory of operation

CHARACTER DEVICE. Using the standard open() and read() system calls, you can read random data from the hardware RNG device. This data is NOT CHECKED by any fitness tests, and could potentially be bogus (if the hardware is faulty or has been tampered with). Data is only output if the hardware ”has-data” flag is set, but nevertheless a security-conscious person would run fitness tests on the data before assuming it is truly random.

The rng-tools package uses such tests in ”rngd”, and lets you run them by hand with a ”rngtest” utility.

/dev/hwrng is char device major 10, minor 183.

CLASS DEVICE. There is a /sys/class/misc/hw_random node with two unique attributes, ”rng_available” and ”rng_current”. The ”rng_available” attribute lists the hardware-specific drivers available, while ”rng_current” lists the one which is currently connected to /dev/hwrng. If your system has more than one RNG available, you may change the one used by writing a name from the list in ”rng_available” into ”rng_current”.

Hardware driver for Intel/AMD/VIA Random Number Generators (RNG)

- Copyright 2000,2001 Jeff Garzik <jgarzik@pobox.com>
- Copyright 2000,2001 Philipp Rumpf <prumpf@mandrakesoft.com>

47.3 About the Intel RNG hardware, from the firmware hub datasheet

The Firmware Hub integrates a Random Number Generator (RNG) using thermal noise generated from inherently random quantum mechanical properties of silicon. When not generating new random bits the RNG circuitry will enter a low power state. Intel will provide a binary software driver to give third party software access to our RNG for use as a security feature. At this time, the RNG is only to be used with a system in an OS-present state.

47.4 Intel RNG Driver notes

FIXME: support poll(2)

Note: request_mem_region was removed, for three reasons:

1) Only one RNG is supported by this driver;
2) The location used by the RNG is a fixed location in MMIO-addressable memory;
3) users with properly working BIOS e820 handling will always have the region in which the RNG is located reserved, so request_mem_region calls always fail for proper setups. However, for people who use mem=XX, BIOS e820 information is **not** in /proc/iomem, and request_mem_region(RNG_ADDR) can succeed.

CHAPTER

FORTYEIGHT

USING THE INITIAL RAM DISK (INITRD)

Written 1996,2000 by Werner Almesberger <werner.almesberger@epfl.ch> and Hans Lermen <lermen@fgan.de>

initrd provides the capability to load a RAM disk by the boot loader. This RAM disk can then be mounted as the root file system and programs can be run from it. Afterwards, a new root file system can be mounted from a different device. The previous root (from initrd) is then moved to a directory and can be subsequently unmounted.

initrd is mainly designed to allow system startup to occur in two phases, where the kernel comes up with a minimum set of compiled-in drivers, and where additional modules are loaded from initrd.

This document gives a brief overview of the use of initrd. A more detailed discussion of the boot process can be found in[1].

48.1 Operation

When using initrd, the system typically boots as follows:

1) the boot loader loads the kernel and the initial RAM disk
2) the kernel converts initrd into a ”normal” RAM disk and frees the memory used by initrd
3) if the root device is not `/dev/ram0`, the old (deprecated) change_root procedure is followed. see the ”Obsolete root change mechanism” section below.
4) root device is mounted. if it is `/dev/ram0`, the initrd image is then mounted as root
5) /sbin/init is executed (this can be any valid executable, including shell scripts; it is run with uid 0 and can do basically everything init can do).
6) init mounts the ”real” root file system
7) init places the root file system at the root directory using the pivot_root system call
8) init execs the `/sbin/init` on the new root filesystem, performing the usual boot sequence
9) the initrd file system is removed

Note that changing the root directory does not involve unmounting it. It is therefore possible to leave processes running on initrd during that procedure. Also note that file systems mounted under initrd continue to be accessible.

[1] Almesberger, Werner; ”Booting Linux: The History and the Future” https://www.almesberger.net/cv/papers/ols2k-9.ps.gz

48.2 Boot command-line options

initrd adds the following new options:

```
initrd=<path>    (e.g. LOADLIN)

  Loads the specified file as the initial RAM disk. When using LILO, you
  have to specify the RAM disk image file in /etc/lilo.conf, using the
  INITRD configuration variable.

noinitrd

  initrd data is preserved but it is not converted to a RAM disk and
  the "normal" root file system is mounted. initrd data can be read
  from /dev/initrd. Note that the data in initrd can have any structure
  in this case and doesn't necessarily have to be a file system image.
  This option is used mainly for debugging.

  Note: /dev/initrd is read-only and it can only be used once. As soon
  as the last process has closed it, all data is freed and /dev/initrd
  can't be opened anymore.

root=/dev/ram0

  initrd is mounted as root, and the normal boot procedure is followed,
  with the RAM disk mounted as root.
```

48.3 Compressed cpio images

Recent kernels have support for populating a ramdisk from a compressed cpio archive. On such systems, the creation of a ramdisk image doesn't need to involve special block devices or loopbacks; you merely create a directory on disk with the desired initrd content, cd to that directory, and run (as an example):

```
find . | cpio --quiet -H newc -o | gzip -9 -n > /boot/imagefile.img
```

Examining the contents of an existing image file is just as simple:

```
mkdir /tmp/imagefile
cd /tmp/imagefile
gzip -cd /boot/imagefile.img | cpio -imd --quiet
```

48.4 Installation

First, a directory for the initrd file system has to be created on the "normal" root file system, e.g.:

```
# mkdir /initrd
```

The name is not relevant. More details can be found on the *pivot_root(2)* man page.

If the root file system is created during the boot procedure (i.e. if you're building an install floppy), the root file system creation procedure should create the `/initrd` directory.

If initrd will not be mounted in some cases, its content is still accessible if the following device has been created:

```
# mknod /dev/initrd b 1 250
# chmod 400 /dev/initrd
```

Second, the kernel has to be compiled with RAM disk support and with support for the initial RAM disk enabled. Also, at least all components needed to execute programs from initrd (e.g. executable format and file system) must be compiled into the kernel.

Third, you have to create the RAM disk image. This is done by creating a file system on a block device, copying files to it as needed, and then copying the content of the block device to the initrd file. With recent kernels, at least three types of devices are suitable for that:

- a floppy disk (works everywhere but it's painfully slow)
- a RAM disk (fast, but allocates physical memory)
- a loopback device (the most elegant solution)

We'll describe the loopback device method:

1) make sure loopback block devices are configured into the kernel
2) create an empty file system of the appropriate size, e.g.:

   ```
   # dd if=/dev/zero of=initrd bs=300k count=1
   # mke2fs -F -m0 initrd
   ```

   (if space is critical, you may want to use the Minix FS instead of Ext2)
3) mount the file system, e.g.:

   ```
   # mount -t ext2 -o loop initrd /mnt
   ```
4) create the console device:

   ```
   # mkdir /mnt/dev
   # mknod /mnt/dev/console c 5 1
   ```
5) copy all the files that are needed to properly use the initrd environment. Don't forget the most important file, `/sbin/init`

   Note: `/sbin/init` permissions must include "x" (execute).

6) correct operation the initrd environment can frequently be tested even without rebooting with the command:

```
# chroot /mnt /sbin/init
```

This is of course limited to initrds that do not interfere with the general system state (e.g. by reconfiguring network interfaces, overwriting mounted devices, trying to start already running demons, etc. Note however that it is usually possible to use pivot_root in such a chroot'ed initrd environment.)

7) unmount the file system:

```
# umount /mnt
```

8) the initrd is now in the file "initrd". Optionally, it can now be compressed:

```
# gzip -9 initrd
```

For experimenting with initrd, you may want to take a rescue floppy and only add a symbolic link from `/sbin/init` to `/bin/sh`. Alternatively, you can try the experimental newlib environment[2] to create a small initrd.

Finally, you have to boot the kernel and load initrd. Almost all Linux boot loaders support initrd. Since the boot process is still compatible with an older mechanism, the following boot command line parameters have to be given:

```
root=/dev/ram0 rw
```

(rw is only necessary if writing to the initrd file system.)

With LOADLIN, you simply execute:

```
LOADLIN <kernel> initrd=<disk_image>
```

e.g.:

```
LOADLIN C:\LINUX\BZIMAGE initrd=C:\LINUX\INITRD.GZ root=/dev/ram0 rw
```

With LILO, you add the option `INITRD=<path>` to either the global section or to the section of the respective kernel in `/etc/lilo.conf`, and pass the options using APPEND, e.g.:

```
image = /bzImage
  initrd = /boot/initrd.gz
  append = "root=/dev/ram0 rw"
```

and run `/sbin/lilo`

For other boot loaders, please refer to the respective documentation.

Now you can boot and enjoy using initrd.

[2] newlib package (experimental), with initrd example https://www.sourceware.org/newlib/

48.5 Changing the root device

When finished with its duties, init typically changes the root device and proceeds with starting the Linux system on the "real" root device.

The procedure involves the following steps:

- mounting the new root file system
- turning it into the root file system
- removing all accesses to the old (initrd) root file system
- unmounting the initrd file system and de-allocating the RAM disk

Mounting the new root file system is easy: it just needs to be mounted on a directory under the current root. Example:

```
# mkdir /new-root
# mount -o ro /dev/hda1 /new-root
```

The root change is accomplished with the pivot_root system call, which is also available via the `pivot_root` utility (see *`pivot_root(8)`* man page; `pivot_root` is distributed with util-linux version 2.10h or higher[3]). `pivot_root` moves the current root to a directory under the new root, and puts the new root at its place. The directory for the old root must exist before calling `pivot_root`. Example:

```
# cd /new-root
# mkdir initrd
# pivot_root . initrd
```

Now, the init process may still access the old root via its executable, shared libraries, standard input/output/error, and its current root directory. All these references are dropped by the following command:

```
# exec chroot . what-follows <dev/console >dev/console 2>&1
```

Where what-follows is a program under the new root, e.g. `/sbin/init` If the new root file system will be used with udev and has no valid `/dev` directory, udev must be initialized before invoking chroot in order to provide `/dev/console`.

Note: implementation details of pivot_root may change with time. In order to ensure compatibility, the following points should be observed:

- before calling pivot_root, the current directory of the invoking process should point to the new root directory
- use . as the first argument, and the _relative_ path of the directory for the old root as the second argument
- a chroot program must be available under the old and the new root
- chroot to the new root afterwards
- use relative paths for dev/console in the exec command

[3] util-linux: Miscellaneous utilities for Linux https://www.kernel.org/pub/linux/utils/util-linux/

Now, the initrd can be unmounted and the memory allocated by the RAM disk can be freed:

```
# umount /initrd
# blockdev --flushbufs /dev/ram0
```

It is also possible to use initrd with an NFS-mounted root, see the *pivot_root(8)* man page for details.

48.6 Usage scenarios

The main motivation for implementing initrd was to allow for modular kernel configuration at system installation. The procedure would work as follows:

1) system boots from floppy or other media with a minimal kernel (e.g. support for RAM disks, initrd, a.out, and the Ext2 FS) and loads initrd
2) `/sbin/init` determines what is needed to (1) mount the "real" root FS (i.e. device type, device drivers, file system) and (2) the distribution media (e.g. CD-ROM, network, tape, ...). This can be done by asking the user, by auto-probing, or by using a hybrid approach.
3) `/sbin/init` loads the necessary kernel modules
4) `/sbin/init` creates and populates the root file system (this doesn't have to be a very usable system yet)
5) `/sbin/init` invokes `pivot_root` to change the root file system and execs - via chroot - a program that continues the installation
6) the boot loader is installed
7) the boot loader is configured to load an initrd with the set of modules that was used to bring up the system (e.g. `/initrd` can be modified, then unmounted, and finally, the image is written from `/dev/ram0` or `/dev/rd/0` to a file)
8) now the system is bootable and additional installation tasks can be performed

The key role of initrd here is to re-use the configuration data during normal system operation without requiring the use of a bloated "generic" kernel or re-compiling or re-linking the kernel.

A second scenario is for installations where Linux runs on systems with different hardware configurations in a single administrative domain. In such cases, it is desirable to generate only a small set of kernels (ideally only one) and to keep the system-specific part of configuration information as small as possible. In this case, a common initrd could be generated with all the necessary modules. Then, only `/sbin/init` or a file read by it would have to be different.

A third scenario is more convenient recovery disks, because information like the location of the root FS partition doesn't have to be provided at boot time, but the system loaded from initrd can invoke a user-friendly dialog and it can also perform some sanity checks (or even some form of auto-detection).

Last not least, CD-ROM distributors may use it for better installation from CD, e.g. by using a boot floppy and bootstrapping a bigger RAM disk via initrd from CD; or by booting via a loader like `LOADLIN` or directly from the CD-ROM, and loading the RAM disk from CD without need of floppies.

48.7 Obsolete root change mechanism

The following mechanism was used before the introduction of pivot_root. Current kernels still support it, but you should _not_ rely on its continued availability.

It works by mounting the ”real” root device (i.e. the one set with rdev in the kernel image or with root=... at the boot command line) as the root file system when linuxrc exits. The initrd file system is then unmounted, or, if it is still busy, moved to a directory `/initrd`, if such a directory exists on the new root file system.

In order to use this mechanism, you do not have to specify the boot command options root, init, or rw. (If specified, they will affect the real root file system, not the initrd environment.)

If /proc is mounted, the ”real” root device can be changed from within linuxrc by writing the number of the new root FS device to the special file /proc/sys/kernel/real-root-dev, e.g.:

```
# echo 0x301 >/proc/sys/kernel/real-root-dev
```

Note that the mechanism is incompatible with NFS and similar file systems.

This old, deprecated mechanism is commonly called `change_root`, while the new, supported mechanism is called `pivot_root`.

48.8 Mixed change_root and pivot_root mechanism

In case you did not want to use `root=/dev/ram0` to trigger the pivot_root mechanism, you may create both `/linuxrc` and `/sbin/init` in your initrd image.

`/linuxrc` would contain only the following:

```
#! /bin/sh
mount -n -t proc proc /proc
echo 0x0100 >/proc/sys/kernel/real-root-dev
umount -n /proc
```

Once linuxrc exited, the kernel would mount again your initrd as root, this time executing `/sbin/init`. Again, it would be the duty of this init to build the right environment (maybe using the `root= device` passed on the cmdline) before the final execution of the real `/sbin/init`.

48.9 Resources

CHAPTER

FORTYNINE

I/O STATISTICS FIELDS

Since 2.4.20 (and some versions before, with patches), and 2.5.45, more extensive disk statistics have been introduced to help measure disk activity. Tools such as `sar` and `iostat` typically interpret these and do the work for you, but in case you are interested in creating your own tools, the fields are explained here.

In 2.4 now, the information is found as additional fields in `/proc/partitions`. In 2.6 and upper, the same information is found in two places: one is in the file `/proc/diskstats`, and the other is within the sysfs file system, which must be mounted in order to obtain the information. Throughout this document we'll assume that sysfs is mounted on `/sys`, although of course it may be mounted anywhere. Both `/proc/diskstats` and sysfs use the same source for the information and so should not differ.

Here are examples of these different formats:

```
2.4:
   3     0   39082680 hda 446216 784926 9550688 4382310 424847 312726 5922052␣
↪19310380 0 3376340 23705160
   3     1    9221278 hda1 35486 0 35496 38030 0 0 0 0 0 38030 38030

2.6+ sysfs:
   446216 784926 9550688 4382310 424847 312726 5922052 19310380 0 3376340␣
↪23705160
   35486    38030    38030    38030

2.6+ diskstats:
   3    0   hda 446216 784926 9550688 4382310 424847 312726 5922052 19310380 0␣
↪3376340 23705160
   3    1   hda1 35486 38030 38030 38030

4.18+ diskstats:
   3    0   hda 446216 784926 9550688 4382310 424847 312726 5922052 19310380 0␣
↪3376340 23705160 0 0 0 0
```

On 2.4 you might execute `grep 'hda ' /proc/partitions`. On 2.6+, you have a choice of `cat /sys/block/hda/stat` or `grep 'hda ' /proc/diskstats`.

The advantage of one over the other is that the sysfs choice works well if you are watching a known, small set of disks. `/proc/diskstats` may be a better choice if you are watching a large number of disks because you'll avoid the overhead of 50, 100, or 500 or more opens/closes with each snapshot of your disk statistics.

In 2.4, the statistics fields are those after the device name. In the above example, the first field of statistics would be 446216. By contrast, in 2.6+ if you look at `/sys/block/hda/stat`, you'll find just the 15 fields, beginning with 446216. If you look at `/proc/diskstats`, the 15 fields will be preceded by the major and minor device numbers, and device name. Each of these formats provides 15 fields of statistics, each meaning exactly the same things. All fields except field 9 are cumulative since boot. Field 9 should go to zero as I/Os complete; all others only increase (unless they overflow and wrap). Wrapping might eventually occur on a very busy or long-lived system; so applications should be prepared to deal with it. Regarding wrapping, the types of the fields are either unsigned int (32 bit) or unsigned long (32-bit or 64-bit, depending on your machine) as noted per-field below. Unless your observations are very spread in time, these fields should not wrap twice before you notice it.

Each set of stats only applies to the indicated device; if you want system-wide stats you'll have to find all the devices and sum them all up.

Field 1 -- # of reads completed (unsigned long)
This is the total number of reads completed successfully.

Field 2 -- # of reads merged, field 6 -- # of writes merged (unsigned long)
Reads and writes which are adjacent to each other may be merged for efficiency. Thus two 4K reads may become one 8K read before it is ultimately handed to the disk, and so it will be counted (and queued) as only one I/O. This field lets you know how often this was done.

Field 3 -- # of sectors read (unsigned long)
This is the total number of sectors read successfully.

Field 4 -- # of milliseconds spent reading (unsigned int)
This is the total number of milliseconds spent by all reads (as measured from blk_mq_alloc_request() to __blk_mq_end_request()).

Field 5 -- # of writes completed (unsigned long)
This is the total number of writes completed successfully.

Field 6 -- # of writes merged (unsigned long)
See the description of field 2.

Field 7 -- # of sectors written (unsigned long)
This is the total number of sectors written successfully.

Field 8 -- # of milliseconds spent writing (unsigned int)
This is the total number of milliseconds spent by all writes (as measured from blk_mq_alloc_request() to __blk_mq_end_request()).

Field 9 -- # of I/Os currently in progress (unsigned int)
The only field that should go to zero. Incremented as requests are given to appropriate struct request_queue and decremented as they finish.

Field 10 -- # of milliseconds spent doing I/Os (unsigned int)
This field increases so long as field 9 is nonzero.

Since 5.0 this field counts jiffies when at least one request was started or completed. If request runs more than 2 jiffies then some I/O time might be not accounted in case of concurrent requests.

Field 11 -- weighted # of milliseconds spent doing I/Os (unsigned int)
This field is incremented at each I/O start, I/O completion, I/O merge, or read of these stats by the number of I/Os in progress (field 9) times the number of milliseconds spent

doing I/O since the last update of this field. This can provide an easy measure of both I/O completion time and the backlog that may be accumulating.

Field 12 -- # of discards completed (unsigned long)
This is the total number of discards completed successfully.

Field 13 -- # of discards merged (unsigned long)
See the description of field 2

Field 14 -- # of sectors discarded (unsigned long)
This is the total number of sectors discarded successfully.

Field 15 -- # of milliseconds spent discarding (unsigned int)
This is the total number of milliseconds spent by all discards (as measured from blk_mq_alloc_request() to __blk_mq_end_request()).

Field 16 -- # of flush requests completed
This is the total number of flush requests completed successfully.

Block layer combines flush requests and executes at most one at a time. This counts flush requests executed by disk. Not tracked for partitions.

Field 17 -- # of milliseconds spent flushing
This is the total number of milliseconds spent by all flush requests.

To avoid introducing performance bottlenecks, no locks are held while modifying these counters. This implies that minor inaccuracies may be introduced when changes collide, so (for instance) adding up all the read I/Os issued per partition should equal those made to the disks ... but due to the lack of locking it may only be very close.

In 2.6+, there are counters for each CPU, which make the lack of locking almost a non-issue. When the statistics are read, the per-CPU counters are summed (possibly overflowing the unsigned long variable they are summed to) and the result given to the user. There is no convenient user interface for accessing the per-CPU counters themselves.

Since 4.19 request times are measured with nanoseconds precision and truncated to milliseconds before showing in this interface.

49.1 Disks vs Partitions

There were significant changes between 2.4 and 2.6+ in the I/O subsystem. As a result, some statistic information disappeared. The translation from a disk address relative to a partition to the disk address relative to the host disk happens much earlier. All merges and timings now happen at the disk level rather than at both the disk and partition level as in 2.4. Consequently, you'll see a different statistics output on 2.6+ for partitions from that for disks. There are only *four* fields available for partitions on 2.6+ machines. This is reflected in the examples above.

