78 USB4 and Thunderbolt 2707
79 Using UFS 2713
80 Unicode support 2715

81 Software cursor for VGA 2719

82 Video Output Switcher Control 2721

83 The SGI XFS Filesystem 2723

Index 2733

The following is a collection of user-oriented documents that have been added to the kernel over time. There is, as yet, little overall order or organization here — this material was not written to be a single, coherent document! With luck things will improve quickly over time.

This initial section contains overall information, including the README file describing the kernel as a whole, documentation on kernel parameters, etc.

CHAPTER

ONE

LINUX KERNEL RELEASE 6.X <HTTP://KERNEL.ORG/>

These are the release notes for Linux version 6. Read them carefully, as they tell you what this is all about, explain how to install the kernel, and what to do if something goes wrong.

1.1 What is Linux?

Linux is a clone of the operating system Unix, written from scratch by Linus Torvalds with assistance from a loosely-knit team of hackers across the Net. It aims towards POSIX and Single UNIX Specification compliance.

It has all the features you would expect in a modern fully-fledged Unix, including true multitasking, virtual memory, shared libraries, demand loading, shared copy-on-write executables, proper memory management, and multistack networking including IPv4 and IPv6.

It is distributed under the GNU General Public License v2 - see the accompanying COPYING file for more details.

1.2 On what hardware does it run?

Although originally developed first for 32-bit x86-based PCs (386 or higher), today Linux also runs on (at least) the Compaq Alpha AXP, Sun SPARC and UltraSPARC, Motorola 68000, PowerPC, PowerPC64, ARM, Hitachi SuperH, Cell, IBM S/390, MIPS, HP PA-RISC, Intel IA-64, DEC VAX, AMD x86-64 Xtensa, and ARC architectures.

Linux is easily portable to most general-purpose 32- or 64-bit architectures as long as they have a paged memory management unit (PMMU) and a port of the GNU C compiler (gcc) (part of The GNU Compiler Collection, GCC). Linux has also been ported to a number of architectures without a PMMU, although functionality is then obviously somewhat limited. Linux has also been ported to itself. You can now run the kernel as a userspace application - this is called UserMode Linux (UML).

1.3 Documentation

- There is a lot of documentation available both in electronic form on the Internet and in books, both Linux-specific and pertaining to general UNIX questions. I'd recommend looking into the documentation subdirectories on any Linux FTP site for the LDP (Linux Documentation Project) books. This README is not meant to be documentation on the system: there are much better sources available.
- There are various README files in the Documentation/ subdirectory: these typically contain kernel-specific installation notes for some drivers for example. Please read the Documentation/process/changes.rst file, as it contains information about the problems, which may result by upgrading your kernel.

1.4 Installing the kernel source

- If you install the full sources, put the kernel tarball in a directory where you have permissions (e.g. your home directory) and unpack it:

  ```
  xz -cd linux-6.x.tar.xz | tar xvf -
  ```

  Replace "X" with the version number of the latest kernel.

  Do NOT use the /usr/src/linux area! This area has a (usually incomplete) set of kernel headers that are used by the library header files. They should match the library, and not get messed up by whatever the kernel-du-jour happens to be.

- You can also upgrade between 6.x releases by patching. Patches are distributed in the xz format. To install by patching, get all the newer patch files, enter the top level directory of the kernel source (linux-6.x) and execute:

  ```
  xz -cd ../patch-6.x.xz | patch -p1
  ```

  Replace "x" for all versions bigger than the version "x" of your current source tree, **in_order**, and you should be ok. You may want to remove the backup files (some-file-name~ or some-file-name.orig), and make sure that there are no failed patches (some-file-name# or some-file-name.rej). If there are, either you or I have made a mistake.

  Unlike patches for the 6.x kernels, patches for the 6.x.y kernels (also known as the -stable kernels) are not incremental but instead apply directly to the base 6.x kernel. For example, if your base kernel is 6.0 and you want to apply the 6.0.3 patch, you must not first apply the 6.0.1 and 6.0.2 patches. Similarly, if you are running kernel version 6.0.2 and want to jump to 6.0.3, you must first reverse the 6.0.2 patch (that is, patch -R) **before** applying the 6.0.3 patch. You can read more on this in Documentation/process/applying-patches.rst.

  Alternatively, the script patch-kernel can be used to automate this process. It determines the current kernel version and applies any patches found:

  ```
  linux/scripts/patch-kernel linux
  ```

  The first argument in the command above is the location of the kernel source. Patches are applied from the current directory, but an alternative directory can be specified as the second argument.

- Make sure you have no stale .o files and dependencies lying around:

```
cd linux
make mrproper
```

You should now have the sources correctly installed.

1.5 Software requirements

Compiling and running the 6.x kernels requires up-to-date versions of various software packages. Consult Documentation/process/changes.rst for the minimum version numbers required and how to get updates for these packages. Beware that using excessively old versions of these packages can cause indirect errors that are very difficult to track down, so don't assume that you can just update packages when obvious problems arise during build or operation.

1.6 Build directory for the kernel

When compiling the kernel, all output files will per default be stored together with the kernel source code. Using the option `make O=output/dir` allows you to specify an alternate place for the output files (including .config). Example:

```
kernel source code: /usr/src/linux-6.x
build directory:    /home/name/build/kernel
```

To configure and build the kernel, use:

```
cd /usr/src/linux-6.x
make O=/home/name/build/kernel menuconfig
make O=/home/name/build/kernel
sudo make O=/home/name/build/kernel modules_install install
```

Please note: If the `O=output/dir` option is used, then it must be used for all invocations of make.

1.7 Configuring the kernel

Do not skip this step even if you are only upgrading one minor version. New configuration options are added in each release, and odd problems will turn up if the configuration files are not set up as expected. If you want to carry your existing configuration to a new version with minimal work, use `make oldconfig`, which will only ask you for the answers to new questions.

- Alternative configuration commands are:

```
"make config"      Plain text interface.

"make menuconfig"  Text based color menus, radiolists & dialogs.
```

```
"make nconfig"     Enhanced text based color menus.

"make xconfig"     Qt based configuration tool.

"make gconfig"     GTK+ based configuration tool.

"make oldconfig"   Default all questions based on the contents of
                   your existing ./.config file and asking about
                   new config symbols.

"make olddefconfig"
                   Like above, but sets new symbols to their␣
↪default
                   values without prompting.

"make defconfig"   Create a ./.config file by using the default
                   symbol values from either arch/$ARCH/defconfig
                   or arch/$ARCH/configs/${PLATFORM}_defconfig,
                   depending on the architecture.

"make ${PLATFORM}_defconfig"
                   Create a ./.config file by using the default
                   symbol values from
                   arch/$ARCH/configs/${PLATFORM}_defconfig.
                   Use "make help" to get a list of all available
                   platforms of your architecture.

"make allyesconfig"
                   Create a ./.config file by setting symbol
                   values to 'y' as much as possible.

"make allmodconfig"
                   Create a ./.config file by setting symbol
                   values to 'm' as much as possible.

"make allnoconfig" Create a ./.config file by setting symbol
                   values to 'n' as much as possible.

"make randconfig"  Create a ./.config file by setting symbol
                   values to random values.

"make localmodconfig" Create a config based on current config and
                      loaded modules (lsmod). Disables any module
                      option that is not needed for the loaded␣
↪modules.

                      To create a localmodconfig for another␣
↪machine,
                      store the lsmod of that machine into a file
```

```
                        and pass it in as a LSMOD parameter.

                        Also, you can preserve modules in certain␣
↪folders
                        or kconfig files by specifying their paths in
                        parameter LMC_KEEP.

               target$ lsmod > /tmp/mylsmod
               target$ scp /tmp/mylsmod host:/tmp

               host$ make LSMOD=/tmp/mylsmod \
                        LMC_KEEP="drivers/usb:drivers/gpu:fs" \
                        localmodconfig

                        The above also works when cross compiling.

"make localyesconfig" Similar to localmodconfig, except it will␣
↪convert
                        all module options to built in (=y) options.␣
↪You can
                        also preserve modules by LMC_KEEP.

"make kvm_guest.config"   Enable additional options for kvm guest␣
↪kernel
                            support.

"make xen.config"   Enable additional options for xen dom0 guest␣
↪kernel
                    support.

"make tinyconfig"  Configure the tiniest possible kernel.
```

You can find more information on using the Linux kernel config tools in Documentation/kbuild/kconfig.rst.

- NOTES on `make config`:
  - Having unnecessary drivers will make the kernel bigger, and can under some circumstances lead to problems: probing for a nonexistent controller card may confuse your other controllers.
  - A kernel with math-emulation compiled in will still use the coprocessor if one is present: the math emulation will just never get used in that case. The kernel will be slightly larger, but will work on different machines regardless of whether they have a math coprocessor or not.
  - The "kernel hacking" configuration details usually result in a bigger or slower kernel (or both), and can even make the kernel less stable by configuring some routines to actively try to break bad code to find kernel problems (kmalloc()). Thus you should probably answer 'n' to the questions for "development", "experimental", or "debugging" features.

1.8 Compiling the kernel

- Make sure you have at least gcc 5.1 available. For more information, refer to Documentation/process/changes.rst.
- Do a `make` to create a compressed kernel image. It is also possible to do `make install` if you have lilo installed to suit the kernel makefiles, but you may want to check your particular lilo setup first.

  To do the actual install, you have to be root, but none of the normal build should require that. Don't take the name of root in vain.
- If you configured any of the parts of the kernel as `modules`, you will also have to do `make modules_install`.
- Verbose kernel compile/build output:

  Normally, the kernel build system runs in a fairly quiet mode (but not totally silent). However, sometimes you or other kernel developers need to see compile, link, or other commands exactly as they are executed. For this, use "verbose" build mode. This is done by passing `V=1` to the `make` command, e.g.:

  ```
  make V=1 all
  ```

  To have the build system also tell the reason for the rebuild of each target, use `V=2`. The default is `V=0`.
- Keep a backup kernel handy in case something goes wrong. This is especially true for the development releases, since each new release contains new code which has not been debugged. Make sure you keep a backup of the modules corresponding to that kernel, as well. If you are installing a new kernel with the same version number as your working kernel, make a backup of your modules directory before you do a `make modules_install`.

  Alternatively, before compiling, use the kernel config option "LOCALVERSION" to append a unique suffix to the regular kernel version. LOCALVERSION can be set in the "General Setup" menu.
- In order to boot your new kernel, you'll need to copy the kernel image (e.g. .../linux/arch/x86/boot/bzImage after compilation) to the place where your regular bootable kernel is found.
- Booting a kernel directly from a floppy without the assistance of a bootloader such as LILO, is no longer supported.

  If you boot Linux from the hard drive, chances are you use LILO, which uses the kernel image as specified in the file /etc/lilo.conf. The kernel image file is usually /vmlinuz, /boot/vmlinuz, /bzImage or /boot/bzImage. To use the new kernel, save a copy of the old image and copy the new image over the old one. Then, you MUST RERUN LILO to update the loading map! If you don't, you won't be able to boot the new kernel image.

  Reinstalling LILO is usually a matter of running /sbin/lilo. You may wish to edit /etc/lilo.conf to specify an entry for your old kernel image (say, /vmlinux.old) in case the new one does not work. See the LILO docs for more information.

  After reinstalling LILO, you should be all set. Shutdown the system, reboot, and enjoy!

If you ever need to change the default root device, video mode, etc. in the kernel image, use your bootloader's boot options where appropriate. No need to recompile the kernel to change these parameters.

- Reboot with the new kernel and enjoy.

1.9 If something goes wrong

If you have problems that seem to be due to kernel bugs, please follow the instructions at '*Reporting issues*'.

Hints on understanding kernel bug reports are in '*Bug hunting*'. More on debugging the kernel with gdb is in 'Documentation/dev-tools/gdb-kernel-debugging.rst' and 'Documentation/dev-tools/kgdb.rst'.

CHAPTER

TWO

THE KERNEL'S COMMAND-LINE PARAMETERS

The following is a consolidated list of the kernel parameters as implemented by the __setup(), early_param(), core_param() and module_param() macros and sorted into English Dictionary order (defined as ignoring all punctuation and sorting digits before letters in a case insensitive manner), and with descriptions where known.

The kernel parses parameters from the kernel command line up to "--"; if it doesn't recognize a parameter and it doesn't contain a '.', the parameter gets passed to init: parameters with '=' go into init's environment, others are passed as command line arguments to init. Everything after "--" is passed as an argument to init.

Module parameters can be specified in two ways: via the kernel command line with a module name prefix, or via modprobe, e.g.:

```
(kernel command line) usbcore.blinkenlights=1
(modprobe command line) modprobe usbcore blinkenlights=1
```

Parameters for modules which are built into the kernel need to be specified on the kernel command line. modprobe looks through the kernel command line (/proc/cmdline) and collects module parameters when it loads a module, so the kernel command line can be used for loadable modules too.

Hyphens (dashes) and underscores are equivalent in parameter names, so:

```
log_buf_len=1M print-fatal-signals=1
```

can also be entered as:

```
log-buf-len=1M print_fatal_signals=1
```

Double-quotes can be used to protect spaces in values, e.g.:

```
param="spaces in here"
```

2.1 cpu lists:

Some kernel parameters take a list of CPUs as a value, e.g. isolcpus, nohz_full, irqaffinity, rcu_nocbs. The format of this list is:

<cpu number>,...,<cpu number>

or

<cpu number>-<cpu number> (must be a positive range in ascending order)

or a mixture

<cpu number>,...,<cpu number>-<cpu number>

Note that for the special case of a range one can split the range into equal sized groups and for each group use some amount from the beginning of that group:

<cpu number>-<cpu number>:<used size>/<group size>

For example one can add to the command line following parameter:

isolcpus=1,2,10-20,100-2000:2/25

where the final item represents CPUs 100,101,125,126,150,151,...

The value "N" can be used to represent the numerically last CPU on the system, i.e "foo_cpus=16-N" would be equivalent to "16-31" on a 32 core system.

Keep in mind that "N" is dynamic, so if system changes cause the bitmap width to change, such as less cores in the CPU list, then N and any ranges using N will also change. Use the same on a small 4 core system, and "16-N" becomes "16-3" and now the same boot input will be flagged as invalid (start > end).

The special case-tolerant group name "all" has a meaning of selecting all CPUs, so that "nohz_full=all" is the equivalent of "nohz_full=0-N".

The semantics of "N" and "all" is supported on a level of bitmaps and holds for all users of bitmap_parselist().

This document may not be entirely up to date and comprehensive. The command "modinfo -p ${modulename}" shows a current list of all parameters of a loadable module. Loadable modules, after being loaded into the running kernel, also reveal their parameters in /sys/module/${modulename}/parameters/. Some of these parameters may be changed at runtime by the command `echo -n ${value} > /sys/module/${modulename}/parameters/${parm}`.

The parameters listed below are only valid if certain kernel build options were enabled and if respective hardware is present. This list should be kept in alphabetical order. The text in square brackets at the beginning of each description states the restrictions within which a parameter is applicable:

```
ACPI    ACPI support is enabled.
AGP     AGP (Accelerated Graphics Port) is enabled.
ALSA    ALSA sound support is enabled.
APIC    APIC support is enabled.
APM     Advanced Power Management support is enabled.
APPARMOR AppArmor support is enabled.
ARM     ARM architecture is enabled.
```

```
ARM64   ARM64 architecture is enabled.
AX25    Appropriate AX.25 support is enabled.
CLK     Common clock infrastructure is enabled.
CMA     Contiguous Memory Area support is enabled.
DRM     Direct Rendering Management support is enabled.
DYNAMIC_DEBUG Build in debug messages and enable them at runtime
EDD     BIOS Enhanced Disk Drive Services (EDD) is enabled
EFI     EFI Partitioning (GPT) is enabled
EVM     Extended Verification Module
FB      The frame buffer device is enabled.
FTRACE  Function tracing enabled.
GCOV    GCOV profiling is enabled.
HIBERNATION HIBERNATION is enabled.
HW      Appropriate hardware is enabled.
HYPER_V HYPERV support is enabled.
IA-64   IA-64 architecture is enabled.
IMA     Integrity measurement architecture is enabled.
IP_PNP  IP DHCP, BOOTP, or RARP is enabled.
IPV6    IPv6 support is enabled.
ISAPNP  ISA PnP code is enabled.
ISDN    Appropriate ISDN support is enabled.
ISOL    CPU Isolation is enabled.
JOY     Appropriate joystick support is enabled.
KGDB    Kernel debugger support is enabled.
KVM     Kernel Virtual Machine support is enabled.
LIBATA  Libata driver is enabled
LOONGARCH LoongArch architecture is enabled.
LOOP    Loopback device support is enabled.
LP      Printer support is enabled.
M68k    M68k architecture is enabled.
                These options have more detailed description inside of
                Documentation/arch/m68k/kernel-options.rst.
MDA     MDA console support is enabled.
MIPS    MIPS architecture is enabled.
MOUSE   Appropriate mouse support is enabled.
MSI     Message Signaled Interrupts (PCI).
MTD     MTD (Memory Technology Device) support is enabled.
NET     Appropriate network support is enabled.
NFS     Appropriate NFS support is enabled.
NUMA    NUMA support is enabled.
OF      Devicetree is enabled.
PARISC  The PA-RISC architecture is enabled.
PCI     PCI bus support is enabled.
PCIE    PCI Express support is enabled.
PCMCIA  The PCMCIA subsystem is enabled.
PNP     Plug & Play support is enabled.
PPC     PowerPC architecture is enabled.
PPT     Parallel port support is enabled.
PS2     Appropriate PS/2 support is enabled.
PV_OPS  A paravirtualized kernel is enabled.
```

```
RAM     RAM disk support is enabled.
RDT     Intel Resource Director Technology.
RISCV   RISCV architecture is enabled.
S390    S390 architecture is enabled.
SCSI    Appropriate SCSI support is enabled.
                A lot of drivers have their options described inside
                the Documentation/scsi/ sub-directory.
SECURITY Different security models are enabled.
SELINUX SELinux support is enabled.
SERIAL  Serial support is enabled.
SH      SuperH architecture is enabled.
SMP     The kernel is an SMP kernel.
SPARC   Sparc architecture is enabled.
SUSPEND System suspend states are enabled.
SWSUSP  Software suspend (hibernation) is enabled.
TPM     TPM drivers are enabled.
UMS     USB Mass Storage support is enabled.
USB     USB support is enabled.
USBHID  USB Human Interface Device support is enabled.
V4L     Video For Linux support is enabled.
VGA     The VGA console has been enabled.
VMMIO   Driver for memory mapped virtio devices is enabled.
VT      Virtual terminal support is enabled.
WDT     Watchdog support is enabled.
X86-32  X86-32, aka i386 architecture is enabled.
X86-64  X86-64 architecture is enabled.
                More X86-64 boot options can be found in
                Documentation/arch/x86/x86_64/boot-options.rst.
X86     Either 32-bit or 64-bit x86 (same as X86-32+X86-64)
X86_UV  SGI UV support is enabled.
XEN     Xen support is enabled
XTENSA  xtensa architecture is enabled.
```

In addition, the following text indicates that the option:

```
BOOT    Is a boot loader parameter.
BUGS=   Relates to possible processor bugs on the said processor.
KNL     Is a kernel start-up parameter.
```

Parameters denoted with BOOT are actually interpreted by the boot loader, and have no meaning to the kernel directly. Do not modify the syntax of boot loader parameters without extreme need or coordination with <Documentation/arch/x86/boot.rst>.

There are also arch-specific kernel-parameters not documented here. See for example <Documentation/arch/x86/x86_64/boot-options.rst>.

Note that ALL kernel parameters listed below are CASE SENSITIVE, and that a trailing = on the name of any parameter states that that parameter will be entered as an environment variable, whereas its absence indicates that it will appear as a kernel argument readable via /proc/cmdline by programs running once the system is up.

The number of kernel parameters is not limited, but the length of the complete command line

(parameters including spaces etc.) is limited to a fixed number of characters. This limit depends on the architecture and is between 256 and 4096 characters. It is defined in the file ./include/uapi/asm-generic/setup.h as COMMAND_LINE_SIZE.