Field 1 -- # of reads issued
This is the total number of reads issued to this partition.

Field 2 -- # of sectors read
This is the total number of sectors requested to be read from this partition.

Field 3 -- # of writes issued
This is the total number of writes issued to this partition.

Field 4 -- # of sectors written

This is the total number of sectors requested to be written to this partition.

Note that since the address is translated to a disk-relative one, and no record of the partition-relative address is kept, the subsequent success or failure of the read cannot be attributed to the partition. In other words, the number of reads for partitions is counted slightly before time of queuing for partitions, and at completion for whole disks. This is a subtle distinction that is probably uninteresting for most cases.

More significant is the error induced by counting the numbers of reads/writes before merges for partitions and after for disks. Since a typical workload usually contains a lot of successive and adjacent requests, the number of reads/writes issued can be several times higher than the number of reads/writes completed.

In 2.6.25, the full statistic set is again available for partitions and disk and partition statistics are consistent again. Since we still don't keep record of the partition-relative address, an operation is attributed to the partition which contains the first sector of the request after the eventual merges. As requests can be merged across partition, this could lead to some (probably insignificant) inaccuracy.

49.2 Additional notes

In 2.6+, sysfs is not mounted by default. If your distribution of Linux hasn't added it already, here's the line you'll want to add to your `/etc/fstab`:

```
none /sys sysfs defaults 0 0
```

In 2.6+, all disk statistics were removed from `/proc/stat`. In 2.4, they appear in both `/proc/partitions` and `/proc/stat`, although the ones in `/proc/stat` take a very different format from those in `/proc/partitions` (see proc(5), if your system has it.)

CHAPTER

FIFTY

JAVA(TM) BINARY KERNEL SUPPORT FOR LINUX V1.03

Linux beats them ALL! While all other OS's are TALKING about direct support of Java Binaries in the OS, Linux is doing it!

You can execute Java applications and Java Applets just like any other program after you have done the following:

1) You MUST FIRST install the Java Developers Kit for Linux. The Java on Linux HOWTO gives the details on getting and installing this. This HOWTO can be found at:

   ftp://sunsite.unc.edu/pub/Linux/docs/HOWTO/Java-HOWTO

   You should also set up a reasonable CLASSPATH environment variable to use Java applications that make use of any nonstandard classes (not included in the same directory as the application itself).

2) You have to compile BINFMT_MISC either as a module or into the kernel (`CONFIG_BINFMT_MISC`) and set it up properly. If you choose to compile it as a module, you will have to insert it manually with modprobe/insmod, as kmod cannot easily be supported with binfmt_misc. Read the file 'binfmt_misc.txt' in this directory to know more about the configuration process.

3) Add the following configuration items to binfmt_misc (you should really have read `binfmt_misc.txt` now): support for Java applications:

```
':Java:M::\xca\xfe\xba\xbe::/usr/local/bin/javawrapper:'
```

   support for executable Jar files:

```
':ExecutableJAR:E::jar::/usr/local/bin/jarwrapper:'
```

   support for Java Applets:

```
':Applet:E::html::/usr/bin/appletviewer:'
```

   or the following, if you want to be more selective:

```
':Applet:M::<!--applet::/usr/bin/appletviewer:'
```

   Of course you have to fix the path names. The path/file names given in this document match the Debian 2.1 system. (i.e. jdk installed in `/usr`, custom wrappers from this document in `/usr/local`)

   Note, that for the more selective applet support you have to modify existing html-files to contain `<!--applet-->` in the first line (< has to be the first character!) to let this work!

For the compiled Java programs you need a wrapper script like the following (this is because Java is broken in case of the filename handling), again fix the path names, both in the script and in the above given configuration string.

You, too, need the little program after the script. Compile like:

```
gcc -O2 -o javaclassname javaclassname.c
```

and stick it to `/usr/local/bin`.

Both the javawrapper shellscript and the javaclassname program were supplied by Colin J. Watson <cjw44@cam.ac.uk>.

Javawrapper shell script:

```
#!/bin/bash
# /usr/local/bin/javawrapper - the wrapper for binfmt_misc/java

if [ -z "$1" ]; then
      exec 1>&2
      echo Usage: $0 class-file
      exit 1
fi

CLASS=$1
FQCLASS=`/usr/local/bin/javaclassname $1`
FQCLASSN=`echo $FQCLASS | sed -e 's/^.*\.\([^.]*\)$/\1/'`
FQCLASSP=`echo $FQCLASS | sed -e 's-\.-/-g' -e 's-^[^/]*$--' -e 's-/[^/]*$--'`

# for example:
# CLASS=Test.class
# FQCLASS=foo.bar.Test
# FQCLASSN=Test
# FQCLASSP=foo/bar

unset CLASSBASE

declare -i LINKLEVEL=0

while :; do
      if [ "`basename $CLASS .class`" == "$FQCLASSN" ]; then
              # See if this directory works straight off
              cd -L `dirname $CLASS`
              CLASSDIR=$PWD
              cd $OLDPWD
              if echo $CLASSDIR | grep -q "$FQCLASSP$"; then
                      CLASSBASE=`echo $CLASSDIR | sed -e "s.$FQCLASSP$.."`
                      break;
              fi
              # Try dereferencing the directory name
              cd -P `dirname $CLASS`
              CLASSDIR=$PWD
              cd $OLDPWD
```

```
                if echo $CLASSDIR | grep -q "$FQCLASSP$"; then
                        CLASSBASE=`echo $CLASSDIR | sed -e "s.$FQCLASSP$.."`
                        break;
                fi
                # If no other possible filename exists

    {
            u_int8_t x = read_8(classfile);
            if((x & 0x80) || !x)
            {
                    if((x & 0xE0) == 0xC0)
                    {
                            u_int8_t y = read_8(classfile);
                            if((y & 0xC0) == 0x80)
                            {
                                    int c = ((x & 0x1f) << 6) + (y & 0x3f);
                                    if(c) putchar(c);
                                    else utf8_error();
                            }
                            else utf8_error();
                    }
                    else utf8_error();
            }
            else if(x == '/') putchar('.');
            else putchar(x);
    }
    putchar('\n');
    free(pool);
    fclose(classfile);
```

```
      return 0;
}
```

jarwrapper:

```
#!/bin/bash
# /usr/local/java/bin/jarwrapper - the wrapper for binfmt_misc/jar

java -jar $1
```

Now simply `chmod +x` the `.class`, `.jar` and/or `.html` files you want to execute.

To add a Java program to your path best put a symbolic link to the main .class file into /usr/bin (or another place you like) omitting the .class extension. The directory containing the original .class file will be added to your CLASSPATH during execution.

To test your new setup, enter in the following simple Java app, and name it "HelloWorld.java":

```
class HelloWorld {
        public static void main(String args[]) {
                System.out.println("Hello World!");
        }
}
```

Now compile the application with:

```
javac HelloWorld.java
```

Set the executable permissions of the binary file, with:

```
chmod 755 HelloWorld.class
```

And then execute it:

```
./HelloWorld.class
```

To execute Java Jar files, simple chmod the `*.jar` files to include the execution bit, then just do:

```
./Application.jar
```

To execute Java Applets, simple chmod the `*.html` files to include the execution bit, then just do:

```
./Applet.html
```

originally by Brian A. Lantz, brian@lantz.com heavily edited for binfmt_misc by Richard Günther new scripts by Colin J. Watson <cjw44@cam.ac.uk> added executable Jar file support by Kurt Huwig <kurt@iku-netz.de>

IBM'S JOURNALED FILE SYSTEM (JFS) FOR LINUX

JFS Homepage: http://jfs.sourceforge.net/

The following mount options are supported:

(*) == default

iocharset=name
Character set to use for converting from Unicode to ASCII. The default is to do no conversion. Use iocharset=utf8 for UTF-8 translations. This requires CONFIG_NLS_UTF8 to be set in the kernel .config file. iocharset=none specifies the default behavior explicitly.

resize=value
Resize the volume to <value> blocks. JFS only supports growing a volume, not shrinking it. This option is only valid during a remount, when the volume is mounted read-write. The resize keyword with no value will grow the volume to the full size of the partition.

nointegrity
Do not write to the journal. The primary use of this option is to allow for higher performance when restoring a volume from backup media. The integrity of the volume is not guaranteed if the system abnormally abends.

integrity(*)
Commit metadata changes to the journal. Use this option to remount a volume where the nointegrity option was previously specified in order to restore normal behavior.

errors=continue
Keep going on a filesystem error.

errors=remount-ro(*)
Remount the filesystem read-only on an error.

errors=panic
Panic and halt the machine if an error occurs.

uid=value
Override on-disk uid with specified value

gid=value
Override on-disk gid with specified value

umask=value
Override on-disk umask with specified octal value. For directories, the execute bit will be set if the corresponding read bit is set.

discard=minlen, discard/nodiscard(*)
This enables/disables the use of discard/TRIM commands. The discard/TRIM commands

are sent to the underlying block device when blocks are freed. This is useful for SSD devices and sparse/thinly-provisioned LUNs. The FITRIM ioctl command is also available together with the nodiscard option. The value of minlen specifies the minimum blockcount, when a TRIM command to the block device is considered useful. When no value is given to the discard option, it defaults to 64 blocks, which means 256KiB in JFS. The minlen value of discard overrides the minlen value given on an FITRIM ioctl().

The JFS mailing list can be subscribed to by using the link labeled ”Mail list Subscribe” at our web page http://jfs.sourceforge.net/

CHAPTER

FIFTYTWO

REDUCING OS JITTER DUE TO PER-CPU KTHREADS

This document lists per-CPU kthreads in the Linux kernel and presents options to control their OS jitter. Note that non-per-CPU kthreads are not listed here. To reduce OS jitter from non-per-CPU kthreads, bind them to a ”housekeeping” CPU dedicated to such work.

52.1 References

- Documentation/core-api/irq/irq-affinity.rst: Binding interrupts to sets of CPUs.
- Documentation/admin-guide/cgroup-v1: Using cgroups to bind tasks to sets of CPUs.
- man taskset: Using the taskset command to bind tasks to sets of CPUs.
- man sched_setaffinity: Using the sched_setaffinity() system call to bind tasks to sets of CPUs.
- /sys/devices/system/cpu/cpuN/online: Control CPU N's hotplug state, writing ”0” to offline and ”1” to online.
- In order to locate kernel-generated OS jitter on CPU N:

  cd /sys/kernel/tracing echo 1 > max_graph_depth # Increase the ”1” for more detail echo function_graph > current_tracer # run workload cat per_cpu/cpuN/trace

52.2 kthreads

Name:
ehca_comp/%u

Purpose:
Periodically process Infiniband-related work.

To reduce its OS jitter, do any of the following:

1. Don't use eHCA Infiniband hardware, instead choosing hardware that does not require per-CPU kthreads. This will prevent these kthreads from being created in the first place. (This will work for most people, as this hardware, though important, is relatively old and is produced in relatively low unit volumes.)
2. Do all eHCA-Infiniband-related work on other CPUs, including interrupts.
3. Rework the eHCA driver so that its per-CPU kthreads are provisioned only on selected CPUs.

Name:
irq/%d-%s

Purpose:
Handle threaded interrupts.

To reduce its OS jitter, do the following:

1. Use irq affinity to force the irq threads to execute on some other CPU.

Name:
kcmtpd_ctr_%d

Purpose:
Handle Bluetooth work.

To reduce its OS jitter, do one of the following:

1. Don't use Bluetooth, in which case these kthreads won't be created in the first place.
2. Use irq affinity to force Bluetooth-related interrupts to occur on some other CPU and furthermore initiate all Bluetooth activity on some other CPU.

Name:
ksoftirqd/%u

Purpose:
Execute softirq handlers when threaded or when under heavy load.

To reduce its OS jitter, each softirq vector must be handled separately as follows:

52.2.1 TIMER_SOFTIRQ

Do all of the following:

1. To the extent possible, keep the CPU out of the kernel when it is non-idle, for example, by avoiding system calls and by forcing both kernel threads and interrupts to execute elsewhere.
2. Build with CONFIG_HOTPLUG_CPU=y. After boot completes, force the CPU offline, then bring it back online. This forces recurring timers to migrate elsewhere. If you are concerned with multiple CPUs, force them all offline before bringing the first one back online. Once you have onlined the CPUs in question, do not offline any other CPUs, because doing so could force the timer back onto one of the CPUs in question.

52.2.2 NET_TX_SOFTIRQ and NET_RX_SOFTIRQ

Do all of the following:

1. Force networking interrupts onto other CPUs.
2. Initiate any network I/O on other CPUs.
3. Once your application has started, prevent CPU-hotplug operations from being initiated from tasks that might run on the CPU to be de-jittered. (It is OK to force this CPU offline and then bring it back online before you start your application.)

52.2.3 BLOCK_SOFTIRQ

Do all of the following:

1. Force block-device interrupts onto some other CPU.
2. Initiate any block I/O on other CPUs.
3. Once your application has started, prevent CPU-hotplug operations from being initiated from tasks that might run on the CPU to be de-jittered. (It is OK to force this CPU offline and then bring it back online before you start your application.)

52.2.4 IRQ_POLL_SOFTIRQ

Do all of the following:

1. Force block-device interrupts onto some other CPU.
2. Initiate any block I/O and block-I/O polling on other CPUs.
3. Once your application has started, prevent CPU-hotplug operations from being initiated from tasks that might run on the CPU to be de-jittered. (It is OK to force this CPU offline and then bring it back online before you start your application.)

52.2.5 TASKLET_SOFTIRQ

Do one or more of the following:

1. Avoid use of drivers that use tasklets. (Such drivers will contain calls to things like tasklet_schedule().)
2. Convert all drivers that you must use from tasklets to workqueues.
3. Force interrupts for drivers using tasklets onto other CPUs, and also do I/O involving these drivers on other CPUs.

52.2.6 SCHED_SOFTIRQ

Do all of the following:

1. Avoid sending scheduler IPIs to the CPU to be de-jittered, for example, ensure that at most one runnable kthread is present on that CPU. If a thread that expects to run on the de-jittered CPU awakens, the scheduler will send an IPI that can result in a subsequent SCHED_SOFTIRQ.
2. CONFIG_NO_HZ_FULL=y and ensure that the CPU to be de-jittered is marked as an adaptive-ticks CPU using the ”nohz_full=” boot parameter. This reduces the number of scheduler-clock interrupts that the de-jittered CPU receives, minimizing its chances of being selected to do the load balancing work that runs in SCHED_SOFTIRQ context.
3. To the extent possible, keep the CPU out of the kernel when it is non-idle, for example, by avoiding system calls and by forcing both kernel threads and interrupts to execute elsewhere. This further reduces the number of scheduler-clock interrupts received by the de-jittered CPU.

52.2.7 HRTIMER_SOFTIRQ

Do all of the following:

1. To the extent possible, keep the CPU out of the kernel when it is non-idle. For example, avoid system calls and force both kernel threads and interrupts to execute elsewhere.
2. Build with CONFIG_HOTPLUG_CPU=y. Once boot completes, force the CPU offline, then bring it back online. This forces recurring timers to migrate elsewhere. If you are concerned with multiple CPUs, force them all offline before bringing the first one back online. Once you have onlined the CPUs in question, do not offline any other CPUs, because doing so could force the timer back onto one of the CPUs in question.

52.2.8 RCU_SOFTIRQ

Do at least one of the following:

1. Offload callbacks and keep the CPU in either dyntick-idle or adaptive-ticks state by doing all of the following:
   a. CONFIG_NO_HZ_FULL=y and ensure that the CPU to be de-jittered is marked as an adaptive-ticks CPU using the "nohz_full=" boot parameter. Bind the rcuo kthreads to housekeeping CPUs, which can tolerate OS jitter.
   b. To the extent possible, keep the CPU out of the kernel when it is non-idle, for example, by avoiding system calls and by forcing both kernel threads and interrupts to execute elsewhere.
2. Enable RCU to do its processing remotely via dyntick-idle by doing all of the following:
   a. Build with CONFIG_NO_HZ=y.
   b. Ensure that the CPU goes idle frequently, allowing other CPUs to detect that it has passed through an RCU quiescent state. If the kernel is built with CONFIG_NO_HZ_FULL=y, userspace execution also allows other CPUs to detect that the CPU in question has passed through a quiescent state.
   c. To the extent possible, keep the CPU out of the kernel when it is non-idle, for example, by avoiding system calls and by forcing both kernel threads and interrupts to execute elsewhere.

Name:
kworker/%u:%d%s (cpu, id, priority)

Purpose:
Execute workqueue requests

To reduce its OS jitter, do any of the following:

1. Run your workload at a real-time priority, which will allow preempting the kworker daemons.
2. A given workqueue can be made visible in the sysfs filesystem by passing the WQ_SYSFS to that workqueue's alloc_workqueue(). Such a workqueue can be confined to a given subset of the CPUs using the `/sys/devices/virtual/workqueue/*/cpumask` sysfs files. The set of WQ_SYSFS workqueues can be displayed using "ls /sys/devices/virtual/workqueue". That said, the workqueues maintainer would like to caution people against indiscriminately sprinkling WQ_SYSFS across all the workqueues. The reason for caution is that it is easy

to add WQ_SYSFS, but because sysfs is part of the formal user/kernel API, it can be nearly impossible to remove it, even if its addition was a mistake.

3. Do any of the following needed to avoid jitter that your application cannot tolerate:

   a. Avoid using oprofile, thus avoiding OS jitter from wq_sync_buffer().

   b. Limit your CPU frequency so that a CPU-frequency governor is not required, possibly enlisting the aid of special heatsinks or other cooling technologies. If done correctly, and if you CPU architecture permits, you should be able to build your kernel with CONFIG_CPU_FREQ=n to avoid the CPU-frequency governor periodically running on each CPU, including cs_dbs_timer() and od_dbs_timer().

      WARNING: Please check your CPU specifications to make sure that this is safe on your particular system.

   c. As of v3.18, Christoph Lameter's on-demand vmstat workers commit prevents OS jitter due to vmstat_update() on CONFIG_SMP=y systems. Before v3.18, is not possible to entirely get rid of the OS jitter, but you can decrease its frequency by writing a large value to /proc/sys/vm/stat_interval. The default value is HZ, for an interval of one second. Of course, larger values will make your virtual-memory statistics update more slowly. Of course, you can also run your workload at a real-time priority, thus preempting vmstat_update(), but if your workload is CPU-bound, this is a bad idea. However, there is an RFC patch from Christoph Lameter (based on an earlier one from Gilad Ben-Yossef) that reduces or even eliminates vmstat overhead for some workloads at https://lore.kernel.org/r/00000140e9dfd6bd-40db3d4f-c1be-434f-8132-7820f81bb586-000000@email.amazonses.com.

   d. If running on high-end powerpc servers, build with CONFIG_PPC_RTAS_DAEMON=n. This prevents the RTAS daemon from running on each CPU every second or so. (This will require editing Kconfig files and will defeat this platform's RAS functionality.) This avoids jitter due to the rtas_event_scan() function. WARNING: Please check your CPU specifications to make sure that this is safe on your particular system.

   e. If running on Cell Processor, build your kernel with CBE_CPUFREQ_SPU_GOVERNOR=n to avoid OS jitter from spu_gov_work(). WARNING: Please check your CPU specifications to make sure that this is safe on your particular system.

   f. If running on PowerMAC, build your kernel with CONFIG_PMAC_RACKMETER=n to disable the CPU-meter, avoiding OS jitter from rackmeter_do_timer().

Name:
rcuc/%u

Purpose:
Execute RCU callbacks in CONFIG_RCU_BOOST=y kernels.

To reduce its OS jitter, do at least one of the following:

1. Build the kernel with CONFIG_PREEMPT=n. This prevents these kthreads from being created in the first place, and also obviates the need for RCU priority boosting. This approach is feasible for workloads that do not require high degrees of responsiveness.

2. Build the kernel with CONFIG_RCU_BOOST=n. This prevents these kthreads from being created in the first place. This approach is feasible only if your workload never requires

RCU priority boosting, for example, if you ensure frequent idle time on all CPUs that might execute within the kernel.

3. Build with CONFIG_RCU_NOCB_CPU=y and boot with the rcu_nocbs= boot parameter offloading RCU callbacks from all CPUs susceptible to OS jitter. This approach prevents the rcuc/%u kthreads from having any work to do, so that they are never awakened.
4. Ensure that the CPU never enters the kernel, and, in particular, avoid initiating any CPU hotplug operations on this CPU. This is another way of preventing any callbacks from being queued on the CPU, again preventing the rcuc/%u kthreads from having any work to do.

Name:
rcuop/%d and rcuos/%d

Purpose:
Offload RCU callbacks from the corresponding CPU.

To reduce its OS jitter, do at least one of the following:

1. Use affinity, cgroups, or other mechanism to force these kthreads to execute on some other CPU.
2. Build with CONFIG_RCU_NOCB_CPU=n, which will prevent these kthreads from being created in the first place. However, please note that this will not eliminate OS jitter, but will instead shift it to RCU_SOFTIRQ.

CHAPTER

FIFTYTHREE

LAPTOP DRIVERS

53.1 Asus Laptop Extras

Version 0.1

August 6, 2009

Corentin Chary <corentincj@iksaif.net> http://acpi4asus.sf.net/

This driver provides support for extra features of ACPI-compatible ASUS laptops. It may also support some MEDION, JVC or VICTOR laptops (such as MEDION 9675 or VICTOR XP7210 for example). It makes all the extra buttons generate input events (like keyboards).

On some models adds support for changing the display brightness and output, switching the LCD backlight on and off, and most importantly, allows you to blink those fancy LEDs intended for reporting mail and wireless status.

This driver supersedes the old asus_acpi driver.

53.1.1 Requirements

Kernel 2.6.X sources, configured for your computer, with ACPI support. You also need CONFIG_INPUT and CONFIG_ACPI.

53.1.2 Status

The features currently supported are the following (see below for detailed description):

- Fn key combinations
- Bluetooth enable and disable
- Wlan enable and disable
- GPS enable and disable
- Video output switching
- Ambient Light Sensor on and off
- LED control
- LED Display control

- LCD brightness control
- LCD on and off

A compatibility table by model and feature is maintained on the web site, http://acpi4asus.sf.net/.

53.1.3 Usage

Try "modprobe asus-laptop". Check your dmesg (simply type dmesg). You should see some lines like this :

Asus Laptop Extras version 0.42

- L2D model detected.

If it is not the output you have on your laptop, send it (and the laptop's DSDT) to me.

That's all, now, all the events generated by the hotkeys of your laptop should be reported via netlink events. You can check with "acpi_genl monitor" (part of the acpica project).

Hotkeys are also reported as input keys (like keyboards) you can check which key are supported using "xev" under X11.

You can get information on the version of your DSDT table by reading the /sys/devices/platform/asus-laptop/infos entry. If you have a question or a bug report to do, please include the output of this entry.

53.1.4 LEDs

You can modify LEDs be echoing values to */sys/class/leds/asus/*/brightness*:

```
echo 1 >  /sys/class/leds/asus::mail/brightness
```

will switch the mail LED on.

You can also know if they are on/off by reading their content and use kernel triggers like disk-activity or heartbeat.

53.1.5 Backlight

You can control lcd backlight power and brightness with /sys/class/backlight/asus-laptop/. Brightness Values are between 0 and 15.

53.1.6 Wireless devices

You can turn the internal Bluetooth adapter on/off with the bluetooth entry (only on models with Bluetooth). This usually controls the associated LED. Same for Wlan adapter.

53.1.7 Display switching

Note: the display switching code is currently considered EXPERIMENTAL.

Switching works for the following models:

- L3800C
- A2500H
- L5800C
- M5200N
- W1000N (albeit with some glitches)
- M6700R
- A6JC
- F3J

Switching doesn't work for the following:

- M3700N
- L2X00D (locks the laptop under certain conditions)

To switch the displays, echo values from 0 to 15 to /sys/devices/platform/asus-laptop/display. The significance of those values is as follows:

Bin	Val	DVI	TV	CRT	LCD
0000	0				
0001	1				X
0010	2			X	
0011	3			X	X
0100	4		X		
0101	5		X		X
0110	6		X	X	
0111	7		X	X	X
1000	8	X			
1001	9	X			X
1010	10	X		X	
1011	11	X		X	X
1100	12	X	X		
1101	13	X	X		X
1110	14	X	X	X	
1111	15	X	X	X	X

In most cases, the appropriate displays must be plugged in for the above combinations to work. TV-Out may need to be initialized at boot time.

Debugging:

1) Check whether the Fn+F8 key:

   a) does not lock the laptop (try a boot with noapic / nolapic if it does)

   b) generates events (0x6n, where n is the value corresponding to the configuration above)

   c) actually works

   Record the disp value at every configuration.

2) Echo values from 0 to 15 to /sys/devices/platform/asus-laptop/display. Record its value, note any change. If nothing changes, try a broader range, up to 65535.

3) Send ANY output (both positive and negative reports are needed, unless your machine is already listed above) to the acpi4asus-user mailing list.

Note: on some machines (e.g. L3C), after the module has been loaded, only 0x6n events are generated and no actual switching occurs. In such a case, a line like:

```
echo $((10#$arg-60)) > /sys/devices/platform/asus-laptop/display
```

will usually do the trick ($arg is the 0000006n-like event passed to acpid).

Note: there is currently no reliable way to read display status on xxN (Centrino) models.

53.1.8 LED display

Some models like the W1N have a LED display that can be used to display several items of information.

LED display works for the following models:

- W1000N
- W1J

To control the LED display, use the following:

```
echo 0x0T000DDD > /sys/devices/platform/asus-laptop/
```

where T control the 3 letters display, and DDD the 3 digits display, according to the tables below:

```
DDD (digits)
000 to 999 = display digits
AAA        = ---
BBB to FFF = turn-off

T  (type)
0 = off
1 = dvd
```

```
2 = vcd
3 = mp3
4 = cd
5 = tv
6 = cpu
7 = vol
```

For example ”echo 0x01000001 >/sys/devices/platform/asus-laptop/ledd” would display ”DVD001”.

53.1.9 Driver options

Options can be passed to the asus-laptop driver using the standard module argument syntax (<param>=<value> when passing the option to the module or asus-laptop.<param>=<value> on the kernel boot line when asus-laptop is statically linked into the kernel).

wapf: WAPF defines the behavior of the Fn+Fx wlan key
The significance of values is yet to be found, but most of the time:

- 0x0 should do nothing
- 0x1 should allow to control the device with Fn+Fx key.
- 0x4 should send an ACPI event (0x88) while pressing the Fn+Fx key
- 0x5 like 0x1 or 0x4

The default value is 0x1.

53.1.10 Unsupported models

These models will never be supported by this module, as they use a completely different mechanism to handle LEDs and extra stuff (meaning we have no clue how it works):

- ASUS A1300 (A1B), A1370D
- ASUS L7300G
- ASUS L8400

53.1.11 Patches, Errors, Questions

I appreciate any success or failure reports, especially if they add to or correct the compatibility table. Please include the following information in your report:

- Asus model name
- a copy of your ACPI tables, using the ”acpidump” utility
- a copy of /sys/devices/platform/asus-laptop/infos
- which driver features work and which don't
- the observed behavior of non-working features

Any other comments or patches are also more than welcome.

53.2 Hard disk shock protection

Author: Elias Oltmanns <eo@nebensachen.de>

Last modified: 2008-10-03

53.2.1 1. Intro

ATA/ATAPI-7 specifies the IDLE IMMEDIATE command with unload feature. Issuing this command should cause the drive to switch to idle mode and unload disk heads. This feature is being used in modern laptops in conjunction with accelerometers and appropriate software to implement a shock protection facility. The idea is to stop all I/O operations on the internal hard drive and park its heads on the ramp when critical situations are anticipated. The desire to have such a feature available on GNU/Linux systems has been the original motivation to implement a generic disk head parking interface in the Linux kernel. Please note, however, that other components have to be set up on your system in order to get disk shock protection working (see section 3. References below for pointers to more information about that).

53.2.2 2. The interface

For each ATA device, the kernel exports the file *block/*/device/unload_heads* in sysfs (here assumed to be mounted under /sys). Access to */sys/block/*/device/unload_heads* is denied with -EOPNOTSUPP if the device does not support the unload feature. Otherwise, writing an integer value to this file will take the heads of the respective drive off the platter and block all I/O operations for the specified number of milliseconds. When the timeout expires and no further disk head park request has been issued in the meantime, normal operation will be resumed. The maximal value accepted for a timeout is 30000 milliseconds. Exceeding this limit will return -EOVERFLOW, but heads will be parked anyway and the timeout will be set to 30 seconds. However, you can always change a timeout to any value between 0 and 30000 by issuing a subsequent head park request before the timeout of the previous one has expired. In particular, the total timeout can exceed 30 seconds and, more importantly, you can cancel a previously set timeout and resume normal operation immediately by specifying a timeout of 0. Values below -2 are rejected with -EINVAL (see below for the special meaning of -1 and -2). If the timeout specified for a recent head park request has not yet expired, reading from */sys/block/*/device/unload_heads* will report the number of milliseconds remaining until normal operation will be resumed; otherwise, reading the unload_heads attribute will return 0.

For example, do the following in order to park the heads of drive /dev/sda and stop all I/O operations for five seconds:

```
# echo 5000 > /sys/block/sda/device/unload_heads
```

A simple:

```
# cat /sys/block/sda/device/unload_heads
```

will show you how many milliseconds are left before normal operation will be resumed.

A word of caution: The fact that the interface operates on a basis of milliseconds may raise expectations that cannot be satisfied in reality. In fact, the ATA specs clearly state that the time for an unload operation to complete is vendor specific. The hint in ATA-7 that this will typically be within 500 milliseconds apparently has been dropped in ATA-8.

There is a technical detail of this implementation that may cause some confusion and should be discussed here. When a head park request has been issued to a device successfully, all I/O operations on the controller port this device is attached to will be deferred. That is to say, any other device that may be connected to the same port will be affected too. The only exception is that a subsequent head unload request to that other device will be executed immediately. Further operations on that port will be deferred until the timeout specified for either device on the port has expired. As far as PATA (old style IDE) configurations are concerned, there can only be two devices attached to any single port. In SATA world we have port multipliers which means that a user-issued head parking request to one device may actually result in stopping I/O to a whole bunch of devices. However, since this feature is supposed to be used on laptops and does not seem to be very useful in any other environment, there will be mostly one device per port. Even if the CD/DVD writer happens to be connected to the same port as the hard drive, it generally *should* recover just fine from the occasional buffer under-run incurred by a head park request to the HD. Actually, when you are using an ide driver rather than its libata counterpart (i.e. your disk is called /dev/hda instead of /dev/sda), then parking the heads of one drive (drive X) will generally not affect the mode of operation of another drive (drive Y) on the same port as described above. It is only when a port reset is required to recover from an exception on drive Y that further I/O operations on that drive (and the reset itself) will be delayed until drive X is no longer in the parked state.

Finally, there are some hard drives that only comply with an earlier version of the ATA standard than ATA-7, but do support the unload feature nonetheless. Unfortunately, there is no safe way Linux can detect these devices, so you won't be able to write to the unload_heads attribute. If you know that your device really does support the unload feature (for instance, because the vendor of your laptop or the hard drive itself told you so), then you can tell the kernel to enable the usage of this feature for that drive by writing the special value -1 to the unload_heads attribute:

```
# echo -1 > /sys/block/sda/device/unload_heads
```

will enable the feature for /dev/sda, and giving -2 instead of -1 will disable it again.

53.2.3 3. References

There are several laptops from different vendors featuring shock protection capabilities. As manufacturers have refused to support open source development of the required software components so far, Linux support for shock protection varies considerably between different hardware implementations. Ideally, this section should contain a list of pointers at different projects aiming at an implementation of shock protection on different systems. Unfortunately, I only know of a single project which, although still considered experimental, is fit for use. Please feel free to add projects that have been the victims of my ignorance.

- https://www.thinkwiki.org/wiki/HDAPS

See this page for information about Linux support of the hard disk active protection system as implemented in IBM/Lenovo Thinkpads.

53.2.4 4. CREDITS

This implementation of disk head parking has been inspired by a patch originally published by Jon Escombe <lists@dresco.co.uk>. My efforts to develop an implementation of this feature that is fit to be merged into mainline have been aided by various kernel developers, in particular by Tejun Heo and Bartlomiej Zolnierkiewicz.

53.3 How to conserve battery power using laptop-mode

Document Author: Bart Samwel (bart@samwel.tk)

Date created: January 2, 2004

Last modified: December 06, 2004

53.3.1 Introduction

Laptop mode is used to minimize the time that the hard disk needs to be spun up, to conserve battery power on laptops. It has been reported to cause significant power savings.

53.3.2 Installation

To use laptop mode, you don't need to set any kernel configuration options or anything. Simply install all the files included in this document, and laptop mode will automatically be started when you're on battery. For your convenience, a tarball containing an installer can be downloaded at:

http://www.samwel.tk/laptop_mode/laptop_mode/

To configure laptop mode, you need to edit the configuration file, which is located in /etc/default/laptop-mode on Debian-based systems, or in /etc/sysconfig/laptop-mode on other systems.

Unfortunately, automatic enabling of laptop mode does not work for laptops that don't have ACPI. On those laptops, you need to start laptop mode manually. To start laptop mode, run ”laptop_mode start”, and to stop it, run ”laptop_mode stop”. (Note: The laptop mode tools package now has experimental support for APM, you might want to try that first.)

53.3.3 Caveats

- The downside of laptop mode is that you have a chance of losing up to 10 minutes of work. If you cannot afford this, don't use it! The supplied ACPI scripts automatically turn off laptop mode when the battery almost runs out, so that you won't lose any data at the end of your battery life.
- Most desktop hard drives have a very limited lifetime measured in spindown cycles, typically about 50.000 times (it's usually listed on the spec sheet). Check your drive's rating, and don't wear down your drive's lifetime if you don't need to.
- If you mount some of your ext3/reiserfs filesystems with the -n option, then the control script will not be able to remount them correctly. You must set DO_REMOUNTS=0 in the control script, otherwise it will remount them with the wrong options -- or it will fail because it cannot write to /etc/mtab.
- If you have your filesystems listed as type ”auto” in fstab, like I did, then the control script will not recognize them as filesystems that need remounting. You must list the filesystems with their true type instead.
- It has been reported that some versions of the mutt mail client use file access times to determine whether a folder contains new mail. If you use mutt and experience this, you must disable the noatime remounting by setting the option DO_REMOUNT_NOATIME to 0 in the configuration file.

53.3.4 The Details

Laptop mode is controlled by the knob /proc/sys/vm/laptop_mode. This knob is present for all kernels that have the laptop mode patch, regardless of any configuration options. When the knob is set, any physical disk I/O (that might have caused the hard disk to spin up) causes Linux to flush all dirty blocks. The result of this is that after a disk has spun down, it will not be spun up anymore to write dirty blocks, because those blocks had already been written immediately after the most recent read operation. The value of the laptop_mode knob determines the time between the occurrence of disk I/O and when the flush is triggered. A sensible value for the knob is 5 seconds. Setting the knob to 0 disables laptop mode.

To increase the effectiveness of the laptop_mode strategy, the laptop_mode control script increases dirty_expire_centisecs and dirty_writeback_centisecs in /proc/sys/vm to about 10 minutes (by default), which means that pages that are dirtied are not forced to be written to disk as often. The control script also changes the dirty background ratio, so that background writeback of dirty pages is not done anymore. Combined with a higher commit value (also 10 minutes) for ext3 or ReiserFS filesystems (also done automatically by the control script), this results in concentration of disk activity in a small time interval which occurs only once every 10 minutes, or whenever the disk is forced to spin up by a cache miss. The disk can then be spun down in the periods of inactivity.

53.3.5 Configuration

The laptop mode configuration file is located in /etc/default/laptop-mode on Debian-based systems, or in /etc/sysconfig/laptop-mode on other systems. It contains the following options:

MAX_AGE:

Maximum time, in seconds, of hard drive spindown time that you are comfortable with. Worst case, it's possible that you could lose this amount of work if your battery fails while you're in laptop mode.

MINIMUM_BATTERY_MINUTES:

Automatically disable laptop mode if the remaining number of minutes of battery power is less than this value. Default is 10 minutes.

AC_HD/BATT_HD:

The idle timeout that should be set on your hard drive when laptop mode is active (BATT_HD) and when it is not active (AC_HD). The defaults are 20 seconds (value 4) for BATT_HD and 2 hours (value 244) for AC_HD. The possible values are those listed in the manual page for ”hdparm” for the ”-S” option.

HD:

The devices for which the spindown timeout should be adjusted by laptop mode. Default is /dev/hda. If you specify multiple devices, separate them by a space.

READAHEAD:

Disk readahead, in 512-byte sectors, while laptop mode is active. A large readahead can prevent disk accesses for things like executable pages (which are loaded on demand while the application executes) and sequentially accessed data (MP3s).

DO_REMOUNTS:

The control script automatically remounts any mounted journaled filesystems with appropriate commit interval options. When this option is set to 0, this feature is disabled.

DO_REMOUNT_NOATIME:

When remounting, should the filesystems be remounted with the noatime option? Normally, this is set to ”1” (enabled), but there may be programs that require access time recording.

DIRTY_RATIO:

The percentage of memory that is allowed to contain ”dirty” or unsaved data before a writeback is forced, while laptop mode is active. Corresponds to the /proc/sys/vm/dirty_ratio sysctl.

DIRTY_BACKGROUND_RATIO:

The percentage of memory that is allowed to contain ”dirty” or unsaved data after a forced writeback is done due to an exceeding of DIRTY_RATIO. Set this nice and low. This corresponds to the /proc/sys/vm/dirty_background_ratio sysctl.

Note that the behaviour of dirty_background_ratio is quite different when laptop mode is active and when it isn't. When laptop mode is inactive, dirty_background_ratio is the threshold percentage at which background writeouts start taking place. When laptop mode is active, however, background writeouts are disabled, and the dirty_background_ratio only determines how much writeback is done when dirty_ratio is reached.

DO_CPU:

Enable CPU frequency scaling when in laptop mode. (Requires CPUFreq to be setup. See *CPU Performance Scaling* for more info. Disabled by default.)

CPU_MAXFREQ:

When on battery, what is the maximum CPU speed that the system should use? Legal values are "slowest" for the slowest speed that your CPU is able to operate at, or a value listed in /sys/devices/system/cpu/cpu0/cpufreq/scaling_available_frequencies.

53.3.6 Tips & Tricks

- Bartek Kania reports getting up to 50 minutes of extra battery life (on top of his regular 3 to 3.5 hours) using a spindown time of 5 seconds (BATT_HD=1).
- You can spin down the disk while playing MP3, by setting disk readahead to 8MB (READAHEAD=16384). Effectively, the disk will read a complete MP3 at once, and will then spin down while the MP3 is playing. (Thanks to Bartek Kania.)
- Drew Scott Daniels observed: "I don't know why, but when I decrease the number of colours that my display uses it consumes less battery power. I've seen this on powerbooks too. I hope that this is a piece of information that might be useful to the Laptop Mode patch or its users."
- In syslog.conf, you can prefix entries with a dash - to omit syncing the file after every logging. When you're using laptop-mode and your disk doesn't spin down, this is a likely culprit.
- Richard Atterer observed that laptop mode does not work well with noflushd (http://noflushd.sourceforge.net/), it seems that noflushd prevents laptop-mode from doing its thing.
- If you're worried about your data, you might want to consider using a USB memory stick or something like that as a "working area". (Be aware though that flash memory can only handle a limited number of writes, and overuse may wear out your memory stick pretty quickly. Do _not_ use journalling filesystems on flash memory sticks.)

53.3.7 Configuration file for control and ACPI battery scripts

This allows the tunables to be changed for the scripts via an external configuration file

It should be installed as /etc/default/laptop-mode on Debian, and as /etc/sysconfig/laptop-mode on Red Hat, SUSE, Mandrake, and other work-alikes.