Finally, the [KMG] suffix is commonly described after a number of kernel parameter values. These 'K', 'M', and 'G' letters represent the _binary_ multipliers 'Kilo', 'Mega', and 'Giga', equaling 2^10, 2^20, and 2^30 bytes respectively. Such letter suffixes can also be entirely omitted:

```
        accept_memory=  [MM]
                        Format: { eager | lazy }
                        default: lazy
                        By default, unaccepted memory is accepted lazily to
                        avoid prolonged boot times. The lazy option will add
                        some runtime overhead until all memory is eventually
                        accepted. In most cases the overhead is negligible.
                        For some workloads or for debugging purposes
                        accept_memory=eager can be used to accept all memory
                        at once during boot.

        acpi=           [HW,ACPI,X86,ARM64,RISCV64]
                        Advanced Configuration and Power Interface
                        Format: { force | on | off | strict | noirq | rsdt |
                                  copy_dsdt }
                        force -- enable ACPI if default was off
                        on -- enable ACPI but allow fallback to DT [arm64,
↪riscv64]
                        off -- disable ACPI if default was on
                        noirq -- do not use ACPI for IRQ routing
                        strict -- Be less tolerant of platforms that are not
                                strictly ACPI specification compliant.
                        rsdt -- prefer RSDT over (default) XSDT
                        copy_dsdt -- copy DSDT to memory
                        For ARM64 and RISCV64, ONLY "acpi=off", "acpi=on" or
                        "acpi=force" are available

                        See also Documentation/power/runtime_pm.rst, pci=noacpi

        acpi_apic_instance=     [ACPI, IOAPIC]
                        Format: <int>
                        2: use 2nd APIC table, if available
                        1,0: use 1st APIC table
                        default: 0

        acpi_backlight= [HW,ACPI]
                        { vendor | video | native | none }
                        If set to vendor, prefer vendor-specific driver
                        (e.g. thinkpad_acpi, sony_acpi, etc.) instead
                        of the ACPI video.ko driver.
                        If set to video, use the ACPI video.ko driver.
                        If set to native, use the device's native backlight␣
↪mode.
                        If set to none, disable the ACPI backlight interface.
```

```
        acpi_force_32bit_fadt_addr
                        force FADT to use 32 bit addresses rather than the
                        64 bit X_* addresses. Some firmware have broken 64
                        bit addresses for force ACPI ignore these and use
                        the older legacy 32 bit addresses.

        acpica_no_return_repair [HW, ACPI]
                        Disable AML predefined validation mechanism
                        This mechanism can repair the evaluation result to make
                        the return objects more ACPI specification compliant.
                        This option is useful for developers to identify the
                        root cause of an AML interpreter issue when the issue
                        has something to do with the repair mechanism.

        acpi.debug_layer=       [HW,ACPI,ACPI_DEBUG]
        acpi.debug_level=       [HW,ACPI,ACPI_DEBUG]
                        Format: <int>
                        CONFIG_ACPI_DEBUG must be enabled to produce any ACPI
                        debug output.  Bits in debug_layer correspond to a
                        _COMPONENT in an ACPI source file, e.g.,
                            #define _COMPONENT ACPI_EVENTS
                        Bits in debug_level correspond to a level in
                        ACPI_DEBUG_PRINT statements, e.g.,
                            ACPI_DEBUG_PRINT((ACPI_DB_INFO, ...
                        The debug_level mask defaults to "info".  See
                        Documentation/firmware-guide/acpi/debug.rst for more␣
↪information about
                        debug layers and levels.

                        Enable processor driver info messages:
                            acpi.debug_layer=0x20000000
                        Enable AML "Debug" output, i.e., stores to the Debug
                        object while interpreting AML:
                            acpi.debug_layer=0xffffffff acpi.debug_level=0x2
                        Enable all messages related to ACPI hardware:
                            acpi.debug_layer=0x2 acpi.debug_level=0xffffffff

                        Some values produce so much output that the system is
                        unusable.  The "log_buf_len" parameter may be useful
                        if you need to capture more output.

        acpi_enforce_resources= [ACPI]
                        { strict | lax | no }
                        Check for resource conflicts between native drivers
                        and ACPI OperationRegions (SystemIO and SystemMemory
                        only). IO ports and memory declared in ACPI might be
                        used by the ACPI subsystem in arbitrary AML code and
                        can interfere with legacy drivers.
                        strict (default): access to resources claimed by ACPI
                        is denied; legacy drivers trying to access reserved
```

```
                resources will fail to bind to device using them.
                lax: access to resources claimed by ACPI is allowed;
                legacy drivers trying to access reserved resources
                will bind successfully but a warning message is logged.
                no: ACPI OperationRegions are not marked as reserved,
                no further checks are performed.

acpi_force_table_verification   [HW,ACPI]
                Enable table checksum verification during early stage.
                By default, this is disabled due to x86 early mapping
                size limitation.

acpi_irq_balance [HW,ACPI]
                ACPI will balance active IRQs
                default in APIC mode

acpi_irq_nobalance [HW,ACPI]
                ACPI will not move active IRQs (default)
                default in PIC mode

acpi_irq_isa=   [HW,ACPI] If irq_balance, mark listed IRQs used by ISA
                Format: <irq>,<irq>...

acpi_irq_pci=   [HW,ACPI] If irq_balance, clear listed IRQs for
                use by PCI
                Format: <irq>,<irq>...

acpi_mask_gpe=  [HW,ACPI]
                Due to the existence of _Lxx/_Exx, some GPEs triggered
                by unsupported hardware/firmware features can result in
                GPE floodings that cannot be automatically disabled by
                the GPE dispatcher.
                This facility can be used to prevent such uncontrolled
                GPE floodings.
                Format: <byte> or <bitmap-list>

acpi_no_auto_serialize  [HW,ACPI]
                Disable auto-serialization of AML methods
                AML control methods that contain the opcodes to create
                named objects will be marked as "Serialized" by the
                auto-serialization feature.
                This feature is enabled by default.
                This option allows to turn off the feature.

acpi_no_memhotplug [ACPI] Disable memory hotplug.  Useful for kdump
                   kernels.

acpi_no_static_ssdt     [HW,ACPI]
                Disable installation of static SSDTs at early boot time
                By default, SSDTs contained in the RSDT/XSDT will be
                installed automatically and they will appear under
```

```
                        /sys/firmware/acpi/tables.
                        This option turns off this feature.
                        Note that specifying this option does not affect
                        dynamic table installation which will install SSDT
                        tables to /sys/firmware/acpi/tables/dynamic.

        acpi_no_watchdog        [HW,ACPI,WDT]
                        Ignore the ACPI-based watchdog interface (WDAT) and let
                        a native driver control the watchdog device instead.

        acpi_rsdp=      [ACPI,EFI,KEXEC]
                        Pass the RSDP address to the kernel, mostly used
                        on machines running EFI runtime service to boot the
                        second kernel for kdump.

        acpi_os_name=   [HW,ACPI] Tell ACPI BIOS the name of the OS
                        Format: To spoof as Windows 98: ="Microsoft Windows"

        acpi_rev_override [ACPI] Override the _REV object to return 5 (instead
                        of 2 which is mandated by ACPI 6) as the supported ACPI
                        specification revision (when using this switch, it may
                        be necessary to carry out a cold reboot _twice_ in a
                        row to make it take effect on the platform firmware).

        acpi_osi=       [HW,ACPI] Modify list of supported OS interface strings
                        acpi_osi="string1"      # add string1
                        acpi_osi="!string2"     # remove string2
                        acpi_osi=!*             # remove all strings
                        acpi_osi=!              # disable all built-in OS␣
↪vendor
                                                  strings
                        acpi_osi=!!             # enable all built-in OS vendor
                                                  strings
                        acpi_osi=               # disable all strings

                        'acpi_osi=!' can be used in combination with single or
                        multiple 'acpi_osi="string1"' to support specific OS
                        vendor string(s).  Note that such command can only
                        affect the default state of the OS vendor strings, thus
                        it cannot affect the default state of the feature group
                        strings and the current state of the OS vendor strings,
                        specifying it multiple times through kernel command␣
↪line
                        is meaningless.  This command is useful when one do not
                        care about the state of the feature group strings which
                        should be controlled by the OSPM.
                        Examples:
                          1. 'acpi_osi=! acpi_osi="Windows 2000"' is equivalent
                             to 'acpi_osi="Windows 2000" acpi_osi=!', they all
                             can make '_OSI("Windows 2000")' TRUE.
```

```
                        'acpi_osi=' cannot be used in combination with other
                        'acpi_osi=' command lines, the _OSI method will not
                        exist in the ACPI namespace.  NOTE that such command␣
↪can
                        only affect the _OSI support state, thus specifying it
                        multiple times through kernel command line is also
                        meaningless.
                        Examples:
                          1. 'acpi_osi=' can make 'CondRefOf(_OSI, Local1)'
                             FALSE.

                        'acpi_osi=!*' can be used in combination with single or
                        multiple 'acpi_osi="string1"' to support specific
                        string(s).  Note that such command can affect the
                        current state of both the OS vendor strings and the
                        feature group strings, thus specifying it multiple␣
↪times
                        through kernel command line is meaningful.  But it may
                        still not able to affect the final state of a string if
                        there are quirks related to this string.  This command
                        is useful when one want to control the state of the
                        feature group strings to debug BIOS issues related to
                        the OSPM features.
                        Examples:
                          1. 'acpi_osi="Module Device" acpi_osi=!*' can make
                             '_OSI("Module Device")' FALSE.
                          2. 'acpi_osi=!* acpi_osi="Module Device"' can make
                             '_OSI("Module Device")' TRUE.
                          3. 'acpi_osi=! acpi_osi=!* acpi_osi="Windows 2000"'␣
↪is
                             equivalent to
                             'acpi_osi=!* acpi_osi=! acpi_osi="Windows 2000"'
                             and
                             'acpi_osi=!* acpi_osi="Windows 2000" acpi_osi=!',
                             they all will make '_OSI("Windows 2000")' TRUE.

        acpi_pm_good    [X86]
                        Override the pmtimer bug detection: force the kernel
                        to assume that this machine's pmtimer latches its value
                        and always returns good values.

        acpi_sci=       [HW,ACPI] ACPI System Control Interrupt trigger mode
                        Format: { level | edge | high | low }

        acpi_skip_timer_override [HW,ACPI]
                        Recognize and ignore IRQ0/pin2 Interrupt Override.
                        For broken nForce2 BIOS resulting in XT-PIC timer.

        acpi_sleep=     [HW,ACPI] Sleep options
                        Format: { s3_bios, s3_mode, s3_beep, s4_hwsig,
                                  s4_nohwsig, old_ordering, nonvs,
```

```
                                sci_force_enable, nobl }
                        See Documentation/power/video.rst for information on
                        s3_bios and s3_mode.
                        s3_beep is for debugging; it makes the PC's speaker␣
↪beep
                        as soon as the kernel's real-mode entry point is␣
↪called.
                        s4_hwsig causes the kernel to check the ACPI hardware
                        signature during resume from hibernation, and␣
↪gracefully
                        refuse to resume if it has changed. This complies with
                        the ACPI specification but not with reality, since
                        Windows does not do this and many laptops do change it
                        on docking. So the default behaviour is to allow resume
                        and simply warn when the signature changes, unless the
                        s4_hwsig option is enabled.
                        s4_nohwsig prevents ACPI hardware signature from being
                        used (or even warned about) during resume.
                        old_ordering causes the ACPI 1.0 ordering of the _PTS
                        control method, with respect to putting devices into
                        low power states, to be enforced (the ACPI 2.0 ordering
                        of _PTS is used by default).
                        nonvs prevents the kernel from saving/restoring the
                        ACPI NVS memory during suspend/hibernation and resume.
                        sci_force_enable causes the kernel to set SCI_EN␣
↪directly
                        on resume from S1/S3 (which is against the ACPI spec,
                        but some broken systems don't work without it).
                        nobl causes the internal blacklist of systems known to
                        behave incorrectly in some ways with respect to system
                        suspend and resume to be ignored (use wisely).

        acpi_use_timer_override [HW,ACPI]
                        Use timer override. For some broken Nvidia NF5 boards
                        that require a timer override, but don't have HPET

        add_efi_memmap  [EFI; X86] Include EFI memory map in
                        kernel's map of available physical RAM.

        agp=            [AGP]
                        { off | try_unsupported }
                        off: disable AGP support
                        try_unsupported: try to drive unsupported chipsets
                                (may crash computer or cause data corruption)

        ALSA            [HW,ALSA]
                        See Documentation/sound/alsa-configuration.rst

        alignment=      [KNL,ARM]
                        Allow the default userspace alignment fault handler
                        behaviour to be specified.  Bit 0 enables warnings,
```

```
                        bit 1 enables fixups, and bit 2 sends a segfault.

        align_va_addr=  [X86-64]
                        Align virtual addresses by clearing slice [14:12] when
                        allocating a VMA at process creation time. This option
                        gives you up to 3% performance improvement on AMD F15h
                        machines (where it is enabled by default) for a
                        CPU-intensive style benchmark, and it can vary highly␣
↪in
                        a microbenchmark depending on workload and compiler.

                        32: only for 32-bit processes
                        64: only for 64-bit processes
                        on: enable for both 32- and 64-bit processes
                        off: disable for both 32- and 64-bit processes

        alloc_snapshot  [FTRACE]
                        Allocate the ftrace snapshot buffer on boot up when the
                        main buffer is allocated. This is handy if debugging
                        and you need to use tracing_snapshot() on boot up, and
                        do not want to use tracing_snapshot_alloc() as it needs
                        to be done where GFP_KERNEL allocations are allowed.

        allow_mismatched_32bit_el0 [ARM64]
                        Allow execve() of 32-bit applications and setting of␣
↪the
                        PER_LINUX32 personality on systems where only a strict
                        subset of the CPUs support 32-bit EL0. When this
                        parameter is present, the set of CPUs supporting 32-bit
                        EL0 is indicated by /sys/devices/system/cpu/aarch32_el0
                        and hot-unplug operations may be restricted.

                        See Documentation/arch/arm64/asymmetric-32bit.rst for␣
↪more
                        information.

        amd_iommu=      [HW,X86-64]
                        Pass parameters to the AMD IOMMU driver in the system.
                        Possible values are:
                        fullflush - Deprecated, equivalent to iommu.strict=1
                        off       - do not initialize any AMD IOMMU found in
                                    the system
                        force_isolation - Force device isolation for all
                                          devices. The IOMMU driver is not
                                          allowed anymore to lift isolation
                                          requirements as needed. This option
                                          does not override iommu=pt
                        force_enable - Force enable the IOMMU on platforms␣
↪known
                                       to be buggy with IOMMU enabled. Use this
                                       option with care.
```

```
                        pgtbl_v1     - Use v1 page table for DMA-API (Default).
                        pgtbl_v2     - Use v2 page table for DMA-API.
                        irtcachedis  - Disable Interrupt Remapping Table (IRT)␣
↪caching.

        amd_iommu_dump= [HW,X86-64]
                        Enable AMD IOMMU driver option to dump the ACPI table
                        for AMD IOMMU. With this option enabled, AMD IOMMU
                        driver will print ACPI tables for AMD IOMMU during
                        IOMMU initialization.

        amd_iommu_intr= [HW,X86-64]
                        Specifies one of the following AMD IOMMU interrupt
                        remapping modes:
                        legacy     - Use legacy interrupt remapping mode.
                        vapic      - Use virtual APIC mode, which allows IOMMU
                                     to inject interrupts directly into guest.
                                     This mode requires kvm-amd.avic=1.
                                     (Default when IOMMU HW support is present.
↪)

        amd_pstate=     [X86]
                        disable
                          Do not enable amd_pstate as the default
                          scaling driver for the supported processors
                        passive
                          Use amd_pstate with passive mode as a scaling driver.
                          In this mode autonomous selection is disabled.
                          Driver requests a desired performance level and␣
↪platform
                          tries to match the same performance level if it is
                          satisfied by guaranteed performance level.
                        active
                          Use amd_pstate_epp driver instance as the scaling␣
↪driver,
                          driver provides a hint to the hardware if software␣
↪wants
                          to bias toward performance (0x0) or energy␣
↪efficiency (0xff)
                          to the CPPC firmware. then CPPC power algorithm will
                          calculate the runtime workload and adjust the␣
↪realtime cores
                          frequency.
                        guided
                          Activate guided autonomous mode. Driver requests␣
↪minimum and
                          maximum performance level and the platform␣
↪autonomously
                          selects a performance level in this range and␣
↪appropriate
                          to the current workload.
```

```
        amijoy.map=     [HW,JOY] Amiga joystick support
                        Map of devices attached to JOY0DAT and JOY1DAT
                        Format: <a>,<b>
                        See also Documentation/input/joydev/joystick.rst

        analog.map=     [HW,JOY] Analog joystick and gamepad support
                        Specifies type or capabilities of an analog joystick
                        connected to one of 16 gameports
                        Format: <type1>,<type2>,..<type16>

        apc=            [HW,SPARC]
                        Power management functions (SPARCstation-4/5 + deriv.)
                        Format: noidle
                        Disable APC CPU standby support. SPARCstation-Fox does
                        not play well with APC CPU idle - disable it if you␣
↪have
                        APC and your system crashes randomly.

        apic=           [APIC,X86] Advanced Programmable Interrupt Controller
                        Change the output verbosity while booting
                        Format: { quiet (default) | verbose | debug }
                        Change the amount of debugging information output
                        when initialising the APIC and IO-APIC components.
                        For X86-32, this can also be used to specify an APIC
                        driver name.
                        Format: apic=driver_name
                        Examples: apic=bigsmp

        apic_extnmi=    [APIC,X86] External NMI delivery setting
                        Format: { bsp (default) | all | none }
                        bsp:  External NMI is delivered only to CPU 0
                        all:  External NMIs are broadcast to all CPUs as a
                              backup of CPU 0
                        none: External NMI is masked for all CPUs. This is
                              useful so that a dump capture kernel won't be
                              shot down by NMI

        autoconf=       [IPV6]
                        See Documentation/networking/ipv6.rst.

        apm=            [APM] Advanced Power Management
                        See header of arch/x86/kernel/apm_32.c.

        apparmor=       [APPARMOR] Disable or enable AppArmor at boot time
                        Format: { "0" | "1" }
                        See security/apparmor/Kconfig help text
                        0 -- disable.
                        1 -- enable.
                        Default value is set via kernel config option.
```

```

baycom_par=     [HW,AX25] BayCom Parallel Port AX.25 Modem
                Format: <io>,<mode>
                See header of drivers/net/hamradio/baycom_par.c.

baycom_ser_fdx= [HW,AX25]
                BayCom Serial Port AX.25 Modem (Full Duplex Mode)
                Format: <io>,<irq>,<mode>[,<baud>]
                See header of drivers/net/hamradio/baycom_ser_fdx.c.

baycom_ser_hdx= [HW,AX25]
                BayCom Serial Port AX.25 Modem (Half Duplex Mode)
                Format: <io>,<irq>,<mode>
                See header of drivers/net/hamradio/baycom_ser_hdx.c.

bert_disable    [ACPI]
                Disable BERT OS support on buggy BIOSes.

bgrt_disable    [ACPI][X86]
                Disable BGRT to avoid flickering OEM logo.

blkdevparts=    Manual partition parsing of block device(s) for
                embedded devices based on command line input.
                See Documentation/block/cmdline-partition.rst

boot_delay=     Milliseconds to delay each printk during boot.
                Only works if CONFIG_BOOT_PRINTK_DELAY is enabled,
                and you may also have to specify "lpj=".  Boot_delay
                values larger than 10 seconds (10000) are assumed
                erroneous and ignored.
                Format: integer

bootconfig      [KNL]
                Extended command line options can be added to an initrd
```

```
                        and this will cause the kernel to look for it.

                        See Documentation/admin-guide/bootconfig.rst

        bttv.card=      [HW,V4L] bttv (bt848 + bt878 based grabber cards)
        bttv.radio=     Most important insmod options are available as
                        kernel args too.
        bttv.pll=       See Documentation/admin-guide/media/bttv.rst
        bttv.tuner=

        bulk_remove=off [PPC]  This parameter disables the use of the pSeries
                        firmware feature for flushing multiple hpte entries
                        at a time.

        c101=           [NET] Moxa C101 synchronous serial card

        cachesize=      [BUGS=X86-32] Override level 2 CPU cache size␣
↪detection.
                        Sometimes CPU hardware bugs make them report the cache
                        size incorrectly. The kernel will attempt work arounds
                        to fix known problems, but for some CPUs it is not
                        possible to determine what the correct size should be.
                        This option provides an override for these situations.

        carrier_timeout=
                        [NET] Specifies amount of time (in seconds) that
                        the kernel should wait for a network carrier. By␣
↪default
                        it waits 120 seconds.

        ca_keys=        [KEYS] This parameter identifies a specific key(s) on
                        the system trusted keyring to be used for certificate
                        trust validation.
                        format: { id:<keyid> | builtin }

        cca=            [MIPS] Override the kernel pages' cache coherency
                        algorithm.  Accepted values range from 0 to 7
                        inclusive. See arch/mips/include/asm/pgtable-bits.h
                        for platform specific values (SB1, Loongson3 and
                        others).

        ccw_timeout_log [S390]
                        See Documentation/arch/s390/common_io.rst for details.

        cgroup_disable= [KNL] Disable a particular controller or optional␣
↪feature
                        Format: {name of the controller(s) or feature(s) to␣
↪disable}
                        The effects of cgroup_disable=foo are:
                        - foo isn't auto-mounted if you mount all cgroups in
                          a single hierarchy
```

```
                        - foo isn't visible as an individually mountable
                          subsystem
                        - if foo is an optional feature then the feature is
                          disabled and corresponding cgroup files are not
                          created
                        {Currently only "memory" controller deal with this and
                        cut the overhead, others just disable the usage. So
                        only cgroup_disable=memory is actually worthy}
                        Specifying "pressure" disables per-cgroup pressure
                        stall information accounting feature

        cgroup_no_v1=   [KNL] Disable cgroup controllers and named hierarchies␣
↪in v1
                        Format: { { controller | "all" | "named" }
                                  [,{ controller | "all" | "named" }...] }
                        Like cgroup_disable, but only applies to cgroup v1;
                        the blacklisted controllers remain available in␣
↪cgroup2.
                        "all" blacklists all controllers and "named" disables
                        named mounts. Specifying both "all" and "named"␣
↪disables
                        all v1 hierarchies.

        cgroup_favordynmods= [KNL] Enable or Disable favordynmods.
                        Format: { "true" | "false" }
                        Defaults to the value of CONFIG_CGROUP_FAVOR_DYNMODS.

        cgroup.memory=  [KNL] Pass options to the cgroup memory controller.
                        Format: <string>
                        nosocket -- Disable socket memory accounting.
                        nokmem -- Disable kernel memory accounting.
                        nobpf -- Disable BPF memory accounting.

        checkreqprot=   [SELINUX] Set initial checkreqprot flag value.
                        Format: { "0" | "1" }
                        See security/selinux/Kconfig help text.
                        0 -- check protection applied by kernel (includes
                                any implied execute protection).
                        1 -- check protection requested by application.
                        Default value is set via a kernel config option.
                        Value can be changed at runtime via
                                /sys/fs/selinux/checkreqprot.
                        Setting checkreqprot to 1 is deprecated.

        cio_ignore=     [S390]
                        See Documentation/arch/s390/common_io.rst for details.

        clearcpuid=X[,X...] [X86]
                        Disable CPUID feature X for the kernel. See
                        arch/x86/include/asm/cpufeatures.h for the valid bit
                        numbers X. Note the Linux-specific bits are not␣
```

```
↪necessarily
                        stable over kernel options, but the vendor-specific
                        ones should be.
                        X can also be a string as appearing in the flags: line
                        in /proc/cpuinfo which does not have the above
                        instability issue. However, not all features have names
                        in /proc/cpuinfo.
                        Note that using this option will taint your kernel.
                        Also note that user programs calling CPUID directly
                        or using the feature without checking anything
                        will still see it. This just prevents it from
                        being used by the kernel or shown in /proc/cpuinfo.
                        Also note the kernel might malfunction if you disable
                        some critical bits.

        clk_ignore_unused
                        [CLK]
                        Prevents the clock framework from automatically gating
                        clocks that have not been explicitly enabled by a Linux
                        device driver but are enabled in hardware at reset or
                        by the bootloader/firmware. Note that this does not
                        force such clocks to be always-on nor does it reserve
                        those clocks in any way. This parameter is useful for
                        debug and development, but should not be needed on a
                        platform with proper driver support.  For more
                        information, see Documentation/driver-api/clk.rst.

        clock=          [BUGS=X86-32, HW] gettimeofday clocksource override.
                        [Deprecated]
                        Forces specified clocksource (if available) to be used
                        when calculating gettimeofday(). If specified
                        clocksource is not available, it defaults to PIT.
                        Format: { pit | tsc | cyclone | pmtmr }

        clocksource=    Override the default clocksource
                        Format: <string>
                        Override the default clocksource and use the␣
↪clocksource
                        with the name specified.
                        Some clocksource names to choose from, depending on
                        the platform:
                        [all] jiffies (this is the base, fallback clocksource)
                        [ACPI] acpi_pm
                        [ARM] imx_timer1,OSTS,netx_timer,mpu_timer2,
                                pxa_timer,timer3,32k_counter,timer0_1
                        [X86-32] pit,hpet,tsc;
                                scx200_hrt on Geode; cyclone on IBM x440
                        [MIPS] MIPS
                        [PARISC] cr16
                        [S390] tod
                        [SH] SuperH
```

```
                [SPARC64] tick
                [X86-64] hpet,tsc

clocksource.arm_arch_timer.evtstrm=
                [ARM,ARM64]
                Format: <bool>
                Enable/disable the eventstream feature of the ARM
                architected timer so that code using WFE-based polling
                loops can be debugged more effectively on production
                systems.

clocksource.max_cswd_read_retries= [KNL]
                Number of clocksource_watchdog() retries due to
                external delays before the clock will be marked
                unstable.  Defaults to two retries, that is,
                three attempts to read the clock under test.

clocksource.verify_n_cpus= [KNL]
                Limit the number of CPUs checked for clocksources
                marked with CLOCK_SOURCE_VERIFY_PERCPU that
                are marked unstable due to excessive skew.
                A negative value says to check all CPUs, while
                zero says not to check any.  Values larger than
                nr_cpu_ids are silently truncated to nr_cpu_ids.
                The actual CPUs are chosen randomly, with
                no replacement if the same CPU is chosen twice.

clocksource-wdtest.holdoff= [KNL]
                Set the time in seconds that the clocksource
                watchdog test waits before commencing its tests.
                Defaults to zero when built as a module and to
                10 seconds when built into the kernel.

cma=nn[MG]@[start[MG][-end[MG]]]
                [KNL,CMA]
                Sets the size of kernel global memory area for
                contiguous memory allocations and optionally the
                placement constraint by the physical address range of
                memory allocations. A value of 0 disables CMA
                altogether. For more information, see
                kernel/dma/contiguous.c

cma_pernuma=nn[MG]
                [KNL,CMA]
                Sets the size of kernel per-numa memory area for
                contiguous memory allocations. A value of 0 disables
                per-numa CMA altogether. And If this option is not
                specified, the default value is 0.
                With per-numa CMA enabled, DMA users on node nid will
                first try to allocate buffer from the pernuma area
                which is located in node nid, if the allocation fails,
```

```
                        they will fallback to the global default memory area.

        numa_cma=<node>:nn[MG][,<node>:nn[MG]]
                        [KNL,CMA]
                        Sets the size of kernel numa memory area for
                        contiguous memory allocations. It will reserve CMA
                        area for the specified node.

                        With numa CMA enabled, DMA users on node nid will
                        first try to allocate buffer from the numa area
                        which is located in node nid, if the allocation fails,
                        they will fallback to the global default memory area.

        cmo_free_hint=  [PPC] Format: { yes | no }
                        Specify whether pages are marked as being inactive
                        when they are freed.  This is used in CMO environments
                        to determine OS memory pressure for page stealing by
                        a hypervisor.
                        Default: yes

        coherent_pool=nn[KMG]   [ARM,KNL]
                        Sets the size of memory pool for coherent, atomic dma
                        allocations, by default set to 256K.

        com20020=       [HW,NET] ARCnet - COM20020 chipset
                        Format:
                        <io>[,<irq>[,<nodeID>[,<backplane>[,<ckp>[,<timeout>
↪]]]]]

        com90io=        [HW,NET] ARCnet - COM90xx chipset (IO-mapped buffers)
                        Format: <io>[,<irq>]

        com90xx=        [HW,NET]
                        ARCnet - COM90xx chipset (memory-mapped buffers)
                        Format: <io>[,<irq>[,<memstart>]]

        condev=         [HW,S390] console device
        conmode=

        con3215_drop=   [S390] 3215 console drop mode.
                        Format: y|n|Y|N|1|0
                        When set to true, drop data on the 3215 console when
                        the console buffer is full. In this case the
                        operator using a 3270 terminal emulator (for example
                        x3270) does not have to enter the clear key for the
                        console output to advance and the kernel to continue.
                        This leads to a much faster boot time when a 3270
                        terminal emulator is active. If no 3270 terminal
                        emulator is used, this parameter has no effect.

        console=        [KNL] Output console device and options.
```

```
                tty<n>  Use the virtual console device <n>.

                ttyS<n>[,options]
                ttyUSB0[,options]
                        Use the specified serial port.  The options are of
                        the form "bbbbpnf", where "bbbb" is the baud rate,
                        "p" is parity ("n", "o", or "e"), "n" is number of
                        bits, and "f" is flow control ("r" for RTS or
                        omit it).  Default is "9600n8".

                        See Documentation/admin-guide/serial-console.rst for␣
↪more
                        information.  See
                        Documentation/networking/netconsole.rst for an
                        alternative.

                uart[8250],io,<addr>[,options]
                uart[8250],mmio,<addr>[,options]
                uart[8250],mmio16,<addr>[,options]
                uart[8250],mmio32,<addr>[,options]
                uart[8250],0x<addr>[,options]
                        Start an early, polled-mode console on the 8250/16550
                        UART at the specified I/O port or MMIO address,
                        switching to the matching ttyS device later.
                        MMIO inter-register address stride is either 8-bit
                        (mmio), 16-bit (mmio16), or 32-bit (mmio32).
                        If none of [io|mmio|mmio16|mmio32], <addr> is assumed
                        to be equivalent to 'mmio'. 'options' are specified in
                        the same format described for ttyS above; if␣
↪unspecified,
                        the h/w is not re-initialized.

                hvc<n>  Use the hypervisor console device <n>. This is for
                        both Xen and PowerPC hypervisors.

                { null | "" }
                        Use to disable console output, i.e., to have kernel
                        console messages discarded.
                        This must be the only console= parameter used on the
                        kernel command line.

                If the device connected to the port is not a TTY but a braille
                device, prepend "brl," before the device type, for instance
                        console=brl,ttyS0
                For now, only VisioBraille is supported.

        console_msg_format=
                        [KNL] Change console messages format
                default
                        By default we print messages on consoles in
```

```
                        "[time stamp] text\n" format (time stamp may not be
                        printed, depending on CONFIG_PRINTK_TIME or
                        `printk_time' param).
                syslog
                        Switch to syslog format: "<%u>[time stamp] text\n"
                        IOW, each message will have a facility and loglevel
                        prefix. The format is similar to one used by syslog()
                        syscall, or to executing "dmesg -S --raw" or to reading
                        from /proc/kmsg.

        consoleblank=   [KNL] The console blank (screen saver) timeout in
                        seconds. A value of 0 disables the blank timer.
                        Defaults to 0.

        coredump_filter=
                        [KNL] Change the default value for
                        /proc/<pid>/coredump_filter.
                        See also Documentation/filesystems/proc.rst.

        coresight_cpu_debug.enable
                        [ARM,ARM64]
                        Format: <bool>
                        Enable/disable the CPU sampling based debugging.
                        0: default value, disable debugging
                        1: enable debugging at boot time

        cpcihp_generic= [HW,PCI] Generic port I/O CompactPCI driver
                        Format:
                        <first_slot>,<last_slot>,<port>,<enum_bit>[,<debug>]

        cpuidle.off=1   [CPU_IDLE]
                        disable the cpuidle sub-system

        cpuidle.governor=
                        [CPU_IDLE] Name of the cpuidle governor to use.

        cpufreq.off=1   [CPU_FREQ]
                        disable the cpufreq sub-system

        cpufreq.default_governor=
                        [CPU_FREQ] Name of the default cpufreq governor or
                        policy to use. This governor must be registered in the
                        kernel before the cpufreq driver probes.

        cpu_init_udelay=N
                        [X86] Delay for N microsec between assert and de-assert
                        of APIC INIT to start processors.  This delay occurs
                        on every CPU online, such as boot, and resume from␣
↪suspend.
                        Default: 10000
```

```
        cpuhp.parallel=
                        [SMP] Enable/disable parallel bringup of secondary CPUs
                        Format: <bool>
                        Default is enabled if CONFIG_HOTPLUG_PARALLEL=y.␣
↪Otherwise
                        the parameter has no effect.

        crash_kexec_post_notifiers
                        Run kdump after running panic-notifiers and dumping
                        kmsg. This only for the users who doubt kdump always
                        succeeds in any situation.
                        Note that this also increases risks of kdump failure,
                        because some panic notifiers can make the crashed
                        kernel more unstable.

        crashkernel=size[KMG][@offset[KMG]]
                        [KNL] Using kexec, Linux can switch to a 'crash kernel'
                        upon panic. This parameter reserves the physical
                        memory region [offset, offset + size] for that kernel
                        image. If '@offset' is omitted, then a suitable offset
                        is selected automatically.
                        [KNL, X86-64, ARM64, RISCV, LoongArch] Select a region
                        under 4G first, and fall back to reserve region above
                        4G when '@offset' hasn't been specified.
                        See Documentation/admin-guide/kdump/kdump.rst for␣
↪further details.

        crashkernel=range1:size1[,range2:size2,...][@offset]
                        [KNL] Same as above, but depends on the memory
                        in the running system. The syntax of range is
                        start-[end] where start and end are both
                        a memory unit (amount[KMG]). See also
                        Documentation/admin-guide/kdump/kdump.rst for an␣
↪example.

        crashkernel=size[KMG],high
                        [KNL, X86-64, ARM64, RISCV, LoongArch] range could be
                        above 4G.
                        Allow kernel to allocate physical memory region from␣
↪top,
                        so could be above 4G if system have more than 4G ram
                        installed. Otherwise memory region will be allocated
                        below 4G, if available.
                        It will be ignored if crashkernel=X is specified.
        crashkernel=size[KMG],low
                        [KNL, X86-64, ARM64, RISCV, LoongArch] range under 4G.
                        When crashkernel=X,high is passed, kernel could␣
↪allocate
                        physical memory region above 4G, that cause second␣
↪kernel
                        crash on system that require some amount of low memory,
```

```
                        e.g. swiotlb requires at least 64M+32K low memory, also
                        enough extra low memory is needed to make sure DMA␣
↪buffers
                        for 32-bit devices won't run out. Kernel would try to␣
↪allocate
                        default size of memory below 4G automatically. The␣
↪default
                        size is platform dependent.
                          --> x86: max(swiotlb_size_or_default() + 8MiB,␣
↪256MiB)
                          --> arm64: 128MiB
                          --> riscv: 128MiB
                          --> loongarch: 128MiB
                        This one lets the user specify own low range under 4G
                        for second kernel instead.
                        0: to disable low allocation.
                        It will be ignored when crashkernel=X,high is not used
                        or memory reserved is below 4G.

        cryptomgr.notests
                        [KNL] Disable crypto self-tests

        cs89x0_dma=     [HW,NET]
                        Format: <dma>

        cs89x0_media=   [HW,NET]
                        Format: { rj45 | aui | bnc }

        csdlock_debug=  [KNL] Enable or disable debug add-ons of cross-CPU
                        function call handling. When switched on,
                        additional debug data is printed to the console
                        in case a hanging CPU is detected, and that
                        CPU is pinged again in order to try to resolve
                        the hang situation.  The default value of this
                        option depends on the CSD_LOCK_WAIT_DEBUG_DEFAULT
                        Kconfig option.

        dasd=           [HW,NET]
                        See header of drivers/s390/block/dasd_devmap.c.

        db9.dev[2|3]=   [HW,JOY] Multisystem joystick support via parallel port
                        (one device per port)
                        Format: <port#>,<type>
                        See also Documentation/input/devices/joystick-parport.
↪rst

        debug           [KNL] Enable kernel debugging (events log level).

        debug_boot_weak_hash
                        [KNL] Enable printing [hashed] pointers early in the
                        boot sequence.  If enabled, we use a weak hash instead
```

```
                        of siphash to hash pointers.  Use this option if you␣
↪are
                        seeing instances of '(___ptrval___)') and need to see a
                        value (hashed pointer) instead. Cryptographically
                        insecure, please do not use on production kernels.

        debug_locks_verbose=
                        [KNL] verbose locking self-tests
                        Format: <int>
                        Print debugging info while doing the locking API
                        self-tests.
                        Bitmask for the various LOCKTYPE_ tests. Defaults to 0
                        (no extra messages), setting it to -1 (all bits set)
                        will print _a_lot_ more information - normally only
                        useful to lockdep developers.

        debug_objects   [KNL] Enable object debugging

        debug_guardpage_minorder=
                        [KNL] When CONFIG_DEBUG_PAGEALLOC is set, this
                        parameter allows control of the order of pages that␣
↪will
                        be intentionally kept free (and hence protected) by the
                        buddy allocator. Bigger value increase the probability
                        of catching random memory corruption, but reduce the
                        amount of memory for normal system use. The maximum
                        possible value is MAX_PAGE_ORDER/2.  Setting this
                        parameter to 1 or 2 should be enough to identify most
                        random memory corruption problems caused by bugs in
                        kernel or driver code when a CPU writes to (or reads
                        from) a random memory location. Note that there exists
                        a class of memory corruptions problems caused by buggy
                        H/W or F/W or by drivers badly programming DMA
                        (basically when memory is written at bus level and the
                        CPU MMU is bypassed) which are not detectable by
                        CONFIG_DEBUG_PAGEALLOC, hence this option will not
                        help tracking down these problems.

        debug_pagealloc=
                        [KNL] When CONFIG_DEBUG_PAGEALLOC is set, this␣
↪parameter
                        enables the feature at boot time. By default, it is
                        disabled and the system will work mostly the same as a
                        kernel built without CONFIG_DEBUG_PAGEALLOC.
                        Note: to get most of debug_pagealloc error reports,␣
↪it's
                        useful to also enable the page_owner functionality.
                        on: enable the feature

        debugfs=        [KNL] This parameter enables what is exposed to␣
↪userspace
```

```
                        and debugfs internal clients.
                        Format: { on, no-mount, off }
                        on:     All functions are enabled.
                        no-mount:
                                Filesystem is not registered but kernel␣
↪clients can
                                access APIs and a crashkernel can be used to␣
↪read
                                its content. There is nothing to mount.
                        off:    Filesystem is not registered and clients
                                get a -EPERM as result when trying to register␣
↪files
                                or directories within debugfs.
                                This is equivalent of the runtime␣
↪functionality if
                                debugfs was not enabled in the kernel at all.
                        Default value is set in build-time with a kernel␣
↪configuration.

        debugpat        [X86] Enable PAT debugging

        default_hugepagesz=
                        [HW] The size of the default HugeTLB page. This is
                        the size represented by the legacy /proc/ hugepages
                        APIs.  In addition, this is the default hugetlb size
                        used for shmget(), mmap() and mounting hugetlbfs
                        filesystems.  If not specified, defaults to the
                        architecture's default huge page size.  Huge page
                        sizes are architecture dependent.  See also
                        Documentation/admin-guide/mm/hugetlbpage.rst.
                        Format: size[KMG]

        deferred_probe_timeout=
                        [KNL] Debugging option to set a timeout in seconds for
                        deferred probe to give up waiting on dependencies to
                        probe. Only specific dependencies (subsystems or
                        drivers) that have opted in will be ignored. A timeout
                        of 0 will timeout at the end of initcalls. If the time
                        out hasn't expired, it'll be restarted by each
                        successful driver registration. This option will also
                        dump out devices still on the deferred probe list after
                        retrying.

        delayacct       [KNL] Enable per-task delay accounting

        dell_smm_hwmon.ignore_dmi=
                        [HW] Continue probing hardware even if DMI data
                        indicates that the driver is running on unsupported
                        hardware.

        dell_smm_hwmon.force=
```

```
                        [HW] Activate driver even if SMM BIOS signature does
                        not match list of supported models and enable otherwise
                        blacklisted features.

        dell_smm_hwmon.power_status=
                        [HW] Report power status in /proc/i8k
                        (disabled by default).

        dell_smm_hwmon.restricted=
                        [HW] Allow controlling fans only if SYS_ADMIN
                        capability is set.

        dell_smm_hwmon.fan_mult=
                        [HW] Factor to multiply fan speed with.

        dell_smm_hwmon.fan_max=
                        [HW] Maximum configurable fan speed.

        dfltcc=         [HW,S390]
                        Format: { on | off | def_only | inf_only | always }
                        on:       s390 zlib hardware support for compression on
                                  level 1 and decompression (default)
                        off:      No s390 zlib hardware support
                        def_only: s390 zlib hardware support for deflate
                                  only (compression on level 1)
                        inf_only: s390 zlib hardware support for inflate
                                  only (decompression)
                        always:   Same as 'on' but ignores the selected␣
↪compression
                                  level always using hardware support (used␣
↪for debugging)

        dhash_entries=  [KNL]
                        Set number of hash buckets for dentry cache.

        disable_1tb_segments [PPC]
                        Disables the use of 1TB hash page table segments. This
                        causes the kernel to fall back to 256MB segments which
                        can be useful when debugging issues that require an SLB
                        miss to occur.

        disable=        [IPV6]
                        See Documentation/networking/ipv6.rst.

        disable_radix   [PPC]
                        Disable RADIX MMU mode on POWER9

        disable_tlbie   [PPC]
                        Disable TLBIE instruction. Currently does not work
                        with KVM, with HASH MMU, or with coherent accelerators.
```

```
disable_cpu_apicid= [X86,APIC,SMP]
                Format: <int>
                The number of initial APIC ID for the
                corresponding CPU to be disabled at boot,
                mostly used for the kdump 2nd kernel to
                disable BSP to wake up multiple CPUs without
                causing system reset or hang due to sending
                INIT from AP to BSP.

disable_ddw     [PPC/PSERIES]
                Disable Dynamic DMA Window support. Use this
                to workaround buggy firmware.

disable_ipv6=   [IPV6]
                See Documentation/networking/ipv6.rst.

disable_mtrr_cleanup [X86]
                The kernel tries to adjust MTRR layout from continuous
                to discrete, to make X server driver able to add WB
                entry later. This parameter disables that.

disable_mtrr_trim [X86, Intel and AMD only]
                By default the kernel will trim any uncacheable
                memory out of your available memory pool based on
                MTRR settings.  This parameter disables that behavior,
                possibly causing your machine to run very slowly.

disable_timer_pin_1 [X86]
                Disable PIN 1 of APIC timer
                Can be useful to work around chipset bugs.

dis_ucode_ldr   [X86] Disable the microcode loader.

dma_debug=off   If the kernel is compiled with DMA_API_DEBUG support,
                this option disables the debugging code at boot.

dma_debug_entries=<number>
                This option allows to tune the number of preallocated
                entries for DMA-API debugging code. One entry is
                required per DMA-API allocation. Use this if the
                DMA-API debugging code disables itself because the
                architectural default is too low.

dma_debug_driver=<driver_name>
                With this option the DMA-API debugging driver
                filter feature can be enabled at boot time. Just
                pass the driver to filter for as the parameter.
                The filter can be disabled or changed to another
                driver later using sysfs.

driver_async_probe=  [KNL]
```

```
                        List of driver names to be probed asynchronously. *
                        matches with all driver names. If * is specified, the
                        rest of the listed driver names are those that will NOT
                        match the *.
                        Format: <driver_name1>,<driver_name2>...

        drm.edid_firmware=[<connector>:]<file>[,[<connector>:]<file>]
                        Broken monitors, graphic adapters, KVMs and EDIDless
                        panels may send no or incorrect EDID data sets.
                        This parameter allows to specify an EDID data sets
                        in the /lib/firmware directory that are used instead.
                        Generic built-in EDID data sets are used, if one of
                        edid/1024x768.bin, edid/1280x1024.bin,
                        edid/1680x1050.bin, or edid/1920x1080.bin is given
                        and no file with the same name exists. Details and
                        instructions how to build your own EDID data are
                        available in Documentation/admin-guide/edid.rst. An␣
↪EDID
                        data set will only be used for a particular connector,
                        if its name and a colon are prepended to the EDID
                        name. Each connector may use a unique EDID data
                        set by separating the files with a comma.  An EDID
                        data set with no connector name will be used for
                        any connectors not explicitly specified.

        dscc4.setup=    [NET]

        dt_cpu_ftrs=    [PPC]
                        Format: {"off" | "known"}
                        Control how the dt_cpu_ftrs device-tree binding is
                        used for CPU feature discovery and setup (if it
                        exists).
                        off: Do not use it, fall back to legacy cpu table.
                        known: Do not pass through unknown features to guests
                        or userspace, only those that the kernel is aware of.

        dump_apple_properties   [X86]
                        Dump name and content of EFI device properties on
                        x86 Macs.  Useful for driver authors to determine
                        what data is available or for reverse-engineering.

        dyndbg[="val"]          [KNL,DYNAMIC_DEBUG]
        <module>.dyndbg[="val"]
                        Enable debug messages at boot time.  See
                        Documentation/admin-guide/dynamic-debug-howto.rst
                        for details.

        early_ioremap_debug [KNL]
                        Enable debug messages in early_ioremap support. This
                        is useful for tracking down temporary early mappings
                        which are not unmapped.
```

```
earlycon=       [KNL] Output early console device and options.

                When used with no options, the early console is
                determined by stdout-path property in device tree's
                chosen node or the ACPI SPCR table if supported by
                the platform.

        cdns,<addr>[,options]
                Start an early, polled-mode console on a Cadence
                (xuartps) serial port at the specified address. Only
                supported option is baud rate. If baud rate is not
                specified, the serial port must already be setup and
                configured.

        uart[8250],io,<addr>[,options[,uartclk]]
        uart[8250],mmio,<addr>[,options[,uartclk]]
        uart[8250],mmio32,<addr>[,options[,uartclk]]
        uart[8250],mmio32be,<addr>[,options[,uartclk]]
        uart[8250],0x<addr>[,options]
                Start an early, polled-mode console on the 8250/16550
                UART at the specified I/O port or MMIO address.
                MMIO inter-register address stride is either 8-bit
                (mmio) or 32-bit (mmio32 or mmio32be).
                If none of [io|mmio|mmio32|mmio32be], <addr> is assumed
                to be equivalent to 'mmio'. 'options' are specified
                in the same format described for "console=ttyS<n>"; if
                unspecified, the h/w is not initialized. 'uartclk' is
                the uart clock frequency; if unspecified, it is set
                to 'BASE_BAUD' * 16.

        pl011,<addr>
        pl011,mmio32,<addr>
                Start an early, polled-mode console on a pl011 serial
                port at the specified address. The pl011 serial port
                must already be setup and configured. Options are not
                yet supported.  If 'mmio32' is specified, then only
                the driver will use only 32-bit accessors to read/write
                the device registers.

        liteuart,<addr>
                Start an early console on a litex serial port at the
                specified address. The serial port must already be
                setup and configured. Options are not yet supported.

        meson,<addr>
                Start an early, polled-mode console on a meson serial
                port at the specified address. The serial port must
                already be setup and configured. Options are not yet
                supported.
```

```
msm_serial,<addr>
        Start an early, polled-mode console on an msm serial
        port at the specified address. The serial port
        must already be setup and configured. Options are not
        yet supported.

msm_serial_dm,<addr>
        Start an early, polled-mode console on an msm serial
        dm port at the specified address. The serial port
        must already be setup and configured. Options are not
        yet supported.

owl,<addr>
        Start an early, polled-mode console on a serial port
        of an Actions Semi SoC, such as S500 or S900, at the
        specified address. The serial port must already be
        setup and configured. Options are not yet supported.

rda,<addr>
        Start an early, polled-mode console on a serial port
        of an RDA Micro SoC, such as RDA8810PL, at the
        specified address. The serial port must already be
        setup and configured. Options are not yet supported.

sbi
        Use RISC-V SBI (Supervisor Binary Interface) for early
        console.

smh     Use ARM semihosting calls for early console.

s3c2410,<addr>
s3c2412,<addr>
s3c2440,<addr>
s3c6400,<addr>
s5pv210,<addr>
exynos4210,<addr>
        Use early console provided by serial driver available
        on Samsung SoCs, requires selecting proper type and
        a correct base address of the selected UART port. The
        serial port must already be setup and configured.
        Options are not yet supported.

lantiq,<addr>
        Start an early, polled-mode console on a lantiq serial
        (lqasc) port at the specified address. The serial port
        must already be setup and configured. Options are not
        yet supported.

lpuart,<addr>
lpuart32,<addr>
        Use early console provided by Freescale LP UART driver
```

```
                        found on Freescale Vybrid and QorIQ LS1021A processors.
                        A valid base address must be provided, and the serial
                        port must already be setup and configured.

                ec_imx21,<addr>
                ec_imx6q,<addr>
                        Start an early, polled-mode, output-only console on the
                        Freescale i.MX UART at the specified address. The UART
                        must already be setup and configured.

                ar3700_uart,<addr>
                        Start an early, polled-mode console on the
                        Armada 3700 serial port at the specified
                        address. The serial port must already be setup
                        and configured. Options are not yet supported.

                qcom_geni,<addr>
                        Start an early, polled-mode console on a Qualcomm
                        Generic Interface (GENI) based serial port at the
                        specified address. The serial port must already be
                        setup and configured. Options are not yet supported.

                efifb,[options]
                        Start an early, unaccelerated console on the EFI
                        memory mapped framebuffer (if available). On cache
                        coherent non-x86 systems that use system memory for
                        the framebuffer, pass the 'ram' option so that it is
                        mapped with the correct attributes.

                linflex,<addr>
                        Use early console provided by Freescale LINFlexD UART
                        serial driver for NXP S32V234 SoCs. A valid base
                        address must be provided, and the serial port must
                        already be setup and configured.

        earlyprintk=    [X86,SH,ARM,M68k,S390]
                        earlyprintk=vga
                        earlyprintk=sclp
                        earlyprintk=xen
                        earlyprintk=serial[,ttySn[,baudrate]]
                        earlyprintk=serial[,0x...[,baudrate]]
                        earlyprintk=ttySn[,baudrate]
                        earlyprintk=dbgp[debugController#]
                        earlyprintk=pciserial[,force],bus:device.function[,
↪baudrate]
                        earlyprintk=xdbc[xhciController#]
                        earlyprintk=bios

                        earlyprintk is useful when the kernel crashes before
                        the normal console is initialized. It is not enabled by
                        default because it has some cosmetic problems.
```

```
                    Append ",keep" to not disable it when the real console
                    takes over.

                    Only one of vga, serial, or usb debug port can
                    be used at a time.

                    Currently only ttyS0 and ttyS1 may be specified by
                    name.  Other I/O ports may be explicitly specified
                    on some architectures (x86 and arm at least) by
                    replacing ttySn with an I/O port address, like this:
                            earlyprintk=serial,0x1008,115200
                    You can find the port for a given device in
                    /proc/tty/driver/serial:
                            2: uart:ST16650V2 port:00001008 irq:18 ...

                    Interaction with the standard serial driver is not
                    very good.

                    The VGA output is eventually overwritten by
                    the real console.

                    The xen option can only be used in Xen domains.

                    The sclp output can only be used on s390.

                    The bios output can only be used on SuperH.

                    The optional "force" to "pciserial" enables use of a
                    PCI device even when its classcode is not of the
                    UART class.

    edac_report=    [HW,EDAC] Control how to report EDAC event
                    Format: {"on" | "off" | "force"}
                    on: enable EDAC to report H/W event. May be overridden
                    by other higher priority error reporting module.
                    off: disable H/W event reporting through EDAC.
                    force: enforce the use of EDAC to report H/W event.
                    default: on.

    edd=            [EDD]
                    Format: {"off" | "on" | "skip[mbr]"}

    efi=            [EFI]
                    Format: { "debug", "disable_early_pci_dma",
                              "nochunk", "noruntime", "nosoftreserve",
                              "novamap", "no_disable_early_pci_dma" }
                    debug: enable misc debug output.
                    disable_early_pci_dma: disable the busmaster bit on all
                    PCI bridges while in the EFI boot stub.
                    nochunk: disable reading files in "chunks" in the EFI
```

```
                        boot stub, as chunking can cause problems with some
                        firmware implementations.
                        noruntime : disable EFI runtime services support
                        nosoftreserve: The EFI_MEMORY_SP (Specific Purpose)
                        attribute may cause the kernel to reserve the
                        memory range for a memory mapping driver to
                        claim. Specify efi=nosoftreserve to disable this
                        reservation and treat the memory by its base type
                        (i.e. EFI_CONVENTIONAL_MEMORY / "System RAM").
                        novamap: do not call SetVirtualAddressMap().
                        no_disable_early_pci_dma: Leave the busmaster bit set
                        on all PCI bridges while in the EFI boot stub

        efi_no_storage_paranoia [EFI; X86]
                        Using this parameter you can use more than 50% of
                        your efi variable storage. Use this parameter only if
                        you are really sure that your UEFI does sane gc and
                        fulfills the spec otherwise your board may brick.

        efi_fake_mem=   nn[KMG]@ss[KMG]:aa[,nn[KMG]@ss[KMG]:aa,..] [EFI; X86]
                        Add arbitrary attribute to specific memory range by
                        updating original EFI memory map.
                        Region of memory which aa attribute is added to is
                        from ss to ss+nn.

                        If efi_fake_mem=2G@4G:0x10000,2G@0x10a0000000:0x10000
                        is specified, EFI_MEMORY_MORE_RELIABLE(0x10000)
                        attribute is added to range 0x100000000-0x180000000 and
                        0x10a0000000-0x1120000000.

                        If efi_fake_mem=8G@9G:0x40000 is specified, the
                        EFI_MEMORY_SP(0x40000) attribute is added to
                        range 0x240000000-0x43fffffff.

                        Using this parameter you can do debugging of EFI memmap
                        related features. For example, you can do debugging of
                        Address Range Mirroring feature even if your box
                        doesn't support it, or mark specific memory as
                        "soft reserved".

        efivar_ssdt=    [EFI; X86] Name of an EFI variable that contains an␣
↪SSDT
                        that is to be dynamically loaded by Linux. If there are
                        multiple variables with the same name but with␣
↪different
                        vendor GUIDs, all of them will be loaded. See
                        Documentation/admin-guide/acpi/ssdt-overlays.rst for␣
↪details.

        eisa_irq_edge=  [PARISC,HW]
```

```
                        See header of drivers/parisc/eisa.c.

        ekgdboc=        [X86,KGDB] Allow early kernel console debugging
                        Format: ekgdboc=kbd

                        This is designed to be used in conjunction with
                        the boot argument: earlyprintk=vga

                        This parameter works in place of the kgdboc parameter
                        but can only be used if the backing tty is available
                        very early in the boot process. For early debugging
                        via a serial port see kgdboc_earlycon instead.

        elanfreq=       [X86-32]
                        See comment before function elanfreq_setup() in
                        arch/x86/kernel/cpu/cpufreq/elanfreq.c.

        elfcorehdr=[size[KMG]@]offset[KMG] [PPC,SH,X86,S390]
                        Specifies physical address of start of kernel core
                        image elf header and optionally the size. Generally
                        kexec loader will pass this option to capture kernel.
                        See Documentation/admin-guide/kdump/kdump.rst for␣
↪details.

        enable_mtrr_cleanup [X86]
                        The kernel tries to adjust MTRR layout from continuous
                        to discrete, to make X server driver able to add WB
                        entry later. This parameter enables that.

        enable_timer_pin_1 [X86]
                        Enable PIN 1 of APIC timer
                        Can be useful to work around chipset bugs
                        (in particular on some ATI chipsets).
                        The kernel tries to set a reasonable default.

        enforcing=      [SELINUX] Set initial enforcing status.
                        Format: {"0" | "1"}
                        See security/selinux/Kconfig help text.
                        0 -- permissive (log only, no denials).
                        1 -- enforcing (deny and log).
                        Default value is 0.
                        Value can be changed at runtime via
                        /sys/fs/selinux/enforce.

        erst_disable    [ACPI]
                        Disable Error Record Serialization Table (ERST)
                        support.

        ether=          [HW,NET] Ethernet cards parameters
                        This option is obsoleted by the "netdev=" option, which
                        has equivalent usage. See its documentation for␣
```

```
↪details.

        evm=            [EVM]
                        Format: { "fix" }
                        Permit 'security.evm' to be updated regardless of
                        current integrity status.

        early_page_ext [KNL] Enforces page_ext initialization to earlier
                        stages so cover more early boot allocations.
                        Please note that as side effect some optimizations
                        might be disabled to achieve that (e.g. parallelized
                        memory initialization is disabled) so the boot process
                        might take longer, especially on systems with a lot of
                        memory. Available with CONFIG_PAGE_EXTENSION=y.

        failslab=
        fail_usercopy=
        fail_page_alloc=
        fail_make_request=[KNL]
                        General fault injection mechanism.
                        Format: <interval>,<probability>,<space>,<times>
                        See also Documentation/fault-injection/.

        fb_tunnels=     [NET]
                        Format: { initns | none }
                        See Documentation/admin-guide/sysctl/net.rst for
                        fb_tunnels_only_for_init_ns

        floppy=         [HW]
                        See Documentation/admin-guide/blockdev/floppy.rst.

        forcepae        [X86-32]
                        Forcefully enable Physical Address Extension (PAE).
                        Many Pentium M systems disable PAE but may have a
                        functionally usable PAE implementation.
                        Warning: use of this parameter will taint the kernel
                        and may cause unknown problems.

        ftrace=[tracer]
                        [FTRACE] will set and start the specified tracer
                        as early as possible in order to facilitate early
                        boot debugging.

        ftrace_boot_snapshot
                        [FTRACE] On boot up, a snapshot will be taken of the
                        ftrace ring buffer that can be read at:
                        /sys/kernel/tracing/snapshot.
                        This is useful if you need tracing information from␣
↪kernel
                        boot up that is likely to be overridden by user space
                        start up functionality.
```

```
                        Optionally, the snapshot can also be defined for a␣
↪tracing
                        instance that was created by the trace_instance=␣
↪command
                        line parameter.

                        trace_instance=foo,sched_switch ftrace_boot_
↪snapshot=foo

                        The above will cause the "foo" tracing instance to␣
↪trigger
                        a snapshot at the end of boot up.

        ftrace_dump_on_oops[=orig_cpu]
                        [FTRACE] will dump the trace buffers on oops.
                        If no parameter is passed, ftrace will dump
                        buffers of all CPUs, but if you pass orig_cpu, it will
                        dump only the buffer of the CPU that triggered the
                        oops.

        ftrace_filter=[function-list]
                        [FTRACE] Limit the functions traced by the function
                        tracer at boot up. function-list is a comma-separated
                        list of functions. This list can be changed at run
                        time by the set_ftrace_filter file in the debugfs
                        tracing directory.

        ftrace_notrace=[function-list]
                        [FTRACE] Do not trace the functions specified in
                        function-list. This list can be changed at run time
                        by the set_ftrace_notrace file in the debugfs
                        tracing directory.

        ftrace_graph_filter=[function-list]
                        [FTRACE] Limit the top level callers functions traced
                        by the function graph tracer at boot up.
                        function-list is a comma-separated list of functions
                        that can be changed at run time by the
                        set_graph_function file in the debugfs tracing␣
↪directory.

        ftrace_graph_notrace=[function-list]
                        [FTRACE] Do not trace from the functions specified in
                        function-list.  This list is a comma-separated list of
                        functions that can be changed at run time by the
                        set_graph_notrace file in the debugfs tracing␣
↪directory.

        ftrace_graph_max_depth=<uint>
                        [FTRACE] Used with the function graph tracer. This is
```

```
                        the max depth it will trace into a function. This value
                        can be changed at run time by the max_graph_depth file
                        in the tracefs tracing directory. default: 0 (no limit)

        fw_devlink=     [KNL] Create device links between consumer and supplier
                        devices by scanning the firmware to infer the
                        consumer/supplier relationships. This feature is
                        especially useful when drivers are loaded as modules as
                        it ensures proper ordering of tasks like device probing
                        (suppliers first, then consumers), supplier boot state
                        clean up (only after all consumers have probed),
                        suspend/resume & runtime PM (consumers first, then
                        suppliers).
                        Format: { off | permissive | on | rpm }
                        off --  Don't create device links from firmware info.
                        permissive -- Create device links from firmware info
                                but use it only for ordering boot state clean
                                up (sync_state() calls).
                        on --   Create device links from firmware info and use␣
↪it
                                to enforce probe and suspend/resume ordering.
                        rpm --  Like "on", but also use to order runtime PM.

        fw_devlink.strict=<bool>
                        [KNL] Treat all inferred dependencies as mandatory
                        dependencies. This only applies for fw_devlink=on|rpm.
                        Format: <bool>

        fw_devlink.sync_state =
                        [KNL] When all devices that could probe have finished
                        probing, this parameter controls what to do with
                        devices that haven't yet received their sync_state()
                        calls.
                        Format: { strict | timeout }
                        strict -- Default. Continue waiting on consumers to
                                probe successfully.
                        timeout -- Give up waiting on consumers and call
                                sync_state() on any devices that haven't yet
                                received their sync_state() calls after
                                deferred_probe_timeout has expired or by
                                late_initcall() if !CONFIG_MODULES.

        gamecon.map[2|3]=
                        [HW,JOY] Multisystem joystick and NES/SNES/PSX pad
                        support via parallel port (up to 5 devices per port)
                        Format: <port#>,<pad1>,<pad2>,<pad3>,<pad4>,<pad5>
                        See also Documentation/input/devices/joystick-parport.

        hest_disable    [ACPI]
                        Disable Hardware Error Source Table (HEST) support;
                        corresponding firmware-first mode error processing
                        logic will be disabled.

        hibernate=      [HIBERNATION]
```

```
        noresume        Don't check if there's a hibernation image
                        present during boot.
        nocompress      Don't compress/decompress hibernation images.
        no              Disable hibernation and resume.
        protect_image   Turn on image protection during restoration
                        (that will set all pages holding image data
                        during restoration read-only).

highmem=nn[KMG] [KNL,BOOT] forces the highmem zone to have an exact
                size of <nn>. This works even on boxes that have no
                highmem otherwise. This also works to reduce highmem
                size on bigger boxes.

highres=        [KNL] Enable/disable high resolution timer mode.
                Valid parameters: "on", "off"
                Default: "on"

hlt             [BUGS=ARM,SH]

hostname=       [KNL] Set the hostname (aka UTS nodename).
                Format: <string>
                This allows setting the system's hostname during early
                startup. This sets the name returned by gethostname.
                Using this parameter to set the hostname makes it
                possible to ensure the hostname is correctly set before
                any userspace processes run, avoiding the possibility
                that a process may call gethostname before the hostname
                has been explicitly set, resulting in the calling
                process getting an incorrect result. The string must
                not exceed the maximum allowed hostname length (usually
                64 characters) and will be truncated otherwise.

hpet=           [X86-32,HPET] option to control HPET usage
                Format: { enable (default) | disable | force |
                        verbose }
                disable: disable HPET and use PIT instead
                force: allow force enabled of undocumented chips (ICH4,
                        VIA, nVidia)
                verbose: show contents of HPET registers during setup

hpet_mmap=      [X86, HPET_MMAP] Allow userspace to mmap HPET
                registers.  Default set by CONFIG_HPET_MMAP_DEFAULT.

hugepages=      [HW] Number of HugeTLB pages to allocate at boot.
                If this follows hugepagesz (below), it specifies
                the number of pages of hugepagesz to be allocated.
                If this is the first HugeTLB parameter on the command
                line, it specifies the number of pages to allocate for
                the default huge page size. If using node format, the
                number of pages to allocate per-node can be specified.
                See also Documentation/admin-guide/mm/hugetlbpage.rst.
```

```
                        Format: <integer> or (node format)
                                <node>:<integer>[,<node>:<integer>]

        hugepagesz=
                        [HW] The size of the HugeTLB pages.  This is used in
                        conjunction with hugepages (above) to allocate huge
                        pages of a specific size at boot.  The pair
                        hugepagesz=X hugepages=Y can be specified once for
                        each supported huge page size. Huge page sizes are
                        architecture dependent.  See also
                        Documentation/admin-guide/mm/hugetlbpage.rst.
                        Format: size[KMG]

        hugetlb_cma=    [HW,CMA] The size of a CMA area used for allocation
                        of gigantic hugepages. Or using node format, the size
                        of a CMA area per node can be specified.
                        Format: nn[KMGTPE] or (node format)
                                <node>:nn[KMGTPE][,<node>:nn[KMGTPE]]

                        Reserve a CMA area of given size and allocate gigantic
                        hugepages using the CMA allocator. If enabled, the
                        boot-time allocation of gigantic hugepages is skipped.

        hugetlb_free_vmemmap=
                        [KNL] Requires CONFIG_HUGETLB_PAGE_OPTIMIZE_VMEMMAP
                        enabled.
                        Control if HugeTLB Vmemmap Optimization (HVO) is␣
↪enabled.
                        Allows heavy hugetlb users to free up some more
                        memory (7 * PAGE_SIZE for each 2MB hugetlb page).
                        Format: { on | off (default) }

                        on: enable HVO
                        off: disable HVO

                        Built with CONFIG_HUGETLB_PAGE_OPTIMIZE_VMEMMAP_
↪DEFAULT_ON=y,
                        the default is on.

                        Note that the vmemmap pages may be allocated from the␣
↪added
                        memory block itself when memory_hotplug.memmap_on_
↪memory is
                        enabled, those vmemmap pages cannot be optimized even␣
↪if this
                        feature is enabled.  Other vmemmap pages not allocated␣
↪from
                        the added memory block itself do not be affected.

        hung_task_panic=
                        [KNL] Should the hung task detector generate panics.
```

```
                        Format: 0 | 1

                        A value of 1 instructs the kernel to panic when a
                        hung task is detected. The default value is controlled
                        by the CONFIG_BOOTPARAM_HUNG_TASK_PANIC build-time
                        option. The value selected by this boot parameter can
                        be changed later by the kernel.hung_task_panic sysctl.

        hvc_iucv=       [S390]  Number of z/VM IUCV hypervisor console (HVC)
                                terminal devices. Valid values: 0..8
        hvc_iucv_allow= [S390]  Comma-separated list of z/VM user IDs.
                                If specified, z/VM IUCV HVC accepts connections
                                from listed z/VM user IDs only.

        hv_nopvspin     [X86,HYPER_V] Disables the paravirt spinlock␣
↪optimizations
                                      which allow the hypervisor to 'idle' the
                                      guest on lock contention.

        i2c_bus=        [HW]    Override the default board specific I2C bus␣
↪speed
                                or register an additional I2C bus that is not
                                registered from board initialization code.
                                Format:
                                <bus_id>,<clkrate>

        i8042.debug     [HW] Toggle i8042 debug mode
        i8042.unmask_kbd_data
                        [HW] Enable printing of interrupt data from the KBD␣
↪port
                             (disabled by default, and as a pre-condition
                             requires that i8042.debug=1 be enabled)
        i8042.direct    [HW] Put keyboard port into non-translated mode
        i8042.dumbkbd   [HW] Pretend that controller can only read data from
                             keyboard and cannot control its state
                             (Don't attempt to blink the leds)
        i8042.noaux     [HW] Don't check for auxiliary (== mouse) port
        i8042.nokbd     [HW] Don't check/create keyboard port
        i8042.noloop    [HW] Disable the AUX Loopback command while probing
                             for the AUX port
        i8042.nomux     [HW] Don't check presence of an active multiplexing
                             controller
        i8042.nopnp     [HW] Don't use ACPIPnP / PnPBIOS to discover KBD/AUX
                             controllers
        i8042.notimeout [HW] Ignore timeout condition signalled by controller
        i8042.reset     [HW] Reset the controller during init, cleanup and
                             suspend-to-ram transitions, only during s2r
                             transitions, or never reset