Config file:

```
# Maximum time, in seconds, of hard drive spindown time that you are
# comfortable with. Worst case, it's possible that you could lose this
# amount of work if your battery fails you while in laptop mode.
#MAX_AGE=600

# Automatically disable laptop mode when the number of minutes of battery
# that you have left goes below this threshold.
MINIMUM_BATTERY_MINUTES=10
```

```
# Read-ahead, in 512-byte sectors. You can spin down the disk while playing␣
↪MP3/OGG
# by setting the disk readahead to 8MB (READAHEAD=16384). Effectively, the disk
# will read a complete MP3 at once, and will then spin down while the MP3/OGG␣
↪is
# playing.
#READAHEAD=4096

# Shall we remount journaled fs. with appropriate commit interval? (1=yes)
#DO_REMOUNTS=1

# And shall we add the "noatime" option to that as well? (1=yes)
#DO_REMOUNT_NOATIME=1

# Dirty synchronous ratio.  At this percentage of dirty pages the process
# which
# calls write() does its own writeback
#DIRTY_RATIO=40

#
# Allowed dirty background ratio, in percent.  Once DIRTY_RATIO has been
# exceeded, the kernel will wake flusher threads which will then reduce the
# amount of dirty memory to dirty_background_ratio.  Set this nice and low,
# so once some writeout has commenced, we do a lot of it.
#
#DIRTY_BACKGROUND_RATIO=5

# kernel default dirty buffer age
#DEF_AGE=30
#DEF_UPDATE=5
#DEF_DIRTY_BACKGROUND_RATIO=10
#DEF_DIRTY_RATIO=40
#DEF_XFS_AGE_BUFFER=15
#DEF_XFS_SYNC_INTERVAL=30
#DEF_XFS_BUFD_INTERVAL=1

# This must be adjusted manually to the value of HZ in the running kernel
# on 2.4, until the XFS people change their 2.4 external interfaces to work in
# centisecs. This can be automated, but it's a work in progress that still
# needs# some fixes. On 2.6 kernels, XFS uses USER_HZ instead of HZ for
# external interfaces, and that is currently always set to 100. So you don't
# need to change this on 2.6.
#XFS_HZ=100

# Should the maximum CPU frequency be adjusted down while on battery?
# Requires CPUFreq to be setup.
# See Documentation/admin-guide/pm/cpufreq.rst for more info
#DO_CPU=0
```

```
# When on battery what is the maximum CPU speed that the system should
# use? Legal values are "slowest" for the slowest speed that your
# CPU is able to operate at, or a value listed in:
# /sys/devices/system/cpu/cpu0/cpufreq/scaling_available_frequencies
# Only applicable if DO_CPU=1.
#CPU_MAXFREQ=slowest

# Idle timeout for your hard drive (man hdparm for valid values, -S option)
# Default is 2 hours on AC (AC_HD=244) and 20 seconds for battery (BATT_HD=4).
#AC_HD=244
#BATT_HD=4

# The drives for which to adjust the idle timeout. Separate them by a space,
# e.g. HD="/dev/hda /dev/hdb".
#HD="/dev/hda"

# Set the spindown timeout on a hard drive?
#DO_HD=1
```

53.3.8 Control script

Please note that this control script works for the Linux 2.4 and 2.6 series (thanks to Kiko Piris).

Control script:

```
#!/bin/bash

# start or stop laptop_mode, best run by a power management daemon when
# ac gets connected/disconnected from a laptop
#
# install as /sbin/laptop_mode
#
# Contributors to this script:   Kiko Piris
#                               Bart Samwel
#                               Micha Feigin
#                               Andrew Morton
#                               Herve Eychenne
#                               Dax Kelson
#
# Original Linux 2.4 version by: Jens Axboe

###############################################################################

# This must be adjusted manually to the value of HZ in the running kernel
# on 2.4, until the XFS people change their 2.4 external interfaces to work in
# centisecs. This can be automated, but it's a work in progress that still␣
↪needs
# some fixes. On 2.6 kernels, XFS uses USER_HZ instead of HZ for external
# interfaces, and that is currently always set to 100. So you don't need to
# change this on 2.6.
XFS_HZ=${XFS_HZ:-'100'}

53.3.9 ACPI integration

Dax Kelson submitted this so that the ACPI acpid daemon will kick off the laptop_mode script and run hdparm. The part that automatically disables laptop mode when the battery is low was written by Jan Topinski.

/etc/acpi/events/ac_adapter:

```
event=ac_adapter
action=/etc/acpi/actions/ac.sh %e
```

/etc/acpi/events/battery:

```
event=battery.*
action=/etc/acpi/actions/battery.sh %e
```

/etc/acpi/actions/ac.sh:

```
#!/bin/bash
```

```
# ac on/offline event handler

status=`awk '/^state: / { print $2 }' /proc/acpi/ac_adapter/$2/state`

case $status in
        "on-line")
                /sbin/laptop_mode stop
                exit 0
        ;;
        "off-line")
                /sbin/laptop_mode start
                exit 0
        ;;
esac
```

/etc/acpi/actions/battery.sh:

```
#! /bin/bash

# Automatically disable laptop mode when the battery almost runs out.

BATT_INFO=/proc/acpi/battery/$2/state

if [[ -f /proc/sys/vm/laptop_mode ]]
then
   LM=`cat /proc/sys/vm/laptop_mode`
   if [[ $LM -gt 0 ]]
   then
     if [[ -f $BATT_INFO ]]
     then
        # Source the config file only now that we know we need
        if [ -f /etc/default/laptop-mode ] ; then
                # Debian
                . /etc/default/laptop-mode
        elif [ -f /etc/sysconfig/laptop-mode ] ; then
                # Others
                . /etc/sysconfig/laptop-mode
        fi
        MINIMUM_BATTERY_MINUTES=${MINIMUM_BATTERY_MINUTES:-'10'}

        ACTION="`cat $BATT_INFO | grep charging | cut -c 26-`"
        if [[ ACTION -eq "discharging" ]]
        then

53.3.10 Monitoring tool

Bartek Kania submitted this, it can be used to measure how much time your disk spends spun up/down. See tools/laptop/dslm/dslm.c

53.4 LG Gram laptop extra features

By Matan Ziv-Av <matan@svgalib.org>

53.4.1 Hotkeys

The following FN keys are ignored by the kernel without this driver:

- FN-F1 (LG control panel) - Generates F15
- FN-F5 (Touchpad toggle) - Generates F21
- FN-F6 (Airplane mode) - Generates RFKILL
- FN-F9 (Reader mode) - Generates F14

The rest of the FN keys work without a need for a special driver.

53.4.2 Reader mode

Writing 0/1 to /sys/devices/platform/lg-laptop/reader_mode disables/enables reader mode. In this mode the screen colors change (blue color reduced), and the reader mode indicator LED (on F9 key) turns on.

53.4.3 FN Lock

Writing 0/1 to /sys/devices/platform/lg-laptop/fn_lock disables/enables FN lock.

53.4.4 Battery care limit

Writing 80/100 to /sys/class/power_supply/CMB0/charge_control_end_threshold sets the maximum capacity to charge the battery. Limiting the charge reduces battery capacity loss over time.

This value is reset to 100 when the kernel boots.

53.4.5 Fan mode

Writing 1/0 to /sys/devices/platform/lg-laptop/fan_mode disables/enables the fan silent mode.

53.4.6 USB charge

Writing 0/1 to /sys/devices/platform/lg-laptop/usb_charge disables/enables charging another device from the USB port while the device is turned off.

This value is reset to 0 when the kernel boots.

LEDs

The are two LED devices supported by the driver:

53.4.7 Keyboard backlight

A led device named kbd_led controls the keyboard backlight. There are three lighting level: off (0), low (127) and high (255).

The keyboard backlight is also controlled by the key combination FN-F8 which cycles through those levels.

53.4.8 Touchpad indicator LED

On the F5 key. Controlled by led device names tpad_led.

53.5 Sony Notebook Control Driver (SNC) Readme

- Copyright (C) 2004- 2005 Stelian Pop <stelian@popies.net>
- Copyright (C) 2007 Mattia Dongili <malattia@linux.it>

This mini-driver drives the SNC and SPIC device present in the ACPI BIOS of the Sony Vaio laptops. This driver mixes both devices functions under the same (hopefully consistent) interface. This also means that the sonypi driver is obsoleted by sony-laptop now.

53.5.1 Fn keys (hotkeys):

Some models report hotkeys through the SNC or SPIC devices, such events are reported both through the ACPI subsystem as acpi events and through the INPUT subsystem. See the logs of /proc/bus/input/devices to find out what those events are and which input devices are created by the driver. Additionally, loading the driver with the debug option will report all events in the kernel log.

The "scancodes" passed to the input system (that can be remapped with udev) are indexes to the table "sony_laptop_input_keycode_map" in the sony-laptop.c module. For example the "FN/E" key combination (EJECTCD on some models) generates the scancode 20 (0x14).

53.5.2 Backlight control:

If your laptop model supports it, you will find sysfs files in the /sys/class/backlight/sony/ directory. You will be able to query and set the current screen brightness:

brightness	get/set screen brightness (an integer between 0 and 7)
actual_brightness	reading from this file will query the HW to get real brightness value
max_brightness	the maximum brightness value

53.5.3 Platform specific:

Loading the sony-laptop module will create a /sys/devices/platform/sony-laptop/ directory populated with some files.

You then read/write integer values from/to those files by using standard UNIX tools.

The files are:

brightness_default	screen brightness which will be set when the laptop will be rebooted
cdpower	power on/off the internal CD drive
audiopower	power on/off the internal sound card
lanpower	power on/off the internal ethernet card (only in debug mode)
bluetoothpower	power on/off the internal bluetooth device
fanspeed	get/set the fan speed

Note that some files may be missing if they are not supported by your particular laptop model.

Example usage:

```
# echo "1" > /sys/devices/platform/sony-laptop/brightness_default
```

sets the lowest screen brightness for the next and later reboots

```
# echo "8" > /sys/devices/platform/sony-laptop/brightness_default
```

sets the highest screen brightness for the next and later reboots

```
# cat /sys/devices/platform/sony-laptop/brightness_default
```

retrieves the value

```
# echo "0" > /sys/devices/platform/sony-laptop/audiopower
```

powers off the sound card

```
# echo "1" > /sys/devices/platform/sony-laptop/audiopower
```

powers on the sound card.

53.5.4 RFkill control:

More recent Vaio models expose a consistent set of ACPI methods to control radio frequency emitting devices. If you are a lucky owner of such a laptop you will find the necessary rfkill devices under /sys/class/rfkill. Check those starting with sony-* in:

```
# grep . /sys/class/rfkill/*/{state,name}
```

53.5.5 Development:

If you want to help with the development of this driver (and you are not afraid of any side effects doing strange things with your ACPI BIOS could have on your laptop), load the driver and pass the option 'debug=1'.

REPEAT:
DON'T DO THIS IF YOU DON'T LIKE RISKY BUSINESS.

In your kernel logs you will find the list of all ACPI methods the SNC device has on your laptop.

- For new models you will see a long list of meaningless method names, reading the DSDT table source should reveal that:

(1) the SNC device uses an internal capability lookup table

(2) SN00 is used to find values in the lookup table

(3) SN06 and SN07 are used to call into the real methods based on offsets you can obtain iterating the table using SN00

(4) SN02 used to enable events.

Some values in the capability lookup table are more or less known, see the code for all sony_call_snc_handle calls, others are more obscure.

- For old models you can see the GCDP/GCDP methods used to pwer on/off the CD drive, but there are others and they are usually different from model to model.

I HAVE NO IDEA WHAT THOSE METHODS DO.

The sony-laptop driver creates, for some of those methods (the most current ones found on several Vaio models), an entry under /sys/devices/platform/sony-laptop, just like the 'cdpower' one. You can create other entries corresponding to your own laptop methods by further editing

the source (see the 'sony_nc_values' table, and add a new entry to this table with your get/set method names using the SNC_HANDLE_NAMES macro).

Your mission, should you accept it, is to try finding out what those entries are for, by reading/writing random values from/to those files and find out what is the impact on your laptop.

Should you find anything interesting, please report it back to me, I will not disavow all knowledge of your actions :)

See also http://www.linux.it/~malattia/wiki/index.php/Sony_drivers for other useful info.

53.5.6 Bugs/Limitations:

- This driver is not based on official documentation from Sony (because there is none), so there is no guarantee this driver will work at all, or do the right thing. Although this hasn't happened to me, this driver could do very bad things to your laptop, including permanent damage.
- The sony-laptop and sonypi drivers do not interact at all. In the future, sonypi will be removed and replaced by sony-laptop.
- spicctrl, which is the userspace tool used to communicate with the sonypi driver (through /dev/sonypi) is deprecated as well since all its features are now available under the sysfs tree via sony-laptop.

53.6 Sony Programmable I/O Control Device Driver Readme

- Copyright (C) 2001-2004 Stelian Pop <stelian@popies.net>
- Copyright (C) 2001-2002 Alcôve <www.alcove.com>
- Copyright (C) 2001 Michael Ashley <m.ashley@unsw.edu.au>
- Copyright (C) 2001 Junichi Morita <jun1m@mars.dti.ne.jp>
- Copyright (C) 2000 Takaya Kinjo <t-kinjo@tc4.so-net.ne.jp>
- Copyright (C) 2000 Andrew Tridgell <tridge@samba.org>

This driver enables access to the Sony Programmable I/O Control Device which can be found in many Sony Vaio laptops. Some newer Sony laptops (seems to be limited to new FX series laptops, at least the FX501 and the FX702) lack a sonypi device and are not supported at all by this driver.

It will give access (through a user space utility) to some events those laptops generate, like:

- jogdial events (the small wheel on the side of Vaios)
- capture button events (only on Vaio Picturebook series)
- Fn keys
- bluetooth button (only on C1VR model)
- programmable keys, back, help, zoom, thumbphrase buttons, etc. (when available)

Those events (see linux/sonypi.h) can be polled using the character device node /dev/sonypi (major 10, minor auto allocated or specified as a option). A simple daemon which translates the jogdial movements into mouse wheel events can be downloaded at: <http://popies.net/sonypi/>

Another option to intercept the events is to get them directly through the input layer.

This driver supports also some ioctl commands for setting the LCD screen brightness and querying the batteries charge information (some more commands may be added in the future).

This driver can also be used to set the camera controls on Picturebook series (brightness, contrast etc), and is used by the video4linux driver for the Motion Eye camera.

Please note that this driver was created by reverse engineering the Windows driver and the ACPI BIOS, because Sony doesn't agree to release any programming specs for its laptops. If someone convinces them to do so, drop me a note.

53.6.1 Driver options:

Several options can be passed to the sonypi driver using the standard module argument syntax (<param>=<value> when passing the option to the module or sonypi.<param>=<value> on the kernel boot line when sonypi is statically linked into the kernel). Those options are:

minor:	minor number of the misc device /dev/sonypi, default is -1 (automatic allocation, see /proc/misc or kernel logs)
camera:	if you have a PictureBook series Vaio (with the integrated MotionEye camera), set this parameter to 1 in order to let the driver access to the camera
fnkeyinit:	on some Vaios (C1VE, C1VR etc), the Fn key events don't get enabled unless you set this parameter to 1. Do not use this option unless it's actually necessary, some Vaio models don't deal well with this option. This option is available only if the kernel is compiled without ACPI support (since it conflicts with it and it shouldn't be required anyway if ACPI is already enabled).
verbose:	set to 1 to print unknown events received from the sonypi device. set to 2 to print all events received from the sonypi device.
compat:	uses some compatibility code for enabling the sonypi events. If the driver worked for you in the past (prior to version 1.5) and does not work anymore, add this option and report to the author.
mask:	event mask telling the driver what events will be reported to the user. This parameter is required for some Vaio models where the hardware reuses values used in other Vaio models (like the FX series who does not have a jogdial but reuses the jogdial events for programmable keys events). The default event mask is set to 0xffffffff, meaning that all possible events will be tried. You can use the following bits to construct your own event mask (from drivers/char/sonypi.h):

```
SONYPI_JOGGER_MASK                                  ␣
↪0x0001
SONYPI_CAPTURE_MASK                                 ␣
↪0x0002
SONYPI_FNKEY_MASK                                   ␣
↪0x0004
SONYPI_BLUETOOTH_MASK                               ␣
↪0x0008
SONYPI_PKEY_MASK                                    ␣
↪0x0010
SONYPI_BACK_MASK                                    ␣
↪0x0020
SONYPI_HELP_MASK                                    ␣
↪0x0040
SONYPI_LID_MASK                                     ␣
↪0x0080
```

53.6.2 Module use:

In order to automatically load the sonypi module on use, you can put those lines a configuration file in /etc/modprobe.d/:

```
alias char-major-10-250 sonypi
options sonypi minor=250
```

This supposes the use of minor 250 for the sonypi device:

```
# mknod /dev/sonypi c 10 250
```

53.6.3 Bugs:

- several users reported that this driver disables the BIOS-managed Fn-keys which put the laptop in sleeping state, or switch the external monitor on/off. There is no workaround yet, since this driver disables all APM management for those keys, by enabling the ACPI management (and the ACPI core stuff is not complete yet). If you have one of those laptops with working Fn keys and want to continue to use them, don't use this driver.
- some users reported that the laptop speed is lower (dhrystone tested) when using the driver with the fnkeyinit parameter. I cannot reproduce it on my laptop and not all users have this problem. This happens because the fnkeyinit parameter enables the ACPI mode (but without additional ACPI control, like processor speed handling etc). Use ACPI instead of APM if it works on your laptop.
- sonypi lacks the ability to distinguish between certain key events on some models.
- some models with the nvidia card (geforce go 6200 tc) uses a different way to adjust the backlighting of the screen. There is a userspace utility to adjust the brightness on those models, which can be downloaded from https://www.acc.umu.se/~erikw/program/smartdimmer-0.1.tar.bz2
- since all development was done by reverse engineering, there is *absolutely no guarantee* that this driver will not crash your laptop. Permanently.

53.7 ThinkPad ACPI Extras Driver

Version 0.25

October 16th, 2013

- Borislav Deianov <borislav@users.sf.net>
- Henrique de Moraes Holschuh <hmh@hmh.eng.br>

http://ibm-acpi.sf.net/

This is a Linux driver for the IBM and Lenovo ThinkPad laptops. It supports various features of these laptops which are accessible through the ACPI and ACPI EC framework, but not otherwise fully supported by the generic Linux ACPI drivers.

This driver used to be named ibm-acpi until kernel 2.6.21 and release 0.13-20070314. It used to be in the drivers/acpi tree, but it was moved to the drivers/misc tree and renamed to thinkpad-acpi for kernel 2.6.22, and release 0.14. It was moved to drivers/platform/x86 for kernel 2.6.29 and release 0.22.

The driver is named ”thinkpad-acpi”. In some places, like module names and log messages, ”thinkpad_acpi” is used because of userspace issues.

”tpacpi” is used as a shorthand where ”thinkpad-acpi” would be too long due to length limitations on some Linux kernel versions.

53.7.1 Status

The features currently supported are the following (see below for detailed description):

- Fn key combinations
- Bluetooth enable and disable
- video output switching, expansion control
- ThinkLight on and off
- CMOS/UCMS control
- LED control
- ACPI sounds
- temperature sensors
- Experimental: embedded controller register dump
- LCD brightness control
- Volume control
- Fan control and monitoring: fan speed, fan enable/disable
- WAN enable and disable
- UWB enable and disable
- LCD Shadow (PrivacyGuard) enable and disable
- Lap mode sensor
- Setting keyboard language
- WWAN Antenna type
- Auxmac

A compatibility table by model and feature is maintained on the web site, http://ibm-acpi.sf.net/. I appreciate any success or failure reports, especially if they add to or correct the compatibility table. Please include the following information in your report:

- ThinkPad model name
- a copy of your ACPI tables, using the ”acpidump” utility
- a copy of the output of dmidecode, with serial numbers and UUIDs masked off
- which driver features work and which don't

- the observed behavior of non-working features

Any other comments or patches are also more than welcome.

53.7.2 Installation

If you are compiling this driver as included in the Linux kernel sources, look for the CONFIG_THINKPAD_ACPI Kconfig option. It is located on the menu path: ”Device Drivers” -> ”X86 Platform Specific Device Drivers” -> ”ThinkPad ACPI Laptop Extras”.

53.7.3 Features

The driver exports two different interfaces to userspace, which can be used to access the features it provides. One is a legacy procfs-based interface, which will be removed at some time in the future. The other is a new sysfs-based interface which is not complete yet.

The procfs interface creates the /proc/acpi/ibm directory. There is a file under that directory for each feature it supports. The procfs interface is mostly frozen, and will change very little if at all: it will not be extended to add any new functionality in the driver, instead all new functionality will be implemented on the sysfs interface.

The sysfs interface tries to blend in the generic Linux sysfs subsystems and classes as much as possible. Since some of these subsystems are not yet ready or stabilized, it is expected that this interface will change, and any and all userspace programs must deal with it.

Notes about the sysfs interface

Unlike what was done with the procfs interface, correctness when talking to the sysfs interfaces will be enforced, as will correctness in the thinkpad-acpi's implementation of sysfs interfaces.

Also, any bugs in the thinkpad-acpi sysfs driver code or in the thinkpad-acpi's implementation of the sysfs interfaces will be fixed for maximum correctness, even if that means changing an interface in non-compatible ways. As these interfaces mature both in the kernel and in thinkpad-acpi, such changes should become quite rare.

Applications interfacing to the thinkpad-acpi sysfs interfaces must follow all sysfs guidelines and correctly process all errors (the sysfs interface makes extensive use of errors). File descriptors and open / close operations to the sysfs inodes must also be properly implemented.

The version of thinkpad-acpi's sysfs interface is exported by the driver as a driver attribute (see below).