                        Format: { 1 | Y | y | 0 | N | n }
                        1, Y, y: always reset controller
                        0, N, n: don't ever reset controller
```

```
                        Default: only on s2r transitions on x86; most other
                        architectures force reset to be always executed
        i8042.unlock    [HW] Unlock (ignore) the keylock
        i8042.kbdreset  [HW] Reset device connected to KBD port
        i8042.probe_defer
                        [HW] Allow deferred probing upon i8042 probe errors

        i810=           [HW,DRM]

        i915.invert_brightness=
                        [DRM] Invert the sense of the variable that is used to
                        set the brightness of the panel backlight. Normally a
                        brightness value of 0 indicates backlight switched off,
                        and the maximum of the brightness value sets the␣
↪backlight
                        to maximum brightness. If this parameter is set to 0
                        (default) and the machine requires it, or this␣
↪parameter
                        is set to 1, a brightness value of 0 sets the backlight
                        to maximum brightness, and the maximum of the␣
↪brightness
                        value switches the backlight off.
                        -1 -- never invert brightness
                         0 -- machine default
                         1 -- force brightness inversion

        ia32_emulation= [X86-64]
                        Format: <bool>
                        When true, allows loading 32-bit programs and␣
↪executing 32-bit
                        syscalls, essentially overriding IA32_EMULATION_
↪DEFAULT_DISABLED at
                        boot time. When false, unconditionally disables IA32␣
↪emulation.

        icn=            [HW,ISDN]
                        Format: <io>[,<membase>[,<icn_id>[,<icn_id2>]]]

        idle=           [X86]
                        Format: idle=poll, idle=halt, idle=nomwait
                        Poll forces a polling idle loop that can slightly
                        improve the performance of waking up a idle CPU, but
                        will use a lot of power and make the system run hot.
                        Not recommended.
                        idle=halt: Halt is forced to be used for CPU idle.
                        In such case C2/C3 won't be used again.
                        idle=nomwait: Disable mwait for CPU C-states

        idxd.sva=       [HW]
                        Format: <bool>
```

```
                Allow force disabling of Shared Virtual Memory (SVA)
                support for the idxd driver. By default it is set to
                true (1).

idxd.tc_override= [HW]
                Format: <bool>
                Allow override of default traffic class configuration
                for the device. By default it is set to false (0).

ieee754=        [MIPS] Select IEEE Std 754 conformance mode
                Format: { strict | legacy | 2008 | relaxed }
                Default: strict

                Choose which programs will be accepted for execution
                based on the IEEE 754 NaN encoding(s) supported by
                the FPU and the NaN encoding requested with the value
                of an ELF file header flag individually set by each
                binary.  Hardware implementations are permitted to
                support either or both of the legacy and the 2008 NaN
                encoding mode.

                Available settings are as follows:
                strict  accept binaries that request a NaN encoding
                        supported by the FPU
                legacy  only accept legacy-NaN binaries, if supported
                        by the FPU
                2008    only accept 2008-NaN binaries, if supported
                        by the FPU
                relaxed accept any binaries regardless of whether
                        supported by the FPU

                The FPU emulator is always able to support both NaN
                encodings, so if no FPU hardware is present or it has
                been disabled with 'nofpu', then the settings of
                'legacy' and '2008' strap the emulator accordingly,
                'relaxed' straps the emulator for both legacy-NaN and
                2008-NaN, whereas 'strict' enables legacy-NaN only on
                legacy processors and both NaN encodings on MIPS32 or
                MIPS64 CPUs.

                The setting for ABS.fmt/NEG.fmt instruction execution
                mode generally follows that for the NaN encoding,
                except where unsupported by hardware.

ignore_loglevel [KNL]
                Ignore loglevel setting - this will print /all/
                kernel messages to the console. Useful for debugging.
                We also add it as printk module parameter, so users
                could change it dynamically, usually by
                /sys/module/printk/parameters/ignore_loglevel.
```

```
        ignore_rlimit_data
                        Ignore RLIMIT_DATA setting for data mappings,
                        print warning at first misuse.  Can be changed via
                        /sys/module/kernel/parameters/ignore_rlimit_data.

        ihash_entries=  [KNL]
                        Set number of hash buckets for inode cache.

        ima_appraise=   [IMA] appraise integrity measurements
                        Format: { "off" | "enforce" | "fix" | "log" }
                        default: "enforce"

        ima_appraise_tcb [IMA] Deprecated.  Use ima_policy= instead.
                        The builtin appraise policy appraises all files
                        owned by uid=0.

        ima_canonical_fmt [IMA]
                        Use the canonical format for the binary runtime
                        measurements, instead of host native format.

        ima_hash=       [IMA]
                        Format: { md5 | sha1 | rmd160 | sha256 | sha384
                                   | sha512 | ... }
                        default: "sha1"

                        The list of supported hash algorithms is defined
                        in crypto/hash_info.h.

        ima_policy=     [IMA]
                        The builtin policies to load during IMA setup.
                        Format: "tcb | appraise_tcb | secure_boot |
                                 fail_securely | critical_data"

                        The "tcb" policy measures all programs exec'd, files
                        mmap'd for exec, and all files opened with the read
                        mode bit set by either the effective uid (euid=0) or
                        uid=0.

                        The "appraise_tcb" policy appraises the integrity of
                        all files owned by root.

                        The "secure_boot" policy appraises the integrity
                        of files (eg. kexec kernel image, kernel modules,
                        firmware, policy, etc) based on file signatures.

                        The "fail_securely" policy forces file signature
                        verification failure also on privileged mounted
                        filesystems with the SB_I_UNVERIFIABLE_SIGNATURE
                        flag.

                        The "critical_data" policy measures kernel integrity
```

```
                        critical data.

        ima_tcb         [IMA] Deprecated.  Use ima_policy= instead.
                        Load a policy which meets the needs of the Trusted
                        Computing Base.  This means IMA will measure all
                        programs exec'd, files mmap'd for exec, and all files
                        opened for read by uid=0.

        ima_template=   [IMA]
                        Select one of defined IMA measurements template␣
↪formats.
                        Formats: { "ima" | "ima-ng" | "ima-ngv2" | "ima-sig" |
                                   "ima-sigv2" }
                        Default: "ima-ng"

        ima_template_fmt=
                        [IMA] Define a custom template format.
                        Format: { "field1|...|fieldN" }

        ima.ahash_minsize= [IMA] Minimum file size for asynchronous hash usage
                        Format: <min_file_size>
                        Set the minimal file size for using asynchronous hash.
                        If left unspecified, ahash usage is disabled.

                        ahash performance varies for different data sizes on
                        different crypto accelerators. This option can be used
                        to achieve the best performance for a particular HW.

        ima.ahash_bufsize= [IMA] Asynchronous hash buffer size
                        Format: <bufsize>
                        Set hashing buffer size. Default: 4k.

                        ahash performance varies for different chunk sizes on
                        different crypto accelerators. This option can be used
                        to achieve best performance for particular HW.

        init=           [KNL]
                        Format: <full_path>
                        Run specified binary instead of /sbin/init as init
                        process.

        initcall_debug  [KNL] Trace initcalls as they are executed.  Useful
                        for working out where the kernel is dying during
                        startup.

        initcall_blacklist=  [KNL] Do not execute a comma-separated list of
                        initcall functions.  Useful for debugging built-in
                        modules and initcalls.

        initramfs_async= [KNL]
                        Format: <bool>
```

```
                        Default: 1
                        This parameter controls whether the initramfs
                        image is unpacked asynchronously, concurrently
                        with devices being probed and
                        initialized. This should normally just work,
                        but as a debugging aid, one can get the
                        historical behaviour of the initramfs
                        unpacking being completed before device_ and
                        late_ initcalls.

        initrd=         [BOOT] Specify the location of the initial ramdisk

        initrdmem=      [KNL] Specify a physical address and size from which to
                        load the initrd. If an initrd is compiled in or
                        specified in the bootparams, it takes priority over␣
↪this
                        setting.
                        Format: ss[KMG],nn[KMG]
                        Default is 0, 0

        init_on_alloc=  [MM] Fill newly allocated pages and heap objects with
                        zeroes.
                        Format: 0 | 1
                        Default set by CONFIG_INIT_ON_ALLOC_DEFAULT_ON.

        init_on_free=   [MM] Fill freed pages and heap objects with zeroes.
                        Format: 0 | 1
                        Default set by CONFIG_INIT_ON_FREE_DEFAULT_ON.

        init_pkru=      [X86] Specify the default memory protection keys rights
                        register contents for all processes.  0x55555554 by
                        default (disallow access to all but pkey 0).  Can
                        override in debugfs after boot.

        inport.irq=     [HW] Inport (ATI XL and Microsoft) busmouse driver
                        Format: <irq>

        int_pln_enable  [X86] Enable power limit notification interrupt

        integrity_audit=[IMA]
                        Format: { "0" | "1" }
                        0 -- basic integrity auditing messages. (Default)
                        1 -- additional integrity auditing messages.

        intel_iommu=    [DMAR] Intel IOMMU driver (DMAR) option
                on
                        Enable intel iommu driver.
                off
                        Disable intel iommu driver.
                igfx_off [Default Off]
                        By default, gfx is mapped as normal device. If a gfx
```

```
                        device has a dedicated DMAR unit, the DMAR unit is
                        bypassed by not enabling DMAR with this option. In
                        this case, gfx device will use physical address for
                        DMA.
                strict [Default Off]
                        Deprecated, equivalent to iommu.strict=1.
                sp_off [Default Off]
                        By default, super page will be supported if Intel IOMMU
                        has the capability. With this option, super page will
                        not be supported.
                sm_on
                        Enable the Intel IOMMU scalable mode if the hardware
                        advertises that it has support for the scalable mode
                        translation.
                sm_off
                        Disallow use of the Intel IOMMU scalable mode.
                tboot_noforce [Default Off]
                        Do not force the Intel IOMMU enabled under tboot.
                        By default, tboot will force Intel IOMMU on, which
                        could harm performance of some high-throughput
                        devices like 40GBit network cards, even if identity
                        mapping is enabled.
                        Note that using this option lowers the security
                        provided by tboot because it makes the system
                        vulnerable to DMA attacks.

        intel_idle.max_cstate=  [KNL,HW,ACPI,X86]
                        0       disables intel_idle and fall back on acpi_idle.
                        1 to 9  specify maximum depth of C-state.

        intel_pstate=   [X86]
                        disable
                          Do not enable intel_pstate as the default
                          scaling driver for the supported processors
                        active
                          Use intel_pstate driver to bypass the scaling
                          governors layer of cpufreq and provides it own
                          algorithms for p-state selection. There are two
                          P-state selection algorithms provided by
                          intel_pstate in the active mode: powersave and
                          performance.  The way they both operate depends
                          on whether or not the hardware managed P-states
                          (HWP) feature has been enabled in the processor
                          and possibly on the processor model.
                        passive
                          Use intel_pstate as a scaling driver, but configure␣
↪it
                          to work with generic cpufreq governors (instead of
                          enabling its internal governor).  This mode cannot be
                          used along with the hardware-managed P-states (HWP)
                          feature.
```

```
                        force
                          Enable intel_pstate on systems that prohibit it by␣
↪default
                          in favor of acpi-cpufreq. Forcing the intel_pstate␣
↪driver
                          instead of acpi-cpufreq may disable platform␣
↪features, such

                merge
                nomerge
                soft
                pt              [X86]
                nopt            [X86]
                nobypass        [PPC/POWERNV]
                        Disable IOMMU bypass, using IOMMU for PCI devices.

        iommu.forcedac= [ARM64, X86] Control IOVA allocation for PCI devices.
                        Format: { "0" | "1" }
                        0 - Try to allocate a 32-bit DMA address first, before
                          falling back to the full range if needed.
                        1 - Allocate directly from the full usable range,
                          forcing Dual Address Cycle for PCI cards supporting
                          greater than 32-bit addressing.

        iommu.strict=   [ARM64, X86, S390] Configure TLB invalidation behaviour
                        Format: { "0" | "1" }
                        0 - Lazy mode.
                          Request that DMA unmap operations use deferred
                          invalidation of hardware TLBs, for increased
                          throughput at the cost of reduced device isolation.
                          Will fall back to strict mode if not supported by
                          the relevant IOMMU driver.
                        1 - Strict mode.
                          DMA unmap operations invalidate IOMMU hardware TLBs
                          synchronously.
                        unset - Use value of CONFIG_IOMMU_DEFAULT_DMA_{LAZY,
↪STRICT}.
                        Note: on x86, strict mode specified via one of the
                        legacy driver-specific options takes precedence.

        iommu.passthrough=
                        [ARM64, X86] Configure DMA to bypass the IOMMU by␣
↪default.
                        Format: { "0" | "1" }
                        0 - Use IOMMU translation for DMA.
                        1 - Bypass the IOMMU for DMA.
                        unset - Use value of CONFIG_IOMMU_DEFAULT_PASSTHROUGH.

        io7=            [HW] IO7 for Marvel-based Alpha systems
                        See comment before marvel_specify_io7 in
                        arch/alpha/kernel/core_marvel.c.

        io_delay=       [X86] I/O delay method
                0x80
                        Standard port 0x80 based delay
```

```
                0xed
                        Alternate port 0xed based delay (needed on some␣
↪systems)
                udelay
                        Simple two microseconds delay
                none
                        No delay

        ip=             [IP_PNP]
                        See Documentation/admin-guide/nfs/nfsroot.rst.

        ipcmni_extend   [KNL] Extend the maximum number of unique System V
                        IPC identifiers from 32,768 to 16,777,216.

        irqaffinity=    [SMP] Set the default irq affinity mask
                        The argument is a cpu list, as described above.

        irqchip.gicv2_force_probe=
                        [ARM, ARM64]
                        Format: <bool>
                        Force the kernel to look for the second 4kB page
                        of a GICv2 controller even if the memory range
                        exposed by the device tree is too small.

        irqchip.gicv3_nolpi=
                        [ARM, ARM64]
                        Force the kernel to ignore the availability of
                        LPIs (and by consequence ITSs). Intended for system
                        that use the kernel as a bootloader, and thus want
                        to let secondary kernels in charge of setting up
                        LPIs.

        irqchip.gicv3_pseudo_nmi= [ARM64]
                        Enables support for pseudo-NMIs in the kernel. This
                        requires the kernel to be built with
                        CONFIG_ARM64_PSEUDO_NMI.

        irqfixup        [HW]
                        When an interrupt is not handled search all handlers
                        for it. Intended to get systems with badly broken
                        firmware running.

        irqpoll         [HW]
                        When an interrupt is not handled search all handlers
                        for it. Also check all handlers each timer
                        interrupt. Intended to get systems with badly broken
                        firmware running.

        isapnp=         [ISAPNP]
                        Format: <RDP>,<reset>,<pci_scan>,<verbosity>
```

```
        isolcpus=       [KNL,SMP,ISOL] Isolate a given set of CPUs from␣
↪disturbance.
                        [Deprecated - use cpusets instead]
                        Format: [flag-list,]<cpu-list>

                        Specify one or more CPUs to isolate from disturbances
                        specified in the flag list (default: domain):

                        nohz
                          Disable the tick when a single task runs.

                          A residual 1Hz tick is offloaded to workqueues,␣
↪which you
                          need to affine to housekeeping through the global
                          workqueue's affinity configured via the
                          /sys/devices/virtual/workqueue/cpumask sysfs file, or
                          by using the 'domain' flag described below.

                          NOTE: by default the global workqueue runs on all␣
↪CPUs,
                          so to protect individual CPUs the 'cpumask' file has␣
↪to
                          be configured manually after bootup.

                        domain
                          Isolate from the general SMP balancing and scheduling
                          algorithms. Note that performing domain isolation␣
↪this way
                          is irreversible: it's not possible to bring back a␣
↪CPU to
                          the domains once isolated through isolcpus. It's␣
↪strongly
                          advised to use cpusets instead to disable scheduler␣
↪load
                          balancing through the "cpuset.sched_load_balance"␣
↪file.
                          It offers a much more flexible interface where CPUs␣
↪can
                          move in and out of an isolated set anytime.

                          You can move a process onto or off an "isolated" CPU␣
↪via
                          the CPU affinity syscalls or cpuset.
                          <cpu number> begins at 0 and the maximum value is
                          "number of CPUs in system - 1".

                        managed_irq

                          Isolate from being targeted by managed interrupts
                          which have an interrupt mask containing isolated
                          CPUs. The affinity of managed interrupts is
```

```
                    handled by the kernel and cannot be changed via
                    the /proc/irq/* interfaces.

                    This isolation is best effort and only effective
                    if the automatically assigned interrupt mask of a
                    device queue contains isolated and housekeeping
                    CPUs. If housekeeping CPUs are online then such
                    interrupts are directed to the housekeeping CPU
                    so that IO submitted on the housekeeping CPU
                    cannot disturb the isolated CPU.

                    If a queue's affinity mask contains only isolated
                    CPUs then this parameter has no effect on the
                    interrupt routing decision, though interrupts are
                    only delivered when tasks running on those
                    isolated CPUs submit IO. IO submitted on
                    housekeeping CPUs has no influence on those
                    queues.

                  The format of <cpu-list> is described above.

iucv=             [HW,NET]

ivrs_ioapic       [HW,X86-64]
                  Provide an override to the IOAPIC-ID<->DEVICE-ID
                  mapping provided in the IVRS ACPI table.
                  By default, PCI segment is 0, and can be omitted.

                  For example, to map IOAPIC-ID decimal 10 to
                  PCI segment 0x1 and PCI device 00:14.0,
                  write the parameter as:
                          ivrs_ioapic=10@0001:00:14.0

                  Deprecated formats:
                  * To map IOAPIC-ID decimal 10 to PCI device 00:14.0
                    write the parameter as:
                          ivrs_ioapic[10]=00:14.0
                  * To map IOAPIC-ID decimal 10 to PCI segment 0x1 and
                    PCI device 00:14.0 write the parameter as:
                          ivrs_ioapic[10]=0001:00:14.0

ivrs_hpet         [HW,X86-64]
                  Provide an override to the HPET-ID<->DEVICE-ID
                  mapping provided in the IVRS ACPI table.
                  By default, PCI segment is 0, and can be omitted.

                  For example, to map HPET-ID decimal 10 to
                  PCI segment 0x1 and PCI device 00:14.0,
                  write the parameter as:
                          ivrs_hpet=10@0001:00:14.0
```

```
                        Deprecated formats:
                        * To map HPET-ID decimal 0 to PCI device 00:14.0
                          write the parameter as:
                                ivrs_hpet[0]=00:14.0
                        * To map HPET-ID decimal 10 to PCI segment 0x1 and
                          PCI device 00:14.0 write the parameter as:
                                ivrs_ioapic[10]=0001:00:14.0

        ivrs_acpihid    [HW,X86-64]
                        Provide an override to the ACPI-HID:UID<->DEVICE-ID
                        mapping provided in the IVRS ACPI table.
                        By default, PCI segment is 0, and can be omitted.

                        For example, to map UART-HID:UID AMD0020:0 to
                        PCI segment 0x1 and PCI device ID 00:14.5,
                        write the parameter as:
                                ivrs_acpihid=AMD0020:0@0001:00:14.5

                        Deprecated formats:
                        * To map UART-HID:UID AMD0020:0 to PCI segment is 0,
                          PCI device ID 00:14.5, write the parameter as:
                                ivrs_acpihid[00:14.5]=AMD0020:0
                        * To map UART-HID:UID AMD0020:0 to PCI segment 0x1 and
                          PCI device ID 00:14.5, write the parameter as:
                                ivrs_acpihid[0001:00:14.5]=AMD0020:0

        js=             [HW,JOY] Analog joystick
                        See Documentation/input/joydev/joystick.rst.

        kasan_multi_shot
                        [KNL] Enforce KASAN (Kernel Address Sanitizer) to print
                        report on every invalid memory access. Without this
                        parameter KASAN will print report only for the first
                        invalid access.

        keep_bootcon    [KNL]
                        Do not unregister boot console at start. This is only
                        useful for debugging when something happens in the␣
↪window
                        between unregistering the boot console and initializing
                        the real console.

        keepinitrd      [HW,ARM] See retain_initrd.

        kernelcore=     [KNL,X86,IA-64,PPC]
                        Format: nn[KMGTPE] | nn% | "mirror"
                        This parameter specifies the amount of memory usable by
                        the kernel for non-movable allocations.  The requested
                        amount is spread evenly throughout all nodes in the
                        system as ZONE_NORMAL.  The remaining memory is used␣
↪for
```

```
                        movable memory in its own zone, ZONE_MOVABLE.  In the
                        event, a node is too small to have both ZONE_NORMAL and
                        ZONE_MOVABLE, kernelcore memory will take priority and
                        other nodes will have a larger ZONE_MOVABLE.

                        ZONE_MOVABLE is used for the allocation of pages that
                        may be reclaimed or moved by the page migration
                        subsystem.  Note that allocations like␣
↪PTEs-from-HighMem
                        still use the HighMem zone if it exists, and the Normal
                        zone if it does not.

                        It is possible to specify the exact amount of memory in
                        the form of "nn[KMGTPE]", a percentage of total system
                        memory in the form of "nn%", or "mirror".  If "mirror"
                        option is specified, mirrored (reliable) memory is used
                        for non-movable allocations and remaining memory is␣
↪used
                        for Movable pages.  "nn[KMGTPE]", "nn%", and "mirror"
                        are exclusive, so you cannot specify multiple forms.

        kgdbdbgp=       [KGDB,HW] kgdb over EHCI usb debug port.
                        Format: <Controller#>[,poll interval]
                        The controller # is the number of the ehci usb debug
                        port as it is probed via PCI.  The poll interval is
                        optional and is the number seconds in between
                        each poll cycle to the debug port in case you need
                        the functionality for interrupting the kernel with
                        gdb or control-c on the dbgp connection.  When
                        not using this parameter you use sysrq-g to break into
                        the kernel debugger.

        kgdboc=         [KGDB,HW] kgdb over consoles.
                        Requires a tty driver that supports console polling,
                        or a supported polling keyboard driver (non-usb).
                         Serial only format: <serial_device>[,baud]
                         keyboard only format: kbd
                         keyboard and serial format: kbd,<serial_device>[,baud]
                        Optional Kernel mode setting:
                         kms, kbd format: kms,kbd
                         kms, kbd and serial format: kms,kbd,<ser_dev>[,baud]

        kgdboc_earlycon=        [KGDB,HW]
                        If the boot console provides the ability to read
                        characters and can work in polling mode, you can use
                        this parameter to tell kgdb to use it as a backend
                        until the normal console is registered. Intended to
                        be used together with the kgdboc parameter which
                        specifies the normal console to transition to.

                        The name of the early console should be specified
```

```
                  as the value of this parameter. Note that the name of
                  the early console might be different than the tty
                  name passed to kgdboc. It's OK to leave the value
                  blank and the first boot console that implements
                  read() will be picked.

kgdbwait          [KGDB] Stop kernel execution and enter the
                  kernel debugger at the earliest opportunity.

kmac=             [MIPS] Korina ethernet MAC address.
                  Configure the RouterBoard 532 series on-chip
                  Ethernet adapter MAC address.

kmemleak=         [KNL] Boot-time kmemleak enable/disable
                  Valid arguments: on, off
                  Default: on
                  Built with CONFIG_DEBUG_KMEMLEAK_DEFAULT_OFF=y,
                  the default is off.

kprobe_event=[probe-list]
                  [FTRACE] Add kprobe events and enable at boot time.
                  The probe-list is a semicolon delimited list of probe
                  definitions. Each definition is same as kprobe_events
                  interface, but the parameters are comma delimited.
                  For example, to add a kprobe event on vfs_read with
                  arg1 and arg2, add to the command line;

                        kprobe_event=p,vfs_read,$arg1,$arg2

                  See also Documentation/trace/kprobetrace.rst "Kernel
                  Boot Parameter" section.

kpti=             [ARM64] Control page table isolation of user
                  and kernel address spaces.
                  Default: enabled on cores which need mitigation.
                  0: force disabled
                  1: force enabled

kunit.enable=     [KUNIT] Enable executing KUnit tests. Requires
                  CONFIG_KUNIT to be set to be fully enabled. The
                  default value can be overridden via
                  KUNIT_DEFAULT_ENABLED.
                  Default is 1 (enabled)

kvm.ignore_msrs=[KVM] Ignore guest accesses to unhandled MSRs.
                  Default is 0 (don't ignore, but inject #GP)

kvm.eager_page_split=
                  [KVM,X86] Controls whether or not KVM will try to
                  proactively split all huge pages during dirty logging.
                  Eager page splitting reduces interruptions to vCPU
```

```
                        execution by eliminating the write-protection faults
                        and MMU lock contention that would otherwise be
                        required to split huge pages lazily.

                        VM workloads that rarely perform writes or that write
                        only to a small region of VM memory may benefit from
                        disabling eager page splitting to allow huge pages to
                        still be used for reads.

                        The behavior of eager page splitting depends on whether
                        KVM_DIRTY_LOG_INITIALLY_SET is enabled or disabled. If
                        disabled, all huge pages in a memslot will be eagerly
                        split when dirty logging is enabled on that memslot. If
                        enabled, eager page splitting will be performed during
                        the KVM_CLEAR_DIRTY ioctl, and only for the pages being
                        cleared.

                        Eager page splitting is only supported when kvm.tdp_
↪mmu=Y.

                        Default is Y (on).

        kvm.enable_vmware_backdoor=[KVM] Support VMware backdoor PV interface.
                                   Default is false (don't support).

        kvm.nx_huge_pages=
                        [KVM] Controls the software workaround for the
                        X86_BUG_ITLB_MULTIHIT bug.
                        force   : Always deploy workaround.
                        off     : Never deploy workaround.
                        auto    : Deploy workaround based on the presence of
                                  X86_BUG_ITLB_MULTIHIT.

                        Default is 'auto'.

                        If the software workaround is enabled for the host,
                        guests do need not to enable it for nested guests.

        kvm.nx_huge_pages_recovery_ratio=
                        [KVM] Controls how many 4KiB pages are periodically␣
↪zapped
                        back to huge pages.  0 disables the recovery,␣
↪otherwise if
                        the value is N KVM will zap 1/Nth of the 4KiB pages␣
↪every
                        period (see below).  The default is 60.

        kvm.nx_huge_pages_recovery_period_ms=
                        [KVM] Controls the time period at which KVM zaps 4KiB␣
↪pages
                        back to huge pages. If the value is a non-zero N, KVM␣
```

```
↪will
                        zap a portion (see ratio above) of the pages every N␣
↪msecs.
                        If the value is 0 (the default), KVM will pick a␣
↪period based
                        on the ratio, such that a page is zapped after 1 hour␣
↪on average.

        kvm-amd.nested= [KVM,AMD] Control nested virtualization feature in
                        KVM/SVM. Default is 1 (enabled).

        kvm-amd.npt=    [KVM,AMD] Control KVM's use of Nested Page Tables,
                        a.k.a. Two-Dimensional Page Tables. Default is 1
                        (enabled). Disable by KVM if hardware lacks support
                        for NPT.

        kvm-arm.mode=
                        [KVM,ARM] Select one of KVM/arm64's modes of operation.

                        none: Forcefully disable KVM.

                        nvhe: Standard nVHE-based mode, without support for
                              protected guests.

                        protected: nVHE-based mode with support for guests␣
↪whose
                                   state is kept private from the host.

                        nested: VHE-based mode with support for nested
                                virtualization. Requires at least ARMv8.3
                                hardware.

                        Defaults to VHE/nVHE based on hardware support. Setting
                        mode to "protected" will disable kexec and hibernation
                        for the host. "nested" is experimental and should be
                        used with extreme caution.

        kvm-arm.vgic_v3_group0_trap=
                        [KVM,ARM] Trap guest accesses to GICv3 group-0
                        system registers

        kvm-arm.vgic_v3_group1_trap=
                        [KVM,ARM] Trap guest accesses to GICv3 group-1
                        system registers

        kvm-arm.vgic_v3_common_trap=
                        [KVM,ARM] Trap guest accesses to GICv3 common
                        system registers

        kvm-arm.vgic_v4_enable=
                        [KVM,ARM] Allow use of GICv4 for direct injection of
```

```
                        LPIs.

        kvm_cma_resv_ratio=n [PPC]
                        Reserves given percentage from system memory area for
                        contiguous memory allocation for KVM hash pagetable
                        allocation.
                        By default it reserves 5% of total system memory.
                        Format: <integer>
                        Default: 5

        kvm-intel.ept=  [KVM,Intel] Control KVM's use of Extended Page Tables,
                        a.k.a. Two-Dimensional Page Tables.  Default is 1
                        (enabled). Disable by KVM if hardware lacks support
                        for EPT.

        kvm-intel.emulate_invalid_guest_state=
                        [KVM,Intel] Control whether to emulate invalid guest
                        state. Ignored if kvm-intel.enable_unrestricted_
↪guest=1,
                        as guest state is never invalid for unrestricted
                        guests. This param doesn't apply to nested guests (L2),
                        as KVM never emulates invalid L2 guest state.
                        Default is 1 (enabled).

        kvm-intel.flexpriority=
                        [KVM,Intel] Control KVM's use of FlexPriority feature
                        (TPR shadow). Default is 1 (enabled). Disable by KVM if
                        hardware lacks support for it.

        kvm-intel.nested=
                        [KVM,Intel] Control nested virtualization feature in
                        KVM/VMX. Default is 1 (enabled).

        kvm-intel.unrestricted_guest=
                        [KVM,Intel] Control KVM's use of unrestricted guest
                        feature (virtualized real and unpaged mode). Default
                        is 1 (enabled). Disable by KVM if EPT is disabled or
                        hardware lacks support for it.

        kvm-intel.vmentry_l1d_flush=[KVM,Intel] Mitigation for L1 Terminal␣
↪Fault
                        CVE-2018-3620.

                        Valid arguments: never, cond, always

                        always: L1D cache flush on every VMENTER.
                        cond:   Flush L1D on VMENTER only when the code between
                                VMEXIT and VMENTER can leak host memory.
                        never:  Disables the mitigation

                        Default is cond (do L1 cache flush in specific␣
```

```
↪instances)

        kvm-intel.vpid= [KVM,Intel] Control KVM's use of Virtual Processor
                        Identification feature (tagged TLBs). Default is 1
                        (enabled). Disable by KVM if hardware lacks support
                        for it.

        l1d_flush=      [X86,INTEL]
                        Control mitigation for L1D based snooping␣
↪vulnerability.

                        Certain CPUs are vulnerable to an exploit against CPU
                        internal buffers which can forward information to a
                        disclosure gadget under certain conditions.

                        In vulnerable processors, the speculatively
                        forwarded data can be used in a cache side channel
                        attack, to access data to which the attacker does
                        not have direct access.

                        This parameter controls the mitigation. The
                        options are:

                        on         - enable the interface for the mitigation

        l1tf=           [X86] Control mitigation of the L1TF vulnerability on
                              affected CPUs

                        The kernel PTE inversion protection is unconditionally
                        enabled and cannot be disabled.

                        full
                                Provides all available mitigations for the
                                L1TF vulnerability. Disables SMT and
                                enables all mitigations in the
                                hypervisors, i.e. unconditional L1D flush.

                                SMT control and L1D flush control via the
                                sysfs interface is still possible after
                                boot.  Hypervisors will issue a warning
                                when the first VM is started in a
                                potentially insecure configuration,
                                i.e. SMT enabled or L1D flush disabled.

                        full,force
                                Same as 'full', but disables SMT and L1D
                                flush runtime control. Implies the
                                'nosmt=force' command line option.
                                (i.e. sysfs control of SMT is disabled.)

                        flush
```

```
                                Leaves SMT enabled and enables the default
                                hypervisor mitigation, i.e. conditional
                                L1D flush.

                                SMT control and L1D flush control via the
                                sysfs interface is still possible after
                                boot.  Hypervisors will issue a warning
                                when the first VM is started in a
                                potentially insecure configuration,
                                i.e. SMT enabled or L1D flush disabled.

                        flush,nosmt

                                Disables SMT and enables the default
                                hypervisor mitigation.

                                SMT control and L1D flush control via the
                                sysfs interface is still possible after
                                boot.  Hypervisors will issue a warning
                                when the first VM is started in a
                                potentially insecure configuration,
                                i.e. SMT enabled or L1D flush disabled.

                        flush,nowarn
                                Same as 'flush', but hypervisors will not
                                warn when a VM is started in a potentially
                                insecure configuration.

                        off
                                Disables hypervisor mitigations and doesn't
                                emit any warnings.
                                It also drops the swap size and available
                                RAM limit restriction on both hypervisor and
                                bare metal.

                        Default is 'flush'.

                        For details see: Documentation/admin-guide/hw-vuln/
↪l1tf.rst

        l2cr=           [PPC]

        l3cr=           [PPC]

        lapic           [X86-32,APIC] Enable the local APIC even if BIOS
                        disabled it.

        lapic=          [X86,APIC] Do not use TSC deadline
                        value for LAPIC timer one-shot implementation. Default
                        back to the programmable timer unit in the LAPIC.
                        Format: notscdeadline
```

```
        lapic_timer_c2_ok       [X86,APIC] trust the local apic timer
                                in C2 power state.

        libata.dma=     [LIBATA] DMA control
                        libata.dma=0      Disable all PATA and SATA DMA
                        libata.dma=1      PATA and SATA Disk DMA only
                        libata.dma=2      ATAPI (CDROM) DMA only
                        libata.dma=4      Compact Flash DMA only
                        Combinations also work, so libata.dma=3 enables DMA
                        for disks and CDROMs, but not CFs.

        libata.ignore_hpa=      [LIBATA] Ignore HPA limit
                        libata.ignore_hpa=0       keep BIOS limits (default)
                        libata.ignore_hpa=1       ignore limits, using full␣
↪disk

        libata.noacpi   [LIBATA] Disables use of ACPI in libata suspend/resume
                        when set.
                        Format: <int>

        libata.force=   [LIBATA] Force configurations.  The format is a comma-
                        separated list of "[ID:]VAL" where ID is PORT[.DEVICE].
                        PORT and DEVICE are decimal numbers matching port, link
                        or device.  Basically, it matches the ATA ID string
                        printed on console by libata.  If the whole ID part is
                        omitted, the last PORT and DEVICE values are used.  If
                        ID hasn't been specified yet, the configuration applies
                        to all ports, links and devices.

                        If only DEVICE is omitted, the parameter applies to
                        the port and all links and devices behind it.  DEVICE
                        number of 0 either selects the first device or the
                        first fan-out link behind PMP device.  It does not
                        select the host link.  DEVICE number of 15 selects the
                        host link and device attached to it.

                        The VAL specifies the configuration to force.  As long
                        as there is no ambiguity, shortcut notation is allowed.
                        For example, both 1.5 and 1.5G would work for 1.5Gbps.
                        The following configurations can be forced.

                        * Cable type: 40c, 80c, short40c, unk, ign or sata.
                          Any ID with matching PORT is used.

                        * SATA link speed limit: 1.5Gbps or 3.0Gbps.

                        * Transfer mode: pio[0-7], mwdma[0-4] and udma[0-7].
                          udma[/][16,25,33,44,66,100,133] notation is also
                          allowed.
```

```
                        * nohrst, nosrst, norst: suppress hard, soft and both
                          resets.

                        * rstonce: only attempt one reset during hot-unplug
                          link recovery.

                        * [no]dbdelay: Enable or disable the extra 200ms delay
                          before debouncing a link PHY and device presence
                          detection.

                        * [no]ncq: Turn on or off NCQ.

                        * [no]ncqtrim: Enable or disable queued DSM TRIM.

                        * [no]ncqati: Enable or disable NCQ trim on ATI␣
↪chipset.

                        * [no]trim: Enable or disable (unqueued) TRIM.

                        * trim_zero: Indicate that TRIM command zeroes data.

                        * max_trim_128m: Set 128M maximum trim size limit.

                        * [no]dma: Turn on or off DMA transfers.

                        * atapi_dmadir: Enable ATAPI DMADIR bridge support.

                        * atapi_mod16_dma: Enable the use of ATAPI DMA for
                          commands that are not a multiple of 16 bytes.

                        * [no]dmalog: Enable or disable the use of the
                          READ LOG DMA EXT command to access logs.

                        * [no]iddevlog: Enable or disable access to the
                          identify device data log.

                        * [no]logdir: Enable or disable access to the general
                          purpose log directory.

                        * max_sec_128: Set transfer size limit to 128 sectors.

                        * max_sec_1024: Set or clear transfer size limit to
                          1024 sectors.

                        * max_sec_lba48: Set or clear transfer size limit to
                          65535 sectors.

                        * [no]lpm: Enable or disable link power management.

                        * [no]setxfer: Indicate if transfer speed mode setting
                          should be skipped.
```

```
                  * [no]fua: Disable or enable FUA (Force Unit Access)
                    support for devices supporting this feature.

                  * dump_id: Dump IDENTIFY data.

                  * disable: Disable this device.

                  If there are multiple matching configurations changing
                  the same attribute, the last one is used.

    load_ramdisk=   [RAM] [Deprecated]

    lockdown=       [SECURITY]
                  { integrity | confidentiality }
                  Enable the kernel lockdown feature. If set to
                  integrity, kernel features that allow userland to
                  modify the running kernel are disabled. If set to
                  confidentiality, kernel features that allow userland
                  to extract confidential information from the kernel
                  are also disabled.

    locktorture.acq_writer_lim= [KNL]
                  Set the time limit in jiffies for a lock
                  acquisition.  Acquisitions exceeding this limit
                  will result in a splat once they do complete.

    locktorture.bind_readers= [KNL]
                  Specify the list of CPUs to which the readers are
                  to be bound.

    locktorture.bind_writers= [KNL]
                  Specify the list of CPUs to which the writers are
                  to be bound.

    locktorture.call_rcu_chains= [KNL]
                  Specify the number of self-propagating call_rcu()
                  chains to set up.  These are used to ensure that
                  there is a high probability of an RCU grace period
```

```
                in progress at any given time.  Defaults to 0,
                which disables these call_rcu() chains.

        locktorture.long_hold= [KNL]
                Specify the duration in milliseconds for the
                occasional long-duration lock hold time.  Defaults
                to 100 milliseconds.  Select 0 to disable.

        locktorture.nested_locks= [KNL]
                Specify the maximum lock nesting depth that
                locktorture is to exercise, up to a limit of 8
                (MAX_NESTED_LOCKS).  Specify zero to disable.
                Note that this parameter is ineffective on types
                of locks that do not support nested acquisition.

        locktorture.nreaders_stress= [KNL]
                Set the number of locking read-acquisition kthreads.
                Defaults to being automatically set based on the
                number of online CPUs.

        locktorture.nwriters_stress= [KNL]
                Set the number of locking write-acquisition kthreads.

        locktorture.onoff_holdoff= [KNL]
                Set time (s) after boot for CPU-hotplug testing.

        locktorture.onoff_interval= [KNL]
                Set time (s) between CPU-hotplug operations, or
                zero to disable CPU-hotplug testing.

        locktorture.rt_boost= [KNL]
                Do periodic testing of real-time lock priority
                boosting.  Select 0 to disable, 1 to boost
                only rt_mutex, and 2 to boost unconditionally.
                Defaults to 2, which might seem to be an
                odd choice, but which should be harmless for
                non-real-time spinlocks, due to their disabling
                of preemption.  Note that non-realtime mutexes
                disable boosting.

        locktorture.rt_boost_factor= [KNL]
                Number that determines how often and for how
                long priority boosting is exercised.  This is
                scaled down by the number of writers, so that the
                number of boosts per unit time remains roughly
                constant as the number of writers increases.
                On the other hand, the duration of each boost
                increases with the number of writers.

        locktorture.shuffle_interval= [KNL]
                Set task-shuffle interval (jiffies).  Shuffling
```

```
                        tasks allows some CPUs to go into dyntick-idle
                        mode during the locktorture test.

        locktorture.shutdown_secs= [KNL]
                        Set time (s) after boot system shutdown.  This
                        is useful for hands-off automated testing.

        locktorture.stat_interval= [KNL]
                        Time (s) between statistics printk()s.

        locktorture.stutter= [KNL]
                        Time (s) to stutter testing, for example,
                        specifying five seconds causes the test to run for
                        five seconds, wait for five seconds, and so on.
                        This tests the locking primitive's ability to
                        transition abruptly to and from idle.

        locktorture.torture_type= [KNL]
                        Specify the locking implementation to test.

        locktorture.verbose= [KNL]
                        Enable additional printk() statements.

        locktorture.writer_fifo= [KNL]
                        Run the write-side locktorture kthreads at
                        sched_set_fifo() real-time priority.

        logibm.irq=     [HW,MOUSE] Logitech Bus Mouse Driver
                        Format: <irq>

        loglevel=       All Kernel Messages with a loglevel smaller than the
                        console loglevel will be printed to the console. It can
                        also be changed with klogd or other programs. The
                        loglevels are defined as follows:

                        0 (KERN_EMERG)          system is unusable
                        1 (KERN_ALERT)          action must be taken␣
↪immediately
                        2 (KERN_CRIT)           critical conditions
                        3 (KERN_ERR)            error conditions
                        4 (KERN_WARNING)        warning conditions
                        5 (KERN_NOTICE)         normal but significant␣
↪condition
                        6 (KERN_INFO)           informational
                        7 (KERN_DEBUG)          debug-level messages

        log_buf_len=n[KMG]      Sets the size of the printk ring buffer,
                        in bytes.  n must be a power of two and greater
                        than the minimal size. The minimal size is defined
                        by LOG_BUF_SHIFT kernel config parameter. There is
                        also CONFIG_LOG_CPU_MAX_BUF_SHIFT config parameter
```

```
                        that allows to increase the default size depending on
                        the number of CPUs. See init/Kconfig for more details.

        logo.nologo     [FB] Disables display of the built-in Linux logo.
                        This may be used to provide more screen space for
                        kernel log messages and is useful when debugging
                        kernel boot problems.

        lp=0            [LP]    Specify parallel ports to use, e.g,
        lp=port[,port...]       lp=none,parport0 (lp0 not configured, lp1 uses
        lp=reset                first parallel port). 'lp=0' disables the
        lp=auto                 printer driver. 'lp=reset' (which can be
                                specified in addition to the ports) causes
                                attached printers to be reset. Using
                                lp=port1,port2,... specifies the parallel ports
                                to associate lp devices with, starting with
                                lp0. A port specification may be 'none' to skip
                                that lp device, or a parport name such as
                                'parport0'. Specifying 'lp=auto' instead of a
                                port specification list means that device IDs
                                from each port should be examined, to see if
                                an IEEE 1284-compliant printer is attached; if
                                so, the driver will manage that printer.
                                See also header of drivers/char/lp.c.

        lpj=n           [KNL]
                        Sets loops_per_jiffy to given constant, thus avoiding
                        time-consuming boot-time autodetection (up to 250 ms␣
↪per
                        CPU). 0 enables autodetection (default). To determine
                        the correct value for your kernel, boot with normal
                        autodetection and see what value is printed. Note that
                        on SMP systems the preset will be applied to all CPUs,
                        which is likely to cause problems if your CPUs need
                        significantly divergent settings. An incorrect value
                        will cause delays in the kernel to be wrong, leading to
                        unpredictable I/O errors and other breakage. Although
                        unlikely, in the extreme case this might damage your
                        hardware.

        ltpc=           [NET]
                        Format: <io>,<irq>,<dma>

        lsm.debug       [SECURITY] Enable LSM initialization debugging output.

        lsm=lsm1,...,lsmN
                        [SECURITY] Choose order of LSM initialization. This
                        overrides CONFIG_LSM, and the "security=" parameter.

        machvec=        [IA-64] Force the use of a particular machine-vector
                        (machvec) in a generic kernel.
```

```
                        Example: machvec=hpzx1

        machtype=       [Loongson] Share the same kernel image file between
                        different yeeloong laptops.
                        Example: machtype=lemote-yeeloong-2f-7inch

        max_addr=nn[KMG]        [KNL,BOOT,IA-64] All physical memory greater
                        than or equal to this physical address is ignored.

        maxcpus=        [SMP] Maximum number of processors that an SMP kernel
                        will bring up during bootup.  maxcpus=n : n >= 0 limits
                        the kernel to bring up 'n' processors. Surely after
                        bootup you can bring up the other plugged cpu by␣
↪executing
                        "echo 1 > /sys/devices/system/cpu/cpuX/online". So␣
↪maxcpus
                        only takes effect during system bootup.
                        While n=0 is a special case, it is equivalent to␣
↪"nosmp",
                        which also disables the IO APIC.

        max_loop=       [LOOP] The number of loop block devices that get
        (loop.max_loop) unconditionally pre-created at init time. The default
                        number is configured by BLK_DEV_LOOP_MIN_COUNT. Instead
                        of statically allocating a predefined number, loop
                        devices can be requested on-demand with the
                        /dev/loop-control interface.

        mce             [X86-32] Machine Check Exception

        mce=option      [X86-64] See Documentation/arch/x86/x86_64/
↪boot-options.rst

        md=             [HW] RAID subsystems devices and level
                        See Documentation/admin-guide/md.rst.

        mdacon=         [MDA]
                        Format: <first>,<last>
                        Specifies range of consoles to be captured by the MDA.

        mds=            [X86,INTEL]
                        Control mitigation for the Micro-architectural Data
                        Sampling (MDS) vulnerability.

                        Certain CPUs are vulnerable to an exploit against CPU
                        internal buffers which can forward information to a
                        disclosure gadget under certain conditions.

                        In vulnerable processors, the speculatively
                        forwarded data can be used in a cache side channel
                        attack, to access data to which the attacker does
```

```
                        not have direct access.

                        This parameter controls the MDS mitigation. The
                        options are:

                        full       - Enable MDS mitigation on vulnerable CPUs
                        full,nosmt - Enable MDS mitigation and disable
                                     SMT on vulnerable CPUs
                        off        - Unconditionally disable MDS mitigation

                        On TAA-affected machines, mds=off can be prevented by
                        an active TAA mitigation as both vulnerabilities are
                        mitigated with the same mechanism so in order to␣
↪disable
                        this mitigation, you need to specify tsx_async_
↪abort=off
                        too.

                        Not specifying this option is equivalent to
                        mds=full.

                        For details see: Documentation/admin-guide/hw-vuln/mds.
↪rst

       mem=nn[KMG]      [HEXAGON] Set the memory size.
                        Must be specified, otherwise memory size will be 0.

       mem=nn[KMG]      [KNL,BOOT] Force usage of a specific amount of memory
                        Amount of memory to be used in cases as follows:

                        1 for test;
                        2 when the kernel is not able to see the whole system␣
↪memory;
                        3 memory that lies after 'mem=' boundary is excluded␣
↪from
                         the hypervisor, then assigned to KVM guests.
                        4 to limit the memory available for kdump kernel.

                        [ARC,MICROBLAZE] - the limit applies only to low␣
↪memory,
                        high memory is not affected.

                        [ARM64] - only limits memory covered by the linear
                        mapping. The NOMAP regions are not affected.

                        [X86] Work as limiting max address. Use together
                        with memmap= to avoid physical address space␣
↪collisions.
                        Without memmap= PCI devices could be placed at␣
↪addresses
                        belonging to unused RAM.
```

```
                        Note that this only takes effects during boot time␣
↪since
                        in above case 3, memory may need be hot added after␣
↪boot
                        if system memory of hypervisor is not sufficient.

        mem=nn[KMG]@ss[KMG]
                        [ARM,MIPS] - override the memory layout reported by
                        firmware.
                        Define a memory region of size nn[KMG] starting at
                        ss[KMG].
                        Multiple different regions can be specified with
                        multiple mem= parameters on the command line.

        mem=nopentium   [BUGS=X86-32] Disable usage of 4MB pages for kernel
                        memory.

        memblock=debug  [KNL] Enable memblock debug messages.

        memchunk=nn[KMG]
                        [KNL,SH] Allow user to override the default size for
                        per-device physically contiguous DMA buffers.

        memhp_default_state=online/offline/online_kernel/online_movable
                        [KNL] Set the initial state for the memory hotplug
                        onlining policy. If not specified, the default value is
                        set according to the
                        CONFIG_MEMORY_HOTPLUG_DEFAULT_ONLINE kernel config
                        option.
                        See Documentation/admin-guide/mm/memory-hotplug.rst.

        memmap=exactmap [KNL,X86] Enable setting of an exact
                        E820 memory map, as specified by the user.
                        Such memmap=exactmap lines can be constructed based on
                        BIOS output or other requirements. See the memmap=nn@ss
                        option description.

        memmap=nn[KMG]@ss[KMG]
                        [KNL, X86, MIPS, XTENSA] Force usage of a specific␣
↪region of memory.
                        Region of memory to be used is from ss to ss+nn.
                        If @ss[KMG] is omitted, it is equivalent to␣
↪mem=nn[KMG],
                        which limits max address to nn[KMG].
                        Multiple different regions can be specified,
                        comma delimited.
                        Example:
                                memmap=100M@2G,100M#3G,1G!1024G

        memmap=nn[KMG]#ss[KMG]
```

```
                        [KNL,ACPI] Mark specific memory as ACPI data.
                        Region of memory to be marked is from ss to ss+nn.

        memmap=nn[KMG]$ss[KMG]
                        [KNL,ACPI] Mark specific memory as reserved.
                        Region of memory to be reserved is from ss to ss+nn.
                        Example: Exclude memory from 0x18690000-0x1869ffff
                                 memmap=64K$0x18690000
                                 or
                                 memmap=0x10000$0x18690000
                        Some bootloaders may need an escape character before '
↪$',
                        like Grub2, otherwise '$' and the following number
                        will be eaten.

        memmap=nn[KMG]!ss[KMG]
                        [KNL,X86] Mark specific memory as protected.
                        Region of memory to be used, from ss to ss+nn.
                        The memory region may be marked as e820 type 12 (0xc)
                        and is NVDIMM or ADR memory.

        memmap=<size>%<offset>-<oldtype>+<newtype>
                        [KNL,ACPI] Convert memory within the specified region
                        from <oldtype> to <newtype>. If "-<oldtype>" is left
                        out, the whole region will be marked as <newtype>,
                        even if previously unavailable. If "+<newtype>" is left
                        out, matching memory will be removed. Types are
                        specified as e820 types, e.g., 1 = RAM, 2 = reserved,
                        3 = ACPI, 12 = PRAM.

        memory_corruption_check=0/1 [X86]
                        Some BIOSes seem to corrupt the first 64k of
                        memory when doing things like suspend/resume.
                        Setting this option will scan the memory
                        looking for corruption.  Enabling this will
                        both detect corruption and prevent the kernel
                        from using the memory being corrupted.
                        However, its intended as a diagnostic tool; if
                        repeatable BIOS-originated corruption always
                        affects the same memory, you can use memmap=
                        to prevent the kernel from using that memory.

        memory_corruption_check_size=size [X86]
                        By default it checks for corruption in the low
                        64k, making this memory unavailable for normal
                        use.  Use this parameter to scan for
                        corruption in more or less memory.

        memory_corruption_check_period=seconds [X86]
                        By default it checks for corruption every 60
                        seconds.  Use this parameter to check at some
```

```
                        other rate.  0 disables periodic checking.

        memory_hotplug.memmap_on_memory
                        [KNL,X86,ARM] Boolean flag to enable this feature.
                        Format: {on | off (default)}
                        When enabled, runtime hotplugged memory will
                        allocate its internal metadata (struct pages,
                        those vmemmap pages cannot be optimized even
                        if hugetlb_free_vmemmap is enabled) from the
                        hotadded memory which will allow to hotadd a
                        lot of memory without requiring additional
                        memory to do so.
                        This feature is disabled by default because it
                        has some implication on large (e.g. GB)
                        allocations in some configurations (e.g. small
                        memory blocks).
                        The state of the flag can be read in
                        /sys/module/memory_hotplug/parameters/memmap_on_memory.
                        Note that even when enabled, there are a few cases␣
↪where
                        the feature is not effective.

        memtest=        [KNL,X86,ARM,M68K,PPC,RISCV] Enable memtest
                        Format: <integer>
                        default : 0 <disable>
                        Specifies the number of memtest passes to be
                        performed. Each pass selects another test
                        pattern from a given set of patterns. Memtest
                        fills the memory with this pattern, validates
                        memory contents and reserves bad memory
                        regions that are detected.

        mem_encrypt=    [X86-64] AMD Secure Memory Encryption (SME) control
                        Valid arguments: on, off
                        Default (depends on kernel configuration option):
                          on  (CONFIG_AMD_MEM_ENCRYPT_ACTIVE_BY_DEFAULT=y)
                          off (CONFIG_AMD_MEM_ENCRYPT_ACTIVE_BY_DEFAULT=n)
                        mem_encrypt=on:         Activate SME
                        mem_encrypt=off:        Do not activate SME

                        Refer to Documentation/virt/kvm/x86/
↪amd-memory-encryption.rst
                        for details on when memory encryption can be activated.

        mem_sleep_default=      [SUSPEND] Default system suspend mode:
                        s2idle  - Suspend-To-Idle
                        shallow - Power-On Suspend or equivalent (if supported)
                        deep    - Suspend-To-RAM or equivalent (if supported)
                        See Documentation/admin-guide/pm/sleep-states.rst.

        mfgpt_irq=      [IA-32] Specify the IRQ to use for the
```

```
                Multi-Function General Purpose Timers on AMD Geode
                platforms.

mfgptfix        [X86-32] Fix MFGPT timers on AMD Geode platforms when
                the BIOS has incorrectly applied a workaround. TinyBIOS
                version 0.98 is known to be affected, 0.99 fixes the
                problem by letting the user disable the workaround.

mga=            [HW,DRM]

microcode.force_minrev= [X86]
                Format: <bool>
                Enable or disable the microcode minimal revision
                enforcement for the runtime microcode loader.

min_addr=nn[KMG]        [KNL,BOOT,IA-64] All physical memory below this
                physical address is ignored.

mini2440=       [ARM,HW,KNL]
                Format:[0..2][b][c][t]
                Default: "0tb"
                MINI2440 configuration specification:
                0 - The attached screen is the 3.5" TFT
                1 - The attached screen is the 7" TFT
                2 - The VGA Shield is attached (1024x768)
                Leaving out the screen size parameter will not load
                the TFT driver, and the framebuffer will be left
                unconfigured.
                b - Enable backlight. The TFT backlight pin will be
                linked to the kernel VESA blanking code and a GPIO
                LED. This parameter is not necessary when using the
                VGA shield.
                c - Enable the s3c camera interface.
                t - Reserved for enabling touchscreen support. The
                touchscreen support is not enabled in the mainstream
                kernel as of 2.6.30, a preliminary port can be found
                in the "bleeding edge" mini2440 support kernel at
                https://repo.or.cz/w/linux-2.6/mini2440.git

mitigations=
                [X86,PPC,S390,ARM64] Control optional mitigations for
                CPU vulnerabilities.  This is a set of curated,
                arch-independent options, each of which is an
                aggregation of existing arch-specific options.

                off
                        Disable all optional CPU mitigations.  This
                        improves system performance, but it may also
                        expose users to several CPU vulnerabilities.
                        Equivalent to: if nokaslr then kpti=0 [ARM64]

↪[X86,PPC]
                                                spectre_v2_user=off [X86]
                                                srbds=off [X86,INTEL]
                                                ssbd=force-off [ARM64]
                                                tsx_async_abort=off [X86]

                                        Exceptions:
                                                This does not have any effect on
                                                kvm.nx_huge_pages when
                                                kvm.nx_huge_pages=force.

                                auto (default)
                                        Mitigate all CPU vulnerabilities, but leave SMT
                                        enabled, even if it's vulnerable.  This is for
                                        users who don't want to be surprised by SMT
                                        getting disabled across kernel upgrades, or who
                                        have other ways of avoiding SMT-based attacks.
                                        Equivalent to: (default behavior)

                                auto,nosmt
                                        Mitigate all CPU vulnerabilities, disabling SMT
                                        if needed.  This is for users who always want␣
↪to
                                        be fully mitigated, even if it means losing␣
↪SMT.
                                        Equivalent to: l1tf=flush,nosmt [X86]
                                                mds=full,nosmt [X86]
                                                tsx_async_abort=full,nosmt [X86]
                                                mmio_stale_data=full,nosmt [X86]
                                                retbleed=auto,nosmt [X86]

        mminit_loglevel=
                                [KNL] When CONFIG_DEBUG_MEMORY_INIT is set, this
                                parameter allows control of the logging verbosity for
                                the additional memory initialisation checks. A value
                                of 0 disables mminit logging and a level of 4 will
                                log everything. Information is printed at KERN_DEBUG
```

```
                        so loglevel=8 may also need to be specified.

        mmio_stale_data=
                        [X86,INTEL] Control mitigation for the Processor
                        MMIO Stale Data vulnerabilities.

                        Processor MMIO Stale Data is a class of
                        vulnerabilities that may expose data after an MMIO
                        operation. Exposed data could originate or end in
                        the same CPU buffers as affected by MDS and TAA.
                        Therefore, similar to MDS and TAA, the mitigation
                        is to clear the affected CPU buffers.

                        This parameter controls the mitigation. The
                        options are:

                        full       - Enable mitigation on vulnerable CPUs

                        full,nosmt - Enable mitigation and disable SMT on
                                     vulnerable CPUs.

                        off        - Unconditionally disable mitigation

                        On MDS or TAA affected machines,
                        mmio_stale_data=off can be prevented by an active
                        MDS or TAA mitigation as these vulnerabilities are
                        mitigated with the same mechanism so in order to
                        disable this mitigation, you need to specify
                        mds=off and tsx_async_abort=off too.

                        Not specifying this option is equivalent to
                        mmio_stale_data=full.

                        For details see:
                        Documentation/admin-guide/hw-vuln/processor_mmio_stale_
↪data.rst

        <module>.async_probe[=<bool>] [KNL]
                        If no <bool> value is specified or if the value
                        specified is not a valid <bool>, enable asynchronous
                        probe on this module.  Otherwise, enable/disable
                        asynchronous probe on this module as indicated by the
                        <bool> value. See also: module.async_probe

        module.async_probe=<bool>
                        [KNL] When set to true, modules will use async probing
                        by default. To enable/disable async probing for a
                        specific module, use the module specific control that
                        is documented under <module>.async_probe. When both
                        module.async_probe and <module>.async_probe are
                        specified, <module>.async_probe takes precedence for
```

```
                        the specific module.

        module.enable_dups_trace
                        [KNL] When CONFIG_MODULE_DEBUG_AUTOLOAD_DUPS is set,
                        this means that duplicate request_module() calls will
                        trigger a WARN_ON() instead of a pr_warn(). Note that
                        if MODULE_DEBUG_AUTOLOAD_DUPS_TRACE is set, WARN_ON()s
                        will always be issued and this option does nothing.
        module.sig_enforce
                        [KNL] When CONFIG_MODULE_SIG is set, this means that
                        modules without (valid) signatures will fail to load.
                        Note that if CONFIG_MODULE_SIG_FORCE is set, that
                        is always true, so this option does nothing.

        module_blacklist=  [KNL] Do not load a comma-separated list of
                        modules.  Useful for debugging problem modules.

        mousedev.tap_time=
                        [MOUSE] Maximum time between finger touching and
                        leaving touchpad surface for touch to be considered
                        a tap and be reported as a left button click (for
                        touchpads working in absolute mode only).
                        Format: <msecs>
        mousedev.xres=  [MOUSE] Horizontal screen resolution, used for devices
                        reporting absolute coordinates, such as tablets
        mousedev.yres=  [MOUSE] Vertical screen resolution, used for devices
                        reporting absolute coordinates, such as tablets

        movablecore=    [KNL,X86,IA-64,PPC]
                        Format: nn[KMGTPE] | nn%
                        This parameter is the complement to kernelcore=, it
                        specifies the amount of memory used for migratable
                        allocations.  If both kernelcore and movablecore is
                        specified, then kernelcore will be at *least* the
                        specified value but may be more.  If movablecore on its
                        own is specified, the administrator must be careful
                        that the amount of memory usable for all allocations
                        is not too small.

        movable_node    [KNL] Boot-time switch to make hotplugable memory
                        NUMA nodes to be movable. This means that the memory
                        of such nodes will be usable only for movable
                        allocations which rules out almost all kernel
                        allocations. Use with caution!

        MTD_Partition=  [MTD]
                        Format: <name>,<region-number>,<size>,<offset>

        MTD_Region=     [MTD] Format:
                        <name>,<region-number>[,<base>,<size>,<buswidth>,
↪<altbuswidth>]
```

```
mtdparts=       [MTD]
                See drivers/mtd/parsers/cmdlinepart.c

mtdset=         [ARM]
                ARM/S3C2412 JIVE boot control

                See arch/arm/mach-s3c/mach-jive.c

mtouchusb.raw_coordinates=
                [HW] Make the MicroTouch USB driver use raw coordinates
                ('y', default) or cooked coordinates ('n')

mtrr=debug      [X86]
                Enable printing debug information related to MTRR
                registers at boot time.

mtrr_chunk_size=nn[KMG] [X86]
                used for mtrr cleanup. It is largest continuous chunk
                that could hold holes aka. UC entries.

mtrr_gran_size=nn[KMG] [X86]
                Used for mtrr cleanup. It is granularity of mtrr block.
                Default is 1.
                Large value could prevent small alignment from
                using up MTRRs.

mtrr_spare_reg_nr=n [X86]
                Format: <integer>
                Range: 0,7 : spare reg number
                Default : 1
                Used for mtrr cleanup. It is spare mtrr entries number.
                Set to 2 or more if your graphical card needs more.

multitce=off    [PPC]  This parameter disables the use of the pSeries
                firmware feature for updating multiple TCE entries
                at a time.

n2=             [NET] SDL Inc. RISCom/N2 synchronous serial card

netdev=         [NET] Network devices parameters
                Format: <irq>,<io>,<mem_start>,<mem_end>,<name>
                Note that mem_start is often overloaded to mean
                something different and driver-specific.
                This usage is only documented in each driver source
                file if at all.

netpoll.carrier_timeout=
                [NET] Specifies amount of time (in seconds) that
                netpoll should wait for a carrier. By default netpoll
                waits 4 seconds.
```

```
nf_conntrack.acct=
                [NETFILTER] Enable connection tracking flow accounting
                0 to disable accounting
                1 to enable accounting
                Default value is 0.

nfs.cache_getent=
                [NFS] sets the pathname to the program which is used
                to update the NFS client cache entries.

nfs.cache_getent_timeout=
                [NFS] sets the timeout after which an attempt to
                update a cache entry is deemed to have failed.

nfs.callback_nr_threads=
                [NFSv4] set the total number of threads that the
                NFS client will assign to service NFSv4 callback
                requests.

nfs.callback_tcpport=
                [NFS] set the TCP port on which the NFSv4 callback
                channel should listen.

nfs.delay_retrans=
                [NFS] specifies the number of times the NFSv4 client
                retries the request before returning an EAGAIN error,
                after a reply of NFS4ERR_DELAY from the server.
                Only applies if the softerr mount option is enabled,
                and the specified value is >= 0.

nfs.enable_ino64=
                [NFS] enable 64-bit inode numbers.
                If zero, the NFS client will fake up a 32-bit inode
                number for the readdir() and stat() syscalls instead
                of returning the full 64-bit number.
                The default is to return 64-bit inode numbers.

nfs.idmap_cache_timeout=
                [NFS] set the maximum lifetime for idmapper cache
                entries.

nfs.max_session_cb_slots=
                [NFSv4.1] Sets the maximum number of session
                slots the client will assign to the callback
                channel. This determines the maximum number of
                callbacks the client will process in parallel for
                a particular server.

nfs.max_session_slots=
                [NFSv4.1] Sets the maximum number of session slots
```

```
                        the client will attempt to negotiate with the server.
                        This limits the number of simultaneous RPC requests
                        that the client can send to the NFSv4.1 server.
                        Note that there is little point in setting this
                        value higher than the max_tcp_slot_table_limit.

        nfs.nfs4_disable_idmapping=
                        [NFSv4] When set to the default of '1', this option
                        ensures that both the RPC level authentication
                        scheme and the NFS level operations agree to use
                        numeric uids/gids if the mount is using the
                        'sec=sys' security flavour. In effect it is
                        disabling idmapping, which can make migration from
                        legacy NFSv2/v3 systems to NFSv4 easier.
                        Servers that do not support this mode of operation
                        will be autodetected by the client, and it will fall
                        back to using the idmapper.
                        To turn off this behaviour, set the value to '0'.

        nfs.nfs4_unique_id=
                        [NFS4] Specify an additional fixed unique ident-
                        ification string that NFSv4 clients can insert into
                        their nfs_client_id4 string.  This is typically a
                        UUID that is generated at system install time.

        nfs.recover_lost_locks=
                        [NFSv4] Attempt to recover locks that were lost due
                        to a lease timeout on the server. Please note that
                        doing this risks data corruption, since there are
                        no guarantees that the file will remain unchanged
                        after the locks are lost.
                        If you want to enable the kernel legacy behaviour of
                        attempting to recover these locks, then set this
                        parameter to '1'.
                        The default parameter value of '0' causes the kernel
                        not to attempt recovery of lost locks.

        nfs.send_implementation_id=
                        [NFSv4.1] Send client implementation identification
                        information in exchange_id requests.
                        If zero, no implementation identification information
                        will be sent.
                        The default is to send the implementation␣
↪identification
                        information.

        nfs4.layoutstats_timer=
                        [NFSv4.2] Change the rate at which the kernel sends
                        layoutstats to the pNFS metadata server.

                        Setting this to value to 0 causes the kernel to use
```

```
                whatever value is the default set by the layout
                driver. A non-zero value sets the minimum interval
                in seconds between layoutstats transmissions.

nfsd.inter_copy_offload_enable=
                [NFSv4.2] When set to 1, the server will support
                server-to-server copies for which this server is
                the destination of the copy.

nfsd.nfs4_disable_idmapping=
                [NFSv4] When set to the default of '1', the NFSv4
                server will return only numeric uids and gids to
                clients using auth_sys, and will accept numeric uids
                and gids from such clients.  This is intended to ease
                migration from NFSv2/v3.

nfsd.nfsd4_ssc_umount_timeout=
                [NFSv4.2] When used as the destination of a
                server-to-server copy, knfsd temporarily mounts
                the source server.  It caches the mount in case
                it will be needed again, and discards it if not
                used for the number of milliseconds specified by
                this parameter.

nfsaddrs=       [NFS] Deprecated.  Use ip= instead.
                See Documentation/admin-guide/nfs/nfsroot.rst.

nfsroot=        [NFS] nfs root filesystem for disk-less boxes.
                See Documentation/admin-guide/nfs/nfsroot.rst.

nfsrootdebug    [NFS] enable nfsroot debugging messages.
                See Documentation/admin-guide/nfs/nfsroot.rst.

nmi_backtrace.backtrace_idle [KNL]
                Dump stacks even of idle CPUs in response to an
                NMI stack-backtrace request.

nmi_debug=      [KNL,SH] Specify one or more actions to take
                when a NMI is triggered.
                Format: [state][,regs][,debounce][,die]

nmi_watchdog=   [KNL,BUGS=X86] Debugging features for SMP kernels
                Format: [panic,][nopanic,][num]
                Valid num: 0 or 1
                0 - turn hardlockup detector in nmi_watchdog off
                1 - turn hardlockup detector in nmi_watchdog on
                When panic is specified, panic when an NMI watchdog
                timeout occurs (or 'nopanic' to not panic on an NMI
                watchdog, if CONFIG_BOOTPARAM_HARDLOCKUP_PANIC is set)
                To disable both hard and soft lockup detectors,
                please see 'nowatchdog'.
```

```
                        This is useful when you use a panic=... timeout and
                        need the box quickly up again.

                        These settings can be accessed at runtime via
                        the nmi_watchdog and hardlockup_panic sysctls.

        no387           [BUGS=X86-32] Tells the kernel to use the 387 maths
                        emulation library even if a 387 maths coprocessor
                        is present.

        no4lvl          [RISCV] Disable 4-level and 5-level paging modes.␣
↪Forces
                        kernel to use 3-level paging instead.

        no5lvl          [X86-64,RISCV] Disable 5-level paging mode. Forces
                        kernel to use 4-level paging instead.

        noaliencache    [MM, NUMA, SLAB] Disables the allocation of alien
                        caches in the slab allocator.  Saves per-node memory,
                        but will impact performance.

        noalign         [KNL,ARM]

        noaltinstr      [S390] Disables alternative instructions patching