Sysfs driver attributes are on the driver's sysfs attribute space, for 2.6.23+ this is /sys/bus/platform/drivers/thinkpad_acpi/ and /sys/bus/platform/drivers/thinkpad_hwmon/

Sysfs device attributes are on the thinkpad_acpi device sysfs attribute space, for 2.6.23+ this is /sys/devices/platform/thinkpad_acpi/.

Sysfs device attributes for the sensors and fan are on the thinkpad_hwmon device's sysfs attribute space, but you should locate it looking for a hwmon device with the name attribute of ”thinkpad”, or better yet, through libsensors. For 4.14+ sysfs attributes were moved to the hwmon device (/sys/bus/platform/devices/thinkpad_hwmon/hwmon/hwmon? or /sys/class/hwmon/hwmon?).

53.7.4 Driver version

procfs: /proc/acpi/ibm/driver

sysfs driver attribute: version

The driver name and version. No commands can be written to this file.

53.7.5 Sysfs interface version

sysfs driver attribute: interface_version

Version of the thinkpad-acpi sysfs interface, as an unsigned long (output in hex format: 0xAAAABBCC), where:

AAAA

- major revision

BB

- minor revision

CC

- bugfix revision

The sysfs interface version changelog for the driver can be found at the end of this document. Changes to the sysfs interface done by the kernel subsystems are not documented here, nor are they tracked by this attribute.

Changes to the thinkpad-acpi sysfs interface are only considered non-experimental when they are submitted to Linux mainline, at which point the changes in this interface are documented and interface_version may be updated. If you are using any thinkpad-acpi features not yet sent to mainline for merging, you do so on your own risk: these features may disappear, or be implemented in a different and incompatible way by the time they are merged in Linux mainline.

Changes that are backwards-compatible by nature (e.g. the addition of attributes that do not change the way the other attributes work) do not always warrant an update of interface_version. Therefore, one must expect that an attribute might not be there, and deal with it properly (an attribute not being there *is* a valid way to make it clear that a feature is not available in sysfs).

53.7.6 Hot keys

procfs: /proc/acpi/ibm/hotkey

sysfs device attribute: hotkey_*

In a ThinkPad, the ACPI HKEY handler is responsible for communicating some important events and also keyboard hot key presses to the operating system. Enabling the hotkey functionality of thinkpad-acpi signals the firmware that such a driver is present, and modifies how the ThinkPad firmware will behave in many situations.

The driver enables the HKEY (”hot key”) event reporting automatically when loaded, and disables it when it is removed.

The driver will report HKEY events in the following format:

```
ibm/hotkey HKEY 00000080 0000xxxx
```

Some of these events refer to hot key presses, but not all of them.

The driver will generate events over the input layer for hot keys and radio switches, and over the ACPI netlink layer for other events. The input layer support accepts the standard IOCTLs to remap the keycodes assigned to each hot key.

The hot key bit mask allows some control over which hot keys generate events. If a key is "masked" (bit set to 0 in the mask), the firmware will handle it. If it is "unmasked", it signals the firmware that thinkpad-acpi would prefer to handle it, if the firmware would be so kind to allow it (and it often doesn't!).

Not all bits in the mask can be modified. Not all bits that can be modified do anything. Not all hot keys can be individually controlled by the mask. Some models do not support the mask at all. The behaviour of the mask is, therefore, highly dependent on the ThinkPad model.

The driver will filter out any unmasked hotkeys, so even if the firmware doesn't allow disabling an specific hotkey, the driver will not report events for unmasked hotkeys.

Note that unmasking some keys prevents their default behavior. For example, if Fn+F5 is unmasked, that key will no longer enable/disable Bluetooth by itself in firmware.

Note also that not all Fn key combinations are supported through ACPI depending on the ThinkPad model and firmware version. On those ThinkPads, it is still possible to support some extra hotkeys by polling the "CMOS NVRAM" at least 10 times per second. The driver attempts to enables this functionality automatically when required.

procfs notes

The following commands can be written to the /proc/acpi/ibm/hotkey file:

```
echo 0xffffffff > /proc/acpi/ibm/hotkey -- enable all hot keys
echo 0 > /proc/acpi/ibm/hotkey -- disable all possible hot keys
... any other 8-hex-digit mask ...
echo reset > /proc/acpi/ibm/hotkey -- restore the recommended mask
```

The following commands have been deprecated and will cause the kernel to log a warning:

```
echo enable > /proc/acpi/ibm/hotkey -- does nothing
echo disable > /proc/acpi/ibm/hotkey -- returns an error
```

The procfs interface does not support NVRAM polling control. So as to maintain maximum bug-to-bug compatibility, it does not report any masks, nor does it allow one to manipulate the hot key mask when the firmware does not support masks at all, even if NVRAM polling is in use.

sysfs notes

hotkey_bios_enabled:
DEPRECATED, WILL BE REMOVED SOON.

Returns 0.

hotkey_bios_mask:
DEPRECATED, DON'T USE, WILL BE REMOVED IN THE FUTURE.

Returns the hot keys mask when thinkpad-acpi was loaded. Upon module unload, the hot keys mask will be restored to this value. This is always 0x80c, because those are the hotkeys that were supported by ancient firmware without mask support.

hotkey_enable:
DEPRECATED, WILL BE REMOVED SOON.

0: returns -EPERM 1: does nothing

hotkey_mask:
bit mask to enable reporting (and depending on the firmware, ACPI event generation) for each hot key (see above). Returns the current status of the hot keys mask, and allows one to modify it.

hotkey_all_mask:
bit mask that should enable event reporting for all supported hot keys, when echoed to hotkey_mask above. Unless you know which events need to be handled passively (because the firmware *will* handle them anyway), do *not* use hotkey_all_mask. Use hotkey_recommended_mask, instead. You have been warned.

hotkey_recommended_mask:
bit mask that should enable event reporting for all supported hot keys, except those which are always handled by the firmware anyway. Echo it to hotkey_mask above, to use. This is the default mask used by the driver.

hotkey_source_mask:
bit mask that selects which hot keys will the driver poll the NVRAM for. This is auto-detected by the driver based on the capabilities reported by the ACPI firmware, but it can be overridden at runtime.

Hot keys whose bits are set in hotkey_source_mask are polled for in NVRAM, and reported as hotkey events if enabled in hotkey_mask. Only a few hot keys are available through CMOS NVRAM polling.

Warning: when in NVRAM mode, the volume up/down/mute keys are synthesized according to changes in the mixer, which uses a single volume up or volume down hotkey press to unmute, as per the ThinkPad volume mixer user interface. When in ACPI event mode, volume up/down/mute events are reported by the firmware and can behave differently (and that behaviour changes with firmware version -- not just with firmware models -- as well as OSI(Linux) state).

hotkey_poll_freq:
frequency in Hz for hot key polling. It must be between 0 and 25 Hz. Polling is only carried out when strictly needed.

Setting hotkey_poll_freq to zero disables polling, and will cause hot key presses that require NVRAM polling to never be reported.

Setting hotkey_poll_freq too low may cause repeated pressings of the same hot key to be misreported as a single key press, or to not even be detected at all. The recommended polling frequency is 10Hz.

hotkey_radio_sw:
If the ThinkPad has a hardware radio switch, this attribute will read 0 if the switch is in the "radios disabled" position, and 1 if the switch is in the "radios enabled" position.

This attribute has poll()/select() support.

hotkey_tablet_mode:
If the ThinkPad has tablet capabilities, this attribute will read 0 if the ThinkPad is in normal mode, and 1 if the ThinkPad is in tablet mode.

This attribute has poll()/select() support.

wakeup_reason:
Set to 1 if the system is waking up because the user requested a bay ejection. Set to 2 if the system is waking up because the user requested the system to undock. Set to zero for normal wake-ups or wake-ups due to unknown reasons.

This attribute has poll()/select() support.

wakeup_hotunplug_complete:
Set to 1 if the system was waken up because of an undock or bay ejection request, and that request was successfully completed. At this point, it might be useful to send the system back to sleep, at the user's choice. Refer to HKEY events 0x4003 and 0x3003, below.

This attribute has poll()/select() support.

input layer notes

A Hot key is mapped to a single input layer EV_KEY event, possibly followed by an EV_MSC MSC_SCAN event that shall contain that key's scan code. An EV_SYN event will always be generated to mark the end of the event block.

Do not use the EV_MSC MSC_SCAN events to process keys. They are to be used as a helper to remap keys, only. They are particularly useful when remapping KEY_UNKNOWN keys.

The events are available in an input device, with the following id:

Bus	BUS_HOST
vendor	0x1014 (PCI_VENDOR_ID_IBM) or 0x17aa (PCI_VENDOR_ID_LENOVO)
product	0x5054 ("TP")
version	0x4101

The version will have its LSB incremented if the keymap changes in a backwards-compatible way. The MSB shall always be 0x41 for this input device. If the MSB is not 0x41, do not use the device as described in this section, as it is either something else (e.g. another input device exported by a thinkpad driver, such as HDAPS) or its functionality has been changed in a non-backwards compatible way.

Adding other event types for other functionalities shall be considered a backwards-compatible change for this input device.

Thinkpad-acpi Hot Key event map (version 0x4101):

ACPI event	Scan code	Key	Notes
0x1001	0x00	FN+F1	•
0x1002	0x01	FN+F2	IBM: battery (rare) Lenovo: Screen lock
0x1003	0x02	FN+F3	Many IBM models always report this hot key, even with hot keys disabled or with Fn+F3 masked off IBM: screen lock, often turns off the ThinkLight as side-effect Lenovo: battery
0x1004	0x03	FN+F4	Sleep button (ACPI sleep button semantics, i.e. sleep-to-RAM). It always generates some kind of event, either the hot key event or an ACPI sleep button event. The firmware may refuse to generate further FN+F4 key presses until a S3 or S4 ACPI sleep cycle is performed or some time passes.
0x1005	0x04	FN+F5	Radio. Enables/disables the internal Bluetooth hardware and W-WAN card if left in control of the firmware. Does not affect the WLAN card. Should be used to turn on/off all radios (Bluetooth+W-WAN+WLAN), really.
0x1006	0x05	FN+F6	•
0x1007	0x06	FN+F7	Video output cycle. Do you feel lucky today?
0x1008	0x07	FN+F8	IBM: toggle screen expand Lenovo: configure UltraNav, or toggle screen expand
0x1009	0x08	FN+F9	•

The ThinkPad firmware does not allow one to differentiate when most hot keys are pressed or released (either that, or we don't know how to, yet). For these keys, the driver generates a set of events for a key press and immediately issues the same set of events for a key release. It is unknown by the driver if the ThinkPad firmware triggered these events on hot key press or release, but the firmware will do it for either one, not both.

If a key is mapped to KEY_RESERVED, it generates no input events at all. If a key is mapped to KEY_UNKNOWN, it generates an input event that includes an scan code. If a key is mapped to anything else, it will generate input device EV_KEY events.

In addition to the EV_KEY events, thinkpad-acpi may also issue EV_SW events for switches:

SW_RFKILL_ALL	T60 and later hardware rfkill rocker switch
SW_TABLET_MODE	Tablet ThinkPads HKEY events 0x5009 and 0x500A

53.7.7 Non hotkey ACPI HKEY event map

Events that are never propagated by the driver:

0x2304	System is waking up from suspend to undock
0x2305	System is waking up from suspend to eject bay
0x2404	System is waking up from hibernation to undock
0x2405	System is waking up from hibernation to eject bay
0x5001	Lid closed
0x5002	Lid opened
0x5009	Tablet swivel: switched to tablet mode
0x500A	Tablet swivel: switched to normal mode
0x5010	Brightness level changed/control event
0x6000	KEYBOARD: Numlock key pressed
0x6005	KEYBOARD: Fn key pressed (TO BE VERIFIED)
0x7000	Radio Switch may have changed state

Events that are propagated by the driver to userspace:

0x2313	ALARM: System is waking up from suspend because the battery is nearly empty
0x2413	ALARM: System is waking up from hibernation because the battery is nearly empty
0x3003	Bay ejection (see 0x2x05) complete, can sleep again
0x3006	Bay hotplug request (hint to power up SATA link when the optical drive tray is ejected)
0x4003	Undocked (see 0x2x04), can sleep again
0x4010	Docked into hotplug port replicator (non-ACPI dock)
0x4011	Undocked from hotplug port replicator (non-ACPI dock)
0x500B	Tablet pen inserted into its storage bay
0x500C	Tablet pen removed from its storage bay
0x6011	ALARM: battery is too hot
0x6012	ALARM: battery is extremely hot
0x6021	ALARM: a sensor is too hot
0x6022	ALARM: a sensor is extremely hot
0x6030	System thermal table changed
0x6032	Thermal Control command set completion (DYTC, Windows)
0x6040	Nvidia Optimus/AC adapter related (TO BE VERIFIED)
0x60C0	X1 Yoga 2016, Tablet mode status changed
0x60F0	Thermal Transformation changed (GMTS, Windows)

Battery nearly empty alarms are a last resort attempt to get the operating system to hibernate or shutdown cleanly (0x2313), or shutdown cleanly (0x2413) before power is lost. They must be acted upon, as the wake up caused by the firmware will have negated most safety nets...

When any of the ”too hot” alarms happen, according to Lenovo the user should suspend or hibernate the laptop (and in the case of battery alarms, unplug the AC adapter) to let it cool down. These alarms do signal that something is wrong, they should never happen on normal operating conditions.

The ”extremely hot” alarms are emergencies. According to Lenovo, the operating system is to force either an immediate suspend or hibernate cycle, or a system shutdown. Obviously, something is very wrong if this happens.

Brightness hotkey notes

Don't mess with the brightness hotkeys in a Thinkpad. If you want notifications for OSD, use the sysfs backlight class event support.

The driver will issue KEY_BRIGHTNESS_UP and KEY_BRIGHTNESS_DOWN events automatically for the cases were userspace has to do something to implement brightness changes. When you override these events, you will either fail to handle properly the ThinkPads that require explicit action to change backlight brightness, or the ThinkPads that require that no action be taken to work properly.

53.7.8 Bluetooth

procfs: /proc/acpi/ibm/bluetooth

sysfs device attribute: bluetooth_enable (deprecated)

sysfs rfkill class: switch "tpacpi_bluetooth_sw"

This feature shows the presence and current state of a ThinkPad Bluetooth device in the internal ThinkPad CDC slot.

If the ThinkPad supports it, the Bluetooth state is stored in NVRAM, so it is kept across reboots and power-off.

Procfs notes

If Bluetooth is installed, the following commands can be used:

```
echo enable > /proc/acpi/ibm/bluetooth
echo disable > /proc/acpi/ibm/bluetooth
```

Sysfs notes

If the Bluetooth CDC card is installed, it can be enabled / disabled through the "bluetooth_enable" thinkpad-acpi device attribute, and its current status can also be queried.

enable:

- 0: disables Bluetooth / Bluetooth is disabled
- 1: enables Bluetooth / Bluetooth is enabled.

Note: this interface has been superseded by the generic rfkill class. It has been deprecated, and it will be removed in year 2010.

rfkill controller switch "tpacpi_bluetooth_sw": refer to Documentation/driver-api/rfkill.rst for details.

53.7.9 Video output control -- /proc/acpi/ibm/video

This feature allows control over the devices used for video output - LCD, CRT or DVI (if available). The following commands are available:

```
echo lcd_enable > /proc/acpi/ibm/video
echo lcd_disable > /proc/acpi/ibm/video
echo crt_enable > /proc/acpi/ibm/video
echo crt_disable > /proc/acpi/ibm/video
echo dvi_enable > /proc/acpi/ibm/video
echo dvi_disable > /proc/acpi/ibm/video
echo auto_enable > /proc/acpi/ibm/video
echo auto_disable > /proc/acpi/ibm/video
echo expand_toggle > /proc/acpi/ibm/video
echo video_switch > /proc/acpi/ibm/video
```

NOTE:
Access to this feature is restricted to processes owning the CAP_SYS_ADMIN capability for safety reasons, as it can interact badly enough with some versions of X.org to crash it.

Each video output device can be enabled or disabled individually. Reading /proc/acpi/ibm/video shows the status of each device.

Automatic video switching can be enabled or disabled. When automatic video switching is enabled, certain events (e.g. opening the lid, docking or undocking) cause the video output device to change automatically. While this can be useful, it also causes flickering and, on the X40, video corruption. By disabling automatic switching, the flickering or video corruption can be avoided.

The video_switch command cycles through the available video outputs (it simulates the behavior of Fn-F7).

Video expansion can be toggled through this feature. This controls whether the display is expanded to fill the entire LCD screen when a mode with less than full resolution is used. Note that the current video expansion status cannot be determined through this feature.

Note that on many models (particularly those using Radeon graphics chips) the X driver configures the video card in a way which prevents Fn-F7 from working. This also disables the video output switching features of this driver, as it uses the same ACPI methods as Fn-F7. Video switching on the console should still work.

UPDATE: refer to https://bugs.freedesktop.org/show_bug.cgi?id=2000

53.7.10 ThinkLight control

procfs: /proc/acpi/ibm/light

sysfs attributes: as per LED class, for the "tpacpi::thinklight" LED

procfs notes

The ThinkLight status can be read and set through the procfs interface. A few models which do not make the status available will show the ThinkLight status as "unknown". The available commands are:

```
echo on  > /proc/acpi/ibm/light
echo off > /proc/acpi/ibm/light
```

sysfs notes

The ThinkLight sysfs interface is documented by the LED class documentation, in Documentation/leds/leds-class.rst. The ThinkLight LED name is ”tpacpi::thinklight”.

Due to limitations in the sysfs LED class, if the status of the ThinkLight cannot be read or if it is unknown, thinkpad-acpi will report it as ”off”. It is impossible to know if the status returned through sysfs is valid.

53.7.11 CMOS/UCMS control

procfs: /proc/acpi/ibm/cmos

sysfs device attribute: cmos_command

This feature is mostly used internally by the ACPI firmware to keep the legacy CMOS NVRAM bits in sync with the current machine state, and to record this state so that the ThinkPad will retain such settings across reboots.

Some of these commands actually perform actions in some ThinkPad models, but this is expected to disappear more and more in newer models. As an example, in a T43 and in a X40, commands 12 and 13 still control the ThinkLight state for real, but commands 0 to 2 don't control the mixer anymore (they have been phased out) and just update the NVRAM.

The range of valid cmos command numbers is 0 to 21, but not all have an effect and the behavior varies from model to model. Here is the behavior on the X40 (tpb is the ThinkPad Buttons utility):

- 0 - Related to ”Volume down” key press
- 1 - Related to ”Volume up” key press
- 2 - Related to ”Mute on” key press
- 3 - Related to ”Access IBM” key press
- 4 - Related to ”LCD brightness up” key press
- 5 - Related to ”LCD brightness down” key press
- 11 - Related to ”toggle screen expansion” key press/function
- 12 - Related to ”ThinkLight on”
- 13 - Related to ”ThinkLight off”
- 14 - Related to ”ThinkLight” key press (toggle ThinkLight)

The cmos command interface is prone to firmware split-brain problems, as in newer ThinkPads it is just a compatibility layer. Do not use it, it is exported just as a debug tool.

53.7.12 LED control

procfs: /proc/acpi/ibm/led sysfs attributes: as per LED class, see below for names

Some of the LED indicators can be controlled through this feature. On some older ThinkPad models, it is possible to query the status of the LED indicators as well. Newer ThinkPads cannot query the real status of the LED indicators.

Because misuse of the LEDs could induce an unaware user to perform dangerous actions (like undocking or ejecting a bay device while the buses are still active), or mask an important alarm (such as a nearly empty battery, or a broken battery), access to most LEDs is restricted.

Unrestricted access to all LEDs requires that thinkpad-acpi be compiled with the CONFIG_THINKPAD_ACPI_UNSAFE_LEDS option enabled. Distributions must never enable this option. Individual users that are aware of the consequences are welcome to enabling it.

Audio mute and microphone mute LEDs are supported, but currently not visible to userspace. They are used by the snd-hda-intel audio driver.

procfs notes

The available commands are:

```
echo '<LED number> on' >/proc/acpi/ibm/led
echo '<LED number> off' >/proc/acpi/ibm/led
echo '<LED number> blink' >/proc/acpi/ibm/led
```

The <LED number> range is 0 to 15. The set of LEDs that can be controlled varies from model to model. Here is the common ThinkPad mapping:

- 0 - power
- 1 - battery (orange)
- 2 - battery (green)
- 3 - UltraBase/dock
- 4 - UltraBay
- 5 - UltraBase battery slot
- 6 - (unknown)
- 7 - standby
- 8 - dock status 1
- 9 - dock status 2
- 10, 11 - (unknown)
- 12 - thinkvantage
- 13, 14, 15 - (unknown)

All of the above can be turned on and off and can be made to blink.

sysfs notes

The ThinkPad LED sysfs interface is described in detail by the LED class documentation, in Documentation/leds/leds-class.rst.