                        (CPU alternatives feature).

        noapic          [SMP,APIC] Tells the kernel to not make use of any
                        IOAPICs that may be present in the system.

        noautogroup     Disable scheduler automatic task group creation.

        nocache         [ARM]

        no_console_suspend
                        [HW] Never suspend the console
                        Disable suspending of consoles during suspend and
                        hibernate operations.  Once disabled, debugging
                        messages can reach various consoles while the rest
                        of the system is being put to sleep (ie, while
                        debugging driver suspend/resume hooks).  This may
                        not work reliably with all consoles, but is known
                        to work with serial and VGA consoles.
                        To facilitate more flexible debugging, we also add
                        console_suspend, a printk module parameter to control
                        it. Users could use console_suspend (usually
                        /sys/module/printk/parameters/console_suspend) to
                        turn on/off it dynamically.

        no_debug_objects
                        [KNL] Disable object debugging
```

```
        nodsp           [SH] Disable hardware DSP at boot time.

        noefi           Disable EFI runtime services support.

        no_entry_flush  [PPC] Don't flush the L1-D cache when entering the␣
↪kernel.

        noexec          [IA-64]

        noexec32        [X86-64]
                        This affects only 32-bit executables.
                        noexec32=on: enable non-executable mappings (default)
                                read doesn't imply executable mappings
                        noexec32=off: disable non-executable mappings
                                read implies executable mappings

        no_file_caps    Tells the kernel not to honor file capabilities.  The
                        only way then for a file to be executed with privilege
                        is to be setuid root or executed by root.

        nofpu           [MIPS,SH] Disable hardware FPU at boot time.

        nofsgsbase      [X86] Disables FSGSBASE instructions.

        nofxsr          [BUGS=X86-32] Disables x86 floating point extended
                        register save and restore. The kernel will only save
                        legacy floating-point registers on task switch.

        nohalt          [IA-64] Tells the kernel not to use the power saving
                        function PAL_HALT_LIGHT when idle. This increases
                        power-consumption. On the positive side, it reduces
                        interrupt wake-up latency, which may improve␣
↪performance
                        in certain environments such as networked servers or
                        real-time systems.

        no_hash_pointers
                        Force pointers printed to the console or buffers to be
                        unhashed.  By default, when a pointer is printed via %p
                        format string, that pointer is "hashed", i.e. obscured
                        by hashing the pointer value.  This is a security␣
↪feature
                        that hides actual kernel addresses from unprivileged
                        users, but it also makes debugging the kernel more
                        difficult since unequal pointers can no longer be
                        compared.  However, if this command-line option is
                        specified, then all normal pointers will have their␣
↪true
                        value printed. This option should only be specified␣
↪when
                        debugging the kernel.  Please do not use on production
```

```
                        kernels.

        nohibernate     [HIBERNATION] Disable hibernation and resume.

        nohlt           [ARM,ARM64,MICROBLAZE,MIPS,PPC,SH] Forces the kernel to
                        busy wait in do_idle() and not use the arch_cpu_idle()
                        implementation; requires CONFIG_GENERIC_IDLE_POLL_SETUP
                        to be effective. This is useful on platforms where the
                        sleep(SH) or wfi(ARM,ARM64) instructions do not work
                        correctly or when doing power measurements to evaluate
                        the impact of the sleep instructions. This is also
                        useful when using JTAG debugger.

        nohugeiomap     [KNL,X86,PPC,ARM64] Disable kernel huge I/O mappings.

        nohugevmalloc   [KNL,X86,PPC,ARM64] Disable kernel huge vmalloc␣
↪mappings.

        nohz=           [KNL] Boottime enable/disable dynamic ticks
                        Valid arguments: on, off
                        Default: on

        nohz_full=      [KNL,BOOT,SMP,ISOL]
                        The argument is a cpu list, as described above.
                        In kernels built with CONFIG_NO_HZ_FULL=y, set
                        the specified list of CPUs whose tick will be stopped
                        whenever possible. The boot CPU will be forced outside
                        the range to maintain the timekeeping.  Any CPUs
                        in this list will have their RCU callbacks offloaded,
                        just as if they had also been called out in the
                        rcu_nocbs= boot parameter.

                        Note that this argument takes precedence over
                        the CONFIG_RCU_NOCB_CPU_DEFAULT_ALL option.

        noinitrd        [RAM] Tells the kernel not to load any configured
                        initial RAM disk.

        nointremap      [X86-64, Intel-IOMMU] Do not enable interrupt
                        remapping.
                        [Deprecated - use intremap=off]

        nointroute      [IA-64]

        noinvpcid       [X86] Disable the INVPCID cpu feature.

        noiotrap        [SH] Disables trapped I/O port accesses.

        noirqdebug      [X86-32] Disables the code which attempts to detect and
                        disable unhandled interrupt sources.
```

```
noisapnp        [ISAPNP] Disables ISA PnP code.

nojitter        [IA-64] Disables jitter checking for ITC timers.

nokaslr         [KNL]
                When CONFIG_RANDOMIZE_BASE is set, this disables
                kernel and module base offset ASLR (Address Space
                Layout Randomization).

no-kvmapf       [X86,KVM] Disable paravirtualized asynchronous page
                fault handling.

no-kvmclock     [X86,KVM] Disable paravirtualized KVM clock driver

nolapic         [X86-32,APIC] Do not enable or use the local APIC.

nolapic_timer   [X86-32,APIC] Do not use the local APIC timer.

nomca           [IA-64] Disable machine check abort handling

nomce           [X86-32] Disable Machine Check Exception

nomfgpt         [X86-32] Disable Multi-Function General Purpose
                Timer usage (for AMD Geode machines).

nomodeset       Disable kernel modesetting. Most systems' firmware
                sets up a display mode and provides framebuffer memory
                for output. With nomodeset, DRM and fbdev drivers will
                not load if they could possibly displace the pre-
                initialized output. Only the system framebuffer will
                be available for use. The respective drivers will not
                perform display-mode changes or accelerated rendering.

                Useful as error fallback, or for testing and debugging.

nomodule        Disable module load

nonmi_ipi       [X86] Disable using NMI IPIs during panic/reboot to
                shutdown the other cpus.  Instead use the REBOOT_VECTOR
                irq.

nopat           [X86] Disable PAT (page attribute table extension of
                pagetables) support.

nopcid          [X86-64] Disable the PCID cpu feature.

nopku           [X86] Disable Memory Protection Keys CPU feature found
                in some Intel CPUs.

nopti           [X86-64]
                Equivalent to pti=off
```

```
        nopv=           [X86,XEN,KVM,HYPER_V,VMWARE]
                        Disables the PV optimizations forcing the guest to run
                        as generic guest with no PV drivers. Currently support
                        XEN HVM, KVM, HYPER_V and VMWARE guest.

        nopvspin        [X86,XEN,KVM]
                        Disables the qspinlock slow path using PV optimizations
                        which allow the hypervisor to 'idle' the guest on lock
                        contention.

        norandmaps      Don't use address space randomization.  Equivalent to
                        echo 0 > /proc/sys/kernel/randomize_va_space

        noreplace-smp   [X86-32,SMP] Don't replace SMP instructions
                        with UP alternatives

        noresume        [SWSUSP] Disables resume and restores original swap
                        space.

        nosbagart       [IA-64]

        no-scroll       [VGA] Disables scrollback.
                        This is required for the Braillex ib80-piezo Braille
                        reader made by F.H. Papenmeier (Germany).

        nosgx           [X86-64,SGX] Disables Intel SGX kernel support.

        nosmap          [PPC]
                        Disable SMAP (Supervisor Mode Access Prevention)
                        even if it is supported by processor.

        nosmep          [PPC64s]
                        Disable SMEP (Supervisor Mode Execution Prevention)
                        even if it is supported by processor.

        nosmp           [SMP] Tells an SMP kernel to act as a UP kernel,
                        and disable the IO APIC.  legacy for "maxcpus=0".

        nosmt           [KNL,MIPS,PPC,S390] Disable symmetric multithreading␣
↪(SMT).
                        Equivalent to smt=1.

                        [KNL,X86,PPC] Disable symmetric multithreading (SMT).
                        nosmt=force: Force disable SMT, cannot be undone
                                     via the sysfs control file.

        nosoftlockup    [KNL] Disable the soft-lockup detector.

        nospec_store_bypass_disable
                        [HW] Disable all mitigations for the Speculative Store␣
```

```
↪Bypass vulnerability

        nospectre_bhb   [ARM64] Disable all mitigations for Spectre-BHB (branch
                        history injection) vulnerability. System may allow␣
↪data leaks
                        with this option.

        nospectre_v1    [X86,PPC] Disable mitigations for Spectre Variant 1
                        (bounds check bypass). With this option data leaks are
                        possible in the system.

        nospectre_v2    [X86,PPC_E500,ARM64] Disable all mitigations for
                        the Spectre variant 2 (indirect branch prediction)
                        vulnerability. System may allow data leaks with this
                        option.

        no-steal-acc    [X86,PV_OPS,ARM64,PPC/PSERIES,RISCV] Disable
                        paravirtualized steal time accounting. steal time is
                        computed, but won't influence scheduler behaviour

        nosync          [HW,M68K] Disables sync negotiation for all devices.

        no_timer_check  [X86,APIC] Disables the code which tests for
                        broken timer IRQ sources.

        no_uaccess_flush
                        [PPC] Don't flush the L1-D cache after accessing user␣
↪data.

        novmcoredd      [KNL,KDUMP]
                        Disable device dump. Device dump allows drivers to
                        append dump data to vmcore so you can collect driver
                        specified debug info.  Drivers can append the data
                        without any limit and this data is stored in memory,
                        so this may cause significant memory stress.  Disabling
                        device dump can help save memory but the driver debug
                        data will be no longer available.  This parameter
                        is only available when CONFIG_PROC_VMCORE_DEVICE_DUMP
                        is set.

        no-vmw-sched-clock
                        [X86,PV_OPS] Disable paravirtualized VMware scheduler
                        clock and use the default one.

        nowatchdog      [KNL] Disable both lockup detectors, i.e.
                        soft-lockup and NMI watchdog (hard-lockup).

        nowb            [ARM]

        nox2apic        [X86-64,APIC] Do not enable x2APIC mode.
```

```
                        NOTE: this parameter will be ignored on systems with␣
↪the
                        LEGACY_XAPIC_DISABLED bit set in the
                        IA32_XAPIC_DISABLE_STATUS MSR.

        noxsave         [BUGS=X86] Disables x86 extended register state save
                        and restore using xsave. The kernel will fallback to
                        enabling legacy floating-point and sse state.

        noxsaveopt      [X86] Disables xsaveopt used in saving x86 extended
                        register states. The kernel will fall back to use
                        xsave to save the states. By using this parameter,
                        performance of saving the states is degraded because
                        xsave doesn't support modified optimization while
                        xsaveopt supports it on xsaveopt enabled systems.

        noxsaves        [X86] Disables xsaves and xrstors used in saving and
                        restoring x86 extended register state in compacted
                        form of xsave area. The kernel will fall back to use
                        xsaveopt and xrstor to save and restore the states
                        in standard form of xsave area. By using this
                        parameter, xsave area per process might occupy more
                        memory on xsaves enabled systems.

        nps_mtm_hs_ctr= [KNL,ARC]
                        This parameter sets the maximum duration, in
                        cycles, each HW thread of the CTOP can run
                        without interruptions, before HW switches it.
                        The actual maximum duration is 16 times this
                        parameter's value.
                        Format: integer between 1 and 255
                        Default: 255

        nptcg=          [IA-64] Override max number of concurrent global TLB
                        purges which is reported from either PAL_VM_SUMMARY or
                        SAL PALO.

        nr_cpus=        [SMP] Maximum number of processors that an SMP kernel
                        could support.  nr_cpus=n : n >= 1 limits the kernel to
                        support 'n' processors. It could be larger than the
                        number of already plugged CPU during bootup, later in
                        runtime you can physically add extra cpu until it␣
↪reaches
                        n. So during boot up some boot time memory for per-cpu
                        variables need be pre-allocated for later physical cpu
                        hot plugging.

        nr_uarts=       [SERIAL] maximum number of UARTs to be registered.

        numa=off        [KNL, ARM64, PPC, RISCV, SPARC, X86] Disable NUMA, Only
                        set up a single NUMA node spanning all memory.
```

```
        numa_balancing= [KNL,ARM64,PPC,RISCV,S390,X86] Enable or disable␣
↪automatic
                        NUMA balancing.
                        Allowed values are enable and disable

        numa_zonelist_order= [KNL, BOOT] Select zonelist order for NUMA.
                        'node', 'default' can be specified
                        This can be set from sysctl after boot.
                        See Documentation/admin-guide/sysctl/vm.rst for␣
↪details.

        ohci1394_dma=early      [HW] enable debugging via the ohci1394 driver.
                        See Documentation/core-api/debugging-via-ohci1394.rst␣
↪for more
                        info.

        olpc_ec_timeout= [OLPC] ms delay when issuing EC commands
                        Rather than timing out after 20 ms if an EC
                        command is not properly ACKed, override the length
                        of the timeout.  We have interrupts disabled while
                        waiting for the ACK, so if this is set too high
                        interrupts *may* be lost!

        omap_mux=       [OMAP] Override bootloader pin multiplexing.
                        Format: <mux_mode0.mode_name=value>...
                        For example, to override I2C bus2:
                        omap_mux=i2c2_scl.i2c2_scl=0x100,i2c2_sda.i2c2_
↪sda=0x100

        onenand.bdry=   [HW,MTD] Flex-OneNAND Boundary Configuration

                        Format: [die0_boundary][,die0_lock][,die1_boundary][,
↪die1_lock]

                        boundary - index of last SLC block on Flex-OneNAND.
                                   The remaining blocks are configured as MLC␣
↪blocks.
                        lock     - Configure if Flex-OneNAND boundary should␣
↪be locked.
                                   Once locked, the boundary cannot be changed.
                                   1 indicates lock status, 0 indicates unlock␣
↪status.

        oops=panic      Always panic on oopses. Default is to just kill the
                        process, but there is a small probability of
                        deadlocking the machine.
                        This will also cause panics on machine check␣
↪exceptions.
                        Useful together with panic=30 to trigger a reboot.
```

```
        page_alloc.shuffle=
                        [KNL] Boolean flag to control whether the page␣
↪allocator
                        should randomize its free lists. The randomization may
                        be automatically enabled if the kernel detects it is
                        running on a platform with a direct-mapped memory-side
                        cache, and this parameter can be used to
                        override/disable that behavior. The state of the flag
                        can be read from sysfs at:
                        /sys/module/page_alloc/parameters/shuffle.

        page_owner=     [KNL] Boot-time page_owner enabling option.
                        Storage of the information about who allocated
                        each page is disabled in default. With this switch,
                        we can turn it on.
                        on: enable the feature

        page_poison=    [KNL] Boot-time parameter changing the state of
                        poisoning on the buddy allocator, available with
                        CONFIG_PAGE_POISONING=y.
                        off: turn off poisoning (default)
                        on: turn on poisoning

        page_reporting.page_reporting_order=
                        [KNL] Minimal page reporting order
                        Format: <integer>
                        Adjust the minimal page reporting order. The page
                        reporting is disabled when it exceeds MAX_PAGE_ORDER.

        panic=          [KNL] Kernel behaviour on panic: delay <timeout>
                        timeout > 0: seconds before rebooting
                        timeout = 0: wait forever
                        timeout < 0: reboot immediately
                        Format: <timeout>

        panic_on_taint= Bitmask for conditionally calling panic() in add_
↪taint()
                        Format: <hex>[,nousertaint]
                        Hexadecimal bitmask representing the set of TAINT flags
                        that will cause the kernel to panic when add_taint() is
                        called with any of the flags in this set.
                        The optional switch "nousertaint" can be utilized to
                        prevent userspace forced crashes by writing to sysctl
                        /proc/sys/kernel/tainted any flagset matching with the
                        bitmask set on panic_on_taint.
                        See Documentation/admin-guide/tainted-kernels.rst for
                        extra details on the taint flags that users can pick
                        to compose the bitmask to assign to panic_on_taint.

        panic_on_warn=1 panic() instead of WARN().  Useful to cause kdump
                        on a WARN().
```

```
        panic_print=    Bitmask for printing system info when panic happens.
                        User can chose combination of the following bits:
                        bit 0: print all tasks info
                        bit 1: print system memory info
                        bit 2: print timer info
                        bit 3: print locks info if CONFIG_LOCKDEP is on
                        bit 4: print ftrace buffer
                        bit 5: print all printk messages in buffer
                        bit 6: print all CPUs backtrace (if available in the␣
↪arch)
                        *Be aware* that this option may print a _lot_ of lines,
                        so there are risks of losing older messages in the log.
                        Use this option carefully, maybe worth to setup a
                        bigger log buffer with "log_buf_len" along with this.

        parkbd.port=    [HW] Parallel port number the keyboard adapter is
                        connected to, default is 0.
                        Format: <parport#>
        parkbd.mode=    [HW] Parallel port keyboard adapter mode of operation,
                        0 for XT, 1 for AT (default is AT).
                        Format: <mode>

        parport=        [HW,PPT] Specify parallel ports. 0 disables.
                        Format: { 0 | auto | 0xBBB[,IRQ[,DMA]] }
                        Use 'auto' to force the driver to use any
                        IRQ/DMA settings detected (the default is to
                        ignore detected IRQ/DMA settings because of
                        possible conflicts). You can specify the base
                        address, IRQ, and DMA settings; IRQ and DMA
                        should be numbers, or 'auto' (for using detected
                        settings on that particular port), or 'nofifo'
                        (to avoid using a FIFO even if it is detected).
                        Parallel ports are assigned in the order they
                        are specified on the command line, starting
                        with parport0.

        parport_init_mode=      [HW,PPT]
                        Configure VIA parallel port to operate in
                        a specific mode. This is necessary on Pegasos
                        computer where firmware has no options for setting
                        up parallel port mode and sets it to spp.
                        Currently this function knows 686a and 8231 chips.
                        Format: [spp|ps2|epp|ecp|ecpepp]

        pata_legacy.all=        [HW,LIBATA]
                        Format: <int>
                        Set to non-zero to probe primary and secondary ISA
                        port ranges on PCI systems where no PCI PATA device
                        has been found at either range.  Disabled by default.
```

```
pata_legacy.autospeed=  [HW,LIBATA]
                Format: <int>
                Set to non-zero if a chip is present that snoops speed
                changes.  Disabled by default.

pata_legacy.ht6560a=    [HW,LIBATA]
                Format: <int>
                Set to 1, 2, or 3 for HT 6560A on the primary channel,
                the secondary channel, or both channels respectively.
                Disabled by default.

pata_legacy.ht6560b=    [HW,LIBATA]
                Format: <int>
                Set to 1, 2, or 3 for HT 6560B on the primary channel,
                the secondary channel, or both channels respectively.
                Disabled by default.

pata_legacy.iordy_mask= [HW,LIBATA]
                Format: <int>
                IORDY enable mask.  Set individual bits to allow IORDY
                for the respective channel.  Bit 0 is for the first
                legacy channel handled by this driver, bit 1 is for
                the second channel, and so on.  The sequence will often
                correspond to the primary legacy channel, the secondary
                legacy channel, and so on, but the handling of a PCI
                bus and the use of other driver options may interfere
                with the sequence.  By default IORDY is allowed across
                all channels.

pata_legacy.opti82c46x= [HW,LIBATA]
                Format: <int>
                Set to 1, 2, or 3 for Opti 82c611A on the primary
                channel, the secondary channel, or both channels
                respectively.  Disabled by default.

pata_legacy.opti82c611a=        [HW,LIBATA]
                Format: <int>
                Set to 1, 2, or 3 for Opti 82c465MV on the primary
                channel, the secondary channel, or both channels
                respectively.  Disabled by default.

pata_legacy.pio_mask=   [HW,LIBATA]
                Format: <int>
                PIO mode mask for autospeed devices.  Set individual
                bits to allow the use of the respective PIO modes.
                Bit 0 is for mode 0, bit 1 is for mode 1, and so on.
                All modes allowed by default.

pata_legacy.probe_all=  [HW,LIBATA]
                Format: <int>
                Set to non-zero to probe tertiary and further ISA
```

```
                        port ranges on PCI systems.  Disabled by default.

        pata_legacy.probe_mask= [HW,LIBATA]
                        Format: <int>
                        Probe mask for legacy ISA PATA ports.  Depending on
                        platform configuration and the use of other driver
                        options up to 6 legacy ports are supported: 0x1f0,
                        0x170, 0x1e8, 0x168, 0x1e0, 0x160, however probing
                        of individual ports can be disabled by setting the
                        corresponding bits in the mask to 1.  Bit 0 is for
                        the first port in the list above (0x1f0), and so on.
                        By default all supported ports are probed.

        pata_legacy.qdi=        [HW,LIBATA]
                        Format: <int>
                        Set to non-zero to probe QDI controllers.  By default
                        set to 1 if CONFIG_PATA_QDI_MODULE, 0 otherwise.

        pata_legacy.winbond=    [HW,LIBATA]
                        Format: <int>
                        Set to non-zero to probe Winbond controllers.  Use
                        the standard I/O port (0x130) if 1, otherwise the
                        value given is the I/O port to use (typically 0x1b0).
                        By default set to 1 if CONFIG_PATA_WINBOND_VLB_MODULE,
                        0 otherwise.

        pata_platform.pio_mask= [HW,LIBATA]
                        Format: <int>
                        Supported PIO mode mask.  Set individual bits to allow
                        the use of the respective PIO modes.  Bit 0 is for
                        mode 0, bit 1 is for mode 1, and so on.  Mode 0 only
                        allowed by default.

        pause_on_oops=<int>
                        Halt all CPUs after the first oops has been printed for
                        the specified number of seconds.  This is to be used if
                        your oopses keep scrolling off the screen.

        pcbit=          [HW,ISDN]

        pci=option[,option...]  [PCI] various PCI subsystem options.

                                Some options herein operate on a specific␣
↪device
                                or a set of devices (<pci_dev>). These are
                                specified in one of the following formats:

                                [<domain>:]<bus>:<dev>.<func>[/<dev>.<func>]*
                                pci:<vendor>:<device>[:<subvendor>:<subdevice>]

                                Note: the first format specifies a PCI
```

```
                                bus/device/function address which may change
                                if new hardware is inserted, if motherboard
                                firmware changes, or due to changes caused
                                by other kernel parameters. If the
                                domain is left unspecified, it is
                                taken to be zero. Optionally, a path
                                to a device through multiple device/function
                                addresses can be specified after the base
                                address (this is more robust against
                                renumbering issues).  The second format
                                selects devices using IDs from the
                                configuration space which may match multiple
                                devices in the system.

                earlydump       dump PCI config space before the kernel
                                changes anything
                off             [X86] don't probe for the PCI bus
                bios            [X86-32] force use of PCI BIOS, don't access
                                the hardware directly. Use this if your machine
                                has a non-standard PCI host bridge.
                nobios          [X86-32] disallow use of PCI BIOS, only direct
                                hardware access methods are allowed. Use this
                                if you experience crashes upon bootup and you
                                suspect they are caused by the BIOS.
                conf1           [X86] Force use of PCI Configuration Access
                                Mechanism 1 (config address in IO port 0xCF8,
                                data in IO port 0xCFC, both 32-bit).
                conf2           [X86] Force use of PCI Configuration Access
                                Mechanism 2 (IO port 0xCF8 is an 8-bit port for
                                the function, IO port 0xCFA, also 8-bit, sets
                                bus number. The config space is then accessed
                                through ports 0xC000-0xCFFF).
                                See http://wiki.osdev.org/PCI for more info
                                on the configuration access mechanisms.
                noaer           [PCIE] If the PCIEAER kernel config parameter␣
↪is
                                enabled, this kernel boot option can be used to
                                disable the use of PCIE advanced error␣
↪reporting.
                nodomains       [PCI] Disable support for multiple PCI
                                root domains (aka PCI segments, in ACPI-speak).
                nommconf        [X86] Disable use of MMCONFIG for PCI
                                Configuration
                check_enable_amd_mmconf [X86] check for and enable
                                properly configured MMIO access to PCI
                                config space on AMD family 10h CPU
                nomsi           [MSI] If the PCI_MSI kernel config parameter is
                                enabled, this kernel boot option can be used to
                                disable the use of MSI interrupts system-wide.
                noioapicquirk   [APIC] Disable all boot interrupt quirks.
                                Safety option to keep boot IRQs enabled. This
```

```
                                should never be necessary.
                ioapicreroute   [APIC] Enable rerouting of boot IRQs to the
                                primary IO-APIC for bridges that cannot disable
                                boot IRQs. This fixes a source of spurious IRQs
                                when the system masks IRQs.
                noioapicreroute [APIC] Disable workaround that uses the
                                boot IRQ equivalent of an IRQ that connects to
                                a chipset where boot IRQs cannot be disabled.
                                The opposite of ioapicreroute.
                biosirq         [X86-32] Use PCI BIOS calls to get the␣
↪interrupt
                                routing table. These calls are known to be␣
↪buggy
                                on several machines and they hang the machine
                                when used, but on other computers it's the only
                                way to get the interrupt routing table. Try
                                this option if the kernel is unable to allocate
                                IRQs or discover secondary PCI buses on your
                                motherboard.
                rom             [X86] Assign address space to expansion ROMs.
                                Use with caution as certain devices share
                                address decoders between ROMs and other
                                resources.
                norom           [X86] Do not assign address space to
                                expansion ROMs that do not already have
                                BIOS assigned address ranges.
                nobar           [X86] Do not assign address space to the
                                BARs that weren't assigned by the BIOS.
                irqmask=0xMMMM  [X86] Set a bit mask of IRQs allowed to be
                                assigned automatically to PCI devices. You can
                                make the kernel exclude IRQs of your ISA cards
                                this way.
                pirqaddr=0xAAAAA        [X86] Specify the physical address
                                of the PIRQ table (normally generated
                                by the BIOS) if it is outside the
                                F0000h-100000h range.
                lastbus=N       [X86] Scan all buses thru bus #N. Can be
                                useful if the kernel is unable to find your
                                secondary buses and you want to tell it
                                explicitly which ones they are.
                assign-busses   [X86] Always assign all PCI bus
                                numbers ourselves, overriding
                                whatever the firmware may have done.
                usepirqmask     [X86] Honor the possible IRQ mask stored
                                in the BIOS $PIR table. This is needed on
                                some systems with broken BIOSes, notably
                                some HP Pavilion N5400 and Omnibook XE3
                                notebooks. This will have no effect if ACPI
                                IRQ routing is enabled.
                noacpi          [X86] Do not use ACPI for IRQ routing
                                or for PCI scanning.
```

```
                use_crs         [X86] Use PCI host bridge window information
                                from ACPI.  On BIOSes from 2008 or later, this
                                is enabled by default.  If you need to use␣
↪this,
                                please report a bug.
                nocrs           [X86] Ignore PCI host bridge windows from ACPI.
                                If you need to use this, please report a bug.
                use_e820        [X86] Use E820 reservations to exclude parts of
                                PCI host bridge windows. This is a workaround
                                for BIOS defects in host bridge _CRS methods.
                                If you need to use this, please report a bug to
                                <linux-pci@vger.kernel.org>.
                no_e820         [X86] Ignore E820 reservations for PCI host
                                bridge windows. This is the default on modern
                                hardware. If you need to use this, please␣
↪report
                                a bug to <linux-pci@vger.kernel.org>.
                routeirq        Do IRQ routing for all PCI devices.
                                This is normally done in pci_enable_device(),
                                so this option is a temporary workaround
                                for broken drivers that don't call it.
                skip_isa_align  [X86] do not align io start addr, so can
                                handle more pci cards
                noearly         [X86] Don't do any early type 1 scanning.
                                This might help on some broken boards which
                                machine check when some devices' config space
                                is read. But various workarounds are disabled
                                and some IOMMU drivers will not work.
                bfsort          Sort PCI devices into breadth-first order.
                                This sorting is done to get a device
                                order compatible with older (<= 2.4) kernels.
                nobfsort        Don't sort PCI devices into breadth-first␣
↪order.
                pcie_bus_tune_off       Disable PCIe MPS (Max Payload Size)
                                tuning and use the BIOS-configured MPS␣
↪defaults.
                pcie_bus_safe   Set every device's MPS to the largest value
                                supported by all devices below the root␣
↪complex.
                pcie_bus_perf   Set device MPS to the largest allowable MPS
                                based on its parent bus. Also set MRRS (Max
                                Read Request Size) to the largest supported
                                value (no larger than the MPS that the device
                                or bus can support) for best performance.
                pcie_bus_peer2peer      Set every device's MPS to 128B, which
                                every device is guaranteed to support. This
                                configuration allows peer-to-peer DMA between
                                any pair of devices, possibly at the cost of
                                reduced performance.  This also guarantees
                                that hot-added devices will work.
                cbiosize=nn[KMG]        The fixed amount of bus space which is
```

```
                                reserved for the CardBus bridge's IO window.
                                The default value is 256 bytes.
                cbmemsize=nn[KMG]       The fixed amount of bus space which is
                                reserved for the CardBus bridge's memory
                                window. The default value is 64 megabytes.
                resource_alignment=
                                Format:
                                [<order of align>@]<pci_dev>[; ...]
                                Specifies alignment and device to reassign
                                aligned memory resources. How to
                                specify the device is described above.
                                If <order of align> is not specified,
                                PAGE_SIZE is used as alignment.
                                A PCI-PCI bridge can be specified if resource
                                windows need to be expanded.
                                To specify the alignment for several
                                instances of a device, the PCI vendor,
                                device, subvendor, and subdevice may be
                                specified, e.g., 12@pci:8086:9c22:103c:198f
                                for 4096-byte alignment.
                ecrc=           Enable/disable PCIe ECRC (transaction layer
                                end-to-end CRC checking). Only effective if
                                OS has native AER control (either granted by
                                ACPI _OSC or forced via "pcie_ports=native")
                                bios: Use BIOS/firmware settings. This is the
                                the default.
                                off: Turn ECRC off
                                on: Turn ECRC on.
                hpiosize=nn[KMG]        The fixed amount of bus space which is
                                reserved for hotplug bridge's IO window.
                                Default size is 256 bytes.
                hpmmiosize=nn[KMG]      The fixed amount of bus space which is
                                reserved for hotplug bridge's MMIO window.
                                Default size is 2 megabytes.
                hpmmioprefsize=nn[KMG]  The fixed amount of bus space which is
                                reserved for hotplug bridge's MMIO_PREF window.
                                Default size is 2 megabytes.
                hpmemsize=nn[KMG]       The fixed amount of bus space which is
                                reserved for hotplug bridge's MMIO and
                                MMIO_PREF window.
                                Default size is 2 megabytes.
                hpbussize=nn    The minimum amount of additional bus numbers
                                reserved for buses below a hotplug bridge.
                                Default is 1.
                realloc=        Enable/disable reallocating PCI bridge␣
↪resources
                                if allocations done by BIOS are too small to
                                accommodate resources required by all child
                                devices.
                                off: Turn realloc off
                                on: Turn realloc on
```

```
                realloc         same as realloc=on
                noari           do not use PCIe ARI.
                noats           [PCIE, Intel-IOMMU, AMD-IOMMU]
                                do not use PCIe ATS (and IOMMU device IOTLB).
                pcie_scan_all   Scan all possible PCIe devices.  Otherwise we
                                only look for one device below a PCIe␣
↪downstream
                                port.
                big_root_window Try to add a big 64bit memory window to the␣
↪PCIe
                                root complex on AMD CPUs. Some GFX hardware
                                can resize a BAR to allow access to all VRAM.
                                Adding the window is slightly risky (it may
                                conflict with unreported devices), so this
                                taints the kernel.
                disable_acs_redir=<pci_dev>[; ...]
                                Specify one or more PCI devices (in the format
                                specified above) separated by semicolons.
                                Each device specified will have the PCI ACS
                                redirect capabilities forced off which will
                                allow P2P traffic between devices through
                                bridges without forcing it upstream. Note:
                                this removes isolation between devices and
                                may put more devices in an IOMMU group.
                force_floating  [S390] Force usage of floating interrupts.
                nomio           [S390] Do not use MIO instructions.
                norid           [S390] ignore the RID field and force use of
                                one PCI domain per PCI function

        pcie_aspm=      [PCIE] Forcibly enable or disable PCIe Active State␣
↪Power
                        Management.
                off     Disable ASPM.
                force   Enable ASPM even on devices that claim not to support␣
↪it.
                        WARNING: Forcing ASPM on may cause system lockups.

        pcie_ports=     [PCIE] PCIe port services handling:
                native  Use native PCIe services (PME, AER, DPC, PCIe hotplug)
                        even if the platform doesn't give the OS permission to
                        use them.  This may cause conflicts if the platform
                        also tries to use these services.
                dpc-native      Use native PCIe service for DPC only.  May
                                cause conflicts if firmware uses AER or DPC.
                compat  Disable native PCIe services (PME, AER, DPC, PCIe
                        hotplug).

        pcie_port_pm=   [PCIE] PCIe port power management handling:
                off     Disable power management of all PCIe ports
                force   Forcibly enable power management of all PCIe ports
```

```
        pcie_pme=       [PCIE,PM] Native PCIe PME signaling options:
                nomsi   Do not use MSI for native PCIe PME signaling (this␣
↪makes
                        all PCIe root ports use INTx for all services).

        pcmv=           [HW,PCMCIA] BadgePAD 4

        pd_ignore_unused
                        [PM]
                        Keep all power-domains already enabled by bootloader␣
↪on,
                        even if no driver has claimed them. This is useful
                        for debug and development, but should not be
                        needed on a platform with proper driver support.

        pdcchassis=     [PARISC,HW] Disable/Enable PDC Chassis Status codes at
                        boot time.
                        Format: { 0 | 1 }
                        See arch/parisc/kernel/pdc_chassis.c

        percpu_alloc=   Select which percpu first chunk allocator to use.
                        Currently supported values are "embed" and "page".
                        Archs may support subset or none of the selections.
                        See comments in mm/percpu.c for details on each
                        allocator.  This parameter is primarily for debugging
                        and performance comparison.

        pirq=           [SMP,APIC] Manual mp-table setup
                        See Documentation/arch/x86/i386/IO-APIC.rst.

        plip=           [PPT,NET] Parallel port network link
                        Format: { parport<nr> | timid | 0 }
                        See also Documentation/admin-guide/parport.rst.

        pmtmr=          [X86] Manual setup of pmtmr I/O Port.
                        Override pmtimer IOPort with a hex value.
                        e.g. pmtmr=0x508

        pmu_override=   [PPC] Override the PMU.
                        This option takes over the PMU facility, so it is no
                        longer usable by perf. Setting this option starts the
                        PMU counters by setting MMCR0 to 0 (the FC bit is
                        cleared). If a number is given, then MMCR1 is set to
                        that number, otherwise (e.g., 'pmu_override=on'), MMCR1
                        remains 0.

        pm_debug_messages       [SUSPEND,KNL]
                        Enable suspend/resume debug messages during boot up.

        pnp.debug=1     [PNP]
                        Enable PNP debug messages (depends on the
```

```
                        CONFIG_PNP_DEBUG_MESSAGES option).  Change at run-time
                        via /sys/module/pnp/parameters/debug.  We always show
                        current resource usage; turning this on also shows
                        possible settings and some assignment information.

        pnpacpi=        [ACPI]
                        { off }

        pnpbios=        [ISAPNP]
                        { on | off | curr | res | no-curr | no-res }

        pnp_reserve_irq=
                        [ISAPNP] Exclude IRQs for the autoconfiguration

        pnp_reserve_dma=
                        [ISAPNP] Exclude DMAs for the autoconfiguration

        pnp_reserve_io= [ISAPNP] Exclude I/O ports for the autoconfiguration
                        Ranges are in pairs (I/O port base and size).

        pnp_reserve_mem=
                        [ISAPNP] Exclude memory regions for the
                        autoconfiguration.
                        Ranges are in pairs (memory base and size).

        ports=          [IP_VS_FTP] IPVS ftp helper module
                        Default is 21.
                        Up to 8 (IP_VS_APP_MAX_PORTS) ports
                        may be specified.
                        Format: <port>,<port>....

        powersave=off   [PPC] This option disables power saving features.
                        It specifically disables cpuidle and sets the
                        platform machine description specific power_save
                        function to NULL. On Idle the CPU just reduces
                        execution priority.

        ppc_strict_facility_enable
                        [PPC] This option catches any kernel floating point,
                        Altivec, VSX and SPE outside of regions specifically
                        allowed (eg kernel_enable_fpu()/kernel_disable_fpu()).
                        There is some performance impact when enabling this.

        ppc_tm=         [PPC]
                        Format: {"off"}
                        Disable Hardware Transactional Memory

        preempt=        [KNL]
                        Select preemption mode if you have CONFIG_PREEMPT_
↪DYNAMIC
                        none - Limited to cond_resched() calls
```

```
                        voluntary - Limited to cond_resched() and might_
↪sleep() calls
                        full - Any section that isn't explicitly preempt␣
↪disabled
                               can be preempted anytime.

        print-fatal-signals=
                        [KNL] debug: print fatal signals

                        If enabled, warn about various signal handling
                        related application anomalies: too many signals,
                        too many POSIX.1 timers, fatal signals causing a
                        coredump - etc.

                        If you hit the warning due to signal overflow,
                        you might want to try "ulimit -i unlimited".

                        default: off.

        printk.always_kmsg_dump=
                        Trigger kmsg_dump for cases other than kernel oops or
                        panics
                        Format: <bool>  (1/Y/y=enable, 0/N/n=disable)
                        default: disabled

        printk.console_no_auto_verbose=
                        Disable console loglevel raise on oops, panic
                        or lockdep-detected issues (only if lock debug is on).
                        With an exception to setups with low baudrate on
                        serial console, keeping this 0 is a good choice
                        in order to provide more debug information.
                        Format: <bool>
                        default: 0 (auto_verbose is enabled)

        printk.devkmsg={on,off,ratelimit}
                        Control writing to /dev/kmsg.
                        on - unlimited logging to /dev/kmsg from userspace
                        off - logging to /dev/kmsg disabled
                        ratelimit - ratelimit the logging
                        Default: ratelimit

        printk.time=    Show timing data prefixed to each printk message line
                        Format: <bool>  (1/Y/y=enable, 0/N/n=disable)

        processor.max_cstate=   [HW,ACPI]
                        Limit processor to maximum C-state
                        max_cstate=9 overrides any DMI blacklist limit.

        processor.nocst [HW,ACPI]
                        Ignore the _CST method to determine C-states,
                        instead using the legacy FADT method
```

```
profile=        [KNL] Enable kernel profiling via /proc/profile
                Format: [<profiletype>,]<number>
                Param: <profiletype>: "schedule", "sleep", or "kvm"
                        [defaults to kernel profiling]
                Param: "schedule" - profile schedule points.
                Param: "sleep" - profile D-state sleeping (millisecs).
                        Requires CONFIG_SCHEDSTATS
                Param: "kvm" - profile VM exits.
                Param: <number> - step/bucket size as a power of 2 for
                        statistical time based profiling.

prompt_ramdisk= [RAM] [Deprecated]

prot_virt=      [S390] enable hosting protected virtual machines
                isolated from the hypervisor (if hardware supports
                that).
                Format: <bool>

psi=            [KNL] Enable or disable pressure stall information
                tracking.
                Format: <bool>

psmouse.proto=  [HW,MOUSE] Highest PS2 mouse protocol extension to
                probe for; one of (bare|imps|exps|lifebook|any).
psmouse.rate=   [HW,MOUSE] Set desired mouse report rate, in reports
                per second.
psmouse.resetafter=     [HW,MOUSE]
                Try to reset the device after so many bad packets
                (0 = never).
psmouse.resolution=
                [HW,MOUSE] Set desired mouse resolution, in dpi.
psmouse.smartscroll=
                [HW,MOUSE] Controls Logitech smartscroll autorepeat.
                0 = disabled, 1 = enabled (default).

pstore.backend= Specify the name of the pstore backend to use

pti=            [X86-64] Control Page Table Isolation of user and
                kernel address spaces.  Disabling this feature
                removes hardening, but improves performance of
                system calls and interrupts.

                on   - unconditionally enable
                off  - unconditionally disable
                auto - kernel detects whether your CPU model is
                       vulnerable to issues that PTI mitigates

                Not specifying this option is equivalent to pti=auto.

pty.legacy_count=
```

```
                [KNL] Number of legacy pty's. Overwrites compiled-in
                default number.

quiet           [KNL] Disable most log messages

r128=           [HW,DRM]

radix_hcall_invalidate=on  [PPC/PSERIES]
                Disable RADIX GTSE feature and use hcall for TLB
                invalidate.

raid=           [HW,RAID]
                See Documentation/admin-guide/md.rst.

ramdisk_size=   [RAM] Sizes of RAM disks in kilobytes
                See Documentation/admin-guide/blockdev/ramdisk.rst.

ramdisk_start=  [RAM] RAM disk image start address

random.trust_cpu=off
                [KNL] Disable trusting the use of the CPU's
                random number generator (if available) to
                initialize the kernel's RNG.

random.trust_bootloader=off
                [KNL] Disable trusting the use of the a seed
                passed by the bootloader (if available) to
                initialize the kernel's RNG.

randomize_kstack_offset=
                [KNL] Enable or disable kernel stack offset
                randomization, which provides roughly 5 bits of
                entropy, frustrating memory corruption attacks
                that depend on stack address determinism or
                cross-syscall address exposures. This is only
                available on architectures that have defined
                CONFIG_HAVE_ARCH_RANDOMIZE_KSTACK_OFFSET.
                Format: <bool>  (1/Y/y=enable, 0/N/n=disable)
                Default is CONFIG_RANDOMIZE_KSTACK_OFFSET_DEFAULT.

ras=option[,option,...] [KNL] RAS-specific options

        cec_disable     [X86]
                        Disable the Correctable Errors Collector,
                        see CONFIG_RAS_CEC help text.

rcu_nocbs[=cpu-list]
                [KNL] The optional argument is a cpu list,
                as described above.

                In kernels built with CONFIG_RCU_NOCB_CPU=y,
```

```
                enable the no-callback CPU mode, which prevents
                such CPUs' callbacks from being invoked in
                softirq context.  Invocation of such CPUs' RCU
                callbacks will instead be offloaded to "rcuox/N"
                kthreads created for that purpose, where "x" is
                "p" for RCU-preempt, "s" for RCU-sched, and "g"
                for the kthreads that mediate grace periods; and
                "N" is the CPU number. This reduces OS jitter on
                the offloaded CPUs, which can be useful for HPC
                and real-time workloads.  It can also improve
                energy efficiency for asymmetric multiprocessors.

                If a cpulist is passed as an argument, the specified
                list of CPUs is set to no-callback mode from boot.

                Otherwise, if the '=' sign and the cpulist
                arguments are omitted, no CPU will be set to
                no-callback mode from boot but the mode may be
                toggled at runtime via cpusets.

                Note that this argument takes precedence over
                the CONFIG_RCU_NOCB_CPU_DEFAULT_ALL option.

        rcu_nocb_poll   [KNL]
                Rather than requiring that offloaded CPUs
                (specified by rcu_nocbs= above) explicitly
                awaken the corresponding "rcuoN" kthreads,
                make these kthreads poll for callbacks.
                This improves the real-time response for the
                offloaded CPUs by relieving them of the need to
                wake up the corresponding kthread, but degrades
                energy efficiency by requiring that the kthreads
                periodically wake up to do the polling.

        rcutree.blimit= [KNL]
                Set maximum number of finished RCU callbacks to
                process in one batch.

        rcutree.do_rcu_barrier= [KNL]
                Request a call to rcu_barrier().  This is
                throttled so that userspace tests can safely
                hammer on the sysfs variable if they so choose.
                If triggered before the RCU grace-period machinery
                is fully active, this will error out with EAGAIN.

        rcutree.dump_tree=      [KNL]
                Dump the structure of the rcu_node combining tree
                out at early boot.  This is used for diagnostic
                purposes, to verify correct tree setup.

        rcutree.gp_cleanup_delay=       [KNL]
```

```
                Set the number of jiffies to delay each step of
                RCU grace-period cleanup.

rcutree.gp_init_delay=  [KNL]
                Set the number of jiffies to delay each step of
                RCU grace-period initialization.

rcutree.gp_preinit_delay=       [KNL]
                Set the number of jiffies to delay each step of
                RCU grace-period pre-initialization, that is,
                the propagation of recent CPU-hotplug changes up
                the rcu_node combining tree.

rcutree.jiffies_till_first_fqs= [KNL]
                Set delay from grace-period initialization to
                first attempt to force quiescent states.
                Units are jiffies, minimum value is zero,
                and maximum value is HZ.

rcutree.jiffies_till_next_fqs= [KNL]
                Set delay between subsequent attempts to force
                quiescent states.  Units are jiffies, minimum
                value is one, and maximum value is HZ.

rcutree.jiffies_till_sched_qs= [KNL]
                Set required age in jiffies for a
                given grace period before RCU starts
                soliciting quiescent-state help from
                rcu_note_context_switch() and cond_resched().
                If not specified, the kernel will calculate
                a value based on the most recent settings
                of rcutree.jiffies_till_first_fqs
                and rcutree.jiffies_till_next_fqs.
                This calculated value may be viewed in
                rcutree.jiffies_to_sched_qs.  Any attempt to set
                rcutree.jiffies_to_sched_qs will be cheerfully
                overwritten.

rcutree.kthread_prio=    [KNL,BOOT]
                Set the SCHED_FIFO priority of the RCU per-CPU
                kthreads (rcuc/N). This value is also used for
                the priority of the RCU boost threads (rcub/N)
                and for the RCU grace-period kthreads (rcu_bh,
                rcu_preempt, and rcu_sched). If RCU_BOOST is
                set, valid values are 1-99 and the default is 1
                (the least-favored priority).  Otherwise, when
                RCU_BOOST is not set, valid values are 0-99 and
                the default is zero (non-realtime operation).
                When RCU_NOCB_CPU is set, also adjust the
                priority of NOCB callback kthreads.
```

```
rcutree.nocb_nobypass_lim_per_jiffy= [KNL]
                On callback-offloaded (rcu_nocbs) CPUs,
                RCU reduces the lock contention that would
                otherwise be caused by callback floods through
                use of the ->nocb_bypass list.  However, in the
                common non-flooded case, RCU queues directly to
                the main ->cblist in order to avoid the extra
                overhead of the ->nocb_bypass list and its lock.
                But if there are too many callbacks queued during
                a single jiffy, RCU pre-queues the callbacks into
                the ->nocb_bypass queue.  The definition of "too
                many" is supplied by this kernel boot parameter.

rcutree.qhimark= [KNL]
                Set threshold of queued RCU callbacks beyond which
                batch limiting is disabled.

rcutree.qlowmark= [KNL]
                Set threshold of queued RCU callbacks below which
                batch limiting is re-enabled.

rcutree.qovld= [KNL]
                Set threshold of queued RCU callbacks beyond which
                RCU's force-quiescent-state scan will aggressively
                enlist help from cond_resched() and sched IPIs to
                help CPUs more quickly reach quiescent states.
                Set to less than zero to make this be set based
                on rcutree.qhimark at boot time and to zero to
                disable more aggressive help enlistment.

rcutree.rcu_delay_page_cache_fill_msec= [KNL]
                Set the page-cache refill delay (in milliseconds)
                in response to low-memory conditions.  The range
                of permitted values is in the range 0:100000.

rcutree.rcu_divisor= [KNL]
                Set the shift-right count to use to compute
                the callback-invocation batch limit bl from
                the number of callbacks queued on this CPU.
                The result will be bounded below by the value of
                the rcutree.blimit kernel parameter.  Every bl
                callbacks, the softirq handler will exit in
                order to allow the CPU to do other work.

                Please note that this callback-invocation batch
                limit applies only to non-offloaded callback
                invocation.  Offloaded callbacks are instead
                invoked in the context of an rcuoc kthread, which
                scheduler will preempt as it does any other task.

rcutree.rcu_fanout_exact= [KNL]
```

```
                Disable autobalancing of the rcu_node combining
                tree.  This is used by rcutorture, and might
                possibly be useful for architectures having high
                cache-to-cache transfer latencies.

rcutree.rcu_fanout_leaf= [KNL]
                Change the number of CPUs assigned to each
                leaf rcu_node structure.  Useful for very
                large systems, which will choose the value 64,
                and for NUMA systems with large remote-access
                latencies, which will choose a value aligned
                with the appropriate hardware boundaries.

rcutree.rcu_min_cached_objs= [KNL]
                Minimum number of objects which are cached and
                maintained per one CPU. Object size is equal
                to PAGE_SIZE. The cache allows to reduce the
                pressure to page allocator, also it makes the
                whole algorithm to behave better in low memory
                condition.

rcutree.rcu_nocb_gp_stride= [KNL]
                Set the number of NOCB callback kthreads in
                each group, which defaults to the square root
                of the number of CPUs.  Larger numbers reduce
                the wakeup overhead on the global grace-period
                kthread, but increases that same overhead on
                each group's NOCB grace-period kthread.

rcutree.rcu_kick_kthreads= [KNL]
                Cause the grace-period kthread to get an extra
                wake_up() if it sleeps three times longer than
                it should at force-quiescent-state time.
                This wake_up() will be accompanied by a
                WARN_ONCE() splat and an ftrace_dump().

rcutree.rcu_resched_ns= [KNL]
                Limit the time spend invoking a batch of RCU
                callbacks to the specified number of nanoseconds.
                By default, this limit is checked only once
                every 32 callbacks in order to limit the pain
                inflicted by local_clock() overhead.

rcutree.rcu_unlock_delay= [KNL]
                In CONFIG_RCU_STRICT_GRACE_PERIOD=y kernels,
                this specifies an rcu_read_unlock()-time delay
                in microseconds.  This defaults to zero.
                Larger delays increase the probability of
                catching RCU pointer leaks, that is, buggy use
                of RCU-protected pointers after the relevant
                rcu_read_unlock() has completed.
```

```
rcutree.sysrq_rcu= [KNL]
                Commandeer a sysrq key to dump out Tree RCU's
                rcu_node tree with an eye towards determining
                why a new grace period has not yet started.

rcutree.use_softirq=    [KNL]
                If set to zero, move all RCU_SOFTIRQ processing to
                per-CPU rcuc kthreads.  Defaults to a non-zero
                value, meaning that RCU_SOFTIRQ is used by default.
                Specify rcutree.use_softirq=0 to use rcuc kthreads.

                But note that CONFIG_PREEMPT_RT=y kernels disable
                this kernel boot parameter, forcibly setting it
                to zero.

rcuscale.gp_async= [KNL]
                Measure performance of asynchronous
                grace-period primitives such as call_rcu().

rcuscale.gp_async_max= [KNL]
                Specify the maximum number of outstanding
                callbacks per writer thread.  When a writer
                thread exceeds this limit, it invokes the
                corresponding flavor of rcu_barrier() to allow
                previously posted callbacks to drain.

rcuscale.gp_exp= [KNL]
                Measure performance of expedited synchronous
                grace-period primitives.

rcuscale.holdoff= [KNL]
                Set test-start holdoff period.  The purpose of
                this parameter is to delay the start of the
                test until boot completes in order to avoid
                interference.

rcuscale.kfree_by_call_rcu= [KNL]
                In kernels built with CONFIG_RCU_LAZY=y, test
                call_rcu() instead of kfree_rcu().

rcuscale.kfree_mult= [KNL]
                Instead of allocating an object of size kfree_obj,
                allocate one of kfree_mult * sizeof(kfree_obj).
                Defaults to 1.

rcuscale.kfree_rcu_test= [KNL]
                Set to measure performance of kfree_rcu() flooding.

rcuscale.kfree_rcu_test_double= [KNL]
                Test the double-argument variant of kfree_rcu().
```

```
                If this parameter has the same value as
                rcuscale.kfree_rcu_test_single, both the single-
                and double-argument variants are tested.

rcuscale.kfree_rcu_test_single= [KNL]
                Test the single-argument variant of kfree_rcu().
                If this parameter has the same value as
                rcuscale.kfree_rcu_test_double, both the single-
                and double-argument variants are tested.

rcuscale.kfree_nthreads= [KNL]
                The number of threads running loops of kfree_rcu().

rcuscale.kfree_alloc_num= [KNL]
                Number of allocations and frees done in an iteration.

rcuscale.kfree_loops= [KNL]
                Number of loops doing rcuscale.kfree_alloc_num number
                of allocations and frees.

rcuscale.minruntime= [KNL]
                Set the minimum test run time in seconds.  This
                does not affect the data-collection interval,
                but instead allows better measurement of things
                like CPU consumption.

rcuscale.nreaders= [KNL]
                Set number of RCU readers.  The value -1 selects
                N, where N is the number of CPUs.  A value
                "n" less than -1 selects N-n+1, where N is again
                the number of CPUs.  For example, -2 selects N
                (the number of CPUs), -3 selects N+1, and so on.
                A value of "n" less than or equal to -N selects
                a single reader.

rcuscale.nwriters= [KNL]
                Set number of RCU writers.  The values operate
                the same as for rcuscale.nreaders.
                N, where N is the number of CPUs

rcuscale.scale_type= [KNL]
                Specify the RCU implementation to test.

rcuscale.shutdown= [KNL]
                Shut the system down after performance tests
                complete.  This is useful for hands-off automated
                testing.

rcuscale.verbose= [KNL]
                Enable additional printk() statements.
```

```
rcuscale.writer_holdoff= [KNL]
                Write-side holdoff between grace periods,
                in microseconds.  The default of zero says
                no holdoff.

rcuscale.writer_holdoff_jiffies= [KNL]
                Additional write-side holdoff between grace
                periods, but in jiffies.  The default of zero
                says no holdoff.

rcutorture.fqs_duration= [KNL]
                Set duration of force_quiescent_state bursts
                in microseconds.

rcutorture.fqs_holdoff= [KNL]
                Set holdoff time within force_quiescent_state bursts
                in microseconds.

rcutorture.fqs_stutter= [KNL]
                Set wait time between force_quiescent_state bursts
                in seconds.

rcutorture.fwd_progress= [KNL]
                Specifies the number of kthreads to be used
                for  RCU grace-period forward-progress testing
                for the types of RCU supporting this notion.
                Defaults to 1 kthread, values less than zero or
                greater than the number of CPUs cause the number
                of CPUs to be used.

rcutorture.fwd_progress_div= [KNL]
                Specify the fraction of a CPU-stall-warning
                period to do tight-loop forward-progress testing.

rcutorture.fwd_progress_holdoff= [KNL]
                Number of seconds to wait between successive
                forward-progress tests.

rcutorture.fwd_progress_need_resched= [KNL]
                Enclose cond_resched() calls within checks for
                need_resched() during tight-loop forward-progress
                testing.

rcutorture.gp_cond= [KNL]
                Use conditional/asynchronous update-side
                primitives, if available.

rcutorture.gp_exp= [KNL]
                Use expedited update-side primitives, if available.

rcutorture.gp_normal= [KNL]
```

```
                Use normal (non-expedited) asynchronous
                update-side primitives, if available.

rcutorture.gp_sync= [KNL]
                Use normal (non-expedited) synchronous
                update-side primitives, if available.  If all
                of rcutorture.gp_cond=, rcutorture.gp_exp=,
                rcutorture.gp_normal=, and rcutorture.gp_sync=
                are zero, rcutorture acts as if is interpreted
                they are all non-zero.

rcutorture.irqreader= [KNL]
                Run RCU readers from irq handlers, or, more
                accurately, from a timer handler.  Not all RCU
                flavors take kindly to this sort of thing.

rcutorture.leakpointer= [KNL]
                Leak an RCU-protected pointer out of the reader.
                This can of course result in splats, and is
                intended to test the ability of things like
                CONFIG_RCU_STRICT_GRACE_PERIOD=y to detect
                such leaks.

rcutorture.n_barrier_cbs= [KNL]
                Set callbacks/threads for rcu_barrier() testing.

rcutorture.nfakewriters= [KNL]
                Set number of concurrent RCU writers.  These just
                stress RCU, they don't participate in the actual
                test, hence the "fake".

rcutorture.nocbs_nthreads= [KNL]
                Set number of RCU callback-offload togglers.
                Zero (the default) disables toggling.

rcutorture.nocbs_toggle= [KNL]
                Set the delay in milliseconds between successive
                callback-offload toggling attempts.

rcutorture.nreaders= [KNL]
                Set number of RCU readers.  The value -1 selects
                N-1, where N is the number of CPUs.  A value
                "n" less than -1 selects N-n-2, where N is again
                the number of CPUs.  For example, -2 selects N
                (the number of CPUs), -3 selects N+1, and so on.

rcutorture.object_debug= [KNL]
                Enable debug-object double-call_rcu() testing.

rcutorture.onoff_holdoff= [KNL]
                Set time (s) after boot for CPU-hotplug testing.
```

```
rcutorture.onoff_interval= [KNL]
                Set time (jiffies) between CPU-hotplug operations,
                or zero to disable CPU-hotplug testing.

rcutorture.read_exit= [KNL]
                Set the number of read-then-exit kthreads used
                to test the interaction of RCU updaters and
                task-exit processing.

rcutorture.read_exit_burst= [KNL]
                The number of times in a given read-then-exit
                episode that a set of read-then-exit kthreads
                is spawned.

rcutorture.read_exit_delay= [KNL]
                The delay, in seconds, between successive
                read-then-exit testing episodes.

rcutorture.shuffle_interval= [KNL]
                Set task-shuffle interval (s).  Shuffling tasks
                allows some CPUs to go into dyntick-idle mode
                during the rcutorture test.

rcutorture.shutdown_secs= [KNL]
                Set time (s) after boot system shutdown.  This
                is useful for hands-off automated testing.

rcutorture.stall_cpu= [KNL]
                Duration of CPU stall (s) to test RCU CPU stall
                warnings, zero to disable.

rcutorture.stall_cpu_block= [KNL]
                Sleep while stalling if set.  This will result
                in warnings from preemptible RCU in addition to
                any other stall-related activity.  Note that
                in kernels built with CONFIG_PREEMPTION=n and
                CONFIG_PREEMPT_COUNT=y, this parameter will
                cause the CPU to pass through a quiescent state.
                Given CONFIG_PREEMPTION=n, this will suppress
                RCU CPU stall warnings, but will instead result
                in scheduling-while-atomic splats.

                Use of this module parameter results in splats.

rcutorture.stall_cpu_holdoff= [KNL]
                Time to wait (s) after boot before inducing stall.

rcutorture.stall_cpu_irqsoff= [KNL]
                Disable interrupts while stalling if set.
```

```
rcutorture.stall_gp_kthread= [KNL]
                Duration (s) of forced sleep within RCU
                grace-period kthread to test RCU CPU stall
                warnings, zero to disable.  If both stall_cpu
                and stall_gp_kthread are specified, the
                kthread is starved first, then the CPU.

rcutorture.stat_interval= [KNL]
                Time (s) between statistics printk()s.

rcutorture.stutter= [KNL]
                Time (s) to stutter testing, for example, specifying
                five seconds causes the test to run for five seconds,
                wait for five seconds, and so on.  This tests RCU's
                ability to transition abruptly to and from idle.

rcutorture.test_boost= [KNL]
                Test RCU priority boosting?  0=no, 1=maybe, 2=yes.
                "Maybe" means test if the RCU implementation
                under test support RCU priority boosting.

rcutorture.test_boost_duration= [KNL]
                Duration (s) of each individual boost test.

rcutorture.test_boost_interval= [KNL]
                Interval (s) between each boost test.

rcutorture.test_no_idle_hz= [KNL]
                Test RCU's dyntick-idle handling.  See also the
                rcutorture.shuffle_interval parameter.

rcutorture.torture_type= [KNL]
                Specify the RCU implementation to test.

rcutorture.verbose= [KNL]
                Enable additional printk() statements.

rcupdate.rcu_cpu_stall_ftrace_dump= [KNL]
                Dump ftrace buffer after reporting RCU CPU
                stall warning.

rcupdate.rcu_cpu_stall_notifiers= [KNL]
                Provide RCU CPU stall notifiers, but see the
                warnings in the RCU_CPU_STALL_NOTIFIER Kconfig
                option's help text.  TL;DR:  You almost certainly
                do not want rcupdate.rcu_cpu_stall_notifiers.

rcupdate.rcu_cpu_stall_suppress= [KNL]
                Suppress RCU CPU stall warning messages.
```

```
rcupdate.rcu_cpu_stall_suppress_at_boot= [KNL]
                Suppress RCU CPU stall warning messages and
                rcutorture writer stall warnings that occur
                during early boot, that is, during the time
                before the init task is spawned.

rcupdate.rcu_cpu_stall_timeout= [KNL]
                Set timeout for RCU CPU stall warning messages.
                The value is in seconds and the maximum allowed
                value is 300 seconds.

rcupdate.rcu_exp_cpu_stall_timeout= [KNL]
                Set timeout for expedited RCU CPU stall warning
                messages.  The value is in milliseconds
                and the maximum allowed value is 21000
                milliseconds. Please note that this value is
                adjusted to an arch timer tick resolution.
                Setting this to zero causes the value from
                rcupdate.rcu_cpu_stall_timeout to be used (after
                conversion from seconds to milliseconds).

rcupdate.rcu_cpu_stall_cputime= [KNL]
                Provide statistics on the cputime and count of
                interrupts and tasks during the sampling period. For
                multiple continuous RCU stalls, all sampling periods
                begin at half of the first RCU stall timeout.

rcupdate.rcu_exp_stall_task_details= [KNL]
                Print stack dumps of any tasks blocking the
                current expedited RCU grace period during an
                expedited RCU CPU stall warning.

rcupdate.rcu_expedited= [KNL]
                Use expedited grace-period primitives, for
                example, synchronize_rcu_expedited() instead
                of synchronize_rcu().  This reduces latency,
                but can increase CPU utilization, degrade
                real-time latency, and degrade energy efficiency.
                No effect on CONFIG_TINY_RCU kernels.

rcupdate.rcu_normal= [KNL]
                Use only normal grace-period primitives,
                for example, synchronize_rcu() instead of
                synchronize_rcu_expedited().  This improves
                real-time latency, CPU utilization, and
                energy efficiency, but can expose users to
                increased grace-period latency.  This parameter
                overrides rcupdate.rcu_expedited.  No effect on
                CONFIG_TINY_RCU kernels.

rcupdate.rcu_normal_after_boot= [KNL]
```

```
                Once boot has completed (that is, after
                rcu_end_inkernel_boot() has been invoked), use
                only normal grace-period primitives.  No effect
                on CONFIG_TINY_RCU kernels.

                But note that CONFIG_PREEMPT_RT=y kernels enables
                this kernel boot parameter, forcibly setting
                it to the value one, that is, converting any
                post-boot attempt at an expedited RCU grace
                period to instead use normal non-expedited
                grace-period processing.

        rcupdate.rcu_task_collapse_lim= [KNL]
                Set the maximum number of callbacks present
                at the beginning of a grace period that allows
                the RCU Tasks flavors to collapse back to using
                a single callback queue.  This switching only
                occurs when rcupdate.rcu_task_enqueue_lim is
                set to the default value of -1.

        rcupdate.rcu_task_contend_lim= [KNL]
                Set the minimum number of callback-queuing-time
                lock-contention events per jiffy required to
                cause the RCU Tasks flavors to switch to per-CPU
                callback queuing.  This switching only occurs
                when rcupdate.rcu_task_enqueue_lim is set to
                the default value of -1.

        rcupdate.rcu_task_enqueue_lim= [KNL]
                Set the number of callback queues to use for the
                RCU Tasks family of RCU flavors.  The default
                of -1 allows this to be automatically (and
                dynamically) adjusted.  This parameter is intended
                for use in testing.

        rcupdate.rcu_task_ipi_delay= [KNL]
                Set time in jiffies during which RCU tasks will
                avoid sending IPIs, starting with the beginning
                of a given grace period.  Setting a large
                number avoids disturbing real-time workloads,
                but lengthens grace periods.

        rcupdate.rcu_task_lazy_lim= [KNL]
                Number of callbacks on a given CPU that will
                cancel laziness on that CPU.  Use -1 to disable
                cancellation of laziness, but be advised that
                doing so increases the danger of OOM due to
                callback flooding.

        rcupdate.rcu_task_stall_info= [KNL]
                Set initial timeout in jiffies for RCU task stall
```

```
                 informational messages, which give some indication
                 of the problem for those not patient enough to
                 wait for ten minutes.  Informational messages are
                 only printed prior to the stall-warning message
                 for a given grace period. Disable with a value
                 less than or equal to zero.  Defaults to ten
                 seconds.  A change in value does not take effect
                 until the beginning of the next grace period.

rcupdate.rcu_task_stall_info_mult= [KNL]
                 Multiplier for time interval between successive
                 RCU task stall informational messages for a given
                 RCU tasks grace period.  This value is clamped
                 to one through ten, inclusive.  It defaults to
                 the value three, so that the first informational
                 message is printed 10 seconds into the grace
                 period, the second at 40 seconds, the third at
                 160 seconds, and then the stall warning at 600
                 seconds would prevent a fourth at 640 seconds.

rcupdate.rcu_task_stall_timeout= [KNL]
                 Set timeout in jiffies for RCU task stall
                 warning messages.  Disable with a value less
                 than or equal to zero.  Defaults to ten minutes.
                 A change in value does not take effect until
                 the beginning of the next grace period.

rcupdate.rcu_tasks_lazy_ms= [KNL]
                 Set timeout in milliseconds RCU Tasks asynchronous
                 callback batching for call_rcu_tasks().
                 A negative value will take the default.  A value
                 of zero will disable batching.  Batching is
                 always disabled for synchronize_rcu_tasks().

rcupdate.rcu_tasks_rude_lazy_ms= [KNL]
                 Set timeout in milliseconds RCU Tasks
                 Rude asynchronous callback batching for
                 call_rcu_tasks_rude().  A negative value
                 will take the default.  A value of zero will
                 disable batching.  Batching is always disabled
                 for synchronize_rcu_tasks_rude().

rcupdate.rcu_tasks_trace_lazy_ms= [KNL]
                 Set timeout in milliseconds RCU Tasks
                 Trace asynchronous callback batching for
                 call_rcu_tasks_trace().  A negative value
                 will take the default.  A value of zero will
                 disable batching.  Batching is always disabled
                 for synchronize_rcu_tasks_trace().

rcupdate.rcu_self_test= [KNL]
```

```
                        Run the RCU early boot self tests

        rdinit=         [KNL]
                        Format: <full_path>
                        Run specified binary instead of /init from the ramdisk,
                        used for early userspace startup. See initrd.

        rdrand=         [X86]
                        force - Override the decision by the kernel to hide the
                                advertisement of RDRAND support (this affects
                                certain AMD processors because of buggy BIOS
                                support, specifically around the suspend/resume
                                path).

        rdt=            [HW,X86,RDT]
                        Turn on/off individual RDT features. List is:
                        cmt, mbmtotal, mbmlocal, l3cat, l3cdp, l2cat, l2cdp,
                        mba, smba, bmec.
                        E.g. to turn on cmt and turn off mba use:
                                rdt=cmt,!mba

        reboot=         [KNL]
                        Format (x86 or x86_64):
                                [w[arm] | c[old] | h[ard] | s[oft] | g[pio]] |␣
↪d[efault] \
                                [[,]s[mp]#### \
                                [[,]b[ios] | a[cpi] | k[bd] | t[riple] | e[fi]␣
↪| p[ci]] \
                                [[,]f[orce]
                        Where reboot_mode is one of warm (soft) or cold (hard)␣
↪or gpio
                                        (prefix with 'panic_' to set mode for␣
↪panic
                                        reboot only),
                              reboot_type is one of bios, acpi, kbd, triple,␣
↪efi, or pci,
                              reboot_force is either force or not specified,
                              reboot_cpu is s[mp]#### with #### being the␣
↪processor
                                        to be used for rebooting.

        refscale.holdoff= [KNL]
                        Set test-start holdoff period.  The purpose of
                        this parameter is to delay the start of the
                        test until boot completes in order to avoid
                        interference.

        refscale.lookup_instances= [KNL]
                        Number of data elements to use for the forms of
                        SLAB_TYPESAFE_BY_RCU testing.  A negative number
                        is negated and multiplied by nr_cpu_ids, while
```

```
                        zero specifies nr_cpu_ids.

        refscale.loops= [KNL]
                        Set the number of loops over the synchronization
                        primitive under test.  Increasing this number
                        reduces noise due to loop start/end overhead,
                        but the default has already reduced the per-pass
                        noise to a handful of picoseconds on ca. 2020
                        x86 laptops.

        refscale.nreaders= [KNL]
                        Set number of readers.  The default value of -1
                        selects N, where N is roughly 75% of the number
                        of CPUs.  A value of zero is an interesting choice.

        refscale.nruns= [KNL]
                        Set number of runs, each of which is dumped onto
                        the console log.

        refscale.readdelay= [KNL]
                        Set the read-side critical-section duration,
                        measured in microseconds.

        refscale.scale_type= [KNL]
                        Specify the read-protection implementation to test.

        refscale.shutdown= [KNL]
                        Shut down the system at the end of the performance
                        test.  This defaults to 1 (shut it down) when
                        refscale is built into the kernel and to 0 (leave
                        it running) when refscale is built as a module.

        refscale.verbose= [KNL]
                        Enable additional printk() statements.

        refscale.verbose_batched= [KNL]
                        Batch the additional printk() statements.  If zero
                        (the default) or negative, print everything. ␣
↪Otherwise,
                        print every Nth verbose statement, where N is the value
                        specified.

        regulator_ignore_unused
                        [REGULATOR]
                        Prevents regulator framework from disabling regulators
                        that are unused, due no driver claiming them. This may
                        be useful for debug and development, but should not be
                        needed on a platform with proper driver support.

        relax_domain_level=
                        [KNL, SMP] Set scheduler's default relax_domain_level.
```

```
                        See Documentation/admin-guide/cgroup-v1/cpusets.rst.

        reserve=        [KNL,BUGS] Force kernel to ignore I/O ports or memory
                        Format: <base1>,<size1>[,<base2>,<size2>,...]
                        Reserve I/O ports or memory so the kernel won't use
                        them.  If <base> is less than 0x10000, the region
                        is assumed to be I/O ports; otherwise it is memory.

        reservetop=     [X86-32]
                        Format: nn[KMG]
                        Reserves a hole at the top of the kernel virtual
                        address space.

        reset_devices   [KNL] Force drivers to reset the underlying device
                        during initialization.

        resume=         [SWSUSP]
                        Specify the partition device for software suspend
                        Format:
                        {/dev/<dev> | PARTUUID=<uuid> | <int>:<int> | <hex>}

        resume_offset=  [SWSUSP]
                        Specify the offset from the beginning of the partition