The LEDs are named (in LED ID order, from 0 to 12): "tpacpi::power", "tpacpi:orange:batt", "tpacpi:green:batt", "tpacpi::dock_active", "tpacpi::bay_active", "tpacpi::dock_batt", "tpacpi::unknown_led", "tpacpi::standby", "tpacpi::dock_status1", "tpacpi::dock_status2", "tpacpi::unknown_led2", "tpacpi::unknown_led3", "tpacpi::thinkvantage".

Due to limitations in the sysfs LED class, if the status of the LED indicators cannot be read due to an error, thinkpad-acpi will report it as a brightness of zero (same as LED off).

If the thinkpad firmware doesn't support reading the current status, trying to read the current LED brightness will just return whatever brightness was last written to that attribute.

These LEDs can blink using hardware acceleration. To request that a ThinkPad indicator LED should blink in hardware accelerated mode, use the "timer" trigger, and leave the delay_on and delay_off parameters set to zero (to request hardware acceleration autodetection).

LEDs that are known not to exist in a given ThinkPad model are not made available through the sysfs interface. If you have a dock and you notice there are LEDs listed for your ThinkPad that do not exist (and are not in the dock), or if you notice that there are missing LEDs, a report to ibm-acpi-devel@lists.sourceforge.net is appreciated.

53.7.13 ACPI sounds -- /proc/acpi/ibm/beep

The BEEP method is used internally by the ACPI firmware to provide audible alerts in various situations. This feature allows the same sounds to be triggered manually.

The commands are non-negative integer numbers:

```
echo <number> >/proc/acpi/ibm/beep
```

The valid <number> range is 0 to 17. Not all numbers trigger sounds and the sounds vary from model to model. Here is the behavior on the X40:

- 0 - stop a sound in progress (but use 17 to stop 16)
- 2 - two beeps, pause, third beep ("low battery")
- 3 - single beep
- 4 - high, followed by low-pitched beep ("unable")
- 5 - single beep
- 6 - very high, followed by high-pitched beep ("AC/DC")
- 7 - high-pitched beep
- 9 - three short beeps
- 10 - very long beep
- 12 - low-pitched beep
- 15 - three high-pitched beeps repeating constantly, stop with 0
- 16 - one medium-pitched beep repeating constantly, stop with 17

- 17 - stop 16

53.7.14 Temperature sensors

procfs: /proc/acpi/ibm/thermal

sysfs device attributes: (hwmon "thinkpad") temp*_input

Most ThinkPads include six or more separate temperature sensors but only expose the CPU temperature through the standard ACPI methods. This feature shows readings from up to eight different sensors on older ThinkPads, and up to sixteen different sensors on newer ThinkPads.

For example, on the X40, a typical output may be:

temperatures:
42 42 45 41 36 -128 33 -128

On the T43/p, a typical output may be:

temperatures:
48 48 36 52 38 -128 31 -128 48 52 48 -128 -128 -128 -128 -128

The mapping of thermal sensors to physical locations varies depending on system-board model (and thus, on ThinkPad model).

https://thinkwiki.org/wiki/Thermal_Sensors is a public wiki page that tries to track down these locations for various models.

Most (newer?) models seem to follow this pattern:

- 1: CPU
- 2: (depends on model)
- 3: (depends on model)
- 4: GPU
- 5: Main battery: main sensor
- 6: Bay battery: main sensor
- 7: Main battery: secondary sensor
- 8: Bay battery: secondary sensor
- 9-15: (depends on model)

For the R51 (source: Thomas Gruber):

- 2: Mini-PCI
- 3: Internal HDD

For the T43, T43/p (source: Shmidoax/Thinkwiki.org) https://thinkwiki.org/wiki/Thermal_Sensors#ThinkPad_T43.2C_T43p

- 2: System board, left side (near PCMCIA slot), reported as HDAPS temp
- 3: PCMCIA slot
- 9: MCH (northbridge) to DRAM Bus

- **10: Clock-generator, mini-pci card and ICH (southbridge), under Mini-PCI** card, under touchpad
- 11: Power regulator, underside of system board, below F2 key

The A31 has a very atypical layout for the thermal sensors (source: Milos Popovic, https://thinkwiki.org/wiki/Thermal_Sensors#ThinkPad_A31)

- 1: CPU
- 2: Main Battery: main sensor
- 3: Power Converter
- 4: Bay Battery: main sensor
- 5: MCH (northbridge)
- 6: PCMCIA/ambient
- 7: Main Battery: secondary sensor
- 8: Bay Battery: secondary sensor

Procfs notes

Readings from sensors that are not available return -128. No commands can be written to this file.

Sysfs notes

Sensors that are not available return the ENXIO error. This status may change at runtime, as there are hotplug thermal sensors, like those inside the batteries and docks.

thinkpad-acpi thermal sensors are reported through the hwmon subsystem, and follow all of the hwmon guidelines at Documentation/hwmon.

53.7.15 EXPERIMENTAL: Embedded controller register dump

This feature is not included in the thinkpad driver anymore. Instead the EC can be accessed through /sys/kernel/debug/ec with a userspace tool which can be found here: ftp://ftp.suse.com/pub/people/trenn/sources/ec

Use it to determine the register holding the fan speed on some models. To do that, do the following:

- make sure the battery is fully charged
- make sure the fan is running
- use above mentioned tool to read out the EC

Often fan and temperature values vary between readings. Since temperatures don't change vary fast, you can take several quick dumps to eliminate them.

You can use a similar method to figure out the meaning of other embedded controller registers - e.g. make sure nothing else changes except the charging or discharging battery to determine

which registers contain the current battery capacity, etc. If you experiment with this, do send me your results (including some complete dumps with a description of the conditions when they were taken.)

53.7.16 LCD brightness control

procfs: /proc/acpi/ibm/brightness

sysfs backlight device ”thinkpad_screen”

This feature allows software control of the LCD brightness on ThinkPad models which don't have a hardware brightness slider.

It has some limitations: the LCD backlight cannot be actually turned on or off by this interface, it just controls the backlight brightness level.

On IBM (and some of the earlier Lenovo) ThinkPads, the backlight control has eight brightness levels, ranging from 0 to 7. Some of the levels may not be distinct. Later Lenovo models that implement the ACPI display backlight brightness control methods have 16 levels, ranging from 0 to 15.

For IBM ThinkPads, there are two interfaces to the firmware for direct brightness control, EC and UCMS (or CMOS). To select which one should be used, use the brightness_mode module parameter: brightness_mode=1 selects EC mode, brightness_mode=2 selects UCMS mode, brightness_mode=3 selects EC mode with NVRAM backing (so that brightness changes are remembered across shutdown/reboot).

The driver tries to select which interface to use from a table of defaults for each ThinkPad model. If it makes a wrong choice, please report this as a bug, so that we can fix it.

Lenovo ThinkPads only support brightness_mode=2 (UCMS).

When display backlight brightness controls are available through the standard ACPI interface, it is best to use it instead of this direct ThinkPad-specific interface. The driver will disable its native backlight brightness control interface if it detects that the standard ACPI interface is available in the ThinkPad.

If you want to use the thinkpad-acpi backlight brightness control instead of the generic ACPI video backlight brightness control for some reason, you should use the acpi_backlight=vendor kernel parameter.

The brightness_enable module parameter can be used to control whether the LCD brightness control feature will be enabled when available. brightness_enable=0 forces it to be disabled. brightness_enable=1 forces it to be enabled when available, even if the standard ACPI interface is also available.

Procfs notes

The available commands are:

```
echo up   >/proc/acpi/ibm/brightness
echo down >/proc/acpi/ibm/brightness
echo 'level <level>' >/proc/acpi/ibm/brightness
```

Sysfs notes

The interface is implemented through the backlight sysfs class, which is poorly documented at this time.

Locate the thinkpad_screen device under /sys/class/backlight, and inside it there will be the following attributes:

max_brightness:
Reads the maximum brightness the hardware can be set to. The minimum is always zero.

actual_brightness:
Reads what brightness the screen is set to at this instant.

brightness:
Writes request the driver to change brightness to the given value. Reads will tell you what brightness the driver is trying to set the display to when "power" is set to zero and the display has not been dimmed by a kernel power management event.

power:
power management mode, where 0 is "display on", and 1 to 3 will dim the display backlight to brightness level 0 because thinkpad-acpi cannot really turn the backlight off. Kernel power management events can temporarily increase the current power management level, i.e. they can dim the display.

WARNING:

Whatever you do, do NOT ever call thinkpad-acpi backlight-level change interface and the ACPI-based backlight level change interface (available on newer BIOSes, and driven by the Linux ACPI video driver) at the same time. The two will interact in bad ways, do funny things, and maybe reduce the life of the backlight lamps by needlessly kicking its level up and down at every change.

53.7.17 Volume control (Console Audio control)

procfs: /proc/acpi/ibm/volume

ALSA: "ThinkPad Console Audio Control", default ID: "ThinkPadEC"

NOTE: by default, the volume control interface operates in read-only mode, as it is supposed to be used for on-screen-display purposes. The read/write mode can be enabled through the use of the "volume_control=1" module parameter.

NOTE: distros are urged to not enable volume_control by default, this should be done by the local admin only. The ThinkPad UI is for the console audio control to be done through the

volume keys only, and for the desktop environment to just provide on-screen-display feedback. Software volume control should be done only in the main AC97/HDA mixer.

About the ThinkPad Console Audio control

ThinkPads have a built-in amplifier and muting circuit that drives the console headphone and speakers. This circuit is after the main AC97 or HDA mixer in the audio path, and under exclusive control of the firmware.

ThinkPads have three special hotkeys to interact with the console audio control: volume up, volume down and mute.

It is worth noting that the normal way the mute function works (on ThinkPads that do not have a ”mute LED”) is:

1. Press mute to mute. It will *always* mute, you can press it as many times as you want, and the sound will remain mute.
2. Press either volume key to unmute the ThinkPad (it will _not_ change the volume, it will just unmute).

This is a very superior design when compared to the cheap software-only mute-toggle solution found on normal consumer laptops: you can be absolutely sure the ThinkPad will not make noise if you press the mute button, no matter the previous state.

The IBM ThinkPads, and the earlier Lenovo ThinkPads have variable-gain amplifiers driving the speakers and headphone output, and the firmware also handles volume control for the headphone and speakers on these ThinkPads without any help from the operating system (this volume control stage exists after the main AC97 or HDA mixer in the audio path).

The newer Lenovo models only have firmware mute control, and depend on the main HDA mixer to do volume control (which is done by the operating system). In this case, the volume keys are filtered out for unmute key press (there are some firmware bugs in this area) and delivered as normal key presses to the operating system (thinkpad-acpi is not involved).

The ThinkPad-ACPI volume control

The preferred way to interact with the Console Audio control is the ALSA interface.

The legacy procfs interface allows one to read the current state, and if volume control is enabled, accepts the following commands:

```
echo up   >/proc/acpi/ibm/volume
echo down >/proc/acpi/ibm/volume
echo mute >/proc/acpi/ibm/volume
echo unmute >/proc/acpi/ibm/volume
echo 'level <level>' >/proc/acpi/ibm/volume
```

The <level> number range is 0 to 14 although not all of them may be distinct. To unmute the volume after the mute command, use either the up or down command (the level command will not unmute the volume), or the unmute command.

You can use the volume_capabilities parameter to tell the driver whether your thinkpad has volume control or mute-only control: volume_capabilities=1 for mixers with mute and volume control, volume_capabilities=2 for mixers with only mute control.

If the driver misdetects the capabilities for your ThinkPad model, please report this to ibm-acpi-devel@lists.sourceforge.net, so that we can update the driver.

There are two strategies for volume control. To select which one should be used, use the volume_mode module parameter: volume_mode=1 selects EC mode, and volume_mode=3 selects EC mode with NVRAM backing (so that volume/mute changes are remembered across shutdown/reboot).

The driver will operate in volume_mode=3 by default. If that does not work well on your ThinkPad model, please report this to ibm-acpi-devel@lists.sourceforge.net.

The driver supports the standard ALSA module parameters. If the ALSA mixer is disabled, the driver will disable all volume functionality.

53.7.18 Fan control and monitoring: fan speed, fan enable/disable

procfs: /proc/acpi/ibm/fan

sysfs device attributes: (hwmon "thinkpad") fan1_input, pwm1, pwm1_enable, fan2_input

sysfs hwmon driver attributes: fan_watchdog

NOTE NOTE NOTE:
fan control operations are disabled by default for safety reasons. To enable them, the module parameter "fan_control=1" must be given to thinkpad-acpi.

This feature attempts to show the current fan speed, control mode and other fan data that might be available. The speed is read directly from the hardware registers of the embedded controller. This is known to work on later R, T, X and Z series ThinkPads but may show a bogus value on other models.

Some Lenovo ThinkPads support a secondary fan. This fan cannot be controlled separately, it shares the main fan control.

Fan levels

Most ThinkPad fans work in "levels" at the firmware interface. Level 0 stops the fan. The higher the level, the higher the fan speed, although adjacent levels often map to the same fan speed. 7 is the highest level, where the fan reaches the maximum recommended speed.

Level "auto" means the EC changes the fan level according to some internal algorithm, usually based on readings from the thermal sensors.

There is also a "full-speed" level, also known as "disengaged" level. In this level, the EC disables the speed-locked closed-loop fan control, and drives the fan as fast as it can go, which might exceed hardware limits, so use this level with caution.

The fan usually ramps up or down slowly from one speed to another, and it is normal for the EC to take several seconds to react to fan commands. The full-speed level may take up to two minutes to ramp up to maximum speed, and in some ThinkPads, the tachometer readings go stale while the EC is transitioning to the full-speed level.

WARNING WARNING WARNING: do not leave the fan disabled unless you are monitoring all of the temperature sensor readings and you are ready to enable it if necessary to avoid overheating.

An enabled fan in level ”auto” may stop spinning if the EC decides the ThinkPad is cool enough and doesn't need the extra airflow. This is normal, and the EC will spin the fan up if the various thermal readings rise too much.

On the X40, this seems to depend on the CPU and HDD temperatures. Specifically, the fan is turned on when either the CPU temperature climbs to 56 degrees or the HDD temperature climbs to 46 degrees. The fan is turned off when the CPU temperature drops to 49 degrees and the HDD temperature drops to 41 degrees. These thresholds cannot currently be controlled.

The ThinkPad's ACPI DSDT code will reprogram the fan on its own when certain conditions are met. It will override any fan programming done through thinkpad-acpi.

The thinkpad-acpi kernel driver can be programmed to revert the fan level to a safe setting if userspace does not issue one of the procfs fan commands: ”enable”, ”disable”, ”level” or ”watchdog”, or if there are no writes to pwm1_enable (or to pwm1 *if and only if* pwm1_enable is set to 1, manual mode) within a configurable amount of time of up to 120 seconds. This functionality is called fan safety watchdog.

Note that the watchdog timer stops after it enables the fan. It will be rearmed again automatically (using the same interval) when one of the above mentioned fan commands is received. The fan watchdog is, therefore, not suitable to protect against fan mode changes made through means other than the ”enable”, ”disable”, and ”level” procfs fan commands, or the hwmon fan control sysfs interface.

Procfs notes

The fan may be enabled or disabled with the following commands:

```
echo enable  >/proc/acpi/ibm/fan
echo disable >/proc/acpi/ibm/fan
```

Placing a fan on level 0 is the same as disabling it. Enabling a fan will try to place it in a safe level if it is too slow or disabled.

The fan level can be controlled with the command:

```
echo 'level <level>' > /proc/acpi/ibm/fan
```

Where <level> is an integer from 0 to 7, or one of the words ”auto” or ”full-speed” (without the quotes). Not all ThinkPads support the ”auto” and ”full-speed” levels. The driver accepts ”disengaged” as an alias for ”full-speed”, and reports it as ”disengaged” for backwards compatibility.

On the X31 and X40 (and ONLY on those models), the fan speed can be controlled to a certain degree. Once the fan is running, it can be forced to run faster or slower with the following command:

```
echo 'speed <speed>' > /proc/acpi/ibm/fan
```

The sustainable range of fan speeds on the X40 appears to be from about 3700 to about 7350. Values outside this range either do not have any effect or the fan speed eventually settles somewhere in that range. The fan cannot be stopped or started with this command. This functionality is incomplete, and not available through the sysfs interface.

To program the safety watchdog, use the ”watchdog” command:

```
echo 'watchdog <interval in seconds>' > /proc/acpi/ibm/fan
```

If you want to disable the watchdog, use 0 as the interval.

Sysfs notes

The sysfs interface follows the hwmon subsystem guidelines for the most part, and the exception is the fan safety watchdog.

Writes to any of the sysfs attributes may return the EINVAL error if that operation is not supported in a given ThinkPad or if the parameter is out-of-bounds, and EPERM if it is forbidden. They may also return EINTR (interrupted system call), and EIO (I/O error while trying to talk to the firmware).

Features not yet implemented by the driver return ENOSYS.

hwmon device attribute pwm1_enable:

- 0: PWM offline (fan is set to full-speed mode)
- 1: Manual PWM control (use pwm1 to set fan level)
- 2: Hardware PWM control (EC "auto" mode)
- 3: reserved (Software PWM control, not implemented yet)

Modes 0 and 2 are not supported by all ThinkPads, and the driver is not always able to detect this. If it does know a mode is unsupported, it will return -EINVAL.

hwmon device attribute pwm1:
Fan level, scaled from the firmware values of 0-7 to the hwmon scale of 0-255. 0 means fan stopped, 255 means highest normal speed (level 7).

This attribute only commands the fan if pmw1_enable is set to 1 (manual PWM control).

hwmon device attribute fan1_input:
Fan tachometer reading, in RPM. May go stale on certain ThinkPads while the EC transitions the PWM to offline mode, which can take up to two minutes. May return rubbish on older ThinkPads.

hwmon device attribute fan2_input:
Fan tachometer reading, in RPM, for the secondary fan. Available only on some ThinkPads. If the secondary fan is not installed, will always read 0.

hwmon driver attribute fan_watchdog:
Fan safety watchdog timer interval, in seconds. Minimum is 1 second, maximum is 120 seconds. 0 disables the watchdog.

To stop the fan: set pwm1 to zero, and pwm1_enable to 1.

To start the fan in a safe mode: set pwm1_enable to 2. If that fails with EINVAL, try to set pwm1_enable to 1 and pwm1 to at least 128 (255 would be the safest choice, though).

53.7.19 WAN

procfs: /proc/acpi/ibm/wan

sysfs device attribute: wwan_enable (deprecated)

sysfs rfkill class: switch "tpacpi_wwan_sw"

This feature shows the presence and current state of the built-in Wireless WAN device.

If the ThinkPad supports it, the WWAN state is stored in NVRAM, so it is kept across reboots and power-off.

It was tested on a Lenovo ThinkPad X60. It should probably work on other ThinkPad models which come with this module installed.

Procfs notes

If the W-WAN card is installed, the following commands can be used:

```
echo enable > /proc/acpi/ibm/wan
echo disable > /proc/acpi/ibm/wan
```

Sysfs notes

If the W-WAN card is installed, it can be enabled / disabled through the "wwan_enable" thinkpad-acpi device attribute, and its current status can also be queried.

enable:

- 0: disables WWAN card / WWAN card is disabled
- 1: enables WWAN card / WWAN card is enabled.

Note: this interface has been superseded by the generic rfkill class. It has been deprecated, and it will be removed in year 2010.

rfkill controller switch "tpacpi_wwan_sw": refer to Documentation/driver-api/rfkill.rst for details.

53.7.20 LCD Shadow control

procfs: /proc/acpi/ibm/lcdshadow

Some newer T480s and T490s ThinkPads provide a feature called PrivacyGuard. By turning this feature on, the usable vertical and horizontal viewing angles of the LCD can be limited (as if some privacy screen was applied manually in front of the display).

procfs notes

The available commands are:

```
echo '0' >/proc/acpi/ibm/lcdshadow
echo '1' >/proc/acpi/ibm/lcdshadow
```

The first command ensures the best viewing angle and the latter one turns on the feature, restricting the viewing angles.

53.7.21 DYTC Lapmode sensor

sysfs: dytc_lapmode

Newer thinkpads and mobile workstations have the ability to determine if the device is in deskmode or lapmode. This feature is used by user space to decide if WWAN transmission can be increased to maximum power and is also useful for understanding the different thermal modes available as they differ between desk and lap mode.

The property is read-only. If the platform doesn't have support the sysfs class is not created.