                        given by "resume=" at which the swap header is located,
                        in <PAGE_SIZE> units (needed only for swap files).
                        See  Documentation/power/swsusp-and-swap-files.rst

        resumedelay=    [HIBERNATION] Delay (in seconds) to pause before␣
↪attempting to
                        read the resume files

        resumewait      [HIBERNATION] Wait (indefinitely) for resume device to␣
↪show up.
                        Useful for devices that are detected asynchronously
                        (e.g. USB and MMC devices).

        retain_initrd   [RAM] Keep initrd memory after extraction. After boot,␣
↪it will
                        be accessible via /sys/firmware/initrd.

        retbleed=       [X86] Control mitigation of RETBleed (Arbitrary
                        Speculative Code Execution with Return Instructions)
                        vulnerability.

                        AMD-based UNRET and IBPB mitigations alone do not stop
                        sibling threads from influencing the predictions of␣
↪other
                        sibling threads. For that reason, STIBP is used on pro-
                        cessors that support it, and mitigate SMT on processors
                        that don't.
```

```
                        off          - no mitigation
                        auto         - automatically select a migitation
                        auto,nosmt   - automatically select a mitigation,
                                       disabling SMT if necessary for
                                       the full mitigation (only on Zen1
                                       and older without STIBP).
                        ibpb         - On AMD, mitigate short speculation
                                       windows on basic block boundaries too.
                                       Safe, highest perf impact. It also
                                       enables STIBP if present. Not suitable
                                       on Intel.
                        ibpb,nosmt   - Like "ibpb" above but will disable SMT
                                       when STIBP is not available. This is
                                       the alternative for systems which do not
                                       have STIBP.
                        unret        - Force enable untrained return thunks,
                                       only effective on AMD f15h-f17h based
                                       systems.
                        unret,nosmt  - Like unret, but will disable SMT when␣
↪STIBP
                                       is not available. This is the␣
↪alternative for
                                       systems which do not have STIBP.

                        Selecting 'auto' will choose a mitigation method at run
                        time according to the CPU.

                        Not specifying this option is equivalent to␣
↪retbleed=auto.

        rfkill.default_state=
                0       "airplane mode".  All wifi, bluetooth, wimax, gps, fm,
                        etc. communication is blocked by default.
                1       Unblocked.

        rfkill.master_switch_mode=
                0       The "airplane mode" button does nothing.
                1       The "airplane mode" button toggles between everything
                        blocked and the previous configuration.
                2       The "airplane mode" button toggles between everything
                        blocked and everything unblocked.

        rhash_entries=  [KNL,NET]
                        Set number of hash buckets for route cache

        ring3mwait=disable
                        [KNL] Disable ring 3 MONITOR/MWAIT feature on supported
                        CPUs.

        riscv_isa_fallback [RISCV]
                        When CONFIG_RISCV_ISA_FALLBACK is not enabled, permit
```

```
                falling back to detecting extension support by parsing
                "riscv,isa" property on devicetree systems when the
                replacement properties are not found. See the Kconfig
                entry for RISCV_ISA_FALLBACK.

ro              [KNL] Mount root device read-only on boot

rodata=         [KNL]
        on      Mark read-only kernel memory as read-only (default).
        off     Leave read-only kernel memory writable for debugging.
        full    Mark read-only kernel memory and aliases as read-only
                [arm64]

rockchip.usb_uart
                Enable the uart passthrough on the designated usb port
                on Rockchip SoCs. When active, the signals of the
                debug-uart get routed to the D+ and D- pins of the usb
                port and the regular usb controller gets disabled.

root=           [KNL] Root filesystem
                Usually this a a block device specifier of some kind,
                see the early_lookup_bdev comment in
                block/early-lookup.c for details.
                Alternatively this can be "ram" for the legacy initial
                ramdisk, "nfs" and "cifs" for root on a network file
                system, or "mtd" and "ubi" for mounting from raw flash.

rootdelay=      [KNL] Delay (in seconds) to pause before attempting to
                mount the root filesystem

rootflags=      [KNL] Set root filesystem mount option string

rootfstype=     [KNL] Set root filesystem type

rootwait        [KNL] Wait (indefinitely) for root device to show up.
                Useful for devices that are detected asynchronously
                (e.g. USB and MMC devices).

rootwait=       [KNL] Maximum time (in seconds) to wait for root device
                to show up before attempting to mount the root
                filesystem.

rproc_mem=nn[KMG][@address]
                [KNL,ARM,CMA] Remoteproc physical memory block.
                Memory area to be used by remote processor image,
                managed by CMA.

rw              [KNL] Mount root device read-write on boot

S               [KNL] Run init in single mode
```

```
s390_iommu=     [HW,S390]
                Set s390 IOTLB flushing mode
        strict
                With strict flushing every unmap operation will result
                in an IOTLB flush. Default is lazy flushing before
                reuse, which is faster. Deprecated, equivalent to
                iommu.strict=1.

s390_iommu_aperture=    [KNL,S390]
                Specifies the size of the per device DMA address space
                accessible through the DMA and IOMMU APIs as a decimal
                factor of the size of main memory.
                The default is 1 meaning that one can concurrently use
                as many DMA addresses as physical memory is installed,
                if supported by hardware, and thus map all of memory
                once. With a value of 2 one can map all of memory twice
                and so on. As a special case a factor of 0 imposes no
                restrictions other than those given by hardware at the
                cost of significant additional memory use for tables.

sa1100ir        [NET]
                See drivers/net/irda/sa1100_ir.c.

sched_verbose   [KNL] Enables verbose scheduler debug messages.

schedstats=     [KNL,X86] Enable or disable scheduled statistics.
                Allowed values are enable and disable. This feature
                incurs a small amount of overhead in the scheduler
                but is useful for debugging and performance tuning.

sched_thermal_decay_shift=
                [KNL, SMP] Set a decay shift for scheduler thermal
                pressure signal. Thermal pressure signal follows the
                default decay period of other scheduler pelt
                signals(usually 32 ms but configurable). Setting
                sched_thermal_decay_shift will left shift the decay
                period for the thermal pressure signal by the shift
                value.
                i.e. with the default pelt decay period of 32 ms
                sched_thermal_decay_shift   thermal pressure decay pr
                        1                       64 ms
                        2                       128 ms
                and so on.
                Format: integer between 0 and 10
                Default is 0.

scftorture.holdoff= [KNL]
                Number of seconds to hold off before starting
                test.  Defaults to zero for module insertion and
                to 10 seconds for built-in smp_call_function()
                tests.
```

```
scftorture.longwait= [KNL]
                Request ridiculously long waits randomly selected
                up to the chosen limit in seconds.  Zero (the
                default) disables this feature.  Please note
                that requesting even small non-zero numbers of
                seconds can result in RCU CPU stall warnings,
                softlockup complaints, and so on.

scftorture.nthreads= [KNL]
                Number of kthreads to spawn to invoke the
                smp_call_function() family of functions.
                The default of -1 specifies a number of kthreads
                equal to the number of CPUs.

scftorture.onoff_holdoff= [KNL]
                Number seconds to wait after the start of the
                test before initiating CPU-hotplug operations.

scftorture.onoff_interval= [KNL]
                Number seconds to wait between successive
                CPU-hotplug operations.  Specifying zero (which
                is the default) disables CPU-hotplug operations.

scftorture.shutdown_secs= [KNL]
                The number of seconds following the start of the
                test after which to shut down the system.  The
                default of zero avoids shutting down the system.
                Non-zero values are useful for automated tests.

scftorture.stat_interval= [KNL]
                The number of seconds between outputting the
                current test statistics to the console.  A value
                of zero disables statistics output.

scftorture.stutter_cpus= [KNL]
                The number of jiffies to wait between each change
                to the set of CPUs under test.

scftorture.use_cpus_read_lock= [KNL]
                Use use_cpus_read_lock() instead of the default
                preempt_disable() to disable CPU hotplug
                while invoking one of the smp_call_function*()
                functions.

scftorture.verbose= [KNL]
                Enable additional printk() statements.

scftorture.weight_single= [KNL]
                The probability weighting to use for the
                smp_call_function_single() function with a zero
```

```
                        "wait" parameter.  A value of -1 selects the
                        default if all other weights are -1.  However,
                        if at least one weight has some other value, a
                        value of -1 will instead select a weight of zero.

        scftorture.weight_single_wait= [KNL]
                        The probability weighting to use for the
                        smp_call_function_single() function with a
                        non-zero "wait" parameter.  See weight_single.

        scftorture.weight_many= [KNL]
                        The probability weighting to use for the
                        smp_call_function_many() function with a zero
                        "wait" parameter.  See weight_single.
                        Note well that setting a high probability for
                        this weighting can place serious IPI load
                        on the system.

        scftorture.weight_many_wait= [KNL]
                        The probability weighting to use for the
                        smp_call_function_many() function with a
                        non-zero "wait" parameter.  See weight_single
                        and weight_many.

        scftorture.weight_all= [KNL]
                        The probability weighting to use for the
                        smp_call_function_all() function with a zero
                        "wait" parameter.  See weight_single and
                        weight_many.

        scftorture.weight_all_wait= [KNL]
                        The probability weighting to use for the
                        smp_call_function_all() function with a
                        non-zero "wait" parameter.  See weight_single
                        and weight_many.

        skew_tick=      [KNL] Offset the periodic timer tick per cpu to␣
↪mitigate
                        xtime_lock contention on larger systems, and/or RCU␣
↪lock
                        contention on all systems with CONFIG_MAXSMP set.
                        Format: { "0" | "1" }
                        0 -- disable. (may be 1 via CONFIG_CMDLINE="skew_
↪tick=1"
                        1 -- enable.
                        Note: increases power consumption, thus should only be
                        enabled if running jitter sensitive (HPC/RT) workloads.

        security=       [SECURITY] Choose a legacy "major" security module to
                        enable at boot. This has been deprecated by the
                        "lsm=" parameter.
```

```
        selinux=        [SELINUX] Disable or enable SELinux at boot time.
                        Format: { "0" | "1" }
                        See security/selinux/Kconfig help text.
                        0 -- disable.
                        1 -- enable.
                        Default value is 1.

        serialnumber    [BUGS=X86-32]

        sev=option[,option...] [X86-64] See Documentation/arch/x86/x86_64/
↪boot-options.rst

        shapers=        [NET]
                        Maximal number of shapers.

        show_lapic=     [APIC,X86] Advanced Programmable Interrupt Controller
                        Limit apic dumping. The parameter defines the maximal
                        number of local apics being dumped. Also it is possible
                        to set it to "all" by meaning -- no limit here.
                        Format: { 1 (default) | 2 | ... | all }.
                        The parameter valid if only apic=debug or
                        apic=verbose is specified.
                        Example: apic=debug show_lapic=all

        simeth=         [IA-64]
        simscsi=

        slram=          [HW,MTD]

        slab_merge      [MM]
                        Enable merging of slabs with similar size when the
                        kernel is built without CONFIG_SLAB_MERGE_DEFAULT.

        slab_nomerge    [MM]
                        Disable merging of slabs with similar size. May be
                        necessary if there is some reason to distinguish
                        allocs to different slabs, especially in hardened
                        environments where the risk of heap overflows and
                        layout control by attackers can usually be
                        frustrated by disabling merging. This will reduce
                        most of the exposure of a heap attack to a single
                        cache (risks via metadata attacks are mostly
                        unchanged). Debug options disable merging on their
                        own.
                        For more information see Documentation/mm/slub.rst.

        slab_max_order= [MM, SLAB]
                        Determines the maximum allowed order for slabs.
                        A high setting may cause OOMs due to memory
                        fragmentation.  Defaults to 1 for systems with
```

```
                more than 32MB of RAM, 0 otherwise.

slub_debug[=options[,slabs][;[options[,slabs]]...]      [MM, SLUB]
                Enabling slub_debug allows one to determine the
                culprit if slab objects become corrupted. Enabling
                slub_debug can create guard zones around objects and
                may poison objects when not in use. Also tracks the
                last alloc / free. For more information see
                Documentation/mm/slub.rst.

slub_max_order= [MM, SLUB]
                Determines the maximum allowed order for slabs.
                A high setting may cause OOMs due to memory
                fragmentation. For more information see
                Documentation/mm/slub.rst.

slub_min_objects=       [MM, SLUB]
                The minimum number of objects per slab. SLUB will
                increase the slab order up to slub_max_order to
                generate a sufficiently large slab able to contain
                the number of objects indicated. The higher the number
                of objects the smaller the overhead of tracking slabs
                and the less frequently locks need to be acquired.
                For more information see Documentation/mm/slub.rst.

slub_min_order= [MM, SLUB]
                Determines the minimum page order for slabs. Must be
                lower than slub_max_order.
                For more information see Documentation/mm/slub.rst.

slub_merge      [MM, SLUB]
                Same with slab_merge.

slub_nomerge    [MM, SLUB]
                Same with slab_nomerge. This is supported for legacy.
                See slab_nomerge for more information.

smart2=         [HW]
                Format: <io1>[,<io2>[,...,<io8>]]

smp.csd_lock_timeout= [KNL]
                Specify the period of time in milliseconds
                that smp_call_function() and friends will wait
                for a CPU to release the CSD lock.  This is
                useful when diagnosing bugs involving CPUs
                disabling interrupts for extended periods
                of time.  Defaults to 5,000 milliseconds, and
                setting a value of zero disables this feature.
                This feature may be more efficiently disabled
                using the csdlock_debug- kernel parameter.
```

```
        smp.panic_on_ipistall= [KNL]
                        If a csd_lock_timeout extends for more than
                        the specified number of milliseconds, panic the
                        system.  By default, let CSD-lock acquisition
                        take as long as they take.  Specifying 300,000
                        for this value provides a 5-minute timeout.

        smsc-ircc2.nopnp        [HW] Don't use PNP to discover SMC devices
        smsc-ircc2.ircc_cfg=    [HW] Device configuration I/O port
        smsc-ircc2.ircc_sir=    [HW] SIR base I/O port
        smsc-ircc2.ircc_fir=    [HW] FIR base I/O port
        smsc-ircc2.ircc_irq=    [HW] IRQ line
        smsc-ircc2.ircc_dma=    [HW] DMA channel
        smsc-ircc2.ircc_transceiver= [HW] Transceiver type:
                                0: Toshiba Satellite 1800 (GP data pin select)
                                1: Fast pin select (default)
                                2: ATC IRMode

        smt=            [KNL,MIPS,S390] Set the maximum number of threads␣
↪(logical
                        CPUs) to use per physical CPU on systems capable of
                        symmetric multithreading (SMT). Will be capped to the
                        actual hardware limit.
                        Format: <integer>
                        Default: -1 (no limit)

        softlockup_panic=
                        [KNL] Should the soft-lockup detector generate panics.
                        Format: 0 | 1

                        A value of 1 instructs the soft-lockup detector
                        to panic the machine when a soft-lockup occurs. It is
                        also controlled by the kernel.softlockup_panic sysctl
                        and CONFIG_BOOTPARAM_SOFTLOCKUP_PANIC, which is the
                        respective build-time switch to that functionality.

        softlockup_all_cpu_backtrace=
                        [KNL] Should the soft-lockup detector generate
                        backtraces on all cpus.
                        Format: 0 | 1

        sonypi.*=       [HW] Sony Programmable I/O Control Device driver
                        See Documentation/admin-guide/laptops/sonypi.rst

        spectre_v2=     [X86] Control mitigation of Spectre variant 2
                        (indirect branch speculation) vulnerability.
                        The default operation protects the kernel from
                        user space attacks.

                        on   - unconditionally enable, implies
                               spectre_v2_user=on
```

```
                    off  - unconditionally disable, implies
                           spectre_v2_user=off
                    auto - kernel detects whether your CPU model is
                           vulnerable

                    Selecting 'on' will, and 'auto' may, choose a
                    mitigation method at run time according to the
                    CPU, the available microcode, the setting of the
                    CONFIG_RETPOLINE configuration option, and the
                    compiler with which the kernel was built.

                    Selecting 'on' will also enable the mitigation
                    against user space to user space task attacks.

                    Selecting 'off' will disable both the kernel and
                    the user space protections.

                    Specific mitigations can also be selected manually:

                    retpoline         - replace indirect branches
                    retpoline,generic - Retpolines
                    retpoline,lfence  - LFENCE; indirect branch
                    retpoline,amd     - alias for retpoline,lfence
                    eibrs             - Enhanced/Auto IBRS
                    eibrs,retpoline   - Enhanced/Auto IBRS + Retpolines
                    eibrs,lfence      - Enhanced/Auto IBRS + LFENCE
                    ibrs              - use IBRS to protect kernel

                    Not specifying this option is equivalent to
                    spectre_v2=auto.

spectre_v2_user=
                    [X86] Control mitigation of Spectre variant 2
                    (indirect branch speculation) vulnerability between
                    user space tasks

                    on      - Unconditionally enable mitigations. Is
                              enforced by spectre_v2=on

                    off     - Unconditionally disable mitigations. Is
                              enforced by spectre_v2=off

                    prctl   - Indirect branch speculation is enabled,
                              but mitigation can be enabled via prctl
                              per thread.  The mitigation control state
                              is inherited on fork.

                    prctl,ibpb
                            - Like "prctl" above, but only STIBP is
                              controlled per thread. IBPB is issued
                              always when switching between different user
```

```
                                  space processes.

                        seccomp
                                - Same as "prctl" above, but all seccomp
                                  threads will enable the mitigation unless
                                  they explicitly opt out.

                        seccomp,ibpb
                                - Like "seccomp" above, but only STIBP is
                                  controlled per thread. IBPB is issued
                                  always when switching between different
                                  user space processes.

                        auto    - Kernel selects the mitigation depending on
                                  the available CPU features and vulnerability.

                        Default mitigation: "prctl"

                        Not specifying this option is equivalent to
                        spectre_v2_user=auto.

        spec_rstack_overflow=
                        [X86] Control RAS overflow mitigation on AMD Zen CPUs

                        off             - Disable mitigation
                        microcode       - Enable microcode mitigation only
                        safe-ret        - Enable sw-only safe RET mitigation␣
↪(default)
                        ibpb            - Enable mitigation by issuing IBPB on
                                          kernel entry
                        ibpb-vmexit     - Issue IBPB only on VMEXIT
                                          (cloud-specific mitigation)

        spec_store_bypass_disable=
                        [HW] Control Speculative Store Bypass (SSB) Disable␣
↪mitigation
                        (Speculative Store Bypass vulnerability)

                        Certain CPUs are vulnerable to an exploit against a
                        a common industry wide performance optimization known
                        as "Speculative Store Bypass" in which recent stores
                        to the same memory location may not be observed by
                        later loads during speculative execution. The idea
                        is that such stores are unlikely and that they can
                        be detected prior to instruction retirement at the
                        end of a particular speculation execution window.

                        In vulnerable processors, the speculatively forwarded
                        store can be used in a cache side channel attack, for
                        example to read memory to which the attacker does not
                        directly have access (e.g. inside sandboxed code).
```

```
                        This parameter controls whether the Speculative Store
                        Bypass optimization is used.

                        On x86 the options are:

                        on      - Unconditionally disable Speculative Store␣
↪Bypass
                        off     - Unconditionally enable Speculative Store␣
↪Bypass
                        auto    - Kernel detects whether the CPU model␣
↪contains an
                                  implementation of Speculative Store Bypass␣
↪and
                                  picks the most appropriate mitigation. If the
                                  CPU is not vulnerable, "off" is selected. If␣
↪the
                                  CPU is vulnerable the default mitigation is
                                  architecture and Kconfig dependent. See␣
↪below.
                        prctl   - Control Speculative Store Bypass per thread
                                  via prctl. Speculative Store Bypass is␣
↪enabled
                                  for a process by default. The state of the␣
↪control
                                  is inherited on fork.
                        seccomp - Same as "prctl" above, but all seccomp␣
↪threads
                                  will disable SSB unless they explicitly opt␣
↪out.

                        Default mitigations:
                        X86:    "prctl"

                        On powerpc the options are:

                        on,auto - On Power8 and Power9 insert a␣
↪store-forwarding
                                  barrier on kernel entry and exit. On Power7
                                  perform a software flush on kernel entry and
                                  exit.
                        off     - No action.

                        Not specifying this option is equivalent to
                        spec_store_bypass_disable=auto.

        spia_io_base=   [HW,MTD]
        spia_fio_base=
        spia_pedr=
        spia_peddr=
```

```
        split_lock_detect=
                        [X86] Enable split lock detection or bus lock detection

                        When enabled (and if hardware support is present),␣
↪atomic
                        instructions that access data across cache line
                        boundaries will result in an alignment check exception
                        for split lock detection or a debug exception for
                        bus lock detection.

                        off     - not enabled

                        warn    - the kernel will emit rate-limited warnings
                                  about applications triggering the #AC
                                  exception or the #DB exception. This mode is
                                  the default on CPUs that support split lock
                                  detection or bus lock detection. Default
                                  behavior is by #AC if both features are
                                  enabled in hardware.

                        fatal   - the kernel will send SIGBUS to applications
                                  that trigger the #AC exception or the #DB
                                  exception. Default behavior is by #AC if
                                  both features are enabled in hardware.

                        ratelimit:N -
                                  Set system wide rate limit to N bus locks
                                  per second for bus lock detection.
                                  0 < N <= 1000.

                                  N/A for split lock detection.

                        If an #AC exception is hit in the kernel or in
                        firmware (i.e. not while executing in user mode)
                        the kernel will oops in either "warn" or "fatal"
                        mode.

                        #DB exception for bus lock is triggered only when
                        CPL > 0.

        srbds=          [X86,INTEL]
                        Control the Special Register Buffer Data Sampling
                        (SRBDS) mitigation.

                        Certain CPUs are vulnerable to an MDS-like
                        exploit which can leak bits from the random
                        number generator.

                        By default, this issue is mitigated by
                        microcode.  However, the microcode fix can cause
```

```
                the RDRAND and RDSEED instructions to become
                much slower.  Among other effects, this will
                result in reduced throughput from /dev/urandom.

                The microcode mitigation can be disabled with
                the following option:

                off:    Disable mitigation and remove
                        performance impact to RDRAND and RDSEED

srcutree.big_cpu_lim [KNL]
                Specifies the number of CPUs constituting a
                large system, such that srcu_struct structures
                should immediately allocate an srcu_node array.
                This kernel-boot parameter defaults to 128,
                but takes effect only when the low-order four
                bits of srcutree.convert_to_big is equal to 3
                (decide at boot).

srcutree.convert_to_big [KNL]
                Specifies under what conditions an SRCU tree
                srcu_struct structure will be converted to big
                form, that is, with an rcu_node tree:

                           0:  Never.
                           1:  At init_srcu_struct() time.
                           2:  When rcutorture decides to.
                           3:  Decide at boot time (default).
                        0x1X:  Above plus if high contention.

                Either way, the srcu_node tree will be sized based
                on the actual runtime number of CPUs (nr_cpu_ids)
                instead of the compile-time CONFIG_NR_CPUS.

srcutree.counter_wrap_check [KNL]
                Specifies how frequently to check for
                grace-period sequence counter wrap for the
                srcu_data structure's ->srcu_gp_seq_needed field.
                The greater the number of bits set in this kernel
                parameter, the less frequently counter wrap will
                be checked for.  Note that the bottom two bits
                are ignored.

srcutree.exp_holdoff [KNL]
                Specifies how many nanoseconds must elapse
                since the end of the last SRCU grace period for
                a given srcu_struct until the next normal SRCU
                grace period will be considered for automatic
                expediting.  Set to zero to disable automatic
                expediting.
```

```
srcutree.srcu_max_nodelay [KNL]
                Specifies the number of no-delay instances
                per jiffy for which the SRCU grace period
                worker thread will be rescheduled with zero
                delay. Beyond this limit, worker thread will
                be rescheduled with a sleep delay of one jiffy.

srcutree.srcu_max_nodelay_phase [KNL]
                Specifies the per-grace-period phase, number of
                non-sleeping polls of readers. Beyond this limit,
                grace period worker thread will be rescheduled
                with a sleep delay of one jiffy, between each
                rescan of the readers, for a grace period phase.

srcutree.srcu_retry_check_delay [KNL]
                Specifies number of microseconds of non-sleeping
                delay between each non-sleeping poll of readers.

srcutree.small_contention_lim [KNL]
                Specifies the number of update-side contention
                events per jiffy will be tolerated before
                initiating a conversion of an srcu_struct
                structure to big form.  Note that the value of
                srcutree.convert_to_big must have the 0x10 bit
                set for contention-based conversions to occur.

ssbd=           [ARM64,HW]
                Speculative Store Bypass Disable control

                On CPUs that are vulnerable to the Speculative
                Store Bypass vulnerability and offer a
                firmware based mitigation, this parameter
                indicates how the mitigation should be used:

                force-on:  Unconditionally enable mitigation for
                           for both kernel and userspace
                force-off: Unconditionally disable mitigation for
                           for both kernel and userspace
                kernel:    Always enable mitigation in the
                           kernel, and offer a prctl interface
                           to allow userspace to register its
                           interest in being mitigated too.

stack_guard_gap=        [MM]
                override the default stack gap protection. The value
                is in page units and it defines how many pages prior
                to (for stacks growing down) resp. after (for stacks
                growing up) the main stack are reserved for no other
                mapping. Default value is 256 pages.

stack_depot_disable= [KNL]
```

```
                        Setting this to true through kernel command line will
                        disable the stack depot thereby saving the static␣
↪memory
                        consumed by the stack hash table. By default this is␣
↪set
                        to false.

        stacktrace      [FTRACE]
                        Enabled the stack tracer on boot up.

        stacktrace_filter=[function-list]
                        [FTRACE] Limit the functions that the stack tracer
                        will trace at boot up. function-list is a␣
↪comma-separated
                        list of functions. This list can be changed at run
                        time by the stack_trace_filter file in the debugfs
                        tracing directory. Note, this enables stack tracing
                        and the stacktrace above is not needed.

        sti=            [PARISC,HW]
                        Format: <num>
                        Set the STI (builtin display/keyboard on the HP-PARISC
                        machines) console (graphic card) which should be used
                        as the initial boot-console.
                        See also comment in drivers/video/console/sticore.c.

        sti_font=       [HW]
                        See comment in drivers/video/console/sticore.c.

        stifb=          [HW]
                        Format: bpp:<bpp1>[:<bpp2>[:<bpp3>...]]

        strict_sas_size=
                        [X86]
                        Format: <bool>
                        Enable or disable strict sigaltstack size checks
                        against the required signal frame size which
                        depends on the supported FPU features. This can
                        be used to filter out binaries which have
                        not yet been made aware of AT_MINSIGSTKSZ.

        stress_hpt      [PPC]
                        Limits the number of kernel HPT entries in the hash
                        page table to increase the rate of hash page table
                        faults on kernel addresses.

        stress_slb      [PPC]
                        Limits the number of kernel SLB entries, and flushes
                        them frequently to increase the rate of SLB faults
                        on kernel addresses.
```

```
        sunrpc.min_resvport=
        sunrpc.max_resvport=
                        [NFS,SUNRPC]
                        SunRPC servers often require that client requests
                        originate from a privileged port (i.e. a port in the
                        range 0 < portnr < 1024).
                        An administrator who wishes to reserve some of these
                        ports for other uses may adjust the range that the
                        kernel's sunrpc client considers to be privileged
                        using these two parameters to set the minimum and
                        maximum port values.

        sunrpc.svc_rpc_per_connection_limit=
                        [NFS,SUNRPC]
                        Limit the number of requests that the server will
                        process in parallel from a single connection.
                        The default value is 0 (no limit).

        sunrpc.pool_mode=
                        [NFS]
                        Control how the NFS server code allocates CPUs to
                        service thread pools.  Depending on how many NICs
                        you have and where their interrupts are bound, this
                        option will affect which CPUs will do NFS serving.
                        Note: this parameter cannot be changed while the
                        NFS server is running.

                        auto        the server chooses an appropriate mode
                                    automatically using heuristics
                        global      a single global pool contains all CPUs
                        percpu      one pool for each CPU
                        pernode     one pool for each NUMA node (equivalent
                                    to global on non-NUMA machines)

        sunrpc.tcp_slot_table_entries=
        sunrpc.udp_slot_table_entries=
                        [NFS,SUNRPC]
                        Sets the upper limit on the number of simultaneous
                        RPC calls that can be sent from the client to a
                        server. Increasing these values may allow you to
                        improve throughput, but will also increase the
                        amount of memory reserved for use by the client.

        suspend.pm_test_delay=
                        [SUSPEND]
                        Sets the number of seconds to remain in a suspend test
                        mode before resuming the system (see
                        /sys/power/pm_test). Only available when CONFIG_PM_
↪DEBUG
                        is set. Default value is 5.
```

```
svm=            [PPC]
                Format: { on | off | y | n | 1 | 0 }
                This parameter controls use of the Protected
                Execution Facility on pSeries.

swiotlb=        [ARM,IA-64,PPC,MIPS,X86]
                Format: { <int> [,<int>] | force | noforce }
                <int> -- Number of I/O TLB slabs
                <int> -- Second integer after comma. Number of swiotlb
                         areas with their own lock. Will be rounded up
                         to a power of 2.
                force -- force using of bounce buffers even if they
                         wouldn't be automatically used by the kernel
                noforce -- Never use bounce buffers (for debugging)

switches=       [HW,M68k]

sysctl.*=       [KNL]
                Set a sysctl parameter, right before loading the init
                process, as if the value was written to the respective
                /proc/sys/... file. Both '.' and '/' are recognized as
                separators. Unrecognized parameters and invalid values
                are reported in the kernel log. Sysctls registered
                later by a loaded module cannot be set this way.
                Example: sysctl.vm.swappiness=40

sysrq_always_enabled
                [KNL]
                Ignore sysrq setting - this boot parameter will
                neutralize any effect of /proc/sys/kernel/sysrq.
                Useful for debugging.

tcpmhash_entries= [KNL,NET]
                Set the number of tcp_metrics_hash slots.
                Default value is 8192 or 16384 depending on total
                ram pages. This is used to specify the TCP metrics
                cache size. See Documentation/networking/ip-sysctl.rst
                "tcp_no_metrics_save" section for more details.

tdfx=           [HW,DRM]

test_suspend=   [SUSPEND]
                Format: { "mem" | "standby" | "freeze" }[,N]
                Specify "mem" (for Suspend-to-RAM) or "standby" (for
                standby suspend) or "freeze" (for suspend type freeze)
                as the system sleep state during system startup with
                the optional capability to repeat N number of times.
                The system is woken from this state using a
                wakeup-capable RTC alarm.

thash_entries=  [KNL,NET]
```

```
                        Set number of hash buckets for TCP connection

        thermal.act=    [HW,ACPI]
                        -1: disable all active trip points in all thermal zones
                        <degrees C>: override all lowest active trip points

        thermal.crt=    [HW,ACPI]
                        -1: disable all critical trip points in all thermal␣
↪zones
                        <degrees C>: override all critical trip points

        thermal.off=    [HW,ACPI]
                        1: disable ACPI thermal control

        thermal.psv=    [HW,ACPI]
                        -1: disable all passive trip points
                        <degrees C>: override all passive trip points to this
                        value

        thermal.tzp=    [HW,ACPI]
                        Specify global default ACPI thermal zone polling rate
                        <deci-seconds>: poll all this frequency
                        0: no polling (default)

        threadirqs      [KNL]
                        Force threading of all interrupt handlers except those
                        marked explicitly IRQF_NO_THREAD.

        topology=       [S390]
                        Format: {off | on}
                        Specify if the kernel should make use of the cpu
                        topology information if the hardware supports this.
                        The scheduler will make use of this information and
                        e.g. base its process migration decisions on it.
                        Default is on.

        topology_updates= [KNL, PPC, NUMA]
                        Format: {off}
                        Specify if the kernel should ignore (off)
                        topology updates sent by the hypervisor to this
                        LPAR.

        torture.disable_onoff_at_boot= [KNL]
                        Prevent the CPU-hotplug component of torturing
                        until after init has spawned.

        torture.ftrace_dump_at_shutdown= [KNL]
                        Dump the ftrace buffer at torture-test shutdown,
                        even if there were no errors.  This can be a
                        very costly operation when many torture tests
                        are running concurrently, especially on systems
```

```
                        with rotating-rust storage.

        torture.verbose_sleep_frequency= [KNL]
                        Specifies how many verbose printk()s should be
                        emitted between each sleep.  The default of zero
                        disables verbose-printk() sleeping.

        torture.verbose_sleep_duration= [KNL]
                        Duration of each verbose-printk() sleep in jiffies.

        tp720=          [HW,PS2]

        tpm_suspend_pcr=[HW,TPM]
                        Format: integer pcr id
                        Specify that at suspend time, the tpm driver
                        should extend the specified pcr with zeros,
                        as a workaround for some chips which fail to
                        flush the last written pcr on TPM_SaveState.
                        This will guarantee that all the other pcrs
                        are saved.

        tpm_tis.interrupts= [HW,TPM]
                        Enable interrupts for the MMIO based physical layer
                        for the FIFO interface. By default it is set to false
                        (0). For more information about TPM hardware interfaces
                        defined by Trusted Computing Group (TCG) see
                        https://trustedcomputinggroup.org/resource/
↪pc-client-platform-tpm-profile-ptp-specification/

        tp_printk       [FTRACE]
                        Have the tracepoints sent to printk as well as the
                        tracing ring buffer. This is useful for early boot up
                        where the system hangs or reboots and does not give the
                        option for reading the tracing buffer or performing a
                        ftrace_dump_on_oops.

                        To turn off having tracepoints sent to printk,
                         echo 0 > /proc/sys/kernel/tracepoint_printk
                        Note, echoing 1 into this file without the
                        tracepoint_printk kernel cmdline option has no effect.

                        The tp_printk_stop_on_boot (see below) can also be used
                        to stop the printing of events to console at
                        late_initcall_sync.

                        ** CAUTION **

                        Having tracepoints sent to printk() and activating high
                        frequency tracepoints such as irq or sched, can cause
                        the system to live lock.
```

```
        tp_printk_stop_on_boot [FTRACE]
                        When tp_printk (above) is set, it can cause a lot of␣
↪noise
                        on the console. It may be useful to only include the
                        printing of events during boot up, as user space may
                        make the system inoperable.

                        This command line option will stop the printing of␣
↪events
                        to console at the late_initcall_sync() time frame.

        trace_buf_size=nn[KMG]
                        [FTRACE] will set tracing buffer size on each cpu.

        trace_clock=    [FTRACE] Set the clock used for tracing events
                        at boot up.
                        local - Use the per CPU time stamp counter
                                (converted into nanoseconds). Fast, but
                                depending on the architecture, may not be
                                in sync between CPUs.
                        global - Event time stamps are synchronize across
                                CPUs. May be slower than the local clock,
                                but better for some race conditions.
                        counter - Simple counting of events (1, 2, ..)
                                note, some counts may be skipped due to the
                                infrastructure grabbing the clock more than
                                once per event.
                        uptime - Use jiffies as the time stamp.
                        perf - Use the same clock that perf uses.
                        mono - Use ktime_get_mono_fast_ns() for time stamps.
                        mono_raw - Use ktime_get_raw_fast_ns() for time
                                stamps.
                        boot - Use ktime_get_boot_fast_ns() for time stamps.
                        Architectures may add more clocks. See
                        Documentation/trace/ftrace.rst for more details.

        trace_event=[event-list]
                        [FTRACE] Set and start specified trace events in order
                        to facilitate early boot debugging. The event-list is a
                        comma-separated list of trace events to enable. See
                        also Documentation/trace/events.rst

        trace_instance=[instance-info]
                        [FTRACE] Create a ring buffer instance early in boot␣
↪up.
                        This will be listed in:

                                /sys/kernel/tracing/instances

                        Events can be enabled at the time the instance is␣
↪created
```

```
                        via:

                                trace_instance=<name>,<system1>:<event1>,
↪<system2>:<event2>

                        Note, the "<system*>:" portion is optional if the␣
↪event is
                        unique.

                                trace_instance=foo,sched:sched_switch,irq_
↪handler_entry,initcall

                        will enable the "sched_switch" event (note, the␣
↪"sched:" is optional, and
                        the same thing would happen if it was left off). The␣
↪irq_handler_entry
                        event, and all events under the "initcall" system.

        trace_options=[option-list]
                        [FTRACE] Enable or disable tracer options at boot.
                        The option-list is a comma delimited list of options
                        that can be enabled or disabled just as if you were
                        to echo the option name into

                            /sys/kernel/tracing/trace_options

                        For example, to enable stacktrace option (to dump the
                        stack trace of each event), add to the command line:

                              trace_options=stacktrace

                        See also Documentation/trace/ftrace.rst "trace options"
                        section.

        trace_trigger=[trigger-list]
                        [FTRACE] Add a event trigger on specific events.
                        Set a trigger on top of a specific event, with an␣
↪optional
                        filter.

                        The format is is "trace_trigger=<event>.<trigger>[ if
↪<filter>],..."
                        Where more than one trigger may be specified that are␣
↪comma deliminated.

                        For example:

                          trace_trigger="sched_switch.stacktrace if prev_state␣
↪== 2"

                        The above will enable the "stacktrace" trigger on the␣
```

```
↪"sched_switch"
                        event but only trigger it if the "prev_state" of the␣
↪"sched_switch"
                        event is "2" (TASK_UNINTERUPTIBLE).

                        See also "Event triggers" in Documentation/trace/
↪events.rst

        traceoff_on_warning
                        [FTRACE] enable this option to disable tracing when a
                        warning is hit. This turns off "tracing_on". Tracing␣
↪can
                        be enabled again by echoing '1' into the "tracing_on"
                        file located in /sys/kernel/tracing/

                        This option is useful, as it disables the trace before
                        the WARNING dump is called, which prevents the trace to
                        be filled with content caused by the warning output.

                        This option can also be set at run time via the sysctl
                        option:  kernel/traceoff_on_warning

        transparent_hugepage=
                        [KNL]
                        Format: [always|madvise|never]
                        Can be used to control the default behavior of the␣
↪system
                        with respect to transparent hugepages.
                        See Documentation/admin-guide/mm/transhuge.rst
                        for more details.

        trusted.source= [KEYS]
                        Format: <string>
                        This parameter identifies the trust source as a backend
                        for trusted keys implementation. Supported trust
                        sources:
                        - "tpm"
                        - "tee"
                        - "caam"
                        If not specified then it defaults to iterating through
                        the trust source list starting with TPM and assigns the
                        first trust source as a backend which is initialized
                        successfully during iteration.

        trusted.rng=    [KEYS]
                        Format: <string>
                        The RNG used to generate key material for trusted keys.
                        Can be one of:
                        - "kernel"
                        - the same value as trusted.source: "tpm" or "tee"
```

```
                        - "default"
                        If not specified, "default" is used. In this case,
                        the RNG's choice is left to each individual trust␣
↪source.

        tsc=            Disable clocksource stability checks for TSC.
                        Format: <string>
                        [x86] reliable: mark tsc clocksource as reliable, this
                        disables clocksource verification at runtime, as well
                        as the stability checks done at bootup. Used to enable
                        high-resolution timer mode on older hardware, and in
                        virtualized environment.
                        [x86] noirqtime: Do not use TSC to do irq accounting.
                        Used to run time disable IRQ_TIME_ACCOUNTING on any
                        platforms where RDTSC is slow and this accounting
                        can add overhead.
                        [x86] unstable: mark the TSC clocksource as unstable,␣
↪this
                        marks the TSC unconditionally unstable at bootup and
                        avoids any further wobbles once the TSC watchdog␣
↪notices.
                        [x86] nowatchdog: disable clocksource watchdog. Used
                        in situations with strict latency requirements (where
                        interruptions from clocksource watchdog are not
                        acceptable).
                        [x86] recalibrate: force recalibration against a HW␣
↪timer
                        (HPET or PM timer) on systems whose TSC frequency was
                        obtained from HW or FW using either an MSR or␣
↪CPUID(0x15).
                        Warn if the difference is more than 500 ppm.
                        [x86] watchdog: Use TSC as the watchdog clocksource␣
↪with
                        which to check other HW timers (HPET or PM timer), but
                        only on systems where TSC has been deemed trustworthy.
                        This will be suppressed by an earlier tsc=nowatchdog␣
↪and
                        can be overridden by a later tsc=nowatchdog.  A console
                        message will flag any such suppression or overriding.

        tsc_early_khz=  [X86] Skip early TSC calibration and use the given
                        value instead. Useful when the early TSC frequency␣
↪discovery
                        procedure is not reliable, such as on overclocked␣
↪systems
                        with CPUID.16h support and partial CPUID.15h support.
                        Format: <unsigned int>

        tsx=            [X86] Control Transactional Synchronization
                        Extensions (TSX) feature in Intel processors that
                        support TSX control.
```

```
                        This parameter controls the TSX feature. The options␣
↪are:

                        on      - Enable TSX on the system. Although there are
                                  mitigations for all known security␣
↪vulnerabilities,
                                  TSX has been known to be an accelerator for
                                  several previous speculation-related CVEs, and
                                  so there may be unknown security risks␣
↪associated
                                  with leaving it enabled.

                        off     - Disable TSX on the system. (Note that this
                                  option takes effect only on newer CPUs which␣
↪are
                                  not vulnerable to MDS, i.e., have
                                  MSR_IA32_ARCH_CAPABILITIES.MDS_NO=1 and which␣
↪get
                                  the new IA32_TSX_CTRL MSR through a microcode
                                  update. This new MSR allows for the reliable
                                  deactivation of the TSX functionality.)

                        auto    - Disable TSX if X86_BUG_TAA is present,
                                  otherwise enable TSX on the system.

                        Not specifying this option is equivalent to tsx=off.

                        See Documentation/admin-guide/hw-vuln/tsx_async_abort.
↪rst
                        for more details.

       tsx_async_abort= [X86,INTEL] Control mitigation for the TSX Async
                        Abort (TAA) vulnerability.

                        Similar to Micro-architectural Data Sampling (MDS)
                        certain CPUs that support Transactional
                        Synchronization Extensions (TSX) are vulnerable to an
                        exploit against CPU internal buffers which can forward
                        information to a disclosure gadget under certain
                        conditions.

                        In vulnerable processors, the speculatively forwarded
                        data can be used in a cache side channel attack, to
                        access data to which the attacker does not have direct
                        access.

                        This parameter controls the TAA mitigation.  The
                        options are:

                        full       - Enable TAA mitigation on vulnerable CPUs
```

```
                                    if TSX is enabled.

                        full,nosmt - Enable TAA mitigation and disable SMT on
                                     vulnerable CPUs. If TSX is disabled, SMT
                                     is not disabled because CPU is not
                                     vulnerable to cross-thread TAA attacks.
                        off        - Unconditionally disable TAA mitigation

                        On MDS-affected machines, tsx_async_abort=off can be
                        prevented by an active MDS mitigation as both␣
↪vulnerabilities
                        are mitigated with the same mechanism so in order to␣
↪disable
                        this mitigation, you need to specify mds=off too.

                        Not specifying this option is equivalent to
                        tsx_async_abort=full.  On CPUs which are MDS affected
                        and deploy MDS mitigation, TAA mitigation is not
                        required and doesn't provide any additional
                        mitigation.

                        For details see:
                        Documentation/admin-guide/hw-vuln/tsx_async_abort.rst

        turbografx.map[2|3]=    [HW,JOY]
                        TurboGraFX parallel port interface
                        Format:
                        <port#>,<js1>,<js2>,<js3>,<js4>,<js5>,<js6>,<js7>
                        See also Documentation/input/devices/joystick-parport.
↪rst

        udbg-immortal   [PPC] When debugging early kernel crashes that
                        happen after console_init() and before a proper
                        console driver takes over, this boot options might
                        help "seeing" what's going on.

        uhash_entries=  [KNL,NET]
                        Set number of hash buckets for UDP/UDP-Lite connections

        uhci-hcd.ignore_oc=
                        [USB] Ignore overcurrent events (default N).
                        Some badly-designed motherboards generate lots of
                        bogus events, for ports that aren't wired to
                        anything.  Set this parameter to avoid log spamming.
                        Note that genuine overcurrent events won't be
                        reported either.

        unknown_nmi_panic
                        [X86] Cause panic on unknown NMI.

        unwind_debug    [X86-64]
```

```
                Enable unwinder debug output.  This can be
                useful for debugging certain unwinder error
                conditions, including corrupt stacks and
                bad/missing unwinder metadata.

usbcore.authorized_default=
                [USB] Default USB device authorization:
                (default -1 = authorized (same as 1),
                0 = not authorized, 1 = authorized, 2 = authorized
                if device connected to internal port)

usbcore.autosuspend=
                [USB] The autosuspend time delay (in seconds) used
                for newly-detected USB devices (default 2).  This
                is the time required before an idle device will be
                autosuspended.  Devices for which the delay is set
                to a negative value won't be autosuspended at all.

usbcore.usbfs_snoop=
                [USB] Set to log all usbfs traffic (default 0 = off).

usbcore.usbfs_snoop_max=
                [USB] Maximum number of bytes to snoop in each URB
                (default = 65536).

usbcore.blinkenlights=
                [USB] Set to cycle leds on hubs (default 0 = off).

usbcore.old_scheme_first=
                [USB] Start with the old device initialization
                scheme (default 0 = off).

usbcore.usbfs_memory_mb=
                [USB] Memory limit (in MB) for buffers allocated by
                usbfs (default = 16, 0 = max = 2047).

usbcore.use_both_schemes=
                [USB] Try the other device initialization scheme
                if the first one fails (default 1 = enabled).

usbcore.initial_descriptor_timeout=
                [USB] Specifies timeout for the initial 64-byte
                USB_REQ_GET_DESCRIPTOR request in milliseconds
                (default 5000 = 5.0 seconds).

usbcore.nousb   [USB] Disable the USB subsystem

usbcore.quirks=
                [USB] A list of quirk entries to augment the built-in
                usb core quirk list. List entries are separated by
                commas. Each entry has the form
```

```
                        VendorID:ProductID:Flags. The IDs are 4-digit hex
                        numbers and Flags is a set of letters. Each letter
                        will change the built-in quirk; setting it if it is
                        clear and clearing it if it is set. The letters have
                        the following meanings:
                                a = USB_QUIRK_STRING_FETCH_255 (string
                                        descriptors must not be fetched using
                                        a 255-byte read);
                                b = USB_QUIRK_RESET_RESUME (device can't resume
                                        correctly so reset it instead);
                                c = USB_QUIRK_NO_SET_INTF (device can't handle
                                        Set-Interface requests);
                                d = USB_QUIRK_CONFIG_INTF_STRINGS (device can't
                                        handle its Configuration or Interface
                                        strings);
                                e = USB_QUIRK_RESET (device can't be reset
                                        (e.g morph devices), don't use reset);
                                f = USB_QUIRK_HONOR_BNUMINTERFACES (device has
                                        more interface descriptions than the
                                        bNumInterfaces count, and can't handle
                                        talking to these interfaces);
                                g = USB_QUIRK_DELAY_INIT (device needs a pause
                                        during initialization, after we read
                                        the device descriptor);
                                h = USB_QUIRK_LINEAR_UFRAME_INTR_BINTERVAL (For
                                        high speed and super speed interrupt
                                        endpoints, the USB 2.0 and USB 3.0 spec
                                        require the interval in microframes (1
                                        microframe = 125 microseconds) to be
                                        calculated as interval = 2 ^
                                        (bInterval-1).
                                        Devices with this quirk report their
                                        bInterval as the result of this
                                        calculation instead of the exponent
                                        variable used in the calculation);
                                i = USB_QUIRK_DEVICE_QUALIFIER (device can't
                                        handle device_qualifier descriptor
                                        requests);
                                j = USB_QUIRK_IGNORE_REMOTE_WAKEUP (device
                                        generates spurious wakeup, ignore
                                        remote wakeup capability);
                                k = USB_QUIRK_NO_LPM (device can't handle Link
                                        Power Management);
                                l = USB_QUIRK_LINEAR_FRAME_INTR_BINTERVAL
                                        (Device reports its bInterval as linear
                                        frames instead of the USB 2.0
                                        calculation);
                                m = USB_QUIRK_DISCONNECT_SUSPEND (Device needs
                                        to be disconnected before suspend to
                                        prevent spurious wakeup);
                                n = USB_QUIRK_DELAY_CTRL_MSG (Device needs a
```

```
                                        pause after every control message);
                                o = USB_QUIRK_HUB_SLOW_RESET (Hub needs extra
                                        delay after resetting its port);
                                p = USB_QUIRK_SHORT_SET_ADDRESS_REQ_TIMEOUT
                                        (Reduce timeout of the SET_ADDRESS
                                        request from 5000 ms to 500 ms);
                        Example: quirks=0781:5580:bk,0a5c:5834:gij

        usbhid.mousepoll=
                        [USBHID] The interval which mice are to be polled at.

        usbhid.jspoll=
                        [USBHID] The interval which joysticks are to be polled␣
↪at.

        usbhid.kbpoll=
                        [USBHID] The interval which keyboards are to be polled␣
↪at.

        usb-storage.delay_use=
                        [UMS] The delay in seconds before a new device is
                        scanned for Logical Units (default 1).

        usb-storage.quirks=
                        [UMS] A list of quirks entries to supplement or
                        override the built-in unusual_devs list.  List
                        entries are separated by commas.  Each entry has
                        the form VID:PID:Flags where VID and PID are Vendor
                        and Product ID values (4-digit hex numbers) and
                        Flags is a set of characters, each corresponding
                        to a common usb-storage quirk flag as follows:
                                a = SANE_SENSE (collect more than 18 bytes
                                        of sense data, not on uas);
                                b = BAD_SENSE (don't collect more than 18
                                        bytes of sense data, not on uas);
                                c = FIX_CAPACITY (decrease the reported
                                        device capacity by one sector);
                                d = NO_READ_DISC_INFO (don't use
                                        READ_DISC_INFO command, not on uas);
                                e = NO_READ_CAPACITY_16 (don't use
                                        READ_CAPACITY_16 command);
                                f = NO_REPORT_OPCODES (don't use report opcodes
                                        command, uas only);
                                g = MAX_SECTORS_240 (don't transfer more than
                                        240 sectors at a time, uas only);
                                h = CAPACITY_HEURISTICS (decrease the
                                        reported device capacity by one
                                        sector if the number is odd);
                                i = IGNORE_DEVICE (don't bind to this
                                        device);
                                j = NO_REPORT_LUNS (don't use report luns
```

```
                                        command, uas only);
                                k = NO_SAME (do not use WRITE_SAME, uas only)
                                l = NOT_LOCKABLE (don't try to lock and
                                        unlock ejectable media, not on uas);
                                m = MAX_SECTORS_64 (don't transfer more
                                        than 64 sectors = 32 KB at a time,
                                        not on uas);
                                n = INITIAL_READ10 (force a retry of the
                                        initial READ(10) command, not on uas);
                                o = CAPACITY_OK (accept the capacity
                                        reported by the device, not on uas);
                                p = WRITE_CACHE (the device cache is ON
                                        by default, not on uas);
                                r = IGNORE_RESIDUE (the device reports
                                        bogus residue values, not on uas);
                                s = SINGLE_LUN (the device has only one
                                        Logical Unit);
                                t = NO_ATA_1X (don't allow ATA(12) and ATA(16)
                                        commands, uas only);
                                u = IGNORE_UAS (don't bind to the uas driver);
                                w = NO_WP_DETECT (don't test whether the
                                        medium is write-protected).
                                y = ALWAYS_SYNC (issue a SYNCHRONIZE_CACHE
                                        even if the device claims no cache,
                                        not on uas)
                        Example: quirks=0419:aaf5:rl,0421:0433:rc

        user_debug=     [KNL,ARM]
                        Format: <int>
                        See arch/arm/Kconfig.debug help text.
                                 1 - undefined instruction events
                                 2 - system calls
                                 4 - invalid data aborts
                                 8 - SIGSEGV faults
                                16 - SIGBUS faults
                        Example: user_debug=31

        userpte=
                        [X86] Flags controlling user PTE allocations.

                                nohigh = do not allocate PTE pages in
                                        HIGHMEM regardless of setting
                                        of CONFIG_HIGHPTE.

        vdso=           [X86,SH,SPARC]
                        On X86_32, this is an alias for vdso32=.  Otherwise:

                        vdso=1: enable VDSO (the default)
                        vdso=0: disable VDSO mapping

        vdso32=         [X86] Control the 32-bit vDSO
```

```
                        vdso32=1: enable 32-bit VDSO
                        vdso32=0 or vdso32=2: disable 32-bit VDSO

                        See the help text for CONFIG_COMPAT_VDSO for more
                        details.  If CONFIG_COMPAT_VDSO is set, the default is
                        vdso32=0; otherwise, the default is vdso32=1.

                        For compatibility with older kernels, vdso32=2 is an
                        alias for vdso32=0.

                        Try vdso32=0 if you encounter an error that says:
                        dl_main: Assertion `(void *) ph->p_vaddr == _rtld_
↪local._dl_sysinfo_dso' failed!

       vector=          [IA-64,SMP]
                        vector=percpu: enable percpu vector domain

       video=           [FB] Frame buffer configuration
                        See Documentation/fb/modedb.rst.

       video.brightness_switch_enabled= [ACPI]
                        Format: [0|1]
                        If set to 1, on receiving an ACPI notify event
                        generated by hotkey, video driver will adjust␣
↪brightness
                        level and then send out the event to user space through
                        the allocated input device. If set to 0, video driver
                        will only send out the event without touching backlight
                        brightness level.
                        default: 1

       virtio_mmio.device=
                        [VMMIO] Memory mapped virtio (platform) device.

                                <size>@<baseaddr>:<irq>[:<id>]
                        where:
                                <size>     := size (can use standard suffixes
                                                like K, M and G)
                                <baseaddr> := physical base address
                                <irq>      := interrupt number (as passed to
                                                request_irq())
                                <id>       := (optional) platform device id
                        example:
                                virtio_mmio.device=1K@0x100b0000:48:7

                        Can be used multiple times for multiple devices.

       vga=             [BOOT,X86-32] Select a particular video mode
                        See Documentation/arch/x86/boot.rst and
                        Documentation/admin-guide/svga.rst.
                        Use vga=ask for menu.
```

```
                This is actually a boot loader parameter; the value is
                passed to the kernel using a special protocol.

vm_debug[=options]      [KNL] Available with CONFIG_DEBUG_VM=y.
                May slow down system boot speed, especially when
                enabled on systems with a large amount of memory.
                All options are enabled by default, and this
                interface is meant to allow for selectively
                enabling or disabling specific virtual memory
                debugging features.

                Available options are:
                  P     Enable page structure init time poisoning
                  -     Disable all of the above options

vmalloc=nn[KMG] [KNL,BOOT] Forces the vmalloc area to have an exact
                size of <nn>. This can be used to increase the
                minimum size (128MB on x86). It can also be used to
                decrease the size and leave more room for directly
                mapped kernel RAM.

vmcp_cma=nn[MG] [KNL,S390]
                Sets the memory size reserved for contiguous memory
                allocations for the vmcp device driver.

vmhalt=         [KNL,S390] Perform z/VM CP command after system halt.
                Format: <command>

vmpanic=        [KNL,S390] Perform z/VM CP command after kernel panic.
                Format: <command>

vmpoff=         [KNL,S390] Perform z/VM CP command after power off.
                Format: <command>

vsyscall=       [X86-64]
                Controls the behavior of vsyscalls (i.e. calls to
                fixed addresses of 0xffffffffff600x00 from legacy
                code).  Most statically-linked binaries and older
                versions of glibc use these calls.  Because these
                functions are at fixed addresses, they make nice
                targets for exploits that can control RIP.

                emulate     Vsyscalls turn into traps and are emulated
                            reasonably safely.  The vsyscall page is
                            readable.

                xonly       [default] Vsyscalls turn into traps and are
                            emulated reasonably safely.  The vsyscall
                            page is not readable.

                none        Vsyscalls don't work at all.  This makes
```

```
                                them quite hard to use for exploits but
                                might break your system.

        vt.color=       [VT] Default text color.
                        Format: 0xYX, X = foreground, Y = background.
                        Default: 0x07 = light gray on black.

        vt.cur_default= [VT] Default cursor shape.
                        Format: 0xCCBBAA, where AA, BB, and CC are the same as
                        the parameters of the <Esc>[?A;B;Cc escape sequence;
                        see VGA-softcursor.txt. Default: 2 = underline.

        vt.default_blu= [VT]
                        Format: <blue0>,<blue1>,<blue2>,...,<blue15>
                        Change the default blue palette of the console.
                        This is a 16-member array composed of values
                        ranging from 0-255.

        vt.default_grn= [VT]
                        Format: <green0>,<green1>,<green2>,...,<green15>
                        Change the default green palette of the console.
                        This is a 16-member array composed of values
                        ranging from 0-255.

        vt.default_red= [VT]
                        Format: <red0>,<red1>,<red2>,...,<red15>
                        Change the default red palette of the console.
                        This is a 16-member array composed of values
                        ranging from 0-255.

        vt.default_utf8=
                        [VT]
                        Format=<0|1>
                        Set system-wide default UTF-8 mode for all tty's.
                        Default is 1, i.e. UTF-8 mode is enabled for all
                        newly opened terminals.

        vt.global_cursor_default=
                        [VT]
                        Format=<-1|0|1>
                        Set system-wide default for whether a cursor
                        is shown on new VTs. Default is -1,
                        i.e. cursors will be created by default unless
                        overridden by individual drivers. 0 will hide
                        cursors, 1 will display them.

        vt.italic=      [VT] Default color for italic text; 0-15.
                        Default: 2 = green.

        vt.underline=   [VT] Default color for underlined text; 0-15.
                        Default: 3 = cyan.
```

```
        watchdog timers [HW,WDT] For information on watchdog timers,
                        see Documentation/watchdog/watchdog-parameters.rst
                        or other driver-specific files in the
                        Documentation/watchdog/ directory.

        watchdog_thresh=
                        [KNL]
                        Set the hard lockup detector stall duration
                        threshold in seconds. The soft lockup detector
                        threshold is set to twice the value. A value of 0
                        disables both lockup detectors. Default is 10
                        seconds.

        workqueue.unbound_cpus=
                        [KNL,SMP] Specify to constrain one or some CPUs
                        to use in unbound workqueues.
                        Format: <cpu-list>
                        By default, all online CPUs are available for
                        unbound workqueues.

        workqueue.watchdog_thresh=
                        If CONFIG_WQ_WATCHDOG is configured, workqueue can
                        warn stall conditions and dump internal state to
                        help debugging.  0 disables workqueue stall
                        detection; otherwise, it's the stall threshold
                        duration in seconds.  The default value is 30 and
                        it can be updated at runtime by writing to the
                        corresponding sysfs file.

        workqueue.cpu_intensive_thresh_us=
                        Per-cpu work items which run for longer than this
                        threshold are automatically considered CPU intensive
                        and excluded from concurrency management to prevent
                        them from noticeably delaying other per-cpu work
                        items. Default is 10000 (10ms).

                        If CONFIG_WQ_CPU_INTENSIVE_REPORT is set, the kernel
                        will report the work functions which violate this
                        threshold repeatedly. They are likely good
                        candidates for using WQ_UNBOUND workqueues instead.

        workqueue.power_efficient
                        Per-cpu workqueues are generally preferred because
                        they show better performance thanks to cache
                        locality; unfortunately, per-cpu workqueues tend to
                        be more power hungry than unbound workqueues.

                        Enabling this makes the per-cpu workqueues which
                        were observed to contribute significantly to power
                        consumption unbound, leading to measurably lower
```

```
                power usage at the cost of small performance
                overhead.

                The default value of this parameter is determined by
                the config option CONFIG_WQ_POWER_EFFICIENT_DEFAULT.

        workqueue.default_affinity_scope=
                Select the default affinity scope to use for unbound
                workqueues. Can be one of "cpu", "smt", "cache",
                "numa" and "system". Default is "cache". For more
                information, see the Affinity Scopes section in
                Documentation/core-api/workqueue.rst.

                This can be changed after boot by writing to the
                matching /sys/module/workqueue/parameters file. All
                workqueues with the "default" affinity scope will be
                updated accordignly.

        workqueue.debug_force_rr_cpu
                Workqueue used to implicitly guarantee that work
                items queued without explicit CPU specified are put
                on the local CPU.  This guarantee is no longer true
                and while local CPU is still preferred work items
                may be put on foreign CPUs.  This debug option
                forces round-robin CPU selection to flush out
                usages which depend on the now broken guarantee.
                When enabled, memory and cache locality will be
                impacted.

        writecombine=   [LOONGARCH] Control the MAT (Memory Access Type) of
                ioremap_wc().

                on   - Enable writecombine, use WUC for ioremap_wc()
                off  - Disable writecombine, use SUC for ioremap_wc()

        x2apic_phys     [X86-64,APIC] Use x2apic physical mode instead of
                default x2apic cluster mode on platforms
                supporting x2apic.

        xen_512gb_limit         [KNL,X86-64,XEN]
                Restricts the kernel running paravirtualized under Xen
                to use only up to 512 GB of RAM. The reason to do so is
                crash analysis tools and Xen tools for doing domain
                save/restore/migration must be enabled to handle larger
                domains.

        xen_emul_unplug=                [HW,X86,XEN]
                Unplug Xen emulated devices
                Format: [unplug0,][unplug1]
                ide-disks -- unplug primary master IDE devices
                aux-ide-disks -- unplug non-primary-master IDE devices
```

```
                        nics -- unplug network devices
                        all -- unplug all emulated devices (NICs and IDE disks)
                        unnecessary -- unplugging emulated devices is
                                unnecessary even if the host did not respond to
                                the unplug protocol
                        never -- do not unplug even if version check succeeds

        xen_legacy_crash        [X86,XEN]
                        Crash from Xen panic notifier, without executing late
                        panic() code such as dumping handler.

        xen_msr_safe=   [X86,XEN]
                        Format: <bool>
                        Select whether to always use non-faulting (safe) MSR
                        access functions when running as Xen PV guest. The
                        default value is controlled by CONFIG_XEN_PV_MSR_SAFE.

        xen_nopvspin    [X86,XEN]
                        Disables the qspinlock slowpath using Xen PV␣
↪optimizations.
                        This parameter is obsoleted by "nopvspin" parameter,␣
↪which
                        has equivalent effect for XEN platform.

        xen_nopv        [X86]
                        Disables the PV optimizations forcing the HVM guest to
                        run as generic HVM guest with no PV drivers.
                        This option is obsoleted by the "nopv" option, which
                        has equivalent effect for XEN platform.

        xen_no_vector_callback
                        [KNL,X86,XEN] Disable the vector callback for Xen
                        event channel interrupts.

        xen_scrub_pages=        [XEN]
                        Boolean option to control scrubbing pages before␣
↪giving them back
                        to Xen, for use by other domains. Can be also changed␣
↪at runtime
                        with /sys/devices/system/xen_memory/xen_memory0/scrub_
↪pages.
                        Default value controlled with CONFIG_XEN_SCRUB_PAGES_
↪DEFAULT.

        xen_timer_slop= [X86-64,XEN]
                        Set the timer slop (in nanoseconds) for the virtual Xen
                        timers (default is 100000). This adjusts the minimum
                        delta of virtualized Xen timers, where lower values
                        improve timer resolution at the expense of processing
                        more timer interrupts.
```

```
        xen.balloon_boot_timeout= [XEN]
                        The time (in seconds) to wait before giving up to boot
                        in case initial ballooning fails to free enough memory.
                        Applies only when running as HVM or PVH guest and
                        started with less memory configured than allowed at
                        max. Default is 180.

        xen.event_eoi_delay=    [XEN]
                        How long to delay EOI handling in case of event
                        storms (jiffies). Default is 10.

        xen.event_loop_timeout= [XEN]
                        After which time (jiffies) the event handling loop
                        should start to delay EOI handling. Default is 2.

        xen.fifo_events=        [XEN]
                        Boolean parameter to disable using fifo event handling
                        even if available. Normally fifo event handling is
                        preferred over the 2-level event handling, as it is
                        fairer and the number of possible event channels is
                        much higher. Default is on (use fifo events).

        xirc2ps_cs=     [NET,PCMCIA]
                        Format:
                        <irq>,<irq_mask>,<io>,<full_duplex>,<do_sound>,<lockup_
↪hack>[,<irq2>[,<irq3>[,<irq4>]]]

        xive=           [PPC]
                        By default on POWER9 and above, the kernel will
                        natively use the XIVE interrupt controller. This option
                        allows the fallback firmware mode to be used:

                        off       Fallback to firmware control of XIVE␣
↪interrupt
                                  controller on both pseries and powernv
                                  platforms. Only useful on POWER9 and above.

        xive.store-eoi=off      [PPC]
                        By default on POWER10 and above, the kernel will use
                        stores for EOI handling when the XIVE interrupt mode
                        is active. This option allows the XIVE driver to use
                        loads instead, as on POWER9.

        xhci-hcd.quirks         [USB,KNL]
                        A hex value specifying bitmask with supplemental xhci
                        host controller quirks. Meaning of each bit can be
                        consulted in header drivers/usb/host/xhci.h.

        xmon            [PPC]
                        Format: { early | on | rw | ro | off }
                        Controls if xmon debugger is enabled. Default is off.
```

```
                        Passing only "xmon" is equivalent to "xmon=early".
                        early   Call xmon as early as possible on boot; xmon
                                debugger is called from setup_arch().
                        on      xmon debugger hooks will be installed so xmon
                                is only called on a kernel crash. Default mode,
                                i.e. either "ro" or "rw" mode, is controlled
                                with CONFIG_XMON_DEFAULT_RO_MODE.
                        rw      xmon debugger hooks will be installed so xmon
                                is called only on a kernel crash, mode is␣
↪write,
                                meaning SPR registers, memory and, other data
                                can be written using xmon commands.
                        ro      same as "rw" option above but SPR registers,
                                memory, and other data can't be written using
                                xmon commands.
                        off     xmon is disabled.
```