53.7.22 EXPERIMENTAL: UWB

This feature is considered EXPERIMENTAL because it has not been extensively tested and validated in various ThinkPad models yet. The feature may not work as expected. USE WITH CAUTION! To use this feature, you need to supply the experimental=1 parameter when loading the module.

sysfs rfkill class: switch ”tpacpi_uwb_sw”

This feature exports an rfkill controller for the UWB device, if one is present and enabled in the BIOS.

Sysfs notes

> rfkill controller switch ”tpacpi_uwb_sw”: refer to Documentation/driver-api/rfkill.rst for details.

53.7.23 Setting keyboard language

sysfs: keyboard_lang

This feature is used to set keyboard language to ECFW using ASL interface. Fewer thinkpads models like T580 , T590 , T15 Gen 1 etc.. has ”=”, ”(', ”)” numeric keys, which are not displaying correctly, when keyboard language is other than ”english”. This is because the default keyboard language in ECFW is set as ”english”. Hence using this sysfs, user can set the correct keyboard language to ECFW and then these key's will work correctly.

Example of command to set keyboard language is mentioned below:

```
echo jp > /sys/devices/platform/thinkpad_acpi/keyboard_lang
```

Text corresponding to keyboard layout to be set in sysfs are: be(Belgian), cz(Czech), da(Danish), de(German), en(English), es(Spain), et(Estonian), fr(French), fr-ch(French(Switzerland)), hu(Hungarian), it(Italy), jp (Japan), nl(Dutch), nn(Norway), pl(Polish), pt(portuguese), sl(Slovenian), sv(Sweden), tr(Turkey)

53.7.24 WWAN Antenna type

sysfs: wwan_antenna_type

On some newer Thinkpads we need to set SAR value based on the antenna type. This interface will be used by userspace to get the antenna type and set the corresponding SAR value, as is required for FCC certification.

The available commands are:

```
cat /sys/devices/platform/thinkpad_acpi/wwan_antenna_type
```

Currently 2 antenna types are supported as mentioned below: - type a - type b

The property is read-only. If the platform doesn't have support the sysfs class is not created.

53.7.25 Auxmac

sysfs: auxmac

Some newer Thinkpads have a feature called MAC Address Pass-through. This feature is implemented by the system firmware to provide a system unique MAC, that can override a dock or USB ethernet dongle MAC, when connected to a network. This property enables user-space to easily determine the MAC address if the feature is enabled.

The values of this auxiliary MAC are:

cat /sys/devices/platform/thinkpad_acpi/auxmac

If the feature is disabled, the value will be 'disabled'.

This property is read-only.

53.7.26 Adaptive keyboard

sysfs device attribute: adaptive_kbd_mode

This sysfs attribute controls the keyboard ”face” that will be shown on the Lenovo X1 Carbon 2nd gen (2014)'s adaptive keyboard. The value can be read and set.

- 0 = Home mode
- 1 = Web-browser mode
- 2 = Web-conference mode
- 3 = Function mode
- 4 = Layflat mode

For more details about which buttons will appear depending on the mode, please review the laptop's user guide: https://download.lenovo.com/ibmdl/pub/pc/pccbbs/mobiles_pdf/x1carbon_2_ug_en.pdf

53.7.27 Battery charge control

sysfs attributes: /sys/class/power_supply/BAT*/charge_control_{start,end}_threshold

These two attributes are created for those batteries that are supported by the driver. They enable the user to control the battery charge thresholds of the given battery. Both values may be read and set. *charge_control_start_threshold* accepts an integer between 0 and 99 (inclusive); this value represents a battery percentage level, below which charging will begin. *charge_control_end_threshold* accepts an integer between 1 and 100 (inclusive); this value represents a battery percentage level, above which charging will stop.

The exact semantics of the attributes may be found in Documentation/ABI/testing/sysfs-class-power.

53.7.28 Multiple Commands, Module Parameters

Multiple commands can be written to the proc files in one shot by separating them with commas, for example:

```
echo enable,0xffff > /proc/acpi/ibm/hotkey
echo lcd_disable,crt_enable > /proc/acpi/ibm/video
```

Commands can also be specified when loading the thinkpad-acpi module, for example:

```
modprobe thinkpad_acpi hotkey=enable,0xffff video=auto_disable
```

53.7.29 Enabling debugging output

The module takes a debug parameter which can be used to selectively enable various classes of debugging output, for example:

```
modprobe thinkpad_acpi debug=0xffff
```

will enable all debugging output classes. It takes a bitmask, so to enable more than one output class, just add their values.

Debug bitmask	Description
0x8000	Disclose PID of userspace programs accessing some functions of the driver
0x0001	Initialization and probing
0x0002	Removal
0x0004	RF Transmitter control (RFKILL) (bluetooth, WWAN, UWB...)
0x0008	HKEY event interface, hotkeys
0x0010	Fan control
0x0020	Backlight brightness
0x0040	Audio mixer/volume control

There is also a kernel build option to enable more debugging information, which may be necessary to debug driver problems.

The level of debugging information output by the driver can be changed at runtime through sysfs, using the driver attribute debug_level. The attribute takes the same bitmask as the debug module parameter above.

53.7.30 Force loading of module

If thinkpad-acpi refuses to detect your ThinkPad, you can try to specify the module parameter force_load=1. Regardless of whether this works or not, please contact ibm-acpi-devel@lists.sourceforge.net with a report.

Sysfs interface changelog

0x000100:	Initial sysfs support, as a single platform driver and device.
0x000200:	Hot key support for 32 hot keys, and radio slider switch support.
0x010000:	Hot keys are now handled by default over the input layer, the radio switch generates input event EV_RADIO, and the driver enables hot key handling by default in the firmware.
0x020000:	ABI fix: added a separate hwmon platform device and driver, which must be located by name (thinkpad) and the hwmon class for libsensors4 (lm-sensors 3) compatibility. Moved all hwmon attributes to this new platform device.
0x020100:	Marker for thinkpad-acpi with hot key NVRAM polling support. If you must, use it to know you should not start a userspace NVRAM poller (allows to detect when NVRAM is compiled out by the user because it is unneeded/undesired in the first place).
0x020101:	Marker for thinkpad-acpi with hot key NVRAM polling and proper hotkey_mask semantics (version 8 of the NVRAM polling patch). Some development snapshots of 0.18 had an earlier version that did strange things to hotkey_mask.
0x020200:	Add poll()/select() support to the following attributes: hotkey_radio_sw, wakeup_hotunplug_complete, wakeup_reason
0x020300:	hotkey enable/disable support removed, attributes hotkey_bios_enabled and hotkey_enable deprecated and marked for removal.
0x020400:	Marker for 16 LEDs support. Also, LEDs that are known to not exist in a given model are not registered with the LED sysfs class anymore.
0x020500:	Updated hotkey driver, hotkey_mask is always available and it is always able to disable hot keys. Very old thinkpads are properly supported. hotkey_bios_mask is deprecated and marked for removal.
0x020600:	Marker for backlight change event support.
0x020700:	Support for mute-only mixers. Volume control in read-only mode by default. Marker for ALSA mixer support.
0x030000:	Thermal and fan sysfs attributes were moved to the hwmon device instead of being attached to the backing platform device.

53.8 Toshiba HDD Active Protection Sensor

Kernel driver: toshiba_haps

Author: Azael Avalos <coproscefalo@gmail.com>

53.8.1 1. Description

This driver provides support for the accelerometer found in various Toshiba laptops, being called "Toshiba HDD Protection - Shock Sensor" officially, and detects laptops automatically with this device. On Windows, Toshiba provided software monitors this device and provides automatic HDD protection (head unload) on sudden moves or harsh vibrations, however, this driver only provides a notification via a sysfs file to let userspace tools or daemons act accordingly, as well as providing a sysfs file to set the desired protection level or sensor sensibility.

53.8.2 2. Interface

This device comes with 3 methods:

_STA	Checks existence of the device, returning Zero if the device does not exists or is not supported.
PTLV	Sets the desired protection level.
RSSS	Shuts down the HDD protection interface for a few seconds, then restores normal operation.

Note:
The presence of Solid State Drives (SSD) can make this driver to fail loading, given the fact that such drives have no movable parts, and thus, not requiring any "protection" as well as failing during the evaluation of the _STA method found under this device.

53.8.3 3. Accelerometer axes

This device does not report any axes, however, to query the sensor position a couple HCI (Hardware Configuration Interface) calls (0x6D and 0xA6) are provided to query such information, handled by the kernel module toshiba_acpi since kernel version 3.15.

53.8.4 4. Supported devices

This driver binds itself to the ACPI device TOS620A, and any Toshiba laptop with this device is supported, given the fact that they have the presence of conventional HDD and not only SSD, or a combination of both HDD and SSD.

53.8.5 5. Usage

The sysfs files under /sys/devices/LNXSYSTM:00/LNXSYBUS:00/TOS620A:00/ are:

protection_level	The protection_level is readable and writeable, and provides a way to let userspace query the current protection level, as well as set the desired protection level, the available protection levels are:
	`============  =======  ========== ␣ ↪ ========`
	`0 - Disabled  1 - Low  2 - Medium ␣ ↪ 3 - High`
	`============  =======  ========== ␣ ↪ ========`

reset_protection	The reset_protection entry is writeable only, being "1" the only parameter it accepts, it is used to trigger a reset of the protection interface.

CHAPTER

FIFTYFOUR

PARALLEL PORT LCD/KEYPAD PANEL SUPPORT

Some LCDs allow you to define up to 8 characters, mapped to ASCII characters 0 to 7. The escape code to define a new character is 'e[LG' followed by one digit from 0 to 7, representing the character number, and up to 8 couples of hex digits terminated by a semi-colon (';'). Each couple of digits represents a line, with 1-bits for each illuminated pixel with LSB on the right. Lines are numbered from the top of the character to the bottom. On a 5x7 matrix, only the 5 lower bits of the 7 first bytes are used for each character. If the string is incomplete, only complete lines will be redefined. Here are some examples:

```
printf "\e[LG0010101050D1F0C04;"  => 0 = [enter]
printf "\e[LG1040E1F0000000000;"  => 1 = [up]
printf "\e[LG2000000001F0E0400;"  => 2 = [down]
printf "\e[LG3040E1F001F0E0400;"  => 3 = [up-down]
printf "\e[LG40002060E1E0E0602;"  => 4 = [left]
printf "\e[LG500080C0E0F0E0C08;"  => 5 = [right]
printf "\e[LG60016051516141400;"  => 6 = "IP"

printf "\e[LG00103071F1F070301;"  => big speaker
printf "\e[LG00002061E1E060200;"  => small speaker
```

LDM - LOGICAL DISK MANAGER (DYNAMIC DISKS)

Author
Originally Written by FlatCap - Richard Russon <ldm@flatcap.org>.

Last Updated
Anton Altaparmakov on 30 March 2007 for Windows Vista.

55.1 Overview

Windows 2000, XP, and Vista use a new partitioning scheme. It is a complete replacement for the MSDOS style partitions. It stores its information in a 1MiB journalled database at the end of the physical disk. The size of partitions is limited only by disk space. The maximum number of partitions is nearly 2000.

Any partitions created under the LDM are called ”Dynamic Disks”. There are no longer any primary or extended partitions. Normal MSDOS style partitions are now known as Basic Disks.

If you wish to use Spanned, Striped, Mirrored or RAID 5 Volumes, you must use Dynamic Disks. The journalling allows Windows to make changes to these partitions and filesystems without the need to reboot.

Once the LDM driver has divided up the disk, you can use the MD driver to assemble any multi-partition volumes, e.g. Stripes, RAID5.

To prevent legacy applications from repartitioning the disk, the LDM creates a dummy MSDOS partition containing one disk-sized partition. This is what is supported with the Linux LDM driver.

A newer approach that has been implemented with Vista is to put LDM on top of a GPT label disk. This is not supported by the Linux LDM driver yet.

55.2 Example

Below we have a 50MiB disk, divided into seven partitions.

Note: The missing 1MiB at the end of the disk is where the LDM database is stored.

Device		Offset Bytes	Sectors	MiB		Size Bytes	Sectors	MiB
hda		0	0	0		52428800	102400	50
hda1		51380224	100352	49		1048576	2048	1
hda2		16384	32	0		6979584	13632	6
hda3		6995968	13664	6		10485760	20480	10
hda4		17481728	34144	16		4194304	8192	4
hda5		21676032	42336	20		5242880	10240	5
hda6		26918912	52576	25		10485760	20480	10
hda7		37404672	73056	35		13959168	27264	13

The LDM Database may not store the partitions in the order that they appear on disk, but the driver will sort them.

When Linux boots, you will see something like:

```
hda: 102400 sectors w/32KiB Cache, CHS=50/64/32
hda: [LDM] hda1 hda2 hda3 hda4 hda5 hda6 hda7
```

55.3 Compiling LDM Support

To enable LDM, choose the following two options:

- ”Advanced partition selection” CONFIG_PARTITION_ADVANCED
- ”Windows Logical Disk Manager (Dynamic Disk) support” CONFIG_LDM_PARTITION

If you believe the driver isn't working as it should, you can enable the extra debugging code. This will produce a LOT of output. The option is:

- ”Windows LDM extra logging” CONFIG_LDM_DEBUG

N.B. The partition code cannot be compiled as a module.

As with all the partition code, if the driver doesn't see signs of its type of partition, it will pass control to another driver, so there is no harm in enabling it.

If you have Dynamic Disks but don't enable the driver, then all you will see is a dummy MSDOS partition filling the whole disk. You won't be able to mount any of the volumes on the disk.

55.4 Booting

If you enable LDM support, then lilo is capable of booting from any of the discovered partitions. However, grub does not understand the LDM partitioning and cannot boot from a Dynamic Disk.

55.5 More Documentation

There is an Overview of the LDM together with complete Technical Documentation. It is available for download.

http://www.linux-ntfs.org/

If you have any LDM questions that aren't answered in the documentation, email me.

Cheers,

FlatCap - Richard Russon ldm@flatcap.org

CHAPTER

FIFTYSIX

SOFTLOCKUP DETECTOR AND HARDLOCKUP DETECTOR (AKA NMI_WATCHDOG)

The Linux kernel can act as a watchdog to detect both soft and hard lockups.

A 'softlockup' is defined as a bug that causes the kernel to loop in kernel mode for more than 20 seconds (see "Implementation" below for details), without giving other tasks a chance to run. The current stack trace is displayed upon detection and, by default, the system will stay locked up. Alternatively, the kernel can be configured to panic; a sysctl, "kernel.softlockup_panic", a kernel parameter, "softlockup_panic" (see "*The kernel's command-line parameters*" for details), and a compile option, "BOOTPARAM_SOFTLOCKUP_PANIC", are provided for this.

A 'hardlockup' is defined as a bug that causes the CPU to loop in kernel mode for more than 10 seconds (see "Implementation" below for details), without letting other interrupts have a chance to run. Similarly to the softlockup case, the current stack trace is displayed upon detection and the system will stay locked up unless the default behavior is changed, which can be done through a sysctl, 'hardlockup_panic', a compile time knob, "BOOTPARAM_HARDLOCKUP_PANIC", and a kernel parameter, "nmi_watchdog" (see "*The kernel's command-line parameters*" for details).

The panic option can be used in combination with panic_timeout (this timeout is set through the confusingly named "kernel.panic" sysctl), to cause the system to reboot automatically after a specified amount of time.

56.1 Implementation

The soft and hard lockup detectors are built on top of the hrtimer and perf subsystems, respectively. A direct consequence of this is that, in principle, they should work in any architecture where these subsystems are present.

A periodic hrtimer runs to generate interrupts and kick the watchdog job. An NMI perf event is generated every "watchdog_thresh" (compile-time initialized to 10 and configurable through sysctl of the same name) seconds to check for hardlockups. If any CPU in the system does not receive any hrtimer interrupt during that time the 'hardlockup detector' (the handler for the NMI perf event) will generate a kernel warning or call panic, depending on the configuration.

The watchdog job runs in a stop scheduling thread that updates a timestamp every time it is scheduled. If that timestamp is not updated for 2*watchdog_thresh seconds (the softlockup threshold) the 'softlockup detector' (coded inside the hrtimer callback function) will dump useful debug information to the system log, after which it will call panic if it was instructed to do so or resume execution of other kernel code.

The period of the hrtimer is 2*watchdog_thresh/5, which means it has two or three chances to generate an interrupt before the hardlockup detector kicks in.

As explained above, a kernel knob is provided that allows administrators to configure the period of the hrtimer and the perf event. The right value for a particular environment is a trade-off between fast response to lockups and detection overhead.

By default, the watchdog runs on all online cores. However, on a kernel configured with NO_HZ_FULL, by default the watchdog runs only on the housekeeping cores, not the cores specified in the "nohz_full" boot argument. If we allowed the watchdog to run by default on the "nohz_full" cores, we would have to run timer ticks to activate the scheduler, which would prevent the "nohz_full" functionality from protecting the user code on those cores from the kernel. Of course, disabling it by default on the nohz_full cores means that when those cores do enter the kernel, by default we will not be able to detect if they lock up. However, allowing the watchdog to continue to run on the housekeeping (non-tickless) cores means that we will continue to detect lockups properly on those cores.

In either case, the set of cores excluded from running the watchdog may be adjusted via the kernel.watchdog_cpumask sysctl. For nohz_full cores, this may be useful for debugging a case where the kernel seems to be hanging on the nohz_full cores.

CHAPTER

FIFTYSEVEN

LINUX SECURITY MODULE USAGE

The Linux Security Module (LSM) framework provides a mechanism for various security checks to be hooked by new kernel extensions. The name ”module” is a bit of a misnomer since these extensions are not actually loadable kernel modules. Instead, they are selectable at build-time via CONFIG_DEFAULT_SECURITY and can be overridden at boot-time via the `"security=..."` kernel command line argument, in the case where multiple LSMs were built into a given kernel.

The primary users of the LSM interface are Mandatory Access Control (MAC) extensions which provide a comprehensive security policy. Examples include SELinux, Smack, Tomoyo, and AppArmor. In addition to the larger MAC extensions, other extensions can be built using the LSM to provide specific changes to system operation when these tweaks are not available in the core functionality of Linux itself.

The Linux capabilities modules will always be included. This may be followed by any number of ”minor” modules and at most one ”major” module. For more details on capabilities, see `capabilities(7)` in the Linux man-pages project.

A list of the active security modules can be found by reading `/sys/kernel/security/lsm`. This is a comma separated list, and will always include the capability module. The list reflects the order in which checks are made. The capability module will always be first, followed by any ”minor” modules (e.g. Yama) and then the one ”major” module (e.g. SELinux) if there is one configured.

Process attributes associated with ”major” security modules should be accessed and maintained using the special files in `/proc/.../attr`. A security module may maintain a module specific subdirectory there, named after the module. `/proc/.../attr/smack` is provided by the Smack security module and contains all its special files. The files directly in `/proc/.../attr` remain as legacy interfaces for modules that provide subdirectories.

57.1 AppArmor

57.1.1 What is AppArmor?

AppArmor is MAC style security extension for the Linux kernel. It implements a task centered policy, with task ”profiles” being created and loaded from user space. Tasks on the system that do not have a profile defined for them run in an unconfined state which is equivalent to standard Linux DAC permissions.

57.1.2 How to enable/disable

set `CONFIG_SECURITY_APPARMOR=y`

If AppArmor should be selected as the default security module then set:

```
CONFIG_DEFAULT_SECURITY="apparmor"
CONFIG_SECURITY_APPARMOR_BOOTPARAM_VALUE=1
```

Build the kernel

If AppArmor is not the default security module it can be enabled by passing `security=apparmor` on the kernel's command line.

If AppArmor is the default security module it can be disabled by passing `apparmor=0`, `security=XXXX` (where `XXXX` is valid security module), on the kernel's command line.

For AppArmor to enforce any restrictions beyond standard Linux DAC permissions policy must be loaded into the kernel from user space (see the Documentation and tools links).

57.1.3 Documentation

Documentation can be found on the wiki, linked below.

57.1.4 Links

Mailing List - apparmor@lists.ubuntu.com

Wiki - http://wiki.apparmor.net

User space tools - https://gitlab.com/apparmor

Kernel module - git://git.kernel.org/pub/scm/linux/kernel/git/jj/linux-apparmor

57.2 LoadPin

LoadPin is a Linux Security Module that ensures all kernel-loaded files (modules, firmware, etc) all originate from the same filesystem, with the expectation that such a filesystem is backed by a read-only device such as dm-verity or CDROM. This allows systems that have a verified and/or unchangeable filesystem to enforce module and firmware loading restrictions without needing to sign the files individually.

The LSM is selectable at build-time with `CONFIG_SECURITY_LOADPIN`, and can be controlled at boot-time with the kernel command line option "`loadpin.enforce`". By default, it is enabled, but can be disabled at boot ("`loadpin.enforce=0`").

LoadPin starts pinning when it sees the first file loaded. If the block device backing the filesystem is not read-only, a sysctl is created to toggle pinning: `/proc/sys/kernel/loadpin/enabled`. (Having a mutable filesystem means pinning is mutable too, but having the sysctl allows for easy testing on systems with a mutable filesystem.)

It's also possible to exclude specific file types from LoadPin using kernel command line option "`loadpin.exclude`". By default, all files are included, but they can be excluded using kernel command line option such as "`loadpin.exclude=kernel-module,kexec-image`". This allows to

use different mechanisms such as `CONFIG_MODULE_SIG` and `CONFIG_KEXEC_VERIFY_SIG` to verify kernel module and kernel image while still use LoadPin to protect the integrity of other files kernel loads. The full list of valid file types can be found in `kernel_read_file_str` defined in `include/linux/kernel_read_file.h`.

57.3 SELinux

If you want to use SELinux, chances are you will want to use the distro-provided policies, or install the latest reference policy release from

https://github.com/SELinuxProject/refpolicy

However, if you want to install a dummy policy for testing, you can do using `mdp` provided under scripts/selinux. Note that this requires the selinux userspace to be installed - in particular you will need checkpolicy to compile a kernel, and setfiles and fixfiles to label the filesystem.

1. Compile the kernel with selinux enabled.
2. Type `make` to compile `mdp`.
3. Make sure that you are not running with SELinux enabled and a real policy. If you are, reboot with selinux disabled before continuing.
4. Run install_policy.sh:

```
cd scripts/selinux
sh install_policy.sh
```

Step 4 will create a new dummy policy valid for your kernel, with a single selinux user, role, and type. It will compile the policy, will set your `SELINUXTYPE` to `dummy` in `/etc/selinux/config`, install the compiled policy as `dummy`, and relabel your filesystem.

57.4 Smack

> "Good for you, you've decided to clean the elevator!" - The Elevator, from Dark Star

Smack is the Simplified Mandatory Access Control Kernel. Smack is a kernel based implementation of mandatory access control that includes simplicity in its primary design goals.

Smack is not the only Mandatory Access Control scheme available for Linux. Those new to Mandatory Access Control are encouraged to compare Smack with the other mechanisms available to determine which is best suited to the problem at hand.

Smack consists of three major components:

- The kernel
- Basic utilities, which are helpful but not required
- Configuration data

The kernel component of Smack is implemented as a Linux Security Modules (LSM) module. It requires netlabel and works best with file systems that support extended attributes, although xattr support is not strictly required. It is safe to run a Smack kernel under a "vanilla" distribution.

Smack kernels use the CIPSO IP option. Some network configurations are intolerant of IP options and can impede access to systems that use them as Smack does.

Smack is used in the Tizen operating system. Please go to http://wiki.tizen.org for information about how Smack is used in Tizen.

The current git repository for Smack user space is:

git://github.com/smack-team/smack.git

This should make and install on most modern distributions. There are five commands included in smackutil:

chsmack:
display or set Smack extended attribute values

smackctl:
load the Smack access rules

smackaccess:
report if a process with one label has access to an object with another

These two commands are obsolete with the introduction of the smackfs/load2 and smackfs/cipso2 interfaces.

smackload:
properly formats data for writing to smackfs/load

smackcipso:
properly formats data for writing to smackfs/cipso

In keeping with the intent of Smack, configuration data is minimal and not strictly required. The most important configuration step is mounting the smackfs pseudo filesystem. If smackutil is installed the startup script will take care of this, but it can be manually as well.

Add this line to `/etc/fstab`:

```
smackfs /sys/fs/smackfs smackfs defaults 0 0
```

The `/sys/fs/smackfs` directory is created by the kernel.

Smack uses extended attributes (xattrs) to store labels on filesystem objects. The attributes are stored in the extended attribute security name space. A process must have `CAP_MAC_ADMIN` to change any of these attributes.

The extended attributes that Smack uses are:

SMACK64
Used to make access control decisions. In almost all cases the label given to a new filesystem object will be the label of the process that created it.

SMACK64EXEC
The Smack label of a process that execs a program file with this attribute set will run with this attribute's value.

SMACK64MMAP
Don't allow the file to be mmapped by a process whose Smack label does not allow all of the access permitted to a process with the label contained in this attribute. This is a very specific use case for shared libraries.

SMACK64TRANSMUTE
Can only have the value "TRUE". If this attribute is present on a directory when an object is created in the directory and the Smack rule (more below) that permitted the write access to the directory includes the transmute ("t") mode the object gets the label of the directory instead of the label of the creating process. If the object being created is a directory the SMACK64TRANSMUTE attribute is set as well.

SMACK64IPIN
This attribute is only available on file descriptors for sockets. Use the Smack label in this attribute for access control decisions on packets being delivered to this socket.

SMACK64IPOUT
This attribute is only available on file descriptors for sockets. Use the Smack label in this attribute for access control decisions on packets coming from this socket.

There are multiple ways to set a Smack label on a file:

```
# attr -S -s SMACK64 -V "value" path
# chsmack -a value path
```

A process can see the Smack label it is running with by reading `/proc/self/attr/current`. A process with `CAP_MAC_ADMIN` can set the process Smack by writing there.

Most Smack configuration is accomplished by writing to files in the smackfs filesystem. This pseudo-filesystem is mounted on `/sys/fs/smackfs`.

access
Provided for backward compatibility. The access2 interface is preferred and should be used instead. This interface reports whether a subject with the specified Smack label has a particular access to an object with a specified Smack label. Write a fixed format access rule to this file. The next read will indicate whether the access would be permitted. The text will be either "1" indicating access, or "0" indicating denial.

access2
This interface reports whether a subject with the specified Smack label has a particular access to an object with a specified Smack label. Write a long format access rule to this file. The next read will indicate whether the access would be permitted. The text will be either "1" indicating access, or "0" indicating denial.

ambient
This contains the Smack label applied to unlabeled network packets.

change-rule
This interface allows modification of existing access control rules. The format accepted on write is:

```
"%s %s %s %s"
```

where the first string is the subject label, the second the object label, the third the access to allow and the fourth the access to deny. The access strings may contain only the characters "rwxat-". If a rule for a given subject and object exists it will be modified by enabling the permissions in the third string and disabling those in the fourth string. If there is no such rule it will be created using the access specified in the third and the fourth strings.

cipso
Provided for backward compatibility. The cipso2 interface is preferred and should be used

instead. This interface allows a specific CIPSO header to be assigned to a Smack label. The format accepted on write is:

```
"%24s%4d%4d"["%4d"]...
```

The first string is a fixed Smack label. The first number is the level to use. The second number is the number of categories. The following numbers are the categories:

```
"level-3-cats-5-19          3   2   5  19"
```

cipso2
This interface allows a specific CIPSO header to be assigned to a Smack label. The format accepted on write is:

```
"%s%4d%4d"["%4d"]...
```

The first string is a long Smack label. The first number is the level to use. The second number is the number of categories. The following numbers are the categories:

```
"level-3-cats-5-19   3   2   5  19"
```

direct
This contains the CIPSO level used for Smack direct label representation in network packets.

doi
This contains the CIPSO domain of interpretation used in network packets.

ipv6host
This interface allows specific IPv6 internet addresses to be treated as single label hosts. Packets are sent to single label hosts only from processes that have Smack write access to the host label. All packets received from single label hosts are given the specified label. The format accepted on write is:

```
"%h:%h:%h:%h:%h:%h:%h:%h label" or
"%h:%h:%h:%h:%h:%h:%h:%h/%d label".
```

The "::" address shortcut is not supported. If label is "-DELETE" a matched entry will be deleted.

load
Provided for backward compatibility. The load2 interface is preferred and should be used instead. This interface allows access control rules in addition to the system defined rules to be specified. The format accepted on write is:

```
"%24s%24s%5s"
```

where the first string is the subject label, the second the object label, and the third the requested access. The access string may contain only the characters "rwxat-", and specifies which sort of access is allowed. The "-" is a placeholder for permissions that are not allowed. The string "r-x--" would specify read and execute access. Labels are limited to 23 characters in length.

load2
This interface allows access control rules in addition to the system defined rules to be

specified. The format accepted on write is:

```
"%s %s %s"
```

where the first string is the subject label, the second the object label, and the third the requested access. The access string may contain only the characters ”rwxat-”, and specifies which sort of access is allowed. The ”-” is a placeholder for permissions that are not allowed. The string ”r-x--” would specify read and execute access.

load-self
Provided for backward compatibility. The load-self2 interface is preferred and should be used instead. This interface allows process specific access rules to be defined. These rules are only consulted if access would otherwise be permitted, and are intended to provide additional restrictions on the process. The format is the same as for the load interface.

load-self2
This interface allows process specific access rules to be defined. These rules are only consulted if access would otherwise be permitted, and are intended to provide additional restrictions on the process. The format is the same as for the load2 interface.

logging
This contains the Smack logging state.

mapped
This contains the CIPSO level used for Smack mapped label representation in network packets.

netlabel
This interface allows specific internet addresses to be treated as single label hosts. Packets are sent to single label hosts without CIPSO headers, but only from processes that have Smack write access to the host label. All packets received from single label hosts are given the specified label. The format accepted on write is:

```
"%d.%d.%d.%d label" or "%d.%d.%d.%d/%d label".
```

If the label specified is ”-CIPSO” the address is treated as a host that supports CIPSO headers.

onlycap
This contains labels processes must have for CAP_MAC_ADMIN and `CAP_MAC_OVERRIDE` to be effective. If this file is empty these capabilities are effective at for processes with any label. The values are set by writing the desired labels, separated by spaces, to the file or cleared by writing ”-” to the file.

ptrace
This is used to define the current ptrace policy

0 - default:
this is the policy that relies on Smack access rules. For the `PTRACE_READ` a subject needs to have a read access on object. For the `PTRACE_ATTACH` a read-write access is required.

1 - exact:
this is the policy that limits `PTRACE_ATTACH`. Attach is only allowed when subject's and object's labels are equal. `PTRACE_READ` is not affected. Can be overridden with `CAP_SYS_PTRACE`.

2 - draconian:
this policy behaves like the 'exact' above with an exception that it can't be overridden with `CAP_SYS_PTRACE`.

revoke-subject
Writing a Smack label here sets the access to '-' for all access rules with that subject label.

unconfined
If the kernel is configured with `CONFIG_SECURITY_SMACK_BRINGUP` a process with `CAP_MAC_ADMIN` can write a label into this interface. Thereafter, accesses that involve that label will be logged and the access permitted if it wouldn't be otherwise. Note that this is dangerous and can ruin the proper labeling of your system. It should never be used in production.

relabel-self
This interface contains a list of labels to which the process can transition to, by writing to `/proc/self/attr/current`. Normally a process can change its own label to any legal value, but only if it has `CAP_MAC_ADMIN`. This interface allows a process without `CAP_MAC_ADMIN` to relabel itself to one of labels from predefined list. A process without `CAP_MAC_ADMIN` can change its label only once. When it does, this list will be cleared. The values are set by writing the desired labels, separated by spaces, to the file or cleared by writing "-" to the file.

If you are using the smackload utility you can add access rules in `/etc/smack/accesses`. They take the form:

```
subjectlabel objectlabel access
```

access is a combination of the letters rwxatb which specify the kind of access permitted a subject with subjectlabel on an object with objectlabel. If there is no rule no access is allowed.

57.4.1 The Simplified Mandatory Access Control Kernel (Whitepaper)

Casey Schaufler casey@schaufler-ca.com

Mandatory Access Control

Computer systems employ a variety of schemes to constrain how information is shared among the people and services using the machine. Some of these schemes allow the program or user to decide what other programs or users are allowed access to pieces of data. These schemes are called discretionary access control mechanisms because the access control is specified at the discretion of the user. Other schemes do not leave the decision regarding what a user or program can access up to users or programs. These schemes are called mandatory access control mechanisms because you don't have a choice regarding the users or programs that have access to pieces of data.

Bell & LaPadula

From the middle of the 1980's until the turn of the century Mandatory Access Control (MAC) was very closely associated with the Bell & LaPadula security model, a mathematical description of the United States Department of Defense policy for marking paper documents. MAC in this form enjoyed a following within the Capital Beltway and Scandinavian supercomputer centers but was often sited as failing to address general needs.

Domain Type Enforcement

Around the turn of the century Domain Type Enforcement (DTE) became popular. This scheme organizes users, programs, and data into domains that are protected from each other. This scheme has been widely deployed as a component of popular Linux distributions. The administrative overhead required to maintain this scheme and the detailed understanding of the whole system necessary to provide a secure domain mapping leads to the scheme being disabled or used in limited ways in the majority of cases.

Smack

Smack is a Mandatory Access Control mechanism designed to provide useful MAC while avoiding the pitfalls of its predecessors. The limitations of Bell & LaPadula are addressed by providing a scheme whereby access can be controlled according to the requirements of the system and its purpose rather than those imposed by an arcane government policy. The complexity of Domain Type Enforcement and avoided by defining access controls in terms of the access modes already in use.

Smack Terminology

The jargon used to talk about Smack will be familiar to those who have dealt with other MAC systems and shouldn't be too difficult for the uninitiated to pick up. There are four terms that are used in a specific way and that are especially important:

Subject:
A subject is an active entity on the computer system. On Smack a subject is a task, which is in turn the basic unit of execution.

Object:
An object is a passive entity on the computer system. On Smack files of all types, IPC, and tasks can be objects.

Access:
Any attempt by a subject to put information into or get information from an object is an access.

Label:
Data that identifies the Mandatory Access Control characteristics of a subject or an object.

These definitions are consistent with the traditional use in the security community. There are also some terms from Linux that are likely to crop up:

Capability:
A task that possesses a capability has permission to violate an aspect of the system security policy, as identified by the specific capability. A task that possesses one or more capabilities is a privileged task, whereas a task with no capabilities is an unprivileged task.

Privilege:
A task that is allowed to violate the system security policy is said to have privilege. As of this writing a task can have privilege either by possessing capabilities or by having an effective user of root.

Smack Basics

Smack is an extension to a Linux system. It enforces additional restrictions on what subjects can access which objects, based on the labels attached to each of the subject and the object.

Labels

Smack labels are ASCII character strings. They can be up to 255 characters long, but keeping them to twenty-three characters is recommended. Single character labels using special characters, that being anything other than a letter or digit, are reserved for use by the Smack development team. Smack labels are unstructured, case sensitive, and the only operation ever performed on them is comparison for equality. Smack labels cannot contain unprintable characters, the ”/” (slash), the ”” (backslash), the ”'” (quote) and '”' (double-quote) characters. Smack labels cannot begin with a '-'. This is reserved for special options.

There are some predefined labels:

```
_       Pronounced "floor", a single underscore character.
^       Pronounced "hat", a single circumflex character.
*       Pronounced "star", a single asterisk character.
?       Pronounced "huh", a single question mark character.
@       Pronounced "web", a single at sign character.
```

Every task on a Smack system is assigned a label. The Smack label of a process will usually be assigned by the system initialization mechanism.

Access Rules

Smack uses the traditional access modes of Linux. These modes are read, execute, write, and occasionally append. There are a few cases where the access mode may not be obvious. These include:

Signals:
A signal is a write operation from the subject task to the object task.

Internet Domain IPC:
Transmission of a packet is considered a write operation from the source task to the destination task.

Smack restricts access based on the label attached to a subject and the label attached to the object it is trying to access. The rules enforced are, in order:

1. Any access requested by a task labeled "*" is denied.
2. A read or execute access requested by a task labeled "^" is permitted.
3. A read or execute access requested on an object labeled "_" is permitted.
4. Any access requested on an object labeled "*" is permitted.
5. Any access requested by a task on an object with the same label is permitted.
6. Any access requested that is explicitly defined in the loaded rule set is permitted.
7. Any other access is denied.

Smack Access Rules

With the isolation provided by Smack access separation is simple. There are many interesting cases where limited access by subjects to objects with different labels is desired. One example is the familiar spy model of sensitivity, where a scientist working on a highly classified project would be able to read documents of lower classifications and anything she writes will be "born" highly classified. To accommodate such schemes Smack includes a mechanism for specifying rules allowing access between labels.

Access Rule Format

The format of an access rule is:

```
subject-label object-label access
```

Where subject-label is the Smack label of the task, object-label is the Smack label of the thing being accessed, and access is a string specifying the sort of access allowed. The access specification is searched for letters that describe access modes:

> a: indicates that append access should be granted. r: indicates that read access should be granted. w: indicates that write access should be granted. x: indicates that execute access should be granted. t: indicates that the rule requests transmutation. b: indicates that the rule should be reported for bring-up.

Uppercase values for the specification letters are allowed as well. Access mode specifications can be in any order. Examples of acceptable rules are:

```
TopSecret Secret  rx
Secret    Unclass R
Manager   Game    x
User      HR      w
Snap      Crackle rwxatb
New       Old     rRrRr
Closed    Off     -
```

Examples of unacceptable rules are:

```
Top Secret Secret     rx
Ace        Ace        r
Odd        spells     waxbeans
```

Spaces are not allowed in labels. Since a subject always has access to files with the same label specifying a rule for that case is pointless. Only valid letters (rwxatbRWXATB) and the dash ('-') character are allowed in access specifications. The dash is a placeholder, so ”a-r” is the same as ”ar”. A lone dash is used to specify that no access should be allowed.

Applying Access Rules

The developers of Linux rarely define new sorts of things, usually importing schemes and concepts from other systems. Most often, the other systems are variants of Unix. Unix has many endearing properties, but consistency of access control models is not one of them. Smack strives to treat accesses as uniformly as is sensible while keeping with the spirit of the underlying mechanism.

File system objects including files, directories, named pipes, symbolic links, and devices require access permissions that closely match those used by mode bit access. To open a file for reading read access is required on the file. To search a directory requires execute access. Creating a file with write access requires both read and write access on the containing directory. Deleting a file requires read and write access to the file and to the containing directory. It is possible that a user may be able to see that a file exists but not any of its attributes by the circumstance of having read access to the containing directory but not to the differently labeled file. This is an artifact of the file name being data in the directory, not a part of the file.

If a directory is marked as transmuting (SMACK64TRANSMUTE=TRUE) and the access rule that allows a process to create an object in that directory includes 't' access the label assigned to the new object will be that of the directory, not the creating process. This makes it much easier for two processes with different labels to share data without granting access to all of their files.

IPC objects, message queues, semaphore sets, and memory segments exist in flat namespaces and access requests are only required to match the object in question.

Process objects reflect tasks on the system and the Smack label used to access them is the same Smack label that the task would use for its own access attempts. Sending a signal via the kill() system call is a write operation from the signaler to the recipient. Debugging a process requires both reading and writing. Creating a new task is an internal operation that results in two tasks with identical Smack labels and requires no access checks.

Sockets are data structures attached to processes and sending a packet from one process to another requires that the sender have write access to the receiver. The receiver is not required to have read access to the sender.

Setting Access Rules

The configuration file /etc/smack/accesses contains the rules to be set at system startup. The contents are written to the special file /sys/fs/smackfs/load2. Rules can be added at any time and take effect immediately. For any pair of subject and object labels there can be only one rule, with the most recently specified overriding any earlier specification.

Task Attribute

The Smack label of a process can be read from /proc/<pid>/attr/current. A process can read its own Smack label from /proc/self/attr/current. A privileged process can change its own Smack label by writing to /proc/self/attr/current but not the label of another process.

File Attribute

The Smack label of a filesystem object is stored as an extended attribute named SMACK64 on the file. This attribute is in the security namespace. It can only be changed by a process with privilege.

Privilege

A process with CAP_MAC_OVERRIDE or CAP_MAC_ADMIN is privileged. CAP_MAC_OVERRIDE allows the process access to objects it would be denied otherwise. CAP_MAC_ADMIN allows a process to change Smack data, including rules and attributes.

Smack Networking

As mentioned before, Smack enforces access control on network protocol transmissions. Every packet sent by a Smack process is tagged with its Smack label. This is done by adding a CIPSO tag to the header of the IP packet. Each packet received is expected to have a CIPSO tag that identifies the label and if it lacks such a tag the network ambient label is assumed. Before the packet is delivered a check is made to determine that a subject with the label on the packet has write access to the receiving process and if that is not the case the packet is dropped.

CIPSO Configuration

It is normally unnecessary to specify the CIPSO configuration. The default values used by the system handle all internal cases. Smack will compose CIPSO label values to match the Smack labels being used without administrative intervention. Unlabeled packets that come into the system will be given the ambient label.