CHAPTER

THREE

LINUX ALLOCATED DEVICES (4.X+ VERSION)

This list is the Linux Device List, the official registry of allocated device numbers and `/dev` directory nodes for the Linux operating system.

The version of this document at lanana.org is no longer maintained. This version in the mainline Linux kernel is the master document. Updates shall be sent as patches to the kernel maintainers (see the Documentation/process/submitting-patches.rst document). Specifically explore the sections titled "CHAR and MISC DRIVERS", and "BLOCK LAYER" in the MAINTAINERS file to find the right maintainers to involve for character and block devices.

This document is included by reference into the Filesystem Hierarchy Standard (FHS). The FHS is available from https://www.pathname.com/fhs/.

Allocations marked (68k/Amiga) apply to Linux/68k on the Amiga platform only. Allocations marked (68k/Atari) apply to Linux/68k on the Atari platform only.

This document is in the public domain. The authors requests, however, that semantically altered versions are not distributed without permission of the authors, assuming the authors can be contacted without an unreasonable effort.

Attention: DEVICE DRIVERS AUTHORS PLEASE READ THIS

Linux now has extensive support for dynamic allocation of device numbering and can use `sysfs` and `udev` (`systemd`) to handle the naming needs. There are still some exceptions in the serial and boot device area. Before asking for a device number make sure you actually need one.

To have a major number allocated, or a minor number in situations where that applies (e.g. busmice), please submit a patch and send to the authors as indicated above.

Keep the description of the device *in the same format as this list*. The reason for this is that it is the only way we have found to ensure we have all the requisite information to publish your device and avoid conflicts.

Finally, sometimes we have to play "namespace police." Please don't be offended. We often get submissions for `/dev` names that would be bound to cause conflicts down the road. We are trying to avoid getting in a situation where we would have to suffer an incompatible forward change. Therefore, please consult with us **before** you make your device names and numbers in any way public, at least to the point where it would be at all difficult to get them changed.

Your cooperation is appreciated.

```
0             Unnamed devices (e.g. non-device mounts)
```

```
                  0 = reserved as null device number
                See block major 144, 145, 146 for expansion areas.

  1 char        Memory devices
                  1 = /dev/mem          Physical memory access
                  2 = /dev/kmem         OBSOLETE - replaced by /proc/kcore
                  3 = /dev/null         Null device
                  4 = /dev/port         I/O port access
                  5 = /dev/zero         Null byte source
                  6 = /dev/core         OBSOLETE - replaced by /proc/kcore
                  7 = /dev/full         Returns ENOSPC on write
                  8 = /dev/random       Nondeterministic random number gen.
                  9 = /dev/urandom      Faster, less secure random number gen.
                 10 = /dev/aio          Asynchronous I/O notification interface
                 11 = /dev/kmsg         Writes to this come out as printk's,␣
↪reads
                                        export the buffered printk records.
                 12 = /dev/oldmem       OBSOLETE - replaced by /proc/vmcore

  1 block       RAM disk
                  0 = /dev/ram0         First RAM disk
                  1 = /dev/ram1         Second RAM disk
                    ...
                250 = /dev/initrd       Initial RAM disk

                Older kernels had /dev/ramdisk (1, 1) here.
                /dev/initrd refers to a RAM disk which was preloaded
                by the boot loader; newer kernels use /dev/ram0 for
                the initrd.

  2 char        Pseudo-TTY masters
                  0 = /dev/ptyp0        First PTY master
                  1 = /dev/ptyp1        Second PTY master
                    ...
                255 = /dev/ptyef        256th PTY master

                Pseudo-tty's are named as follows:
                * Masters are "pty", slaves are "tty";
                * the fourth letter is one of pqrstuvwxyzabcde indicating
                  the 1st through 16th series of 16 pseudo-ttys each, and
                * the fifth letter is one of 0123456789abcdef indicating
                  the position within the series.

                These are the old-style (BSD) PTY devices; Unix98
                devices are on major 128 and above and use the PTY
                master multiplex (/dev/ptmx) to acquire a PTY on
                demand.

  2 block       Floppy disks
                  0 = /dev/fd0          Controller 0, drive 0, autodetect
                  1 = /dev/fd1          Controller 0, drive 1, autodetect
```

```
  2 = /dev/fd2          Controller 0, drive 2, autodetect
  3 = /dev/fd3          Controller 0, drive 3, autodetect
128 = /dev/fd4          Controller 1, drive 0, autodetect
129 = /dev/fd5          Controller 1, drive 1, autodetect
130 = /dev/fd6          Controller 1, drive 2, autodetect
131 = /dev/fd7          Controller 1, drive 3, autodetect

To specify format, add to the autodetect device number:
  0 = /dev/fd?          Autodetect format
  4 = /dev/fd?d360      5.25"  360K in a 360K  drive(1)

(1) Autodetectable format
(2) Autodetectable format in a Double Density (720K) drive only
(3) Autodetectable format in a High Density (1440K) drive only

NOTE: The letter in the device name (d, q, h or u)
signifies the type of drive: 5.25" Double Density (d),
5.25" Quad Density (q), 5.25" High Density (h) or 3.5"
(any model, u).  The use of the capital letters D, H
```

```
                and E for the 3.5" models have been deprecated, since
                the drive type is insignificant for these devices.

  3 char        Pseudo-TTY slaves
                  0 = /dev/ttyp0        First PTY slave
                  1 = /dev/ttyp1        Second PTY slave
                    ...
                255 = /dev/ttyef        256th PTY slave

                These are the old-style (BSD) PTY devices; Unix98
                devices are on major 136 and above.

  3 block       First MFM, RLL and IDE hard disk/CD-ROM interface
                  0 = /dev/hda          Master: whole disk (or CD-ROM)
                 64 = /dev/hdb          Slave: whole disk (or CD-ROM)

                For partitions, add to the whole disk device number:
                  0 = /dev/hd?          Whole disk
                  1 = /dev/hd?1         First partition
                  2 = /dev/hd?2         Second partition
                    ...
                 63 = /dev/hd?63        63rd partition

                For Linux/i386, partitions 1-4 are the primary
                partitions, and 5 and above are logical partitions.
                Other versions of Linux use partitioning schemes
                appropriate to their respective architectures.

  4 char        TTY devices
                  0 = /dev/tty0         Current virtual console

                  1 = /dev/tty1         First virtual console
                    ...
                 63 = /dev/tty63        63rd virtual console
                 64 = /dev/ttyS0        First UART serial port
                    ...
                255 = /dev/ttyS191      192nd UART serial port

                UART serial ports refer to 8250/16450/16550 series devices.

                Older versions of the Linux kernel used this major
                number for BSD PTY devices.  As of Linux 2.1.115, this
                is no longer supported.  Use major numbers 2 and 3.

  4 block       Aliases for dynamically allocated major devices to be used
                when its not possible to create the real device nodes
                because the root filesystem is mounted read-only.

                   0 = /dev/root

  5 char        Alternate TTY devices
```

```
                  0 = /dev/tty          Current TTY device
                  1 = /dev/console      System console
                  2 = /dev/ptmx         PTY master multiplex
                  3 = /dev/ttyprintk    User messages via printk TTY device
                 64 = /dev/cua0         Callout device for ttyS0
                    ...
                255 = /dev/cua191       Callout device for ttyS191

                (5,1) is /dev/console starting with Linux 2.1.71.  See
                the section on terminal devices for more information
                on /dev/console.

  6 char        Parallel printer devices
                  0 = /dev/lp0          Parallel printer on parport0
                  1 = /dev/lp1          Parallel printer on parport1
                    ...

                Current Linux kernels no longer have a fixed mapping
                between parallel ports and I/O addresses.  Instead,
                they are redirected through the parport multiplex layer.

  7 char        Virtual console capture devices
                  0 = /dev/vcs          Current vc text (glyph) contents
                  1 = /dev/vcs1         tty1 text (glyph) contents
                    ...
                 63 = /dev/vcs63        tty63 text (glyph) contents
                 64 = /dev/vcsu         Current vc text (unicode) contents
                65 = /dev/vcsu1         tty1 text (unicode) contents
                    ...
                127 = /dev/vcsu63       tty63 text (unicode) contents
                128 = /dev/vcsa         Current vc text/attribute (glyph)␣
↪contents
                129 = /dev/vcsa1        tty1 text/attribute (glyph) contents
                    ...
                191 = /dev/vcsa63       tty63 text/attribute (glyph) contents

                NOTE: These devices permit both read and write access.

  7 block       Loopback devices
                  0 = /dev/loop0        First loop device
                  1 = /dev/loop1        Second loop device
                    ...

                The loop devices are used to mount filesystems not
                associated with block devices.  The binding to the
                loop devices is handled by mount(8) or losetup(8).

  8 block       SCSI disk devices (0-15)
                  0 = /dev/sda          First SCSI disk whole disk
                 16 = /dev/sdb          Second SCSI disk whole disk
                 32 = /dev/sdc          Third SCSI disk whole disk
```

```
                ...
              240 = /dev/sdp          Sixteenth SCSI disk whole disk

              Partitions are handled in the same way as for IDE
              disks (see major number 3) except that the limit on
              partitions is 15.

  9 char      SCSI tape devices
                0 = /dev/st0          First SCSI tape, mode 0
                1 = /dev/st1          Second SCSI tape, mode 0
                ...
               32 = /dev/st0l         First SCSI tape, mode 1
               33 = /dev/st1l         Second SCSI tape, mode 1
                ...
               64 = /dev/st0m         First SCSI tape, mode 2
               65 = /dev/st1m         Second SCSI tape, mode 2
                ...
               96 = /dev/st0a         First SCSI tape, mode 3
               97 = /dev/st1a         Second SCSI tape, mode 3
                  ...
              128 = /dev/nst0         First SCSI tape, mode 0, no rewind
              129 = /dev/nst1         Second SCSI tape, mode 0, no rewind
                ...
              160 = /dev/nst0l        First SCSI tape, mode 1, no rewind
              161 = /dev/nst1l        Second SCSI tape, mode 1, no rewind
                ...
              192 = /dev/nst0m        First SCSI tape, mode 2, no rewind
              193 = /dev/nst1m        Second SCSI tape, mode 2, no rewind
                ...
              224 = /dev/nst0a        First SCSI tape, mode 3, no rewind
              225 = /dev/nst1a        Second SCSI tape, mode 3, no rewind
                ...

              "No rewind" refers to the omission of the default
              automatic rewind on device close.  The MTREW or MTOFFL
              ioctl()'s can be used to rewind the tape regardless of
              the device used to access it.

  9 block     Metadisk (RAID) devices
                0 = /dev/md0          First metadisk group
                1 = /dev/md1          Second metadisk group
                ...

              The metadisk driver is used to span a
              filesystem across multiple physical disks.

                2 = /dev/sbpcd14      Panasonic CD-ROM controller 3 unit 2
                3 = /dev/sbpcd15      Panasonic CD-ROM controller 3 unit 3

28 block      ACSI disk (68k/Atari)
                0 = /dev/ada          First ACSI disk whole disk
               16 = /dev/adb          Second ACSI disk whole disk
               32 = /dev/adc          Third ACSI disk whole disk
                    ...
              240 = /dev/adp          16th ACSI disk whole disk

              Partitions are handled in the same way as for IDE
              disks (see major number 3) except that the limit on
              partitions is 15, like SCSI.

29 char       Universal frame buffer
                0 = /dev/fb0          First frame buffer
                1 = /dev/fb1          Second frame buffer
                    ...
               31 = /dev/fb31         32nd frame buffer

29 block      Aztech/Orchid/Okano/Wearnes CD-ROM
                0 = /dev/aztcd        Aztech CD-ROM

30 char       iBCS-2 compatibility devices
                0 = /dev/socksys      Socket access
                1 = /dev/spx          SVR3 local X interface
               32 = /dev/inet/ip      Network access
               33 = /dev/inet/icmp
               34 = /dev/inet/ggp
               35 = /dev/inet/ipip
               36 = /dev/inet/tcp
```

```
                 37 = /dev/inet/egp
                 38 = /dev/inet/pup
                 39 = /dev/inet/udp
                 40 = /dev/inet/idp
                 41 = /dev/inet/rawip

                Additionally, iBCS-2 requires the following links:

                /dev/ip -> /dev/inet/ip
                /dev/icmp -> /dev/inet/icmp
                /dev/ggp -> /dev/inet/ggp
                /dev/ipip -> /dev/inet/ipip
                /dev/tcp -> /dev/inet/tcp
                /dev/egp -> /dev/inet/egp
                /dev/pup -> /dev/inet/pup
                /dev/udp -> /dev/inet/udp
                /dev/idp -> /dev/inet/idp
                /dev/rawip -> /dev/inet/rawip
                /dev/inet/arp -> /dev/inet/udp
                /dev/inet/rip -> /dev/inet/udp
                /dev/nfsd -> /dev/socksys
                /dev/X0R -> /dev/null (? apparently not required ?)

30 block        Philips LMS CM-205 CD-ROM
                  0 = /dev/cm205cd      Philips LMS CM-205 CD-ROM

                /dev/lmscd is an older name for this device.  This
                driver does not work with the CM-205MS CD-ROM.

31 char         MPU-401 MIDI
                  0 = /dev/mpu401data   MPU-401 data port
                  1 = /dev/mpu401stat   MPU-401 status port

31 block        ROM/flash memory card
                  0 = /dev/rom0         First ROM card (rw)
                      ...
                  7 = /dev/rom7         Eighth ROM card (rw)
                  8 = /dev/rrom0        First ROM card (ro)
                     ...
                 15 = /dev/rrom7        Eighth ROM card (ro)
                 16 = /dev/flash0       First flash memory card (rw)
                     ...
                 23 = /dev/flash7       Eighth flash memory card (rw)
                 24 = /dev/rflash0      First flash memory card (ro)
                     ...
                 31 = /dev/rflash7      Eighth flash memory card (ro)

                The read-write (rw) devices support back-caching
                written data in RAM, as well as writing to flash RAM
                devices.  The read-only devices (ro) support reading
                only.
```

```
32 char       Specialix serial card

                 0 = /dev/yamm         Yet Another Micro Monitor

41 block

42 char       Demo/sample use

42 block      Demo/sample use

              This number is intended for use in sample code, as
              well as a general "example" device number.  It
              should never be used for a device driver that is being
              distributed; either obtain an official number or use
              the local/experimental range.  The sudden addition or
              removal of a driver with this number should not cause
              ill effects to the system (bugs excepted.)

              IN PARTICULAR, ANY DISTRIBUTION WHICH CONTAINS A
              DEVICE DRIVER USING MAJOR NUMBER 42 IS NONCOMPLIANT.

43 char       isdn4linux virtual modem
                 0 = /dev/ttyI0        First virtual modem
                    ...

43 block      Network block devices
                 0 = /dev/nb0          First network block device
                 1 = /dev/nb1          Second network block device
                    ...

              Network Block Device is somehow similar to loopback
              devices: If you read from it, it sends packet across
              network asking server for data. If you write to it, it
              sends packet telling server to write. It could be used
              to mounting filesystems over the net, swapping over
              the net, implementing block device in userland etc.

                 1 = /dev/cup1         Callout device for ttyP1
                   ...

 58 block      Reserved for logical volume manager

 59 char       sf firewall package
```

```
                0 = /dev/firewall     Communication with sf kernel module

59 block      Generic PDA filesystem device
                0 = /dev/pda0         First PDA device
                1 = /dev/pda1         Second PDA device
                  ...

              The pda devices are used to mount filesystems on
              remote pda's (basically slow handheld machines with
              proprietary OS's and limited memory and storage
              running small fs translation drivers) through serial /
              IRDA / parallel links.

              NAMING CONFLICT -- PROPOSED REVISED NAME /dev/rpda0 etc

60-63 char    LOCAL/EXPERIMENTAL USE

60-63 block   LOCAL/EXPERIMENTAL USE
              Allocated for local/experimental use.  For devices not
              assigned official numbers, these ranges should be
              used in order to avoid conflicting with future assignments.

64 char       ENskip kernel encryption package
                0 = /dev/enskip       Communication with ENskip kernel module

64 block      Scramdisk/DriveCrypt encrypted devices
                0 = /dev/scramdisk/master    Master node for ioctls
                1 = /dev/scramdisk/1         First encrypted device
                2 = /dev/scramdisk/2         Second encrypted device
                ...
              255 = /dev/scramdisk/255       255th encrypted device

              The filename of the encrypted container and the passwords
              are sent via ioctls (using the sdmount tool) to the master
              node which then activates them via one of the
              /dev/scramdisk/x nodes for loop mounting (all handled
              through the sdmount tool).

117 block       Enterprise Volume Management System (EVMS)

               The EVMS driver uses a layered, plug-in model to provide
               unparalleled flexibility and extensibility in managing
               storage.  This allows for easy expansion or customization
               of various levels of volume management.  Requested by
               Mark Peloquin (peloquin at us.ibm.com).

               Note: EVMS populates and manages all the devnodes in
               /dev/evms.

               http://sf.net/projects/evms

                  0 = /dev/evms/block_device   EVMS block device
                  1 = /dev/evms/legacyname1    First EVMS legacy device
                  2 = /dev/evms/legacyname2    Second EVMS legacy device
                   ...
                   Both ranges can grow (down or up) until they meet.
                   ...
                254 = /dev/evms/EVMSname2      Second EVMS native device
                255 = /dev/evms/EVMSname1      First EVMS native device

               Note: legacyname(s) are derived from the normal legacy
               device names.  For example, /dev/hda5 would become
               /dev/evms/hda5.

                    ...

                The OnStream SC-x0 SCSI tapes do not support the
                standard SCSI SASD command set and therefore need
                their own driver "osst". Note that the IDE, USB (and
                maybe ParPort) versions may be driven via ide-scsi or
                usb-storage SCSI emulation and this osst device and
                driver as well.  The ADR-x0 drives are QIC-157
                compliant and don't need osst.

3.1 Additional /dev/ directory entries

This section details additional entries that should or may exist in the /dev directory. It is preferred that symbolic links use the same form (absolute or relative) as is indicated here. Links are classified as ”hard” or ”symbolic” depending on the preferred type of link; if possible, the indicated type of link should be used.

3.1.1 Compulsory links

These links should exist on all systems:

/dev/fd	/proc/self/fd	symbolic	File descriptors
/dev/stdin	fd/0	symbolic	stdin file descriptor
/dev/stdout	fd/1	symbolic	stdout file descriptor
/dev/stderr	fd/2	symbolic	stderr file descriptor
/dev/nfsd	socksys	symbolic	Required by iBCS-2
/dev/X0R	null	symbolic	Required by iBCS-2

Note: `/dev/X0R` is <letter X>-<digit 0>-<letter R>.

3.1.2 Recommended links

It is recommended that these links exist on all systems:

/dev/core	/proc/kcore	symbolic	Backward compatibility
/dev/ramdisk	ram0	symbolic	Backward compatibility
/dev/ftape	qft0	symbolic	Backward compatibility
/dev/bttv0	video0	symbolic	Backward compatibility
/dev/radio	radio0	symbolic	Backward compatibility
/dev/i2o*	/dev/i2o/*	symbolic	Backward compatibility
/dev/scd?	sr?	hard	Alternate SCSI CD-ROM name

3.1.3 Locally defined links

The following links may be established locally to conform to the configuration of the system. This is merely a tabulation of existing practice, and does not constitute a recommendation. However, if they exist, they should have the following uses.

/dev/mouse	mouse port	symbolic	Current mouse device
/dev/tape	tape device	symbolic	Current tape device
/dev/cdrom	CD-ROM device	symbolic	Current CD-ROM device
/dev/cdwriter	CD-writer	symbolic	Current CD-writer device
/dev/scanner	scanner	symbolic	Current scanner device
/dev/modem	modem port	symbolic	Current dialout device
/dev/root	root device	symbolic	Current root filesystem
/dev/swap	swap device	symbolic	Current swap device

`/dev/modem` should not be used for a modem which supports dialin as well as dialout, as it tends to cause lock file problems. If it exists, `/dev/modem` should point to the appropriate primary TTY device (the use of the alternate callout devices is deprecated).

For SCSI devices, `/dev/tape` and `/dev/cdrom` should point to the *cooked* devices (`/dev/st*` and `/dev/sr*`, respectively), whereas `/dev/cdwriter` and /dev/scanner should point to the appropriate generic SCSI devices (/dev/sg*).

`/dev/mouse` may point to a primary serial TTY device, a hardware mouse device, or a socket for a mouse driver program (e.g. `/dev/gpmdata`).

3.1.4 Sockets and pipes

Non-transient sockets and named pipes may exist in /dev. Common entries are:

/dev/printer	socket	lpd local socket
/dev/log	socket	syslog local socket
/dev/gpmdata	socket	gpm mouse multiplexer

3.1.5 Mount points

The following names are reserved for mounting special filesystems under /dev. These special filesystems provide kernel interfaces that cannot be provided with standard device nodes.

/dev/pts	devpts	PTY slave filesystem
/dev/shm	tmpfs	POSIX shared memory maintenance access

3.2 Terminal devices

Terminal, or TTY devices are a special class of character devices. A terminal device is any device that could act as a controlling terminal for a session; this includes virtual consoles, serial ports, and pseudoterminals (PTYs).

All terminal devices share a common set of capabilities known as line disciplines; these include the common terminal line discipline as well as SLIP and PPP modes.

All terminal devices are named similarly; this section explains the naming and use of the various types of TTYs. Note that the naming conventions include several historical warts; some of these are Linux-specific, some were inherited from other systems, and some reflect Linux outgrowing a borrowed convention.

A hash mark (#) in a device name is used here to indicate a decimal number without leading zeroes.

3.2.1 Virtual consoles and the console device

Virtual consoles are full-screen terminal displays on the system video monitor. Virtual consoles are named `/dev/tty#`, with numbering starting at `/dev/tty1`; `/dev/tty0` is the current virtual console. `/dev/tty0` is the device that should be used to access the system video card on those architectures for which the frame buffer devices (`/dev/fb*`) are not applicable. Do not use `/dev/console` for this purpose.

The console device, `/dev/console`, is the device to which system messages should be sent, and on which logins should be permitted in single-user mode. Starting with Linux 2.1.71, `/dev/console` is managed by the kernel; for previous versions it should be a symbolic link to either `/dev/tty0`, a specific virtual console such as `/dev/tty1`, or to a serial port primary (`tty*`, not `cu*`) device, depending on the configuration of the system.

3.2.2 Serial ports

Serial ports are RS-232 serial ports and any device which simulates one, either in hardware (such as internal modems) or in software (such as the ISDN driver.) Under Linux, each serial ports has two device names, the primary or callin device and the alternate or callout one. Each kind of device is indicated by a different letter. For any letter X, the names of the devices are `/dev/ttyX#` and `/dev/cux#`, respectively; for historical reasons, `/dev/ttyS#` and `/dev/ttyC#` correspond to `/dev/cua#` and `/dev/cub#`. In the future, it should be expected that multiple letters will be used; all letters will be upper case for the ”tty” device (e.g. `/dev/ttyDP#`) and lower case for the ”cu” device (e.g. `/dev/cudp#`).

The names /dev/ttyQ# and /dev/cuq# are reserved for local use.

The alternate devices provide for kernel-based exclusion and somewhat different defaults than the primary devices. Their main purpose is to allow the use of serial ports with programs with no inherent or broken support for serial ports. Their use is deprecated, and they may be removed from a future version of Linux.

Arbitration of serial ports is provided by the use of lock files with the names /var/lock/LCK..ttyX#. The contents of the lock file should be the PID of the locking process as an ASCII number.

It is common practice to install links such as /dev/modem which point to serial ports. In order to ensure proper locking in the presence of these links, it is recommended that software chase symlinks and lock all possible names; additionally, it is recommended that a lock file be installed with the corresponding alternate device. In order to avoid deadlocks, it is recommended that the locks are acquired in the following order, and released in the reverse:

1. The symbolic link name, if any (/var/lock/LCK..modem)
2. The "tty" name (/var/lock/LCK..ttyS2)
3. The alternate device name (/var/lock/LCK..cua2)

In the case of nested symbolic links, the lock files should be installed in the order the symlinks are resolved.

Under no circumstances should an application hold a lock while waiting for another to be released. In addition, applications which attempt to create lock files for the corresponding alternate device names should take into account the possibility of being used on a non-serial port TTY, for which no alternate device would exist.

3.2.3 Pseudoterminals (PTYs)

Pseudoterminals, or PTYs, are used to create login sessions or provide other capabilities requiring a TTY line discipline (including SLIP or PPP capability) to arbitrary data-generation processes. Each PTY has a master side, named /dev/pty[p-za-e][0-9a-f], and a slave side, named /dev/tty[p-za-e][0-9a-f]. The kernel arbitrates the use of PTYs by allowing each master side to be opened only once.

Once the master side has been opened, the corresponding slave device can be used in the same manner as any TTY device. The master and slave devices are connected by the kernel, generating the equivalent of a bidirectional pipe with TTY capabilities.

Recent versions of the Linux kernels and GNU libc contain support for the System V/Unix98 naming scheme for PTYs, which assigns a common device, /dev/ptmx, to all the masters (opening it will automatically give you a previously unassigned PTY) and a subdirectory, /dev/pts, for the slaves; the slaves are named with decimal integers (/dev/pts/# in our notation). This removes the problem of exhausting the namespace and enables the kernel to automatically create the device nodes for the slaves on demand using the "devpts" filesystem.

CHAPTER

FOUR

DOCUMENTATION FOR /PROC/SYS

Copyright (c) 1998, 1999, Rik van Riel <riel@nl.linux.org>

'Why', I hear you ask, 'would anyone even _want_ documentation for them sysctl files? If anybody really needs it, it's all in the source...'

Well, this documentation is written because some people either don't know they need to tweak something, or because they don't have the time or knowledge to read the source code.

Furthermore, the programmers who built sysctl have built it to be actually used, not just for the fun of programming it :-)

Legal blurb:

As usual, there are two main things to consider:

1. you get what you pay for
2. it's free

The consequences are that I won't guarantee the correctness of this document, and if you come to me complaining about how you screwed up your system because of wrong documentation, I won't feel sorry for you. I might even laugh at you...

But of course, if you _do_ manage to screw up your system using only the sysctl options used in this file, I'd like to hear of it. Not only to have a great laugh, but also to make sure that you're the last RTFMing person to screw up.

In short, e-mail your suggestions, corrections and / or horror stories to: <riel@nl.linux.org>

Rik van Riel.

4.1 Introduction

Sysctl is a means of configuring certain aspects of the kernel at run-time, and the /proc/sys/ directory is there so that you don't even need special tools to do it! In fact, there are only four things needed to use these config facilities:

- a running Linux system
- root access

- common sense (this is especially hard to come by these days)
- knowledge of what all those values mean

As a quick 'ls /proc/sys' will show, the directory consists of several (arch-dependent?) subdirs. Each subdir is mainly about one part of the kernel, so you can do configuration on a piece by piece basis, or just some 'thematic frobbing'.

This documentation is about:

abi/	execution domains & personalities
debug/	<empty>
dev/	device specific information (eg dev/cdrom/info)
fs/	specific filesystems filehandle, inode, dentry and quota tuning binfmt_misc <*Kernel Support for miscellaneous Binary Formats (binfmt_misc)*>
kernel/	global kernel info / tuning miscellaneous stuff
net/	networking stuff, for documentation look in: <Documentation/networking/>
proc/	<empty>
sunrpc/	SUN Remote Procedure Call (NFS)
vm/	memory management tuning buffer and cache management
user/	Per user per user namespace limits

These are the subdirs I have on my system. There might be more or other subdirs in another setup. If you see another dir, I'd really like to hear about it :-)

4.1.1 Documentation for /proc/sys/abi/

Copyright (c) 2020, Stephen Kitt

For general info, see *Documentation for /proc/sys*.

The files in `/proc/sys/abi` can be used to see and modify ABI-related settings.

Currently, these files might (depending on your configuration) show up in `/proc/sys/kernel`:

- *vsyscall32 (x86)*

vsyscall32 (x86)

Determines whether the kernels maps a vDSO page into 32-bit processes; can be set to 1 to enable, or 0 to disable. Defaults to enabled if `CONFIG_COMPAT_VDSO` is set, disabled otherwise.

This controls the same setting as the `vdso32` kernel boot parameter.

4.1.2 Documentation for /proc/sys/fs/

Copyright (c) 1998, 1999, Rik van Riel <riel@nl.linux.org>

Copyright (c) 2009, Shen Feng<shen@cn.fujitsu.com>

For general info and legal blurb, please look in intro.rst.

This file contains documentation for the sysctl files and directories in `/proc/sys/fs/`.

The files in this directory can be used to tune and monitor miscellaneous and general things in the operation of the Linux kernel. Since some of the files *can* be used to screw up your system, it is advisable to read both documentation and source before actually making adjustments.

1. /proc/sys/fs

Currently, these files might (depending on your configuration) show up in `/proc/sys/fs`:

- *aio-nr & aio-max-nr*
- *dentry-state*
- *file-max & file-nr*
- *inode-nr & inode-state*
- *mount-max*
- *nr_open*
- *overflowgid & overflowuid*
- *pipe-user-pages-hard*
- *pipe-user-pages-soft*
- *protected_fifos*
- *protected_hardlinks*
- *protected_regular*
- *protected_symlinks*
- *suid_dumpable*

aio-nr & aio-max-nr

`aio-nr` shows the current system-wide number of asynchronous io requests. `aio-max-nr` allows you to change the maximum value `aio-nr` can grow to. If `aio-nr` reaches `aio-nr-max` then `io_setup` will fail with `EAGAIN`. Note that raising `aio-max-nr` does not result in the pre-allocation or re-sizing of any kernel data structures.

dentry-state

This file shows the values in `struct dentry_stat_t`, as defined in `fs/dcache.c`:

```
struct dentry_stat_t dentry_stat {
      long nr_dentry;
      long nr_unused;
      long age_limit;         /* age in seconds */
      long want_pages;        /* pages requested by system */
      long nr_negative;       /* # of unused negative dentries */
      long dummy;             /* Reserved for future use */
};
```

Dentries are dynamically allocated and deallocated.

`nr_dentry` shows the total number of dentries allocated (active + unused). `nr_unused shows` the number of dentries that are not actively used, but are saved in the LRU list for future reuse.

`age_limit` is the age in seconds after which dcache entries can be reclaimed when memory is short and `want_pages` is nonzero when `shrink_dcache_pages()` has been called and the dcache isn't pruned yet.

`nr_negative` shows the number of unused dentries that are also negative dentries which do not map to any files. Instead, they help speeding up rejection of non-existing files provided by the users.

file-max & file-nr

The value in `file-max` denotes the maximum number of file- handles that the Linux kernel will allocate. When you get lots of error messages about running out of file handles, you might want to increase this limit.

Historically,the kernel was able to allocate file handles dynamically, but not to free them again. The three values in `file-nr` denote the number of allocated file handles, the number of allocated but unused file handles, and the maximum number of file handles. Linux 2.6 and later always reports 0 as the number of free file handles -- this is not an error, it just means that the number of allocated file handles exactly matches the number of used file handles.

Attempts to allocate more file descriptors than `file-max` are reported with `printk`, look for:

```
VFS: file-max limit <number> reached
```

in the kernel logs.

inode-nr & inode-state

As with file handles, the kernel allocates the inode structures dynamically, but can't free them yet.

The file `inode-nr` contains the first two items from `inode-state`, so we'll skip to that file...

`inode-state` contains three actual numbers and four dummies. The actual numbers are, in order of appearance, `nr_inodes`, `nr_free_inodes` and `preshrink`.

`nr_inodes` stands for the number of inodes the system has allocated.

`nr_free_inodes` represents the number of free inodes (?) and preshrink is nonzero when the system needs to prune the inode list instead of allocating more.

mount-max

This denotes the maximum number of mounts that may exist in a mount namespace.

nr_open

This denotes the maximum number of file-handles a process can allocate. Default value is 1024*1024 (1048576) which should be enough for most machines. Actual limit depends on `RLIMIT_NOFILE` resource limit.

overflowgid & overflowuid

Some filesystems only support 16-bit UIDs and GIDs, although in Linux UIDs and GIDs are 32 bits. When one of these filesystems is mounted with writes enabled, any UID or GID that would exceed 65535 is translated to a fixed value before being written to disk.

These sysctls allow you to change the value of the fixed UID and GID. The default is 65534.

pipe-user-pages-hard

Maximum total number of pages a non-privileged user may allocate for pipes. Once this limit is reached, no new pipes may be allocated until usage goes below the limit again. When set to 0, no limit is applied, which is the default setting.

pipe-user-pages-soft

Maximum total number of pages a non-privileged user may allocate for pipes before the pipe size gets limited to a single page. Once this limit is reached, new pipes will be limited to a single page in size for this user in order to limit total memory usage, and trying to increase them using `fcntl()` will be denied until usage goes below the limit again. The default value allows to allocate up to 1024 pipes at their default size. When set to 0, no limit is applied.

protected_fifos

The intent of this protection is to avoid unintentional writes to an attacker-controlled FIFO, where a program expected to create a regular file.

When set to "0", writing to FIFOs is unrestricted.

When set to "1" don't allow `O_CREAT` open on FIFOs that we don't own in world writable sticky directories, unless they are owned by the owner of the directory.

When set to "2" it also applies to group writable sticky directories.

This protection is based on the restrictions in Openwall.

protected_hardlinks

A long-standing class of security issues is the hardlink-based time-of-check-time-of-use race, most commonly seen in world-writable directories like `/tmp`. The common method of exploitation of this flaw is to cross privilege boundaries when following a given hardlink (i.e. a root process follows a hardlink created by another user). Additionally, on systems without separated partitions, this stops unauthorized users from "pinning" vulnerable setuid/setgid files against being upgraded by the administrator, or linking to special files.

When set to "0", hardlink creation behavior is unrestricted.

When set to "1" hardlinks cannot be created by users if they do not already own the source file, or do not have read/write access to it.

This protection is based on the restrictions in Openwall and grsecurity.

protected_regular

This protection is similar to *protected_fifos*, but it avoids writes to an attacker-controlled regular file, where a program expected to create one.

When set to "0", writing to regular files is unrestricted.

When set to "1" don't allow `O_CREAT` open on regular files that we don't own in world writable sticky directories, unless they are owned by the owner of the directory.

When set to "2" it also applies to group writable sticky directories.

protected_symlinks

A long-standing class of security issues is the symlink-based time-of-check-time-of-use race, most commonly seen in world-writable directories like `/tmp`. The common method of exploitation of this flaw is to cross privilege boundaries when following a given symlink (i.e. a root process follows a symlink belonging to another user). For a likely incomplete list of hundreds of examples across the years, please see: https://cve.mitre.org/cgi-bin/cvekey.cgi?keyword=/tmp

When set to "0", symlink following behavior is unrestricted.

When set to "1" symlinks are permitted to be followed only when outside a sticky world-writable directory, or when the uid of the symlink and follower match, or when the directory owner matches the symlink's owner.

This protection is based on the restrictions in Openwall and grsecurity.

suid_dumpable

This value can be used to query and set the core dump mode for setuid or otherwise protected/tainted binaries. The modes are

0	(default)	Traditional behaviour. Any process which has changed privilege levels or is execute only will not be dumped.
1	(debug)	All processes dump core when possible. The core dump is owned by the current user and no security is applied. This is intended for system debugging situations only. Ptrace is unchecked. This is insecure as it allows regular users to examine the memory contents of privileged processes.
2	(suidsafe)	Any binary which normally would not be dumped is dumped anyway, but only if the `core_pattern` kernel sysctl (see *Documentation/admin-guide/sysctl/kernel.rst*) is set to either a pipe handler or a fully qualified path. (For more details on this limitation, see CVE-2006-2451.) This mode is appropriate when administrators are attempting to debug problems in a normal environment, and either have a core dump pipe handler that knows to treat privileged core dumps with care, or specific directory defined for catching core dumps. If a core dump happens without a pipe handler or fully qualified path, a message will be emitted to syslog warning about the lack of a correct setting.

2. /proc/sys/fs/binfmt_misc

Documentation for the files in `/proc/sys/fs/binfmt_misc` is in *Kernel Support for miscellaneous Binary Formats (binfmt_misc)*.

3. /proc/sys/fs/mqueue - POSIX message queues filesystem

The "mqueue" filesystem provides the necessary kernel features to enable the creation of a user space library that implements the POSIX message queues API (as noted by the MSG tag in the POSIX 1003.1-2001 version of the System Interfaces specification.)

The "mqueue" filesystem contains values for determining/setting the amount of resources used by the file system.

`/proc/sys/fs/mqueue/queues_max` is a read/write file for setting/getting the maximum number of message queues allowed on the system.

`/proc/sys/fs/mqueue/msg_max` is a read/write file for setting/getting the maximum number of messages in a queue value. In fact it is the limiting value for another (user) limit which is set in `mq_open` invocation. This attribute of a queue must be less than or equal to `msg_max`.

`/proc/sys/fs/mqueue/msgsize_max` is a read/write file for setting/getting the maximum message size value (it is an attribute of every message queue, set during its creation).

`/proc/sys/fs/mqueue/msg_default` is a read/write file for setting/getting the default number of messages in a queue value if the `attr` parameter of `mq_open(2)` is `NULL`. If it exceeds `msg_max`, the default value is initialized to `msg_max`.

`/proc/sys/fs/mqueue/msgsize_default` is a read/write file for setting/getting the default message size value if the `attr` parameter of `mq_open(2)` is `NULL`. If it exceeds `msgsize_max`, the default value is initialized to `msgsize_max`.

4. /proc/sys/fs/epoll - Configuration options for the epoll interface

This directory contains configuration options for the epoll(7) interface.

max_user_watches

Every epoll file descriptor can store a number of files to be monitored for event readiness. Each one of these monitored files constitutes a "watch". This configuration option sets the maximum number of "watches" that are allowed for each user. Each "watch" costs roughly 90 bytes on a 32-bit kernel, and roughly 160 bytes on a 64-bit one. The current default value for `max_user_watches` is 4% of the available low memory, divided by the "watch" cost in bytes.

4.1.3 Documentation for /proc/sys/kernel/

Copyright (c) 1998, 1999, Rik van Riel <riel@nl.linux.org>

Copyright (c) 2009, Shen Feng<shen@cn.fujitsu.com>

For general info and legal blurb, please look in *Documentation for /proc/sys*.

This file contains documentation for the sysctl files in `/proc/sys/kernel/`.

The files in this directory can be used to tune and monitor miscellaneous and general things in the operation of the Linux kernel. Since some of the files *can* be used to screw up your system, it is advisable to read both documentation and source before actually making adjustments.

Currently, these files might (depending on your configuration) show up in `/proc/sys/kernel`:

acct

```
highwater lowwater frequency
```

If BSD-style process accounting is enabled these values control its behaviour. If free space on filesystem where the log lives goes below `lowwater`% accounting suspends. If free space gets above `highwater`% accounting resumes. `frequency` determines how often do we check the amount of free space (value is in seconds). Default:

```
4 2 30
```

That is, suspend accounting if free space drops below 2%; resume it if it increases to at least 4%; consider information about amount of free space valid for 30 seconds.

acpi_video_flags

See Documentation/power/video.rst. This allows the video resume mode to be set, in a similar fashion to the `acpi_sleep` kernel parameter, by combining the following values:

1	s3_bios
2	s3_mode
4	s3_beep

arch

The machine hardware name, the same output as `uname -m` (e.g. `x86_64` or `aarch64`).

auto_msgmni

This variable has no effect and may be removed in future kernel releases. Reading it always returns 0. Up to Linux 3.17, it enabled/disabled automatic recomputing of *msgmni* upon memory add/remove or upon IPC namespace creation/removal. Echoing "1" into this file enabled msgmni automatic recomputing. Echoing "0" turned it off. The default value was 1.

bootloader_type (x86 only)

This gives the bootloader type number as indicated by the bootloader, shifted left by 4, and OR'd with the low four bits of the bootloader version. The reason for this encoding is that this used to match the `type_of_loader` field in the kernel header; the encoding is kept for backwards compatibility. That is, if the full bootloader type number is 0x15 and the full version number is 0x234, this file will contain the value 340 = 0x154.

See the `type_of_loader` and `ext_loader_type` fields in Documentation/arch/x86/boot.rst for additional information.

bootloader_version (x86 only)

The complete bootloader version number. In the example above, this file will contain the value 564 = 0x234.

See the `type_of_loader` and `ext_loader_ver` fields in Documentation/arch/x86/boot.rst for additional information.

bpf_stats_enabled

Controls whether the kernel should collect statistics on BPF programs (total time spent running, number of times run...). Enabling statistics causes a slight reduction in performance on each program run. The statistics can be seen using `bpftool`.

0	Don't collect statistics (default).
1	Collect statistics.

cad_pid

This is the pid which will be signalled on reboot (notably, by Ctrl-Alt-Delete). Writing a value to this file which doesn't correspond to a running process will result in `-ESRCH`.

See also *ctrl-alt-del*.

cap_last_cap

Highest valid capability of the running kernel. Exports `CAP_LAST_CAP` from the kernel.

core_pattern

`core_pattern` is used to specify a core dumpfile pattern name.

- max length 127 characters; default value is "core"
- `core_pattern` is used as a pattern template for the output filename; certain string patterns (beginning with '%') are substituted with their actual values.
- backward compatibility with `core_uses_pid`:

  If `core_pattern` does not include "%p" (default does not) and `core_uses_pid` is set, then .PID will be appended to the filename.
- corename format specifiers

%<NUL>	'%' is dropped
%%	output one '%'
%p	pid
%P	global pid (init PID namespace)
%i	tid
%I	global tid (init PID namespace)
%u	uid (in initial user namespace)
%g	gid (in initial user namespace)
%d	dump mode, matches `PR_SET_DUMPABLE` and `/proc/sys/fs/suid_dumpable`
%s	signal number
%t	UNIX time of dump
%h	hostname
%e	executable filename (may be shortened, could be changed by prctl etc)
%f	executable filename
%E	executable path
%c	maximum size of core file by resource limit RLIMIT_CORE
%C	CPU the task ran on
%<OTHER>	both are dropped

- If the first character of the pattern is a '|', the kernel will treat the rest of the pattern as a command to run. The core dump will be written to the standard input of that program instead of to a file.

core_pipe_limit

This sysctl is only applicable when *core_pattern* is configured to pipe core files to a user space helper (when the first character of `core_pattern` is a '|', see above). When collecting cores via a pipe to an application, it is occasionally useful for the collecting application to gather data about the crashing process from its `/proc/pid` directory. In order to do this safely, the kernel must wait for the collecting process to exit, so as not to remove the crashing processes proc files prematurely. This in turn creates the possibility that a misbehaving userspace collecting process can block the reaping of a crashed process simply by never exiting. This sysctl defends against that. It defines how many concurrent crashing processes may be piped to user space applications in parallel. If this value is exceeded, then those crashing processes above that value are noted via the kernel log and their cores are skipped. 0 is a special value, indicating that unlimited processes may be captured in parallel, but that no waiting will take place (i.e. the collecting process is not guaranteed access to `/proc/<crashing pid>/`). This value defaults to 0.

core_uses_pid

The default coredump filename is "core". By setting `core_uses_pid` to 1, the coredump filename becomes core.PID. If *core_pattern* does not include "%p" (default does not) and `core_uses_pid` is set, then .PID will be appended to the filename.

ctrl-alt-del

When the value in this file is 0, ctrl-alt-del is trapped and sent to the `init(1)` program to handle a graceful restart. When, however, the value is > 0, Linux's reaction to a Vulcan Nerve Pinch (tm) will be an immediate reboot, without even syncing its dirty buffers.

Note:
when a program (like dosemu) has the keyboard in 'raw' mode, the ctrl-alt-del is intercepted by the program before it ever reaches the kernel tty layer, and it's up to the program to decide what to do with it.

dmesg_restrict

This toggle indicates whether unprivileged users are prevented from using `dmesg(8)` to view messages from the kernel's log buffer. When `dmesg_restrict` is set to 0 there are no restrictions. When `dmesg_restrict` is set to 1, users must have `CAP_SYSLOG` to use `dmesg(8)`.

The kernel config option `CONFIG_SECURITY_DMESG_RESTRICT` sets the default value of `dmesg_restrict`.

domainname & hostname

These files can be used to set the NIS/YP domainname and the hostname of your box in exactly the same way as the commands domainname and hostname, i.e.:

```
# echo "darkstar" > /proc/sys/kernel/hostname
# echo "mydomain" > /proc/sys/kernel/domainname
```

has the same effect as:

```
# hostname "darkstar"
# domainname "mydomain"
```

Note, however, that the classic darkstar.frop.org has the hostname "darkstar" and DNS (Internet Domain Name Server) domainname "frop.org", not to be confused with the NIS (Network Information Service) or YP (Yellow Pages) domainname. These two domain names are in general different. For a detailed discussion see the `hostname(1)` man page.

firmware_config

See Documentation/driver-api/firmware/fallback-mechanisms.rst.

The entries in this directory allow the firmware loader helper fallback to be controlled:

- `force_sysfs_fallback`, when set to 1, forces the use of the fallback;
- `ignore_sysfs_fallback`, when set to 1, ignores any fallback.

ftrace_dump_on_oops

Determines whether `ftrace_dump()` should be called on an oops (or kernel panic). This will output the contents of the ftrace buffers to the console. This is very useful for capturing traces that lead to crashes and outputting them to a serial console.

0	Disabled (default).
1	Dump buffers of all CPUs.
2	Dump the buffer of the CPU that triggered the oops.

ftrace_enabled, stack_tracer_enabled

See Documentation/trace/ftrace.rst.

hardlockup_all_cpu_backtrace

This value controls the hard lockup detector behavior when a hard lockup condition is detected as to whether or not to gather further debug information. If enabled, arch-specific all-CPU stack dumping will be initiated.

0	Do nothing. This is the default behavior.
1	On detection capture more debug information.

hardlockup_panic

This parameter can be used to control whether the kernel panics when a hard lockup is detected.

0	Don't panic on hard lockup.
1	Panic on hard lockup.

See *Softlockup detector and hardlockup detector (aka nmi_watchdog)* for more information. This can also be set using the nmi_watchdog kernel parameter.

hotplug

Path for the hotplug policy agent. Default value is `CONFIG_UEVENT_HELPER_PATH`, which in turn defaults to the empty string.

This file only exists when `CONFIG_UEVENT_HELPER` is enabled. Most modern systems rely exclusively on the netlink-based uevent source and don't need this.

hung_task_all_cpu_backtrace

If this option is set, the kernel will send an NMI to all CPUs to dump their backtraces when a hung task is detected. This file shows up if CONFIG_DETECT_HUNG_TASK and CONFIG_SMP are enabled.

0: Won't show all CPUs backtraces when a hung task is detected. This is the default behavior.

1: Will non-maskably interrupt all CPUs and dump their backtraces when a hung task is detected.

hung_task_panic

Controls the kernel's behavior when a hung task is detected. This file shows up if `CONFIG_DETECT_HUNG_TASK` is enabled.

0	Continue operation. This is the default behavior.
1	Panic immediately.

hung_task_check_count

The upper bound on the number of tasks that are checked. This file shows up if `CONFIG_DETECT_HUNG_TASK` is enabled.

hung_task_timeout_secs

When a task in D state did not get scheduled for more than this value report a warning. This file shows up if `CONFIG_DETECT_HUNG_TASK` is enabled.

0 means infinite timeout, no checking is done.

Possible values to set are in range {0:`LONG_MAX/HZ`}.

hung_task_check_interval_secs

Hung task check interval. If hung task checking is enabled (see *hung_task_timeout_secs*), the check is done every `hung_task_check_interval_secs` seconds. This file shows up if `CONFIG_DETECT_HUNG_TASK` is enabled.

0 (default) means use `hung_task_timeout_secs` as checking interval.

Possible values to set are in range {0:`LONG_MAX/HZ`}.

hung_task_warnings

The maximum number of warnings to report. During a check interval if a hung task is detected, this value is decreased by 1. When this value reaches 0, no more warnings will be reported. This file shows up if `CONFIG_DETECT_HUNG_TASK` is enabled.

-1: report an infinite number of warnings.

hyperv_record_panic_msg

Controls whether the panic kmsg data should be reported to Hyper-V.

0	Do not report panic kmsg data.
1	Report the panic kmsg data. This is the default behavior.

ignore-unaligned-usertrap

On architectures where unaligned accesses cause traps, and where this feature is supported (`CONFIG_SYSCTL_ARCH_UNALIGN_NO_WARN`; currently, `arc` and `loongarch`), controls whether all unaligned traps are logged.

0	Log all unaligned accesses.
1	Only warn the first time a process traps. This is the default setting.

See also *unaligned-trap*.

io_uring_disabled

Prevents all processes from creating new io_uring instances. Enabling this shrinks the kernel's attack surface.

0	All processes can create io_uring instances as normal. This is the default setting.
1	io_uring creation is disabled (io_uring_setup() will fail with -EPERM) for unprivileged processes not in the io_uring_group group. Existing io_uring instances can still be used. See the documentation for io_uring_group for more information.
2	io_uring creation is disabled for all processes. io_uring_setup() always fails with -EPERM. Existing io_uring instances can still be used.

io_uring_group

When io_uring_disabled is set to 1, a process must either be privileged (CAP_SYS_ADMIN) or be in the io_uring_group group in order to create an io_uring instance. If io_uring_group is set to -1 (the default), only processes with the CAP_SYS_ADMIN capability may create io_uring instances.

kexec_load_disabled

A toggle indicating if the syscalls `kexec_load` and `kexec_file_load` have been disabled. This value defaults to 0 (false: `kexec_*load` enabled), but can be set to 1 (true: `kexec_*load` disabled). Once true, kexec can no longer be used, and the toggle cannot be set back to false. This allows a kexec image to be loaded before disabling the syscall, allowing a system to set up (and later use) an image without it being altered. Generally used together with the *modules_disabled* sysctl.

kexec_load_limit_panic

This parameter specifies a limit to the number of times the syscalls `kexec_load` and `kexec_file_load` can be called with a crash image. It can only be set with a more restrictive value than the current one.

-1	Unlimited calls to kexec. This is the default setting.
N	Number of calls left.

kexec_load_limit_reboot

Similar functionality as `kexec_load_limit_panic`, but for a normal image.

kptr_restrict

This toggle indicates whether restrictions are placed on exposing kernel addresses via `/proc` and other interfaces.

When `kptr_restrict` is set to 0 (the default) the address is hashed before printing. (This is the equivalent to %p.)

When `kptr_restrict` is set to 1, kernel pointers printed using the %pK format specifier will be replaced with 0s unless the user has `CAP_SYSLOG` and effective user and group ids are equal to the real ids. This is because %pK checks are done at read() time rather than open() time, so if permissions are elevated between the open() and the read() (e.g via a setuid binary) then %pK will not leak kernel pointers to unprivileged users. Note, this is a temporary solution only. The correct long-term solution is to do the permission checks at open() time. Consider removing world read permissions from files that use %pK, and using *dmesg_restrict* to protect against uses of %pK in `dmesg(8)` if leaking kernel pointer values to unprivileged users is a concern.

When `kptr_restrict` is set to 2, kernel pointers printed using %pK will be replaced with 0s regardless of privileges.

modprobe

The full path to the usermode helper for autoloading kernel modules, by default `CONFIG_MODPROBE_PATH`, which in turn defaults to "/sbin/modprobe". This binary is executed when the kernel requests a module. For example, if userspace passes an unknown filesystem type to mount(), then the kernel will automatically request the corresponding filesystem module by executing this usermode helper. This usermode helper should insert the needed module into the kernel.

This sysctl only affects module autoloading. It has no effect on the ability to explicitly insert modules.

This sysctl can be used to debug module loading requests:

```
echo '#! /bin/sh' > /tmp/modprobe
echo 'echo "$@" >> /tmp/modprobe.log' >> /tmp/modprobe
echo 'exec /sbin/modprobe "$@"' >> /tmp/modprobe
chmod a+x /tmp/modprobe
echo /tmp/modprobe > /proc/sys/kernel/modprobe
```

Alternatively, if this sysctl is set to the empty string, then module autoloading is completely disabled. The kernel will not try to execute a usermode helper at all, nor will it call the kernel_module_request LSM hook.

If CONFIG_STATIC_USERMODEHELPER=y is set in the kernel configuration, then the configured static usermode helper overrides this sysctl, except that the empty string is still accepted to completely disable module autoloading as described above.

modules_disabled

A toggle value indicating if modules are allowed to be loaded in an otherwise modular kernel. This toggle defaults to off (0), but can be set true (1). Once true, modules can be neither loaded nor unloaded, and the toggle cannot be set back to false. Generally used with the *kexec_load_disabled* toggle.

msgmax, msgmnb, and msgmni

`msgmax` is the maximum size of an IPC message, in bytes. 8192 by default (`MSGMAX`).

`msgmnb` is the maximum size of an IPC queue, in bytes. 16384 by default (`MSGMNB`).

`msgmni` is the maximum number of IPC queues. 32000 by default (`MSGMNI`).

msg_next_id, sem_next_id, and shm_next_id (System V IPC)

These three toggles allows to specify desired id for next allocated IPC object: message, semaphore or shared memory respectively.

By default they are equal to -1, which means generic allocation logic. Possible values to set are in range {0:INT_MAX}.

Notes:

1) kernel doesn't guarantee, that new object will have desired id. So, it's up to userspace, how to handle an object with "wrong" id.
2) Toggle with non-default value will be set back to -1 by kernel after successful IPC object allocation. If an IPC object allocation syscall fails, it is undefined if the value remains unmodified or is reset to -1.

ngroups_max

Maximum number of supplementary groups, _i.e._ the maximum size which setgroups will accept. Exports NGROUPS_MAX from the kernel.

nmi_watchdog

This parameter can be used to control the NMI watchdog (i.e. the hard lockup detector) on x86 systems.

0	Disable the hard lockup detector.
1	Enable the hard lockup detector.

The hard lockup detector monitors each CPU for its ability to respond to timer interrupts. The mechanism utilizes CPU performance counter registers that are programmed to generate Non-Maskable Interrupts (NMIs) periodically while a CPU is busy. Hence, the alternative name 'NMI watchdog'.

The NMI watchdog is disabled by default if the kernel is running as a guest in a KVM virtual machine. This default can be overridden by adding:

```
nmi_watchdog=1
```

to the guest kernel command line (see *The kernel's command-line parameters*).

nmi_wd_lpm_factor (PPC only)

Factor to apply to the NMI watchdog timeout (only when nmi_watchdog is set to 1). This factor represents the percentage added to watchdog_thresh when calculating the NMI watchdog timeout during an LPM. The soft lockup timeout is not impacted.

A value of 0 means no change. The default value is 200 meaning the NMI watchdog is set to 30s (based on watchdog_thresh equal to 10).

numa_balancing

Enables/disables and configures automatic page fault based NUMA memory balancing. Memory is moved automatically to nodes that access it often. The value to set can be the result of ORing the following:

0	NUMA_BALANCING_DISABLED
1	NUMA_BALANCING_NORMAL
2	NUMA_BALANCING_MEMORY_TIERING

Or NUMA_BALANCING_NORMAL to optimize page placement among different NUMA nodes to reduce remote accessing. On NUMA machines, there is a performance penalty if remote memory is accessed by a CPU. When this feature is enabled the kernel samples what task thread is accessing memory by periodically unmapping pages and later trapping a page fault. At the time of the page fault, it is determined if the data being accessed should be migrated to a local memory node.

The unmapping of pages and trapping faults incur additional overhead that ideally is offset by improved memory locality but there is no universal guarantee. If the target workload is already bound to NUMA nodes then this feature should be disabled.

Or NUMA_BALANCING_MEMORY_TIERING to optimize page placement among different types of memory (represented as different NUMA nodes) to place the hot pages in the fast memory. This is implemented based on unmapping and page fault too.

numa_balancing_promote_rate_limit_MBps

Too high promotion/demotion throughput between different memory types may hurt application latency. This can be used to rate limit the promotion throughput. The per-node max promotion throughput in MB/s will be limited to be no more than the set value.

A rule of thumb is to set this to less than 1/10 of the PMEM node write bandwidth.

oops_all_cpu_backtrace

If this option is set, the kernel will send an NMI to all CPUs to dump their backtraces when an oops event occurs. It should be used as a last resort in case a panic cannot be triggered (to protect VMs running, for example) or kdump can't be collected. This file shows up if CONFIG_SMP is enabled.

0: Won't show all CPUs backtraces when an oops is detected. This is the default behavior.

1: Will non-maskably interrupt all CPUs and dump their backtraces when an oops event is detected.

oops_limit

Number of kernel oopses after which the kernel should panic when `panic_on_oops` is not set. Setting this to 0 disables checking the count. Setting this to 1 has the same effect as setting `panic_on_oops=1`. The default value is 10000.

osrelease, ostype & version

```
# cat osrelease
2.1.88
# cat ostype
Linux
# cat version
#5 Wed Feb 25 21:49:24 MET 1998
```

The files `osrelease` and `ostype` should be clear enough. `version` needs a little more clarification however. The '#5' means that this is the fifth kernel built from this source base and the date behind it indicates the time the kernel was built. The only way to tune these values is to rebuild the kernel :-)

overflowgid & overflowuid

if your architecture did not always support 32-bit UIDs (i.e. arm, i386, m68k, sh, and sparc32), a fixed UID and GID will be returned to applications that use the old 16-bit UID/GID system calls, if the actual UID or GID would exceed 65535.

These sysctls allow you to change the value of the fixed UID and GID. The default is 65534.

panic

The value in this file determines the behaviour of the kernel on a panic:

- if zero, the kernel will loop forever;
- if negative, the kernel will reboot immediately;
- if positive, the kernel will reboot after the corresponding number of seconds.

When you use the software watchdog, the recommended setting is 60.

panic_on_io_nmi

Controls the kernel's behavior when a CPU receives an NMI caused by an IO error.

0	Try to continue operation (default).
1	Panic immediately. The IO error triggered an NMI. This indicates a serious system condition which could result in IO data corruption. Rather than continuing, panicking might be a better choice. Some servers issue this sort of NMI when the dump button is pushed, and you can use this option to take a crash dump.

panic_on_oops

Controls the kernel's behaviour when an oops or BUG is encountered.

0	Try to continue operation.
1	Panic immediately. If the *panic* sysctl is also non-zero then the machine will be rebooted.

panic_on_stackoverflow

Controls the kernel's behavior when detecting the overflows of kernel, IRQ and exception stacks except a user stack. This file shows up if `CONFIG_DEBUG_STACKOVERFLOW` is enabled.

0	Try to continue operation.
1	Panic immediately.

panic_on_unrecovered_nmi

The default Linux behaviour on an NMI of either memory or unknown is to continue operation. For many environments such as scientific computing it is preferable that the box is taken out and the error dealt with than an uncorrected parity/ECC error get propagated.

A small number of systems do generate NMIs for bizarre random reasons such as power management so the default is off. That sysctl works like the existing panic controls already in that directory.

panic_on_warn

Calls panic() in the WARN() path when set to 1. This is useful to avoid a kernel rebuild when attempting to kdump at the location of a WARN().

0	Only WARN(), default behaviour.
1	Call panic() after printing out WARN() location.

panic_print

Bitmask for printing system info when panic happens. User can chose combination of the following bits:

bit 0	print all tasks info
bit 1	print system memory info
bit 2	print timer info
bit 3	print locks info if `CONFIG_LOCKDEP` is on
bit 4	print ftrace buffer
bit 5	print all printk messages in buffer
bit 6	print all CPUs backtrace (if available in the arch)

So for example to print tasks and memory info on panic, user can:

```
echo 3 > /proc/sys/kernel/panic_print
```

panic_on_rcu_stall

When set to 1, calls panic() after RCU stall detection messages. This is useful to define the root cause of RCU stalls using a vmcore.

0	Do not panic() when RCU stall takes place, default behavior.
1	panic() after printing RCU stall messages.

max_rcu_stall_to_panic

When `panic_on_rcu_stall` is set to 1, this value determines the number of times that RCU can stall before panic() is called.

When `panic_on_rcu_stall` is set to 0, this value is has no effect.

perf_cpu_time_max_percent

Hints to the kernel how much CPU time it should be allowed to use to handle perf sampling events. If the perf subsystem is informed that its samples are exceeding this limit, it will drop its sampling frequency to attempt to reduce its CPU usage.

Some perf sampling happens in NMIs. If these samples unexpectedly take too long to execute, the NMIs can become stacked up next to each other so much that nothing else is allowed to execute.

0	Disable the mechanism. Do not monitor or correct perf's sampling rate no matter how CPU time it takes.
1-100	Attempt to throttle perf's sample rate to this percentage of CPU. Note: the kernel calculates an ”expected” length of each sample event. 100 here means 100% of that expected length. Even if this is set to 100, you may still see sample throttling if this length is exceeded. Set to 0 if you truly do not care how much CPU is consumed.

perf_event_paranoid

Controls use of the performance events system by unprivileged users (without CAP_PERFMON). The default value is 2.

For backward compatibility reasons access to system performance monitoring and observability remains open for CAP_SYS_ADMIN privileged processes but CAP_SYS_ADMIN usage for secure system performance monitoring and observability operations is discouraged with respect to CAP_PERFMON use cases.

-1	Allow use of (almost) all events by all users. Ignore mlock limit after perf_event_mlock_kb without `CAP_IPC_LOCK`.
>=0	Disallow ftrace function tracepoint by users without `CAP_PERFMON`. Disallow raw tracepoint access by users without `CAP_PERFMON`.
>=1	Disallow CPU event access by users without `CAP_PERFMON`.
>=2	Disallow kernel profiling by users without `CAP_PERFMON`.

perf_event_max_stack

Controls maximum number of stack frames to copy for (`attr.sample_type` & `PERF_SAMPLE_CALLCHAIN`) configured events, for instance, when using '`perf record -g`' or '`perf trace --call-graph fp`'.

This can only be done when no events are in use that have callchains enabled, otherwise writing to this file will return `-EBUSY`.

The default value is 127.

perf_event_mlock_kb

Control size of per-cpu ring buffer not counted against mlock limit.

The default value is 512 + 1 page

perf_event_max_contexts_per_stack

Controls maximum number of stack frame context entries for (`attr.sample_type` & `PERF_SAMPLE_CALLCHAIN`) configured events, for instance, when using '`perf record -g`' or '`perf trace --call-graph fp`'.

This can only be done when no events are in use that have callchains enabled, otherwise writing to this file will return `-EBUSY`.

The default value is 8.

perf_user_access (arm64 and riscv only)

Controls user space access for reading perf event counters.

arm64

The default value is 0 (access disabled).

When set to 1, user space can read performance monitor counter registers directly.

See Documentation/arch/arm64/perf.rst for more information.

riscv

When set to 0, user space access is disabled.

The default value is 1, user space can read performance monitor counter registers through perf, any direct access without perf intervention will trigger an illegal instruction.

When set to 2, which enables legacy mode (user space has direct access to cycle and insret CSRs only). Note that this legacy value is deprecated and will be removed once all user space applications are fixed.

Note that the time CSR is always directly accessible to all modes.

pid_max

PID allocation wrap value. When the kernel's next PID value reaches this value, it wraps back to a minimum PID value. PIDs of value `pid_max` or larger are not allocated.

ns_last_pid

The last pid allocated in the current (the one task using this sysctl lives in) pid namespace. When selecting a pid for a next task on fork kernel tries to allocate a number starting from this one.

powersave-nap (PPC only)

If set, Linux-PPC will use the 'nap' mode of powersaving, otherwise the 'doze' mode will be used.

---

printk

The four values in printk denote: `console_loglevel`, `default_message_loglevel`, `minimum_console_loglevel` and `default_console_loglevel` respectively.

These values influence printk() behavior when printing or logging error messages. See '`man 2 syslog`' for more info on the different loglevels.

console_loglevel	messages with a higher priority than this will be printed to the console
default_message_loglevel	messages without an explicit priority will be printed with this priority
minimum_console_loglevel	minimum (highest) value to which console_loglevel can be set
default_console_loglevel	default value for console_loglevel

printk_delay

Delay each printk message in `printk_delay` milliseconds

Value from 0 - 10000 is allowed.

printk_ratelimit

Some warning messages are rate limited. `printk_ratelimit` specifies the minimum length of time between these messages (in seconds). The default value is 5 seconds.

A value of 0 will disable rate limiting.

printk_ratelimit_burst

While long term we enforce one message per *printk_ratelimit* seconds, we do allow a burst of messages to pass through. `printk_ratelimit_burst` specifies the number of messages we can send before ratelimiting kicks in.

The default value is 10 messages.

printk_devkmsg

Control the logging to `/dev/kmsg` from userspace:

ratelimit	default, ratelimited
on	unlimited logging to /dev/kmsg from userspace
off	logging to /dev/kmsg disabled

The kernel command line parameter `printk.devkmsg=` overrides this and is a one-time setting until next reboot: once set, it cannot be changed by this sysctl interface anymore.

---

pty

See Documentation/filesystems/devpts.rst.

random

This is a directory, with the following entries:

- `boot_id`: a UUID generated the first time this is retrieved, and unvarying after that;
- `uuid`: a UUID generated every time this is retrieved (this can thus be used to generate UUIDs at will);
- `entropy_avail`: the pool's entropy count, in bits;
- `poolsize`: the entropy pool size, in bits;

- `urandom_min_reseed_secs`: obsolete (used to determine the minimum number of seconds between urandom pool reseeding). This file is writable for compatibility purposes, but writing to it has no effect on any RNG behavior;
- `write_wakeup_threshold`: when the entropy count drops below this (as a number of bits), processes waiting to write to `/dev/random` are woken up. This file is writable for compatibility purposes, but writing to it has no effect on any RNG behavior.

randomize_va_space

This option can be used to select the type of process address space randomization that is used in the system, for architectures that support this feature.

0	Turn the process address space randomization off. This is the default for architectures that do not support this feature anyways, and kernels that are booted with the "norandmaps" parameter.
1	Make the addresses of mmap base, stack and VDSO page randomized. This, among other things, implies that shared libraries will be loaded to random addresses. Also for PIE-linked binaries, the location of code start is randomized. This is the default if the `CONFIG_COMPAT_BRK` option is enabled.
2	Additionally enable heap randomization. This is the default if `CONFIG_COMPAT_BRK` is disabled. There are a few legacy applications out there (such as some ancient versions of libc.so.5 from 1996) that assume that brk area starts just after the end of the code+bss. These applications break when start of the brk area is randomized. There are however no known non-legacy applications that would be broken this way, so for most systems it is safe to choose full randomization. Systems with ancient and/or broken binaries should be configured with `CONFIG_COMPAT_BRK` enabled, which excludes the heap from process address space randomization.

real-root-dev

See *Using the initial RAM disk (initrd)*.

reboot-cmd (SPARC only)

??? This seems to be a way to give an argument to the Sparc ROM/Flash boot loader. Maybe to tell it what to do after rebooting. ???

sched_energy_aware

Enables/disables Energy Aware Scheduling (EAS). EAS starts automatically on platforms where it can run (that is, platforms with asymmetric CPU topologies and having an Energy Model available). If your platform happens to meet the requirements for EAS but you do not want to use it, change this value to 0. On Non-EAS platforms, write operation fails and read doesn't return anything.

task_delayacct

Enables/disables task delay accounting (see Documentation/accounting/delay-accounting.rst. Enabling this feature incurs a small amount of overhead in the scheduler but is useful for debugging and performance tuning. It is required by some tools such as iotop.

sched_schedstats

Enables/disables scheduler statistics. Enabling this feature incurs a small amount of overhead in the scheduler but is useful for debugging and performance tuning.

sched_util_clamp_min

Max allowed *minimum* utilization.

Default value is 1024, which is the maximum possible value.

It means that any requested uclamp.min value cannot be greater than sched_util_clamp_min, i.e., it is restricted to the range [0:sched_util_clamp_min].

sched_util_clamp_max

Max allowed *maximum* utilization.

Default value is 1024, which is the maximum possible value.

It means that any requested uclamp.max value cannot be greater than sched_util_clamp_max, i.e., it is restricted to the range [0:sched_util_clamp_max].

sched_util_clamp_min_rt_default

By default Linux is tuned for performance. Which means that RT tasks always run at the highest frequency and most capable (highest capacity) CPU (in heterogeneous systems).

Uclamp achieves this by setting the requested uclamp.min of all RT tasks to 1024 by default, which effectively boosts the tasks to run at the highest frequency and biases them to run on the biggest CPU.

This knob allows admins to change the default behavior when uclamp is being used. In battery powered devices particularly, running at the maximum capacity and frequency will increase energy consumption and shorten the battery life.

This knob is only effective for RT tasks which the user hasn't modified their requested uclamp.min value via sched_setattr() syscall.

This knob will not escape the range constraint imposed by sched_util_clamp_min defined above.

For example if

> sched_util_clamp_min_rt_default = 800 sched_util_clamp_min = 600

Then the boost will be clamped to 600 because 800 is outside of the permissible range of [0:600]. This could happen for instance if a powersave mode will restrict all boosts temporarily by modifying sched_util_clamp_min. As soon as this restriction is lifted, the requested sched_util_clamp_min_rt_default will take effect.

seccomp

See Documentation/userspace-api/seccomp_filter.rst.

sg-big-buff

This file shows the size of the generic SCSI (sg) buffer. You can't tune it just yet, but you could change it on compile time by editing `include/scsi/sg.h` and changing the value of `SG_BIG_BUFF`.

There shouldn't be any reason to change this value. If you can come up with one, you probably know what you are doing anyway :)

shmall

This parameter sets the total amount of shared memory pages that can be used system wide. Hence, `shmall` should always be at least `ceil(shmmax/PAGE_SIZE)`.

If you are not sure what the default `PAGE_SIZE` is on your Linux system, you can run the following command:

```
# getconf PAGE_SIZE
```

shmmax

This value can be used to query and set the run time limit on the maximum shared memory segment size that can be created. Shared memory segments up to 1Gb are now supported in the kernel. This value defaults to `SHMMAX`.

shmmni

This value determines the maximum number of shared memory segments. 4096 by default (`SHMMNI`).

shm_rmid_forced

Linux lets you set resource limits, including how much memory one process can consume, via `setrlimit(2)`. Unfortunately, shared memory segments are allowed to exist without association with any process, and thus might not be counted against any resource limits. If enabled, shared memory segments are automatically destroyed when their attach count becomes zero after a detach or a process termination. It will also destroy segments that were created, but never attached to, on exit from the process. The only use left for `IPC_RMID` is to immediately destroy an unattached segment. Of course, this breaks the way things are defined, so some applications might stop working. Note that this feature will do you no good unless you also configure your resource limits (in particular, `RLIMIT_AS` and `RLIMIT_NPROC`). Most systems don't need this.

Note that if you change this from 0 to 1, already created segments without users and with a dead originative process will be destroyed.

sysctl_writes_strict

Control how file position affects the behavior of updating sysctl values via the `/proc/sys` interface:

-1	Legacy per-write sysctl value handling, with no printk warnings. Each write syscall must fully contain the sysctl value to be written, and multiple writes on the same sysctl file descriptor will rewrite the sysctl value, regardless of file position.
0	Same behavior as above, but warn about processes that perform writes to a sysctl file descriptor when the file position is not 0.
1	(default) Respect file position when writing sysctl strings. Multiple writes will append to the sysctl value buffer. Anything past the max length of the sysctl value buffer will be ignored. Writes to numeric sysctl entries must always be at file position 0 and the value must be fully contained in the buffer sent in the write syscall.

softlockup_all_cpu_backtrace

This value controls the soft lockup detector thread's behavior when a soft lockup condition is detected as to whether or not to gather further debug information. If enabled, each cpu will be issued an NMI and instructed to capture stack trace.

This feature is only applicable for architectures which support NMI.

0	Do nothing. This is the default behavior.
1	On detection capture more debug information.

softlockup_panic

This parameter can be used to control whether the kernel panics when a soft lockup is detected.

0	Don't panic on soft lockup.
1	Panic on soft lockup.

This can also be set using the softlockup_panic kernel parameter.

soft_watchdog

This parameter can be used to control the soft lockup detector.

0	Disable the soft lockup detector.
1	Enable the soft lockup detector.

The soft lockup detector monitors CPUs for threads that are hogging the CPUs without rescheduling voluntarily, and thus prevent the 'migration/N' threads from running, causing the watchdog work fail to execute. The mechanism depends on the CPUs ability to respond to timer interrupts which are needed for the watchdog work to be queued by the watchdog timer function, otherwise the NMI watchdog — if enabled — can detect a hard lockup condition.

split_lock_mitigate (x86 only)

On x86, each ”split lock” imposes a system-wide performance penalty. On larger systems, large numbers of split locks from unprivileged users can result in denials of service to well-behaved and potentially more important users.

The kernel mitigates these bad users by detecting split locks and imposing penalties: forcing them to wait and only allowing one core to execute split locks at a time.

These mitigations can make those bad applications unbearably slow. Setting split_lock_mitigate=0 may restore some application performance, but will also increase system exposure to denial of service attacks from split lock users.

0	Disable the mitigation mode - just warns the split lock on kernel log and exposes the system to denials of service from the split lockers.
1	Enable the mitigation mode (this is the default) - penalizes the split lockers with intentional performance degradation.

stack_erasing

This parameter can be used to control kernel stack erasing at the end of syscalls for kernels built with `CONFIG_GCC_PLUGIN_STACKLEAK`.

That erasing reduces the information which kernel stack leak bugs can reveal and blocks some uninitialized stack variable attacks. The tradeoff is the performance impact: on a single CPU system kernel compilation sees a 1% slowdown, other systems and workloads may vary.

0	Kernel stack erasing is disabled, STACKLEAK_METRICS are not updated.
1	Kernel stack erasing is enabled (default), it is performed before returning to the userspace at the end of syscalls.

stop-a (SPARC only)

Controls Stop-A:

0	Stop-A has no effect.
1	Stop-A breaks to the PROM (default).

Stop-A is always enabled on a panic, so that the user can return to the boot PROM.

sysrq

See *Linux Magic System Request Key Hacks*.

tainted

Non-zero if the kernel has been tainted. Numeric values, which can be ORed together. The letters are seen in "Tainted" line of Oops reports.

1	*(P)*	proprietary module was loaded
2	*(F)*	module was force loaded
4	*(S)*	kernel running on an out of specification system
8	*(R)*	module was force unloaded
16	*(M)*	processor reported a Machine Check Exception (MCE)
32	*(B)*	bad page referenced or some unexpected page flags
64	*(U)*	taint requested by userspace application
128	*(D)*	kernel died recently, i.e. there was an OOPS or BUG
256	*(A)*	an ACPI table was overridden by user
512	*(W)*	kernel issued warning
1024	*(C)*	staging driver was loaded
2048	*(I)*	workaround for bug in platform firmware applied
4096	*(O)*	externally-built (”out-of-tree”) module was loaded
8192	*(E)*	unsigned module was loaded
16384	*(L)*	soft lockup occurred
32768	*(K)*	kernel has been live patched
65536	*(X)*	Auxiliary taint, defined and used by for distros
131072	*(T)*	The kernel was built with the struct randomization plugin

See *Tainted kernels* for more information.

Note:

writes to this sysctl interface will fail with `EINVAL` if the kernel is booted with the command line option `panic_on_taint=<bitmask>,nousertaint` and any of the ORed together values being written to `tainted` match with the bitmask declared on panic_on_taint. See *The kernel's command-line parameters* for more details on that particular kernel command line option and its optional `nousertaint` switch.

threads-max

This value controls the maximum number of threads that can be created using `fork()`.

During initialization the kernel sets this value such that even if the maximum number of threads is created, the thread structures occupy only a part (1/8th) of the available RAM pages.

The minimum value that can be written to `threads-max` is 1.

The maximum value that can be written to `threads-max` is given by the constant `FUTEX_TID_MASK` (0x3fffffff).

If a value outside of this range is written to `threads-max` an `EINVAL` error occurs.

traceoff_on_warning

When set, disables tracing (see Documentation/trace/ftrace.rst) when a `WARN()` is hit.

tracepoint_printk

When tracepoints are sent to printk() (enabled by the `tp_printk` boot parameter), this entry provides runtime control:

```
echo 0 > /proc/sys/kernel/tracepoint_printk
```

will stop tracepoints from being sent to printk(), and:

```
echo 1 > /proc/sys/kernel/tracepoint_printk
```

will send them to printk() again.

This only works if the kernel was booted with `tp_printk` enabled.

See *The kernel's command-line parameters* and Documentation/trace/boottime-trace.rst.

unaligned-trap

On architectures where unaligned accesses cause traps, and where this feature is supported (`CONFIG_SYSCTL_ARCH_UNALIGN_ALLOW`; currently, `arc`, `parisc` and `loongarch`), controls whether unaligned traps are caught and emulated (instead of failing).

0	Do not emulate unaligned accesses.
1	Emulate unaligned accesses. This is the default setting.

See also *ignore-unaligned-usertrap*.

unknown_nmi_panic

The value in this file affects behavior of handling NMI. When the value is non-zero, unknown NMI is trapped and then panic occurs. At that time, kernel debugging information is displayed on console.

NMI switch that most IA32 servers have fires unknown NMI up, for example. If a system hangs up, try pressing the NMI switch.

unprivileged_bpf_disabled

Writing 1 to this entry will disable unprivileged calls to `bpf()`; once disabled, calling `bpf()` without `CAP_SYS_ADMIN` or `CAP_BPF` will return `-EPERM`. Once set to 1, this can't be cleared from the running kernel anymore.

Writing 2 to this entry will also disable unprivileged calls to `bpf()`, however, an admin can still change this setting later on, if needed, by writing 0 or 1 to this entry.

If BPF_UNPRIV_DEFAULT_OFF is enabled in the kernel config, then this entry will default to 2 instead of 0.

0	Unprivileged calls to bpf() are enabled
1	Unprivileged calls to bpf() are disabled without recovery
2	Unprivileged calls to bpf() are disabled

warn_limit

Number of kernel warnings after which the kernel should panic when panic_on_warn is not set. Setting this to 0 disables checking the warning count. Setting this to 1 has the same effect as setting panic_on_warn=1. The default value is 0.

watchdog

This parameter can be used to disable or enable the soft lockup detector *and* the NMI watchdog (i.e. the hard lockup detector) at the same time.

0	Disable both lockup detectors.
1	Enable both lockup detectors.

The soft lockup detector and the NMI watchdog can also be disabled or enabled individually, using the soft_watchdog and nmi_watchdog parameters. If the watchdog parameter is read, for example by executing:

```
cat /proc/sys/kernel/watchdog
```

the output of this command (0 or 1) shows the logical OR of soft_watchdog and nmi_watchdog.

watchdog_cpumask

This value can be used to control on which cpus the watchdog may run. The default cpumask is all possible cores, but if NO_HZ_FULL is enabled in the kernel config, and cores are specified with the nohz_full= boot argument, those cores are excluded by default. Offline cores can be included in this mask, and if the core is later brought online, the watchdog will be started based on the mask value.

Typically this value would only be touched in the nohz_full case to re-enable cores that by default were not running the watchdog, if a kernel lockup was suspected on those cores.

The argument value is the standard cpulist format for cpumasks, so for example to enable the watchdog on cores 0, 2, 3, and 4 you might say:

```
echo 0,2-4 > /proc/sys/kernel/watchdog_cpumask
```

watchdog_thresh

This value can be used to control the frequency of hrtimer and NMI events and the soft and hard lockup thresholds. The default threshold is 10 seconds.

The softlockup threshold is (`2 * watchdog_thresh`). Setting this tunable to zero will disable lockup detection altogether.

For general info and legal blurb, please look in *The Linux kernel user's and administrator's guide*.

This file contains the documentation for the sysctl files in /proc/sys/net

The interface to the networking parts of the kernel is located in /proc/sys/net. The following table shows all possible subdirectories. You may see only some of them, depending on your kernel's configuration.

Table : Subdirectories in /proc/sys/net

Directory	Content		Directory	Content
802	E802 protocol		mptcp	Multipath TCP
appletalk	Appletalk protocol		netfilter	Network Filter
ax25	AX25		netrom	NET/ROM
bridge	Bridging		rose	X.25 PLP layer
core	General parameter		tipc	TIPC
ethernet	Ethernet protocol		unix	Unix domain sockets
ipv4	IP version 4		x25	X.25 protocol
ipv6	IP version 6			

1. /proc/sys/net/core - Network core options

bpf_jit_enable

This enables the BPF Just in Time (JIT) compiler. BPF is a flexible and efficient infrastructure allowing to execute bytecode at various hook points. It is used in a number of Linux kernel subsystems such as networking (e.g. XDP, tc), tracing (e.g. kprobes, uprobes, tracepoints) and security (e.g. seccomp). LLVM has a BPF back end that can compile restricted C into a sequence of BPF instructions. After program load through bpf(2) and passing a verifier in the kernel, a JIT will then translate these BPF proglets into native CPU instructions. There are two flavors of JITs, the newer eBPF JIT currently supported on:

- x86_64
- x86_32
- arm64
- arm32
- ppc64
- ppc32
- sparc64
- mips64
- s390x
- riscv64
- riscv32
- loongarch64

And the older cBPF JIT supported on the following archs:

- mips
- sparc

eBPF JITs are a superset of cBPF JITs, meaning the kernel will migrate cBPF instructions into eBPF instructions and then JIT compile them transparently. Older cBPF JITs can only translate tcpdump filters, seccomp rules, etc, but not mentioned eBPF programs loaded through bpf(2).

Values:

- 0 - disable the JIT (default value)
- 1 - enable the JIT
- 2 - enable the JIT and ask the compiler to emit traces on kernel log.

bpf_jit_harden

This enables hardening for the BPF JIT compiler. Supported are eBPF JIT backends. Enabling hardening trades off performance, but can mitigate JIT spraying.

Values:

- 0 - disable JIT hardening (default value)
- 1 - enable JIT hardening for unprivileged users only
- 2 - enable JIT hardening for all users

where ”privileged user” in this context means a process having CAP_BPF or CAP_SYS_ADMIN in the root user name space.

bpf_jit_kallsyms

When BPF JIT compiler is enabled, then compiled images are unknown addresses to the kernel, meaning they neither show up in traces nor in /proc/kallsyms. This enables export of these addresses, which can be used for debugging/tracing. If bpf_jit_harden is enabled, this feature is disabled.

Values :

- 0 - disable JIT kallsyms export (default value)
- 1 - enable JIT kallsyms export for privileged users only

bpf_jit_limit

This enforces a global limit for memory allocations to the BPF JIT compiler in order to reject unprivileged JIT requests once it has been surpassed. bpf_jit_limit contains the value of the global limit in bytes.

dev_weight

The maximum number of packets that kernel can handle on a NAPI interrupt, it's a Per-CPU variable. For drivers that support LRO or GRO_HW, a hardware aggregated packet is counted as one packet in this context.

Default: 64

dev_weight_rx_bias

RPS (e.g. RFS, aRFS) processing is competing with the registered NAPI poll function of the driver for the per softirq cycle netdev_budget. This parameter influences the proportion of the configured netdev_budget that is spent on RPS based packet processing during RX softirq cycles. It is further meant for making current dev_weight adaptable for asymmetric CPU needs on RX/TX side of the network stack. (see dev_weight_tx_bias) It is effective on a per CPU basis. Determination is based on dev_weight and is calculated multiplicative (dev_weight * dev_weight_rx_bias).

Default: 1

dev_weight_tx_bias

Scales the maximum number of packets that can be processed during a TX softirq cycle. Effective on a per CPU basis. Allows scaling of current dev_weight for asymmetric net stack processing needs. Be careful to avoid making TX softirq processing a CPU hog.

Calculation is based on dev_weight (dev_weight * dev_weight_tx_bias).

Default: 1

default_qdisc

The default queuing discipline to use for network devices. This allows overriding the default of pfifo_fast with an alternative. Since the default queuing discipline is created without additional parameters so is best suited to queuing disciplines that work well without configuration like stochastic fair queue (sfq), CoDel (codel) or fair queue CoDel (fq_codel). Don't use queuing disciplines like Hierarchical Token Bucket or Deficit Round Robin which require setting up classes and bandwidths. Note that physical multiqueue interfaces still use mq as root qdisc, which in turn uses this default for its leaves. Virtual devices (like e.g. lo or veth) ignore this setting and instead default to noqueue.

Default: pfifo_fast

busy_read

Low latency busy poll timeout for socket reads. (needs CONFIG_NET_RX_BUSY_POLL) Approximate time in us to busy loop waiting for packets on the device queue. This sets the default value of the SO_BUSY_POLL socket option. Can be set or overridden per socket by setting socket option SO_BUSY_POLL, which is the preferred method of enabling. If you need to enable the feature globally via sysctl, a value of 50 is recommended.

Will increase power usage.

Default: 0 (off)

busy_poll

Low latency busy poll timeout for poll and select. (needs CONFIG_NET_RX_BUSY_POLL) Approximate time in us to busy loop waiting for events. Recommended value depends on the number of sockets you poll on. For several sockets 50, for several hundreds 100. For more than that you probably want to use epoll. Note that only sockets with SO_BUSY_POLL set will be busy polled, so you want to either selectively set SO_BUSY_POLL on those sockets or set sysctl.net.busy_read globally.

Will increase power usage.

Default: 0 (off)

rmem_default

The default setting of the socket receive buffer in bytes.

rmem_max

The maximum receive socket buffer size in bytes.

rps_default_mask

The default RPS CPU mask used on newly created network devices. An empty mask means RPS disabled by default.

tstamp_allow_data

Allow processes to receive tx timestamps looped together with the original packet contents. If disabled, transmit timestamp requests from unprivileged processes are dropped unless socket option SOF_TIMESTAMPING_OPT_TSONLY is set.

Default: 1 (on)

wmem_default

The default setting (in bytes) of the socket send buffer.

wmem_max

The maximum send socket buffer size in bytes.

message_burst and message_cost

These parameters are used to limit the warning messages written to the kernel log from the networking code. They enforce a rate limit to make a denial-of-service attack impossible. A higher message_cost factor, results in fewer messages that will be written. Message_burst controls when messages will be dropped. The default settings limit warning messages to one every five seconds.

warnings

This sysctl is now unused.

This was used to control console messages from the networking stack that occur because of problems on the network like duplicate address or bad checksums.

These messages are now emitted at KERN_DEBUG and can generally be enabled and controlled by the dynamic_debug facility.

netdev_budget

Maximum number of packets taken from all interfaces in one polling cycle (NAPI poll). In one polling cycle interfaces which are registered to polling are probed in a round-robin manner. Also, a polling cycle may not exceed netdev_budget_usecs microseconds, even if netdev_budget has not been exhausted.

netdev_budget_usecs

Maximum number of microseconds in one NAPI polling cycle. Polling will exit when either netdev_budget_usecs have elapsed during the poll cycle or the number of packets processed reaches netdev_budget.

netdev_max_backlog

Maximum number of packets, queued on the INPUT side, when the interface receives packets faster than kernel can process them.

netdev_rss_key

RSS (Receive Side Scaling) enabled drivers use a 40 bytes host key that is randomly generated. Some user space might need to gather its content even if drivers do not provide ethtool -x support yet.

```
myhost:~# cat /proc/sys/net/core/netdev_rss_key
84:50:f4:00:a8:15:d1:a7:e9:7f:1d:60:35:c7:47:25:42:97:74:ca:56:bb:b6:a1:d8: ...
↪ (52 bytes total)
```

File contains nul bytes if no driver ever called netdev_rss_key_fill() function.

Note:
/proc/sys/net/core/netdev_rss_key contains 52 bytes of key, but most drivers only use 40 bytes of it.

```
myhost:~# ethtool -x eth0
RX flow hash indirection table for eth0 with 8 RX ring(s):
    0:    0     1     2     3     4     5     6     7
RSS hash key:
84:50:f4:00:a8:15:d1:a7:e9:7f:1d:60:35:c7:47:25:42:97:74:ca:56:bb:b6:a1:d8:43:e3:c9:0
```

netdev_tstamp_prequeue

If set to 0, RX packet timestamps can be sampled after RPS processing, when the target CPU processes packets. It might give some delay on timestamps, but permit to distribute the load on several cpus.

If set to 1 (default), timestamps are sampled as soon as possible, before queueing.

netdev_unregister_timeout_secs

Unregister network device timeout in seconds. This option controls the timeout (in seconds) used to issue a warning while waiting for a network device refcount to drop to 0 during device unregistration. A lower value may be useful during bisection to detect a leaked reference faster. A larger value may be useful to prevent false warnings on slow/loaded systems. Default value is 10, minimum 1, maximum 3600.

skb_defer_max

Max size (in skbs) of the per-cpu list of skbs being freed by the cpu which allocated them. Used by TCP stack so far.

Default: 64

optmem_max

Maximum ancillary buffer size allowed per socket. Ancillary data is a sequence of struct cmsghdr structures with appended data. TCP tx zerocopy also uses optmem_max as a limit for its internal structures.

Default : 128 KB

fb_tunnels_only_for_init_net

Controls if fallback tunnels (like tunl0, gre0, gretap0, erspan0, sit0, ip6tnl0, ip6gre0) are automatically created. There are 3 possibilities (a) value = 0; respective fallback tunnels are created when module is loaded in every net namespaces (backward compatible behavior). (b) value = 1; [kcmd value: initns] respective fallback tunnels are created only in init net namespace and every other net namespace will not have them. (c) value = 2; [kcmd value: none] fallback tunnels are not created when a module is loaded in any of the net namespace. Setting value to "2" is pointless after boot if these modules are built-in, so there is a kernel command-line option that can change this default. Please refer to *The kernel's command-line parameters* for additional details.

Not creating fallback tunnels gives control to userspace to create whatever is needed only and avoid creating devices which are redundant.

Default : 0 (for compatibility reasons)

devconf_inherit_init_net

Controls if a new network namespace should inherit all current settings under /proc/sys/net/{ipv4,ipv6}/conf/{all,default}/. By default, we keep the current behavior: for IPv4 we inherit all current settings from init_net and for IPv6 we reset all settings to default.

If set to 1, both IPv4 and IPv6 settings are forced to inherit from current ones in init_net. If set to 2, both IPv4 and IPv6 settings are forced to reset to their default values. If set to 3, both IPv4 and IPv6 settings are forced to inherit from current ones in the netns where this new netns has been created.

Default : 0 (for compatibility reasons)

txrehash

Controls default hash rethink behaviour on socket when SO_TXREHASH option is set to SOCK_TXREHASH_DEFAULT (i. e. not overridden by setsockopt).

If set to 1 (default), hash rethink is performed on listening socket. If set to 0, hash rethink is not performed.

gro_normal_batch

Maximum number of the segments to batch up on output of GRO. When a packet exits GRO, either as a coalesced superframe or as an original packet which GRO has decided not to coalesce, it is placed on a per-NAPI list. This list is then passed to the stack when the number of segments reaches the gro_normal_batch limit.

high_order_alloc_disable

By default the allocator for page frags tries to use high order pages (order-3 on x86). While the default behavior gives good results in most cases, some users might have hit a contention in page allocations/freeing. This was especially true on older kernels (< 5.14) when high-order pages were not stored on per-cpu lists. This allows to opt-in for order-0 allocation instead but is now mostly of historical importance.

Default: 0

2. /proc/sys/net/unix - Parameters for Unix domain sockets

There is only one file in this directory. unix_dgram_qlen limits the max number of datagrams queued in Unix domain socket's buffer. It will not take effect unless PF_UNIX flag is specified.

3. /proc/sys/net/ipv4 - IPV4 settings

Please see: Documentation/networking/ip-sysctl.rst and *Documentation for /proc/sys/net/* for descriptions of these entries.

4. Appletalk

The /proc/sys/net/appletalk directory holds the Appletalk configuration data when Appletalk is loaded. The configurable parameters are:

aarp-expiry-time

The amount of time we keep an ARP entry before expiring it. Used to age out old hosts.

aarp-resolve-time

The amount of time we will spend trying to resolve an Appletalk address.

aarp-retransmit-limit

The number of times we will retransmit a query before giving up.

aarp-tick-time

Controls the rate at which expires are checked.

The directory /proc/net/appletalk holds the list of active Appletalk sockets on a machine.

The fields indicate the DDP type, the local address (in network:node format) the remote address, the size of the transmit pending queue, the size of the received queue (bytes waiting for applications to read) the state and the uid owning the socket.

/proc/net/atalk_iface lists all the interfaces configured for appletalk.It shows the name of the interface, its Appletalk address, the network range on that address (or network number for phase 1 networks), and the status of the interface.

/proc/net/atalk_route lists each known network route. It lists the target (network) that the route leads to, the router (may be directly connected), the route flags, and the device the route is using.

5. TIPC

tipc_rmem

The TIPC protocol now has a tunable for the receive memory, similar to the tcp_rmem - i.e. a vector of 3 INTEGERs: (min, default, max)

```
# cat /proc/sys/net/tipc/tipc_rmem
4252725 34021800        68043600
#
```

The max value is set to CONN_OVERLOAD_LIMIT, and the default and min values are scaled (shifted) versions of that same value. Note that the min value is not at this point in time used in any meaningful way, but the triplet is preserved in order to be consistent with things like tcp_rmem.

named_timeout

TIPC name table updates are distributed asynchronously in a cluster, without any form of transaction handling. This means that different race scenarios are possible. One such is that a name withdrawal sent out by one node and received by another node may arrive after a second, overlapping name publication already has been accepted from a third node, although the conflicting updates originally may have been issued in the correct sequential order. If named_timeout is nonzero, failed topology updates will be placed on a defer queue until another event arrives that clears the error, or until the timeout expires. Value is in milliseconds.

4.1.5 Documentation for /proc/sys/sunrpc/

kernel version 2.2.10

Copyright (c) 1998, 1999, Rik van Riel <riel@nl.linux.org>

For general info and legal blurb, please look in *The Linux kernel user's and administrator's guide*.

This file contains the documentation for the sysctl files in /proc/sys/sunrpc and is valid for Linux kernel version 2.2.

The files in this directory can be used to (re)set the debug flags of the SUN Remote Procedure Call (RPC) subsystem in the Linux kernel. This stuff is used for NFS, KNFSD and maybe a few other things as well.

The files in there are used to control the debugging flags: rpc_debug, nfs_debug, nfsd_debug and nlm_debug.

These flags are for kernel hackers only. You should read the source code in net/sunrpc/ for more information.

4.1.6 Documentation for /proc/sys/user/

kernel version 4.9.0

Copyright (c) 2016 Eric Biederman <ebiederm@xmission.com>

This file contains the documentation for the sysctl files in /proc/sys/user.

The files in this directory can be used to override the default limits on the number of namespaces and other objects that have per user per user namespace limits.

The primary purpose of these limits is to stop programs that malfunction and attempt to create a ridiculous number of objects, before the malfunction becomes a system wide problem. It is the intention that the defaults of these limits are set high enough that no program in normal operation should run into these limits.

The creation of per user per user namespace objects are charged to the user in the user namespace who created the object and verified to be below the per user limit in that user namespace.

The creation of objects is also charged to all of the users who created user namespaces the creation of the object happens in (user namespaces can be nested) and verified to be below the per user limits in the user namespaces of those users.

This recursive counting of created objects ensures that creating a user namespace does not allow a user to escape their current limits.

Currently, these files are in /proc/sys/user:

max_cgroup_namespaces

The maximum number of cgroup namespaces that any user in the current user namespace may create.

max_ipc_namespaces

The maximum number of ipc namespaces that any user in the current user namespace may create.

max_mnt_namespaces

The maximum number of mount namespaces that any user in the current user namespace may create.

max_net_namespaces

The maximum number of network namespaces that any user in the current user namespace may create.

max_pid_namespaces

The maximum number of pid namespaces that any user in the current user namespace may create.

max_time_namespaces

The maximum number of time namespaces that any user in the current user namespace may create.

max_user_namespaces

The maximum number of user namespaces that any user in the current user namespace may create.

max_uts_namespaces

The maximum number of user namespaces that any user in the current user namespace may create.

4.1.7 Documentation for /proc/sys/vm/

kernel version 2.6.29

Copyright (c) 1998, 1999, Rik van Riel <riel@nl.linux.org>

Copyright (c) 2008 Peter W. Morreale <pmorreale@novell.com>

For general info and legal blurb, please look in *The Linux kernel user's and administrator's guide*.

This file contains the documentation for the sysctl files in /proc/sys/vm and is valid for Linux kernel version 2.6.29.

The files in this directory can be used to tune the operation of the virtual memory (VM) subsystem of the Linux kernel and the writeout of dirty data to disk.

Default values and initialization routines for most of these files can be found in mm/swap.c.

Currently, these files are in /proc/sys/vm:

- admin_reserve_kbytes
- compact_memory
- compaction_proactiveness
- compact_unevictable_allowed
- dirty_background_bytes
- dirty_background_ratio
- dirty_bytes
- dirty_expire_centisecs
- dirty_ratio
- dirtytime_expire_seconds
- dirty_writeback_centisecs
- drop_caches
- extfrag_threshold
- highmem_is_dirtyable
- hugetlb_shm_group
- laptop_mode
- legacy_va_layout
- lowmem_reserve_ratio
- max_map_count
- memory_failure_early_kill
- memory_failure_recovery
- min_free_kbytes

- min_slab_ratio
- min_unmapped_ratio
- mmap_min_addr
- mmap_rnd_bits
- mmap_rnd_compat_bits
- nr_hugepages
- nr_hugepages_mempolicy
- nr_overcommit_hugepages
- nr_trim_pages (only if CONFIG_MMU=n)
- numa_zonelist_order
- oom_dump_tasks
- oom_kill_allocating_task
- overcommit_kbytes
- overcommit_memory
- overcommit_ratio
- page-cluster
- page_lock_unfairness
- panic_on_oom
- percpu_pagelist_high_fraction
- stat_interval
- stat_refresh
- numa_stat
- swappiness
- unprivileged_userfaultfd
- user_reserve_kbytes
- vfs_cache_pressure
- watermark_boost_factor
- watermark_scale_factor
- zone_reclaim_mode

admin_reserve_kbytes

The amount of free memory in the system that should be reserved for users with the capability cap_sys_admin.

admin_reserve_kbytes defaults to min(3% of free pages, 8MB)

That should provide enough for the admin to log in and kill a process, if necessary, under the default overcommit 'guess' mode.

Systems running under overcommit 'never' should increase this to account for the full Virtual Memory Size of programs used to recover. Otherwise, root may not be able to log in to recover the system.

How do you calculate a minimum useful reserve?

sshd or login + bash (or some other shell) + top (or ps, kill, etc.)

For overcommit 'guess', we can sum resident set sizes (RSS). On x86_64 this is about 8MB.

For overcommit 'never', we can take the max of their virtual sizes (VSZ) and add the sum of their RSS. On x86_64 this is about 128MB.

Changing this takes effect whenever an application requests memory.

compact_memory

Available only when CONFIG_COMPACTION is set. When 1 is written to the file, all zones are compacted such that free memory is available in contiguous blocks where possible. This can be important for example in the allocation of huge pages although processes will also directly compact memory as required.

compaction_proactiveness

This tunable takes a value in the range [0, 100] with a default value of 20. This tunable determines how aggressively compaction is done in the background. Write of a non zero value to this tunable will immediately trigger the proactive compaction. Setting it to 0 disables proactive compaction.

Note that compaction has a non-trivial system-wide impact as pages belonging to different processes are moved around, which could also lead to latency spikes in unsuspecting applications. The kernel employs various heuristics to avoid wasting CPU cycles if it detects that proactive compaction is not being effective.

Be careful when setting it to extreme values like 100, as that may cause excessive background compaction activity.

compact_unevictable_allowed

Available only when CONFIG_COMPACTION is set. When set to 1, compaction is allowed to examine the unevictable lru (mlocked pages) for pages to compact. This should be used on systems where stalls for minor page faults are an acceptable trade for large contiguous free memory. Set to 0 to prevent compaction from moving pages that are unevictable. Default value is 1. On CONFIG_PREEMPT_RT the default value is 0 in order to avoid a page fault, due to compaction, which would block the task from becoming active until the fault is resolved.

dirty_background_bytes

Contains the amount of dirty memory at which the background kernel flusher threads will start writeback.

Note:

dirty_background_bytes is the counterpart of dirty_background_ratio. Only one of them may be specified at a time. When one sysctl is written it is immediately taken into account to evaluate the dirty memory limits and the other appears as 0 when read.

dirty_background_ratio

Contains, as a percentage of total available memory that contains free pages and reclaimable pages, the number of pages at which the background kernel flusher threads will start writing out dirty data.

The total available memory is not equal to total system memory.

dirty_bytes

Contains the amount of dirty memory at which a process generating disk writes will itself start writeback.

Note: dirty_bytes is the counterpart of dirty_ratio. Only one of them may be specified at a time. When one sysctl is written it is immediately taken into account to evaluate the dirty memory limits and the other appears as 0 when read.

Note: the minimum value allowed for dirty_bytes is two pages (in bytes); any value lower than this limit will be ignored and the old configuration will be retained.

dirty_expire_centisecs

This tunable is used to define when dirty data is old enough to be eligible for writeout by the kernel flusher threads. It is expressed in 100'ths of a second. Data which has been dirty in-memory for longer than this interval will be written out next time a flusher thread wakes up.

dirty_ratio

Contains, as a percentage of total available memory that contains free pages and reclaimable pages, the number of pages at which a process which is generating disk writes will itself start writing out dirty data.

The total available memory is not equal to total system memory.

dirtytime_expire_seconds

When a lazytime inode is constantly having its pages dirtied, the inode with an updated timestamp will never get chance to be written out. And, if the only thing that has happened on the file system is a dirtytime inode caused by an atime update, a worker will be scheduled to make sure that inode eventually gets pushed out to disk. This tunable is used to define when dirty inode is old enough to be eligible for writeback by the kernel flusher threads. And, it is also used as the interval to wakeup dirtytime_writeback thread.

dirty_writeback_centisecs

The kernel flusher threads will periodically wake up and write *old* data out to disk. This tunable expresses the interval between those wakeups, in 100'ths of a second.

Setting this to zero disables periodic writeback altogether.

drop_caches

Writing to this will cause the kernel to drop clean caches, as well as reclaimable slab objects like dentries and inodes. Once dropped, their memory becomes free.

To free pagecache:

```
echo 1 > /proc/sys/vm/drop_caches
```

To free reclaimable slab objects (includes dentries and inodes):

```
echo 2 > /proc/sys/vm/drop_caches
```

To free slab objects and pagecache:

```
echo 3 > /proc/sys/vm/drop_caches
```

This is a non-destructive operation and will not free any dirty objects. To increase the number of objects freed by this operation, the user may run *sync* prior to writing to /proc/sys/vm/drop_caches. This will minimize the number of dirty objects on the system and create more candidates to be dropped.

This file is not a means to control the growth of the various kernel caches (inodes, dentries, pagecache, etc...) These objects are automatically reclaimed by the kernel when memory is needed elsewhere on the system.

Use of this file can cause performance problems. Since it discards cached objects, it may cost a significant amount of I/O and CPU to recreate the dropped objects, especially if they were

under heavy use. Because of this, use outside of a testing or debugging environment is not recommended.

You may see informational messages in your kernel log when this file is used:

```
cat (1234): drop_caches: 3
```

These are informational only. They do not mean that anything is wrong with your system. To disable them, echo 4 (bit 2) into drop_caches.

extfrag_threshold

This parameter affects whether the kernel will compact memory or direct reclaim to satisfy a high-order allocation. The extfrag/extfrag_index file in debugfs shows what the fragmentation index for each order is in each zone in the system. Values tending towards 0 imply allocations would fail due to lack of memory, values towards 1000 imply failures are due to fragmentation and -1 implies that the allocation will succeed as long as watermarks are met.

The kernel will not compact memory in a zone if the fragmentation index is <= extfrag_threshold. The default value is 500.

highmem_is_dirtyable

Available only for systems with CONFIG_HIGHMEM enabled (32b systems).

This parameter controls whether the high memory is considered for dirty writers throttling. This is not the case by default which means that only the amount of memory directly visible/usable by the kernel can be dirtied. As a result, on systems with a large amount of memory and lowmem basically depleted writers might be throttled too early and streaming writes can get very slow.

Changing the value to non zero would allow more memory to be dirtied and thus allow writers to write more data which can be flushed to the storage more effectively. Note this also comes with a risk of pre-mature OOM killer because some writers (e.g. direct block device writes) can only use the low memory and they can fill it up with dirty data without any throttling.

hugetlb_shm_group

hugetlb_shm_group contains group id that is allowed to create SysV shared memory segment using hugetlb page.

laptop_mode

laptop_mode is a knob that controls ”laptop mode”. All the things that are controlled by this knob are discussed in *How to conserve battery power using laptop-mode*.

legacy_va_layout

If non-zero, this sysctl disables the new 32-bit mmap layout - the kernel will use the legacy (2.4) layout for all processes.

lowmem_reserve_ratio

For some specialised workloads on highmem machines it is dangerous for the kernel to allow process memory to be allocated from the "lowmem" zone. This is because that memory could then be pinned via the mlock() system call, or by unavailability of swapspace.

And on large highmem machines this lack of reclaimable lowmem memory can be fatal.

So the Linux page allocator has a mechanism which prevents allocations which *could* use highmem from using too much lowmem. This means that a certain amount of lowmem is defended from the possibility of being captured into pinned user memory.

(The same argument applies to the old 16 megabyte ISA DMA region. This mechanism will also defend that region from allocations which could use highmem or lowmem).

The *lowmem_reserve_ratio* tunable determines how aggressive the kernel is in defending these lower zones.

If you have a machine which uses highmem or ISA DMA and your applications are using mlock(), or if you are running with no swap then you probably should change the lowmem_reserve_ratio setting.

The lowmem_reserve_ratio is an array. You can see them by reading this file:

```
% cat /proc/sys/vm/lowmem_reserve_ratio
256     256     32
```

But, these values are not used directly. The kernel calculates # of protection pages for each zones from them. These are shown as array of protection pages in /proc/zoneinfo like the following. (This is an example of x86-64 box). Each zone has an array of protection pages like this:

```
Node 0, zone      DMA
  pages free     1355
        min      3
        low      3
        high     4
      :
      :
    numa_other   0
        protection: (0, 2004, 2004, 2004)
      ^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^
  pagesets
    cpu: 0 pcp: 0
        :
```

These protections are added to score to judge whether this zone should be used for page allocation or should be reclaimed.

In this example, if normal pages (index=2) are required to this DMA zone and watermark[WMARK_HIGH] is used for watermark, the kernel judges this zone should not be used because pages_free(1355) is smaller than watermark + protection[2] (4 + 2004 = 2008). If this protection value is 0, this zone would be used for normal page requirement. If requirement is DMA zone(index=0), protection[0] (=0) is used.

zone[i]'s protection[j] is calculated by following expression:

```
(i < j):
  zone[i]->protection[j]
  = (total sums of managed_pages from zone[i+1] to zone[j] on the node)
    / lowmem_reserve_ratio[i];
(i = j):
   (should not be protected. = 0;
(i > j):
   (not necessary, but looks 0)
```

The default values of lowmem_reserve_ratio[i] are

256	(if zone[i] means DMA or DMA32 zone)
32	(others)

As above expression, they are reciprocal number of ratio. 256 means 1/256. # of protection pages becomes about "0.39%" of total managed pages of higher zones on the node.

If you would like to protect more pages, smaller values are effective. The minimum value is 1 (1/1 -> 100%). The value less than 1 completely disables protection of the pages.

max_map_count:

This file contains the maximum number of memory map areas a process may have. Memory map areas are used as a side-effect of calling malloc, directly by mmap, mprotect, and madvise, and also when loading shared libraries.

While most applications need less than a thousand maps, certain programs, particularly malloc debuggers, may consume lots of them, e.g., up to one or two maps per allocation.

The default value is 65530.

memory_failure_early_kill:

Control how to kill processes when uncorrected memory error (typically a 2bit error in a memory module) is detected in the background by hardware that cannot be handled by the kernel. In some cases (like the page still having a valid copy on disk) the kernel will handle the failure transparently without affecting any applications. But if there is no other up-to-date copy of the data it will kill to prevent any data corruptions from propagating.

1: Kill all processes that have the corrupted and not reloadable page mapped as soon as the corruption is detected. Note this is not supported for a few types of pages, like kernel internally allocated data or the swap cache, but works for the majority of user pages.

0: Only unmap the corrupted page from all processes and only kill a process who tries to access it.

The kill is done using a catchable SIGBUS with BUS_MCEERR_AO, so processes can handle this if they want to.

This is only active on architectures/platforms with advanced machine check handling and depends on the hardware capabilities.

Applications can override this setting individually with the PR_MCE_KILL prctl

memory_failure_recovery

Enable memory failure recovery (when supported by the platform)

1: Attempt recovery.

0: Always panic on a memory failure.

min_free_kbytes

This is used to force the Linux VM to keep a minimum number of kilobytes free. The VM uses this number to compute a watermark[WMARK_MIN] value for each lowmem zone in the system. Each lowmem zone gets a number of reserved free pages based proportionally on its size.

Some minimal amount of memory is needed to satisfy PF_MEMALLOC allocations; if you set this to lower than 1024KB, your system will become subtly broken, and prone to deadlock under high loads.

Setting this too high will OOM your machine instantly.

min_slab_ratio

This is available only on NUMA kernels.

A percentage of the total pages in each zone. On Zone reclaim (fallback from the local zone occurs) slabs will be reclaimed if more than this percentage of pages in a zone are reclaimable slab pages. This insures that the slab growth stays under control even in NUMA systems that rarely perform global reclaim.

The default is 5 percent.

Note that slab reclaim is triggered in a per zone / node fashion. The process of reclaiming slab memory is currently not node specific and may not be fast.

min_unmapped_ratio

This is available only on NUMA kernels.

This is a percentage of the total pages in each zone. Zone reclaim will only occur if more than this percentage of pages are in a state that zone_reclaim_mode allows to be reclaimed.

If zone_reclaim_mode has the value 4 OR'd, then the percentage is compared against all file-backed unmapped pages including swapcache pages and tmpfs files. Otherwise, only unmapped pages backed by normal files but not tmpfs files and similar are considered.

The default is 1 percent.

mmap_min_addr

This file indicates the amount of address space which a user process will be restricted from mmapping. Since kernel null dereference bugs could accidentally operate based on the information in the first couple of pages of memory userspace processes should not be allowed to write to them. By default this value is set to 0 and no protections will be enforced by the security module. Setting this value to something like 64k will allow the vast majority of applications to work correctly and provide defense in depth against future potential kernel bugs.

mmap_rnd_bits

This value can be used to select the number of bits to use to determine the random offset to the base address of vma regions resulting from mmap allocations on architectures which support tuning address space randomization. This value will be bounded by the architecture's minimum and maximum supported values.

This value can be changed after boot using the /proc/sys/vm/mmap_rnd_bits tunable

mmap_rnd_compat_bits

This value can be used to select the number of bits to use to determine the random offset to the base address of vma regions resulting from mmap allocations for applications run in compatibility mode on architectures which support tuning address space randomization. This value will be bounded by the architecture's minimum and maximum supported values.

This value can be changed after boot using the /proc/sys/vm/mmap_rnd_compat_bits tunable

nr_hugepages

Change the minimum size of the hugepage pool.

See *HugeTLB Pages*

hugetlb_optimize_vmemmap

This knob is not available when the size of 'struct page' (a structure defined in include/linux/mm_types.h) is not power of two (an unusual system config could result in this).

Enable (set to 1) or disable (set to 0) HugeTLB Vmemmap Optimization (HVO).

Once enabled, the vmemmap pages of subsequent allocation of HugeTLB pages from buddy allocator will be optimized (7 pages per 2MB HugeTLB page and 4095 pages per 1GB HugeTLB page), whereas already allocated HugeTLB pages will not be optimized. When those optimized HugeTLB pages are freed from the HugeTLB pool to the buddy allocator, the vmemmap pages representing that range needs to be remapped again and the vmemmap pages discarded earlier need to be rellocated again. If your use case is that HugeTLB pages are allocated 'on the fly' (e.g. never explicitly allocating HugeTLB pages with 'nr_hugepages' but only set 'nr_overcommit_hugepages', those overcommitted HugeTLB pages are allocated 'on the fly') instead of being pulled from the HugeTLB pool, you should weigh the benefits of memory savings against the more overhead (~2x slower than before) of allocation or freeing HugeTLB pages between the HugeTLB pool and the buddy allocator. Another behavior to note is that if

the system is under heavy memory pressure, it could prevent the user from freeing HugeTLB pages from the HugeTLB pool to the buddy allocator since the allocation of vmemmap pages could be failed, you have to retry later if your system encounter this situation.

Once disabled, the vmemmap pages of subsequent allocation of HugeTLB pages from buddy allocator will not be optimized meaning the extra overhead at allocation time from buddy allocator disappears, whereas already optimized HugeTLB pages will not be affected. If you want to make sure there are no optimized HugeTLB pages, you can set "nr_hugepages" to 0 first and then disable this. Note that writing 0 to nr_hugepages will make any "in use" HugeTLB pages become surplus pages. So, those surplus pages are still optimized until they are no longer in use. You would need to wait for those surplus pages to be released before there are no optimized pages in the system.

nr_hugepages_mempolicy

Change the size of the hugepage pool at run-time on a specific set of NUMA nodes.

See *HugeTLB Pages*

nr_overcommit_hugepages

Change the maximum size of the hugepage pool. The maximum is nr_hugepages + nr_overcommit_hugepages.

See *HugeTLB Pages*

nr_trim_pages

This is available only on NOMMU kernels.

This value adjusts the excess page trimming behaviour of power-of-2 aligned NOMMU mmap allocations.

A value of 0 disables trimming of allocations entirely, while a value of 1 trims excess pages aggressively. Any value >= 1 acts as the watermark where trimming of allocations is initiated.

The default value is 1.

See *No-MMU memory mapping support* for more information.

numa_zonelist_order

This sysctl is only for NUMA and it is deprecated. Anything but Node order will fail!

'where the memory is allocated from' is controlled by zonelists.

(This documentation ignores ZONE_HIGHMEM/ZONE_DMA32 for simple explanation. you may be able to read ZONE_DMA as ZONE_DMA32...)

In non-NUMA case, a zonelist for GFP_KERNEL is ordered as following. ZONE_NORMAL -> ZONE_DMA This means that a memory allocation request for GFP_KERNEL will get memory from ZONE_DMA only when ZONE_NORMAL is not available.

In NUMA case, you can think of following 2 types of order. Assume 2 node NUMA and below is zonelist of Node(0)'s GFP_KERNEL:

```
(A) Node(0) ZONE_NORMAL -> Node(0) ZONE_DMA -> Node(1) ZONE_NORMAL
(B) Node(0) ZONE_NORMAL -> Node(1) ZONE_NORMAL -> Node(0) ZONE_DMA.
```

Type(A) offers the best locality for processes on Node(0), but ZONE_DMA will be used before ZONE_NORMAL exhaustion. This increases possibility of out-of-memory(OOM) of ZONE_DMA because ZONE_DMA is tend to be small.

Type(B) cannot offer the best locality but is more robust against OOM of the DMA zone.

Type(A) is called as ”Node” order. Type (B) is ”Zone” order.

”Node order” orders the zonelists by node, then by zone within each node. Specify ”[Nn]ode” for node order

”Zone Order” orders the zonelists by zone type, then by node within each zone. Specify ”[Zz]one” for zone order.

Specify ”[Dd]efault” to request automatic configuration.

On 32-bit, the Normal zone needs to be preserved for allocations accessible by the kernel, so ”zone” order will be selected.

On 64-bit, devices that require DMA32/DMA are relatively rare, so ”node” order will be selected.

Default order is recommended unless this is causing problems for your system/application.

oom_dump_tasks

Enables a system-wide task dump (excluding kernel threads) to be produced when the kernel performs an OOM-killing and includes such information as pid, uid, tgid, vm size, rss, pgtables_bytes, swapents, oom_score_adj score, and name. This is helpful to determine why the OOM killer was invoked, to identify the rogue task that caused it, and to determine why the OOM killer chose the task it did to kill.

If this is set to zero, this information is suppressed. On very large systems with thousands of tasks it may not be feasible to dump the memory state information for each one. Such systems should not be forced to incur a performance penalty in OOM conditions when the information may not be desired.

If this is set to non-zero, this information is shown whenever the OOM killer actually kills a memory-hogging task.

The default value is 1 (enabled).

oom_kill_allocating_task

This enables or disables killing the OOM-triggering task in out-of-memory situations.

If this is set to zero, the OOM killer will scan through the entire tasklist and select a task based on heuristics to kill. This normally selects a rogue memory-hogging task that frees up a large amount of memory when killed.

If this is set to non-zero, the OOM killer simply kills the task that triggered the out-of-memory condition. This avoids the expensive tasklist scan.

If panic_on_oom is selected, it takes precedence over whatever value is used in oom_kill_allocating_task.

The default value is 0.

overcommit_kbytes

When overcommit_memory is set to 2, the committed address space is not permitted to exceed swap plus this amount of physical RAM. See below.

Note: overcommit_kbytes is the counterpart of overcommit_ratio. Only one of them may be specified at a time. Setting one disables the other (which then appears as 0 when read).

overcommit_memory

This value contains a flag that enables memory overcommitment.

When this flag is 0, the kernel compares the userspace memory request size against total memory plus swap and rejects obvious overcommits.

When this flag is 1, the kernel pretends there is always enough memory until it actually runs out.

When this flag is 2, the kernel uses a ”never overcommit” policy that attempts to prevent any overcommit of memory. Note that user_reserve_kbytes affects this policy.

This feature can be very useful because there are a lot of programs that malloc() huge amounts of memory ”just-in-case” and don't use much of it.

The default value is 0.

See Documentation/mm/overcommit-accounting.rst and mm/util.c::__vm_enough_memory() for more information.

overcommit_ratio

When overcommit_memory is set to 2, the committed address space is not permitted to exceed swap plus this percentage of physical RAM. See above.

page-cluster

page-cluster controls the number of pages up to which consecutive pages are read in from swap in a single attempt. This is the swap counterpart to page cache readahead. The mentioned consecutivity is not in terms of virtual/physical addresses, but consecutive on swap space - that means they were swapped out together.

It is a logarithmic value - setting it to zero means "1 page", setting it to 1 means "2 pages", setting it to 2 means "4 pages", etc. Zero disables swap readahead completely.

The default value is three (eight pages at a time). There may be some small benefits in tuning this to a different value if your workload is swap-intensive.

Lower values mean lower latencies for initial faults, but at the same time extra faults and I/O delays for following faults if they would have been part of that consecutive pages readahead would have brought in.

page_lock_unfairness

This value determines the number of times that the page lock can be stolen from under a waiter. After the lock is stolen the number of times specified in this file (default is 5), the "fair lock handoff" semantics will apply, and the waiter will only be awakened if the lock can be taken.

panic_on_oom

This enables or disables panic on out-of-memory feature.

If this is set to 0, the kernel will kill some rogue process, called oom_killer. Usually, oom_killer can kill rogue processes and system will survive.

If this is set to 1, the kernel panics when out-of-memory happens. However, if a process limits using nodes by mempolicy/cpusets, and those nodes become memory exhaustion status, one process may be killed by oom-killer. No panic occurs in this case. Because other nodes' memory may be free. This means system total status may be not fatal yet.

If this is set to 2, the kernel panics compulsorily even on the above-mentioned. Even oom happens under memory cgroup, the whole system panics.

The default value is 0.

1 and 2 are for failover of clustering. Please select either according to your policy of failover.

panic_on_oom=2+kdump gives you very strong tool to investigate why oom happens. You can get snapshot.

percpu_pagelist_high_fraction

This is the fraction of pages in each zone that are can be stored to per-cpu page lists. It is an upper boundary that is divided depending on the number of online CPUs. The min value for this is 8 which means that we do not allow more than 1/8th of pages in each zone to be stored on per-cpu page lists. This entry only changes the value of hot per-cpu page lists. A user can specify a number like 100 to allocate 1/100th of each zone between per-cpu lists.

The batch value of each per-cpu page list remains the same regardless of the value of the high fraction so allocation latencies are unaffected.

The initial value is zero. Kernel uses this value to set the high pcp->high mark based on the low watermark for the zone and the number of local online CPUs. If the user writes '0' to this sysctl, it will revert to this default behavior.

stat_interval

The time interval between which vm statistics are updated. The default is 1 second.

stat_refresh

Any read or write (by root only) flushes all the per-cpu vm statistics into their global totals, for more accurate reports when testing e.g. cat /proc/sys/vm/stat_refresh /proc/meminfo

As a side-effect, it also checks for negative totals (elsewhere reported as 0) and ”fails” with EINVAL if any are found, with a warning in dmesg. (At time of writing, a few stats are known sometimes to be found negative, with no ill effects: errors and warnings on these stats are suppressed.)

numa_stat

This interface allows runtime configuration of numa statistics.

When page allocation performance becomes a bottleneck and you can tolerate some possible tool breakage and decreased numa counter precision, you can do:

```
echo 0 > /proc/sys/vm/numa_stat
```

When page allocation performance is not a bottleneck and you want all tooling to work, you can do:

```
echo 1 > /proc/sys/vm/numa_stat
```

swappiness

This control is used to define the rough relative IO cost of swapping and filesystem paging, as a value between 0 and 200. At 100, the VM assumes equal IO cost and will thus apply memory pressure to the page cache and swap-backed pages equally; lower values signify more expensive swap IO, higher values indicates cheaper.

Keep in mind that filesystem IO patterns under memory pressure tend to be more efficient than swap's random IO. An optimal value will require experimentation and will also be workload-dependent.

The default value is 60.

For in-memory swap, like zram or zswap, as well as hybrid setups that have swap on faster devices than the filesystem, values beyond 100 can be considered. For example, if the random IO against the swap device is on average 2x faster than IO from the filesystem, swappiness should be 133 (x + 2x = 200, 2x = 133.33).

At 0, the kernel will not initiate swap until the amount of free and file-backed pages is less than the high watermark in a zone.

unprivileged_userfaultfd

This flag controls the mode in which unprivileged users can use the userfaultfd system calls. Set this to 0 to restrict unprivileged users to handle page faults in user mode only. In this case, users without SYS_CAP_PTRACE must pass UFFD_USER_MODE_ONLY in order for userfaultfd to succeed. Prohibiting use of userfaultfd for handling faults from kernel mode may make certain vulnerabilities more difficult to exploit.

Set this to 1 to allow unprivileged users to use the userfaultfd system calls without any restrictions.

The default value is 0.

Another way to control permissions for userfaultfd is to use /dev/userfaultfd instead of userfaultfd(2). See *Userfaultfd*.

user_reserve_kbytes

When overcommit_memory is set to 2, ”never overcommit” mode, reserve min(3% of current process size, user_reserve_kbytes) of free memory. This is intended to prevent a user from starting a single memory hogging process, such that they cannot recover (kill the hog).

user_reserve_kbytes defaults to min(3% of the current process size, 128MB).

If this is reduced to zero, then the user will be allowed to allocate all free memory with a single process, minus admin_reserve_kbytes. Any subsequent attempts to execute a command will result in ”fork: Cannot allocate memory”.

Changing this takes effect whenever an application requests memory.

vfs_cache_pressure

This percentage value controls the tendency of the kernel to reclaim the memory which is used for caching of directory and inode objects.

At the default value of vfs_cache_pressure=100 the kernel will attempt to reclaim dentries and inodes at a "fair" rate with respect to pagecache and swapcache reclaim. Decreasing vfs_cache_pressure causes the kernel to prefer to retain dentry and inode caches. When vfs_cache_pressure=0, the kernel will never reclaim dentries and inodes due to memory pressure and this can easily lead to out-of-memory conditions. Increasing vfs_cache_pressure beyond 100 causes the kernel to prefer to reclaim dentries and inodes.

Increasing vfs_cache_pressure significantly beyond 100 may have negative performance impact. Reclaim code needs to take various locks to find freeable directory and inode objects. With vfs_cache_pressure=1000, it will look for ten times more freeable objects than there are.

watermark_boost_factor

This factor controls the level of reclaim when memory is being fragmented. It defines the percentage of the high watermark of a zone that will be reclaimed if pages of different mobility are being mixed within pageblocks. The intent is that compaction has less work to do in the future and to increase the success rate of future high-order allocations such as SLUB allocations, THP and hugetlbfs pages.

To make it sensible with respect to the watermark_scale_factor parameter, the unit is in fractions of 10,000. The default value of 15,000 means that up to 150% of the high watermark will be reclaimed in the event of a pageblock being mixed due to fragmentation. The level of reclaim is determined by the number of fragmentation events that occurred in the recent past. If this value is smaller than a pageblock then a pageblocks worth of pages will be reclaimed (e.g. 2MB on 64-bit x86). A boost factor of 0 will disable the feature.

watermark_scale_factor

This factor controls the aggressiveness of kswapd. It defines the amount of memory left in a node/system before kswapd is woken up and how much memory needs to be free before kswapd goes back to sleep.

The unit is in fractions of 10,000. The default value of 10 means the distances between watermarks are 0.1% of the available memory in the node/system. The maximum value is 3000, or 30% of memory.

A high rate of threads entering direct reclaim (allocstall) or kswapd going to sleep prematurely (kswapd_low_wmark_hit_quickly) can indicate that the number of free pages kswapd maintains for latency reasons is too small for the allocation bursts occurring in the system. This knob can then be used to tune kswapd aggressiveness accordingly.

zone_reclaim_mode

Zone_reclaim_mode allows someone to set more or less aggressive approaches to reclaim memory when a zone runs out of memory. If it is set to zero then no zone reclaim occurs. Allocations will be satisfied from other zones / nodes in the system.

This is value OR'ed together of

1	Zone reclaim on
2	Zone reclaim writes dirty pages out
4	Zone reclaim swaps pages

zone_reclaim_mode is disabled by default. For file servers or workloads that benefit from having their data cached, zone_reclaim_mode should be left disabled as the caching effect is likely to be more important than data locality.

Consider enabling one or more zone_reclaim mode bits if it's known that the workload is partitioned such that each partition fits within a NUMA node and that accessing remote memory would cause a measurable performance reduction. The page allocator will take additional actions before allocating off node pages.

Allowing zone reclaim to write out pages stops processes that are writing large amounts of data from dirtying pages on other nodes. Zone reclaim will write out dirty pages if a zone fills up and so effectively throttle the process. This may decrease the performance of a single process since it cannot use all of system memory to buffer the outgoing writes anymore but it preserve the memory on other nodes so that the performance of other processes running on other nodes will not be affected.

Allowing regular swap effectively restricts allocations to the local node unless explicitly overridden by memory policies or cpuset configurations.

CHAPTER

FIVE

LINUX ABI DESCRIPTION

5.1 ABI stable symbols

Documents the interfaces that the developer has defined to be stable.

Userspace programs are free to use these interfaces with no restrictions, and backward compatibility for them will be guaranteed for at least 2 years.

Most interfaces (like syscalls) are expected to never change and always be available.

5.1.1 Symbols under /dev/fw

/dev/fw[0-9]+

Defined on file *firewire-cdev*

The character device files /dev/fw* are the interface between firewire-core and IEEE 1394 device drivers implemented in userspace. The ioctl(2)- and read(2)-based ABI is defined and documented in <linux/firewire-cdev.h>.

This ABI offers most of the features which firewire-core also exposes to kernelspace IEEE 1394 drivers.

Each /dev/fw* is associated with one IEEE 1394 node, which can be remote or local nodes. Operations on a /dev/fw* file have different scope:

- The 1394 node which is associated with the file:
  - Asynchronous request transmission
  - Get the Configuration ROM
  - Query node ID
  - Query maximum speed of the path between this node and local node
- The 1394 bus (i.e. "card") to which the node is attached to:
  - Isochronous stream transmission and reception
  - Asynchronous stream transmission and reception
  - Asynchronous broadcast request transmission
  - PHY packet transmission and reception

  - Allocate, reallocate, deallocate isochronous resources (channels, bandwidth) at the bus's IRM
  - Query node IDs of local node, root node, IRM, bus manager
  - Query cycle time
  - Bus reset initiation, bus reset event reception
- All 1394 buses:
  - Allocation of IEEE 1212 address ranges on the local link layers, reception of inbound requests to such an address range, asynchronous response transmission to inbound requests
  - Addition of descriptors or directories to the local nodes' Configuration ROM

Due to the different scope of operations and in order to let userland implement different access permission models, some operations are restricted to /dev/fw* files that are associated with a local node:

- Addition of descriptors or directories to the local nodes' Configuration ROM
- PHY packet transmission and reception

A /dev/fw* file remains associated with one particular node during its entire life time. Bus topology changes, and hence node ID changes, are tracked by firewire-core. ABI users do not need to be aware of topology.

The following file operations are supported:

open(2)
Currently the only useful flags are O_RDWR.

ioctl(2)
Initiate various actions. Some take immediate effect, others are performed asynchronously while or after the ioctl returns. See the inline documentation in <linux/firewire-cdev.h> for descriptions of all ioctls.

poll(2), select(2), epoll_wait(2) etc.
Watch for events to become available to be read.

read(2)
Receive various events. There are solicited events like outbound asynchronous transaction completion or isochronous buffer completion, and unsolicited events such as bus resets, request reception, or PHY packet reception. Always use a read buffer which is large enough to receive the largest event that could ever arrive. See <linux/firewire-cdev.h> for descriptions of all event types and for which ioctls affect reception of events.

mmap(2)
Allocate a DMA buffer for isochronous reception or transmission and map it into the process address space. The arguments should be used as follows: addr = NULL, length = the desired buffer size, i.e. number of packets times size of largest packet, prot = at least PROT_READ for reception and at least PROT_WRITE for transmission, flags = MAP_SHARED, fd = the handle to the /dev/fw*, offset = 0.

Isochronous reception works in packet-per-buffer fashion except for multichannel reception which works in buffer-fill mode.

munmap(2)
Unmap the isochronous I/O buffer from the process address space.

close(2)
Besides stopping and freeing I/O contexts that were associated with the file descriptor, back out any changes to the local nodes' Configuration ROM. Deallocate isochronous channels and bandwidth at the IRM that were marked for kernel-assisted re- and deallocation.

Users: libraw1394; libdc1394; libhinawa; tools like linux-firewire-utils, fwhack, ...

5.1.2 Symbols under /sys/accessibility

/sys/accessibility/speakup/<synth-name>/

Defined on file *sysfs-driver-speakup*

In */sys/accessibility/speakup* is a directory corresponding to the synthesizer driver currently in use (E.G) *soft* for the soft driver. This directory contains files which control the speech synthesizer itself, as opposed to controlling the speakup screen reader. The parameters in this directory have the same names and functions across all supported synthesizers. The range of values for freq, pitch, rate, and vol is the same for all supported synthesizers, with the given range being internally mapped by the driver to more or less fit the range of values supported for a given parameter by the individual synthesizer. Below is a description of values and parameters for soft synthesizer, which is currently the most commonly used.

/sys/accessibility/speakup/<synth-name>/caps_start

Defined on file *sysfs-driver-speakup*

This is the string that is sent to the synthesizer to cause it to start speaking uppercase letters. For the soft synthesizer and most others, this causes the pitch of the voice to rise above the currently set pitch.

/sys/accessibility/speakup/<synth-name>/caps_stop

Defined on file *sysfs-driver-speakup*

This is the string sent to the synthesizer to cause it to stop speaking uppercase letters. In the case of the soft synthesizer and most others, this returns the pitch of the voice down to the currently set pitch.

/sys/accessibility/speakup/<synth-name>/delay_time

Defined on file *sysfs-driver-speakup*

TODO:

/sys/accessibility/speakup/<synth-name>/direct

Defined on file *sysfs-driver-speakup*

Controls if punctuation is spoken by speakup, or by the synthesizer.

For example, speakup speaks ”>” as ”greater”, while the espeak synthesizer used by the soft driver speaks ”greater than”. Zero lets speakup speak the punctuation. One lets the synthesizer itself speak punctuation.

/sys/accessibility/speakup/<synth-name>/flush_time

Defined on file *sysfs-driver-speakup*

Gets or sets the timeout to wait for the synthesizer flush to complete. This can be used when the cable gets faulty and flush notifications are getting lost.

/sys/accessibility/speakup/<synth-name>/freq

Defined on file *sysfs-driver-speakup*

Gets or sets the frequency of the speech synthesizer. Range is 0-9.

/sys/accessibility/speakup/<synth-name>/full_time

Defined on file *sysfs-driver-speakup*

TODO:

/sys/accessibility/speakup/<synth-name>/inflection

Defined on file *sysfs-driver-speakup*

Gets or sets the inflection of the synthesizer, i.e. the pitch range. The range is 0-9.

/sys/accessibility/speakup/<synth-name>/jiffy_delta

Defined on file *sysfs-driver-speakup*

This controls how many jiffys the kernel gives to the synthesizer. Setting this too high can make a system unstable, or even crash it.

/sys/accessibility/speakup/<synth-name>/pitch

Defined on file *sysfs-driver-speakup*

Gets or sets the pitch of the synthesizer. The range is 0-9.

/sys/accessibility/speakup/<synth-name>/punct

Defined on file *sysfs-driver-speakup*

Gets or sets the amount of punctuation spoken by the synthesizer. The range for the soft driver seems to be 0-2. TODO: How is this related to speakup's punc_level, or reading_punc.

/sys/accessibility/speakup/<synth-name>/rate

Defined on file *sysfs-driver-speakup*

Gets or sets the rate of the synthesizer. Range is from zero slowest, to nine fastest.

/sys/accessibility/speakup/<synth-name>/tone

Defined on file *sysfs-driver-speakup*

Gets or sets the tone of the speech synthesizer. The range for the soft driver seems to be 0-2. This seems to make no difference if using espeak and the espeakup connector. TODO: does espeakup support different tonalities?

/sys/accessibility/speakup/<synth-name>/trigger_time

Defined on file *sysfs-driver-speakup*

TODO:

/sys/accessibility/speakup/<synth-name>/voice

Defined on file *sysfs-driver-speakup*

Gets or sets the voice used by the synthesizer if the synthesizer can speak in more than one voice. The range for the soft driver is 0-7. Note that while espeak supports multiple voices, this parameter will not set the voice when the espeakup connector is used between speakup and espeak.

/sys/accessibility/speakup/<synth-name>/vol

Defined on file *sysfs-driver-speakup*

Gets or sets the volume of the speech synthesizer. Range is 0-9, with zero being the softest, and nine being the loudest.

/sys/accessibility/speakup/attrib_bleep

Defined on file *sysfs-driver-speakup*

Beeps the PC speaker when there is an attribute change such as foreground or background color when using speakup review commands. One = on, zero = off.

/sys/accessibility/speakup/bell_pos

Defined on file *sysfs-driver-speakup*

This works much like a typewriter bell. If for example 72 is echoed to bell_pos, it will beep the PC speaker when typing on a line past character 72.

/sys/accessibility/speakup/bleep_time

Defined on file *sysfs-driver-speakup*

This controls the duration of the PC speaker beeps speakup produces. TODO: What are the units? Jiffies?

/sys/accessibility/speakup/bleeps

Defined on file *sysfs-driver-speakup*

This controls whether one hears beeps through the PC speaker when using speakup's review commands. TODO: what values does it accept?

/sys/accessibility/speakup/cur_phonetic

Defined on file *sysfs-driver-speakup*

This allows speakup to speak letters phoneticaly when arrowing through a word letter by letter. This doesn't affect the spelling when typing the characters. When cur_phonetic=1, speakup will speak characters phoneticaly when arrowing over a letter. When cur_phonetic=0, speakup will speak letters as normally.

/sys/accessibility/speakup/cursor_time

Defined on file *sysfs-driver-speakup*

This controls cursor delay when using arrow keys. When a connection is very slow, with the default setting, when moving with the arrows, or backspacing etc. speakup says the incorrect characters. Set this to a higher value to adjust for the delay and better synchronisation between cursor position and speech.

/sys/accessibility/speakup/delimiters

Defined on file *sysfs-driver-speakup*

Delimit a word from speakup. TODO: add more info

/sys/accessibility/speakup/ex_num

Defined on file *sysfs-driver-speakup*

TODO:

/sys/accessibility/speakup/i18n/announcements

Defined on file *sysfs-driver-speakup*

This file contains various general announcements, most of which cannot be categorized. You will find messages such as ”You killed Speakup”, ”I'm alive”, ”leaving help”, ”parked”, ”unparked”, and others. You will also find the names of the screen edges and cursor tracking modes here.

/sys/accessibility/speakup/i18n/characters

Defined on file *sysfs-driver-speakup*

Through this sys entry, Speakup gives you the ability to change how Speakup pronounces a given character. You could, for example, change how some punctuation characters are spoken. You can even change how Speakup will pronounce certain letters. For further details see '12. Changing the Pronunciation of Characters' in Speakup User's Guide (file spkguide.txt in source).

/sys/accessibility/speakup/i18n/chartab

Defined on file *sysfs-driver-speakup*

TODO

/sys/accessibility/speakup/i18n/colors

Defined on file *sysfs-driver-speakup*

When you use the "say attributes" function, Speakup says the name of the foreground and background colors. These names come from the i18n/colors file.

/sys/accessibility/speakup/i18n/ctl_keys

Defined on file *sysfs-driver-speakup*

Here, you will find names of control keys. These are used with Speakup's say_control feature.

/sys/accessibility/speakup/i18n/formatted

Defined on file *sysfs-driver-speakup*

This group of messages contains embedded formatting codes, to specify the type and width of displayed data. If you change these, you must preserve all of the formatting codes, and they must appear in the order used by the default messages.

/sys/accessibility/speakup/i18n/function_names

Defined on file *sysfs-driver-speakup*

Here, you will find a list of names for Speakup functions. These are used by the help system. For example, suppose that you have activated help mode, and you pressed keypad 3. Speakup says: "keypad 3 is character, say next." The message "character, say next" names a Speakup function, and it comes from this function_names file.

/sys/accessibility/speakup/i18n/key_names

Defined on file *sysfs-driver-speakup*

Again, key_names is used by Speakup's help system. In the previous example, Speakup said that you pressed "keypad 3." This name came from the key_names file.

/sys/accessibility/speakup/i18n/states

Defined on file *sysfs-driver-speakup*

This file contains names for key states. Again, these are part of the help system. For instance, if you had pressed speakup + keypad 3, you would hear: "speakup keypad 3 is go to bottom edge."

The speakup key is depressed, so the name of the key state is speakup.

This part of the message comes from the states collection.

/sys/accessibility/speakup/key_echo

Defined on file *sysfs-driver-speakup*

Controls if speakup speaks keys when they are typed. One = on, zero = off or don't echo keys.

/sys/accessibility/speakup/keymap

Defined on file *sysfs-driver-speakup*

Speakup keymap remaps keys to Speakup functions. It uses a binary format. A special program called genmap is needed to compile a textual keymap into the binary format which is then loaded into */sys/accessibility/speakup/keymap*.

/sys/accessibility/speakup/no_interrupt

Defined on file *sysfs-driver-speakup*

Controls if typing interrupts output from speakup. With no_interrupt set to zero, typing on the keyboard will interrupt speakup if for example the say screen command is used before the entire screen is read.

With no_interrupt set to one, if the say screen command is used, and one then types on the keyboard, speakup will continue to say the whole screen regardless until it finishes.

/sys/accessibility/speakup/punc_all

Defined on file *sysfs-driver-speakup*

This is a list of all the punctuation speakup should speak when punc_level is set to four.

/sys/accessibility/speakup/punc_level

Defined on file *sysfs-driver-speakup*

Controls the level of punctuation spoken as the screen is displayed, not reviewed. Levels range from zero no punctuation, to four, all punctuation. One corresponds to punc_some, two corresponds to punc_most, and three as well as four both correspond to punc_all. Some hardware synthesizers may have different levels each corresponding to three and four for punc_level. Also note that if punc_level is set to zero, and key_echo is set to one, typed punctuation is still spoken as it is typed.

/sys/accessibility/speakup/punc_most

Defined on file *sysfs-driver-speakup*

This is a list of all the punctuation speakup should speak when punc_level is set to two.

/sys/accessibility/speakup/punc_some

Defined on file *sysfs-driver-speakup*

This is a list of all the punctuation speakup should speak when punc_level is set to one.

/sys/accessibility/speakup/reading_punc

Defined on file *sysfs-driver-speakup*

Almost the same as punc_level, the differences being that reading_punc controls the level of punctuation when reviewing the screen with speakup's screen review commands. The other difference is that reading_punc set to three speaks punc_all, and reading_punc set to four speaks all punctuation, including spaces.

/sys/accessibility/speakup/repeats

Defined on file *sysfs-driver-speakup*

A list of characters speakup repeats. Normally, when there are more than three characters in a row, speakup just reads three of those characters. For example, "....." would be read as dot, dot, dot. If a . is added to the list of characters in repeats, "....." would be read as dot, dot, dot, times six.

/sys/accessibility/speakup/say_control

Defined on file *sysfs-driver-speakup*

If set to one, speakup speaks shift, alt and control when those keys are pressed. If say_control is set to zero, shift, ctrl, and alt are not spoken when they are pressed.

/sys/accessibility/speakup/say_word_ctl

Defined on file *sysfs-driver-speakup*

TODO:

/sys/accessibility/speakup/silent

Defined on file *sysfs-driver-speakup*

TODO:

/sys/accessibility/speakup/spell_delay

Defined on file *sysfs-driver-speakup*

This controls how fast a word is spelled when speakup's say word review command is pressed twice quickly to speak the current word being reviewed. Zero just speaks the letters one after

another, while values one through four seem to introduce more of a pause between the spelling of each letter by speakup.

/sys/accessibility/speakup/synth

Defined on file *sysfs-driver-speakup*

Gets or sets the synthesizer driver currently in use. Reading synth returns the synthesizer driver currently in use. Writing synth switches to the given synthesizer driver, provided it is either built into the kernel, or already loaded as a module.

/sys/accessibility/speakup/synth_direct

Defined on file *sysfs-driver-speakup*

Sends whatever is written to synth_direct directly to the speech synthesizer in use, bypassing speakup. This could be used to make the synthesizer speak a string, or to send control sequences to the synthesizer to change how the synthesizer behaves.

/sys/accessibility/speakup/version

Defined on file *sysfs-driver-speakup*

Reading version returns the version of speakup, and the version of the synthesizer driver currently in use.

5.1.3 Symbols under /sys/block

/sys/block/<disk>/<partition>/alignment_offset

Defined on file *sysfs-block*

Storage devices may report a physical block size that is bigger than the logical block size (for instance a drive with 4KB physical sectors exposing 512-byte logical blocks to the operating system). This parameter indicates how many bytes the beginning of the partition is offset from the disk's natural alignment.

/sys/block/<disk>/<partition>/discard_alignment

Defined on file *sysfs-block*

Devices that support discard functionality may internally allocate space in units that are bigger than the exported logical block size. The discard_alignment parameter indicates how many bytes the beginning of the partition is offset from the internal allocation unit's natural alignment.

/sys/block/<disk>/<partition>/stat

Defined on file *sysfs-block*

The */sys/block/<disk>/<partition>/stat* files display the I/O statistics of partition <partition>. The format is the same as the format of */sys/block/<disk>/stat*.

/sys/block/<disk>/alignment_offset

Defined on file *sysfs-block*

Storage devices may report a physical block size that is bigger than the logical block size (for instance a drive with 4KB physical sectors exposing 512-byte logical blocks to the operating system). This parameter indicates how many bytes the beginning of the device is offset from the disk's natural alignment.

/sys/block/<disk>/discard_alignment

Defined on file *sysfs-block*

Devices that support discard functionality may internally allocate space in units that are bigger than the exported logical block size. The discard_alignment parameter indicates how many bytes the beginning of the device is offset from the internal allocation unit's natural alignment.

/sys/block/<disk>/diskseq

Defined on file *sysfs-block*

The */sys/block/<disk>/diskseq* files reports the disk sequence number, which is a monotonically increasing number assigned to every drive. Some devices, like the loop device, refresh such number every time the backing file is changed. The value type is 64 bit unsigned.

/sys/block/<disk>/hidden

Defined on file *sysfs-block*

[RO] the block device is hidden. it doesn't produce events, and can't be opened from userspace or using blkdev_get*. Used for the underlying components of multipath devices.

/sys/block/<disk>/inflight

Defined on file *sysfs-block*

Reports the number of I/O requests currently in progress (pending / in flight) in a device driver. This can be less than the number of requests queued in the block device queue. The report contains 2 fields: one for read requests and one for write requests. The value type is unsigned int. Cf. /block/stat which contains a single value for requests in flight. This is related to */sys/block/<disk>/queue/nr_requests* and for SCSI device also its queue_depth.

/sys/block/<disk>/integrity/device_is_integrity_capable

Defined on file *sysfs-block*

Indicates whether a storage device is capable of storing integrity metadata. Set if the device is T10 PI-capable.

/sys/block/<disk>/integrity/format

Defined on file *sysfs-block*

Metadata format for integrity capable block device. E.g. T10-DIF-TYPE1-CRC.

/sys/block/<disk>/integrity/protection_interval_bytes

Defined on file *sysfs-block*

Describes the number of data bytes which are protected by one integrity tuple. Typically the device's logical block size.

/sys/block/<disk>/integrity/read_verify

Defined on file *sysfs-block*

Indicates whether the block layer should verify the integrity of read requests serviced by devices that support sending integrity metadata.

/sys/block/<disk>/integrity/tag_size

Defined on file *sysfs-block*

Number of bytes of integrity tag space available per 512 bytes of data.

/sys/block/<disk>/integrity/write_generate

Defined on file *sysfs-block*

Indicates whether the block layer should automatically generate checksums for write requests bound for devices that support receiving integrity metadata.

/sys/block/<disk>/queue/add_random

Defined on file *sysfs-block*

[RW] This file allows to turn off the disk entropy contribution. Default value of this file is '1'(on).

/sys/block/<disk>/queue/chunk_sectors

Defined on file *sysfs-block*

[RO] chunk_sectors has different meaning depending on the type of the disk. For a RAID device (dm-raid), chunk_sectors indicates the size in 512B sectors of the RAID volume stripe segment. For a zoned block device, either host-aware or host-managed, chunk_sectors indicates the size in 512B sectors of the zones of the device, with the eventual exception of the last zone of the device which may be smaller.

/sys/block/<disk>/queue/crypto/

Defined on file *sysfs-block*

The presence of this subdirectory of /sys/block/<disk>/queue/ indicates that the device supports inline encryption. This subdirectory contains files which describe the inline encryption capabilities of the device. For more information about inline encryption, refer to /block/inline-encryption.

/sys/block/<disk>/queue/crypto/max_dun_bits

Defined on file *sysfs-block*

[RO] This file shows the maximum length, in bits, of data unit numbers accepted by the device in inline encryption requests.

/sys/block/<disk>/queue/crypto/modes/<mode>

Defined on file *sysfs-block*

[RO] For each crypto mode (i.e., encryption/decryption algorithm) the device supports with inline encryption, a file will exist at this location. It will contain a hexadecimal number that is a bitmask of the supported data unit sizes, in bytes, for that crypto mode.

Currently, the crypto modes that may be supported are:

- AES-256-XTS
- AES-128-CBC-ESSIV
- Adiantum

For example, if a device supports AES-256-XTS inline encryption with data unit sizes of 512 and 4096 bytes, the file /sys/block/<disk>/queue/crypto/modes/AES-256-XTS will exist and will contain "0x1200".

/sys/block/<disk>/queue/crypto/num_keyslots

Defined on file *sysfs-block*

[RO] This file shows the number of keyslots the device has for use with inline encryption.

/sys/block/<disk>/queue/dax

Defined on file *sysfs-block*

[RO] This file indicates whether the device supports Direct Access (DAX), used by CPU-addressable storage to bypass the pagecache. It shows '1' if true, '0' if not.

/sys/block/<disk>/queue/discard_granularity

Defined on file *sysfs-block*

[RO] Devices that support discard functionality may internally allocate space using units that are bigger than the logical block size. The discard_granularity parameter indicates the size of the internal allocation unit in bytes if reported by the device. Otherwise the discard_granularity will be set to match the device's physical block size. A discard_granularity of 0 means that the device does not support discard functionality.

/sys/block/<disk>/queue/discard_max_bytes

Defined on file *sysfs-block*

[RW] While discard_max_hw_bytes is the hardware limit for the device, this setting is the software limit. Some devices exhibit large latencies when large discards are issued, setting this value lower will make Linux issue smaller discards and potentially help reduce latencies induced by large discard operations.

/sys/block/<disk>/queue/discard_max_hw_bytes

Defined on file *sysfs-block*

[RO] Devices that support discard functionality may have internal limits on the number of bytes that can be trimmed or unmapped in a single operation. The *discard_max_hw_bytes* parameter is set by the device driver to the maximum number of bytes that can be discarded in a single operation. Discard requests issued to the device must not exceed this limit. A *discard_max_hw_bytes* value of 0 means that the device does not support discard functionality.

/sys/block/<disk>/queue/discard_zeroes_data

Defined on file *sysfs-block*

[RO] Will always return 0. Don't rely on any specific behavior for discards, and don't read this file.

/sys/block/<disk>/queue/dma_alignment

Defined on file *sysfs-block*

Reports the alignment that user space addresses must have to be used for raw block device access with O_DIRECT and other driver specific passthrough mechanisms.

/sys/block/<disk>/queue/fua

Defined on file *sysfs-block*

[RO] Whether or not the block driver supports the FUA flag for write requests. FUA stands for Force Unit Access. If the FUA flag is set that means that write requests must bypass the volatile cache of the storage device.

/sys/block/<disk>/queue/hw_sector_size

Defined on file *sysfs-block*

[RO] This is the hardware sector size of the device, in bytes.

/sys/block/<disk>/queue/independent_access_ranges/

Defined on file *sysfs-block*

[RO] The presence of this sub-directory of the /sys/block/xxx/queue/ directory indicates that the device is capable of executing requests targeting different sector ranges in parallel. For instance, single LUN multi-actuator hard-disks will have an independent_access_ranges directory if the device correctly advertises the sector ranges of its actuators.

The independent_access_ranges directory contains one directory per access range, with each range described using the sector (RO) attribute file to indicate the first sector of the range and the nr_sectors (RO) attribute file to indicate the total number of sectors in the range starting from the first sector of the range. For example, a dual-actuator hard-disk will have the following independent_access_ranges entries.:

```
$ tree /sys/block/<disk>/queue/independent_access_ranges/
/sys/block/<disk>/queue/independent_access_ranges/
|-- 0
|   |-- nr_sectors
|   `-- sector
`-- 1
    |-- nr_sectors
    `-- sector
```

The sector and nr_sectors attributes use 512B sector unit, regardless of the actual block size of the device. Independent access ranges do not overlap and include all sectors within the device capacity. The access ranges are numbered in increasing order of the range start sector, that is, the sector attribute of range 0 always has the value 0.

/sys/block/<disk>/queue/io_poll

Defined on file *sysfs-block*

[RW] When read, this file shows whether polling is enabled (1) or disabled (0). Writing '0' to this file will disable polling for this device. Writing any non-zero value will enable this feature.

/sys/block/<disk>/queue/io_poll_delay

Defined on file *sysfs-block*

[RW] This was used to control what kind of polling will be performed. It is now fixed to -1, which is classic polling. In this mode, the CPU will repeatedly ask for completions without giving up any time. <deprecated>

/sys/block/<disk>/queue/io_timeout

Defined on file *sysfs-block*

[RW] io_timeout is the request timeout in milliseconds. If a request does not complete in this time then the block driver timeout handler is invoked. That timeout handler can decide to retry the request, to fail it or to start a device recovery strategy.

/sys/block/<disk>/queue/iostats

Defined on file *sysfs-block*

[RW] This file is used to control (on/off) the iostats accounting of the disk.

/sys/block/<disk>/queue/logical_block_size

Defined on file *sysfs-block*

[RO] This is the smallest unit the storage device can address. It is typically 512 bytes.

/sys/block/<disk>/queue/max_active_zones

Defined on file *sysfs-block*

[RO] For zoned block devices (zoned attribute indicating "host-managed" or "host-aware"), the sum of zones belonging to any of the zone states: EXPLICIT OPEN, IMPLICIT OPEN or CLOSED, is limited by this value. If this value is 0, there is no limit.

If the host attempts to exceed this limit, the driver should report this error with BLK_STS_ZONE_ACTIVE_RESOURCE, which user space may see as the EOVERFLOW errno.

/sys/block/<disk>/queue/max_discard_segments

Defined on file *sysfs-block*

[RO] The maximum number of DMA scatter/gather entries in a discard request.

/sys/block/<disk>/queue/max_hw_sectors_kb

Defined on file *sysfs-block*

[RO] This is the maximum number of kilobytes supported in a single data transfer.

/sys/block/<disk>/queue/max_integrity_segments

Defined on file *sysfs-block*

[RO] Maximum number of elements in a DMA scatter/gather list with integrity data that will be submitted by the block layer core to the associated block driver.

/sys/block/<disk>/queue/max_open_zones

Defined on file *sysfs-block*

[RO] For zoned block devices (zoned attribute indicating "host-managed" or "host-aware"), the sum of zones belonging to any of the zone states: EXPLICIT OPEN or IMPLICIT OPEN, is limited by this value. If this value is 0, there is no limit.

/sys/block/<disk>/queue/max_sectors_kb

Defined on file *sysfs-block*

[RW] This is the maximum number of kilobytes that the block layer will allow for a filesystem request. Must be smaller than or equal to the maximum size allowed by the hardware. Write 0 to use default kernel settings.

/sys/block/<disk>/queue/max_segment_size

Defined on file *sysfs-block*

[RO] Maximum size in bytes of a single element in a DMA scatter/gather list.

/sys/block/<disk>/queue/max_segments

Defined on file *sysfs-block*

[RO] Maximum number of elements in a DMA scatter/gather list that is submitted to the associated block driver.

/sys/block/<disk>/queue/minimum_io_size

Defined on file *sysfs-block*

[RO] Storage devices may report a granularity or preferred minimum I/O size which is the smallest request the device can perform without incurring a performance penalty. For disk drives this is often the physical block size. For RAID arrays it is often the stripe chunk size. A properly aligned multiple of minimum_io_size is the preferred request size for workloads where a high number of I/O operations is desired.

/sys/block/<disk>/queue/nomerges

Defined on file *sysfs-block*

[RW] Standard I/O elevator operations include attempts to merge contiguous I/Os. For known random I/O loads these attempts will always fail and result in extra cycles being spent in the kernel. This allows one to turn off this behavior on one of two ways: When set to 1, complex merge checks are disabled, but the simple one-shot merges with the previous I/O request are enabled. When set to 2, all merge tries are disabled. The default value is 0 - which enables all types of merge tries.

/sys/block/<disk>/queue/nr_requests

Defined on file *sysfs-block*

[RW] This controls how many requests may be allocated in the block layer for read or write requests. Note that the total allocated number may be twice this amount, since it applies only to reads or writes (not the accumulated sum).

To avoid priority inversion through request starvation, a request queue maintains a separate request pool per each cgroup when CONFIG_BLK_CGROUP is enabled, and this parameter applies to each such per-block-cgroup request pool. IOW, if there are N block cgroups, each request queue may have up to N request pools, each independently regulated by nr_requests.

/sys/block/<disk>/queue/nr_zones

Defined on file *sysfs-block*

[RO] nr_zones indicates the total number of zones of a zoned block device (”host-aware” or ”host-managed” zone model). For regular block devices, the value is always 0.

/sys/block/<disk>/queue/optimal_io_size

Defined on file *sysfs-block*

[RO] Storage devices may report an optimal I/O size, which is the device's preferred unit for sustained I/O. This is rarely reported for disk drives. For RAID arrays it is usually the stripe width or the internal track size. A properly aligned multiple of optimal_io_size is the preferred request size for workloads where sustained throughput is desired. If no optimal I/O size is reported this file contains 0.

/sys/block/<disk>/queue/physical_block_size

Defined on file *sysfs-block*

[RO] This is the smallest unit a physical storage device can write atomically. It is usually the same as the logical block size but may be bigger. One example is SATA drives with 4KB sectors that expose a 512-byte logical block size to the operating system. For stacked block devices the physical_block_size variable contains the maximum physical_block_size of the component devices.

/sys/block/<disk>/queue/read_ahead_kb

Defined on file *sysfs-block*

[RW] Maximum number of kilobytes to read-ahead for filesystems on this block device.

/sys/block/<disk>/queue/rotational

Defined on file *sysfs-block*

[RW] This file is used to stat if the device is of rotational type or non-rotational type.

/sys/block/<disk>/queue/rq_affinity

Defined on file *sysfs-block*

[RW] If this option is '1', the block layer will migrate request completions to the cpu ”group” that originally submitted the request. For some workloads this provides a significant reduction in CPU cycles due to caching effects.

For storage configurations that need to maximize distribution of completion processing setting this option to '2' forces the completion to run on the requesting cpu (bypassing the ”group” aggregation logic).

/sys/block/<disk>/queue/scheduler

Defined on file *sysfs-block*

[RW] When read, this file will display the current and available IO schedulers for this block device. The currently active IO scheduler will be enclosed in [] brackets. Writing an IO scheduler name to this file will switch control of this block device to that new IO scheduler. Note that writing an IO scheduler name to this file will attempt to load that IO scheduler module, if it isn't already present in the system.

/sys/block/<disk>/queue/stable_writes

Defined on file *sysfs-block*

[RW] This file will contain '1' if memory must not be modified while it is being used in a write request to this device. When this is the case and the kernel is performing writeback of a page, the kernel will wait for writeback to complete before allowing the page to be modified again, rather than allowing immediate modification as is normally the case. This restriction arises when the device accesses the memory multiple times where the same data must be seen every time -- for example, once to calculate a checksum and once to actually write the data. If no such restriction exists, this file will contain '0'. This file is writable for testing purposes.

/sys/block/<disk>/queue/throttle_sample_time

Defined on file *sysfs-block*

[RW] This is the time window that blk-throttle samples data, in millisecond. blk-throttle makes decision based on the samplings. Lower time means cgroups have more smooth throughput, but higher CPU overhead. This exists only when CONFIG_BLK_DEV_THROTTLING_LOW is enabled.

/sys/block/<disk>/queue/virt_boundary_mask

Defined on file *sysfs-block*

[RO] This file shows the I/O segment memory alignment mask for the block device. I/O requests to this device will be split between segments wherever either the memory address of the end of the previous segment or the memory address of the beginning of the current segment is not aligned to virt_boundary_mask + 1 bytes.

/sys/block/<disk>/queue/wbt_lat_usec

Defined on file *sysfs-block*

[RW] If the device is registered for writeback throttling, then this file shows the target minimum read latency. If this latency is exceeded in a given window of time (see wb_window_usec), then the writeback throttling will start scaling back writes. Writing a value of '0' to this file disables the feature. Writing a value of '-1' to this file resets the value to the default setting.

/sys/block/<disk>/queue/write_cache

Defined on file *sysfs-block*

[RW] When read, this file will display whether the device has write back caching enabled or not. It will return ”write back” for the former case, and ”write through” for the latter. Writing to this file can change the kernels view of the device, but it doesn't alter the device state. This

means that it might not be safe to toggle the setting from "write back" to "write through", since that will also eliminate cache flushes issued by the kernel.

/sys/block/<disk>/queue/write_same_max_bytes

Defined on file *sysfs-block*

[RO] Some devices support a write same operation in which a single data block can be written to a range of several contiguous blocks on storage. This can be used to wipe areas on disk or to initialize drives in a RAID configuration. write_same_max_bytes indicates how many bytes can be written in a single write same command. If write_same_max_bytes is 0, write same is not supported by the device.

/sys/block/<disk>/queue/write_zeroes_max_bytes

Defined on file *sysfs-block*

[RO] Devices that support write zeroes operation in which a single request can be issued to zero out the range of contiguous blocks on storage without having any payload in the request. This can be used to optimize writing zeroes to the devices. write_zeroes_max_bytes indicates how many bytes can be written in a single write zeroes command. If write_zeroes_max_bytes is 0, write zeroes is not supported by the device.

/sys/block/<disk>/queue/zone_append_max_bytes

Defined on file *sysfs-block*

[RO] This is the maximum number of bytes that can be written to a sequential zone of a zoned block device using a zone append write operation (REQ_OP_ZONE_APPEND). This value is always 0 for regular block devices.

/sys/block/<disk>/queue/zone_write_granularity

Defined on file *sysfs-block*

[RO] This indicates the alignment constraint, in bytes, for write operations in sequential zones of zoned block devices (devices with a zoned attributed that reports "host-managed" or "host-aware"). This value is always 0 for regular block devices.

/sys/block/<disk>/queue/zoned

Defined on file *sysfs-block*

[RO] zoned indicates if the device is a zoned block device and the zone model of the device if it is indeed zoned. The possible values indicated by zoned are "none" for regular block devices and "host-aware" or "host-managed" for zoned block devices. The characteristics of host-aware and host-managed zoned block devices are described in the ZBC (Zoned Block Commands) and ZAC (Zoned Device ATA Command Set) standards. These standards also define the "drive-managed" zone model. However, since drive-managed zoned block devices do not support zone commands, they will be treated as regular block devices and zoned will report "none".

/sys/block/<disk>/stat

Defined on file *sysfs-block*

The */sys/block/<disk>/stat* files displays the I/O statistics of disk <disk>. They contain 11 fields:

1	reads completed successfully
2	reads merged
3	sectors read
4	time spent reading (ms)
5	writes completed
6	writes merged
7	sectors written
8	time spent writing (ms)
9	I/Os currently in progress
10	time spent doing I/Os (ms)
11	weighted time spent doing I/Os (ms)
12	discards completed
13	discards merged
14	sectors discarded
15	time spent discarding (ms)
16	flush requests completed
17	time spent flushing (ms)

For more details refer *I/O statistics fields*

5.1.4 Symbols under /sys/bus

/sys/bus/dsa/devices/dsa<m>/cdev_major

Defined on file *sysfs-driver-dma-idxd*

The major number that the character device driver assigned to this device.

/sys/bus/dsa/devices/dsa<m>/cmd_status

Defined on file *sysfs-driver-dma-idxd*

The last executed device administrative command's status/error. Also last configuration error overloaded. Writing to it will clear the status.

/sys/bus/dsa/devices/dsa<m>/configurable

Defined on file *sysfs-driver-dma-idxd*

To indicate if this device is configurable or not.

/sys/bus/dsa/devices/dsa<m>/engine<m>.<n>

Defined on file *sysfs-driver-dma-idxd*

The assigned engine under this device.

/sys/bus/dsa/devices/dsa<m>/errors

Defined on file *sysfs-driver-dma-idxd*

The error information for this device.

/sys/bus/dsa/devices/dsa<m>/event_log_size

Defined on file *sysfs-driver-dma-idxd*

The event log size to be configured. Default is 64 entries and occupies 4k size if the evl entry is 64 bytes. It's visible only on platforms that support the capability.

/sys/bus/dsa/devices/dsa<m>/group<m>.<n>

Defined on file *sysfs-driver-dma-idxd*

The assigned group under this device.

/sys/bus/dsa/devices/dsa<m>/iaa_cap

Defined on file *sysfs-driver-dma-idxd*

IAA (IAX) capability mask. Exported to user space for application consumption. This attribute should only be visible on IAA devices that are version 2 or later.

/sys/bus/dsa/devices/dsa<m>/max_batch_size

Defined on file *sysfs-driver-dma-idxd*

The largest number of work descriptors in a batch. It's not visible when the device does not support batch.

/sys/bus/dsa/devices/dsa<m>/max_engines

Defined on file *sysfs-driver-dma-idxd*

The maximum number of engines supported by this device.

/sys/bus/dsa/devices/dsa<m>/max_groups

Defined on file *sysfs-driver-dma-idxd*

The maximum number of groups can be created under this device.

/sys/bus/dsa/devices/dsa<m>/max_read_buffers

Defined on file *sysfs-driver-dma-idxd*

The total number of read buffers supported by this device. The read buffers represent resources within the DSA implementation, and these resources are allocated by engines to support operations. See DSA spec v1.2 9.2.4 Total Read Buffers. It's not visible when the device does not support Read Buffer allocation control.

/sys/bus/dsa/devices/dsa<m>/max_transfer_size

Defined on file *sysfs-driver-dma-idxd*

The number of bytes to be read from the source address to perform the operation. The maximum transfer size is dependent on the workqueue the descriptor was submitted to.

/sys/bus/dsa/devices/dsa<m>/max_work_queues

Defined on file *sysfs-driver-dma-idxd*

The maximum work queue number that this device supports.

/sys/bus/dsa/devices/dsa<m>/max_work_queues_size

Defined on file *sysfs-driver-dma-idxd*

The maximum work queue size supported by this device.

/sys/bus/dsa/devices/dsa<m>/numa_node

Defined on file *sysfs-driver-dma-idxd*

The numa node number for this device.

/sys/bus/dsa/devices/dsa<m>/op_cap

Defined on file *sysfs-driver-dma-idxd*

The operation capability bit mask specify the operation types supported by the this device.

/sys/bus/dsa/devices/dsa<m>/pasid_enabled

Defined on file *sysfs-driver-dma-idxd*

To indicate if user PASID (process address space identifier) is enabled or not for this device.

/sys/bus/dsa/devices/dsa<m>/read_buffer_limit

Defined on file *sysfs-driver-dma-idxd*

The maximum number of read buffers that may be in use at one time by operations that access low bandwidth memory in the device. See DSA spec v1.2 9.2.8 GENCFG on Global Read Buffer Limit. It's not visible when the device does not support Read Buffer allocation control.

/sys/bus/dsa/devices/dsa<m>/state

Defined on file *sysfs-driver-dma-idxd*

The state information of this device. It can be either enabled or disabled.

/sys/bus/dsa/devices/dsa<m>/version

Defined on file *sysfs-driver-dma-idxd*

The hardware version number.

/sys/bus/dsa/devices/dsa<m>/wq<m>.<n>

Defined on file *sysfs-driver-dma-idxd*

The assigned work queue under this device.

/sys/bus/dsa/devices/engine<m>.<n>/group_id

Defined on file *sysfs-driver-dma-idxd*

The group that this engine belongs to.

/sys/bus/dsa/devices/group<m>.<n>/batch_progress_limit

Defined on file *sysfs-driver-dma-idxd*

Allows control of the number of batch descriptors that can be concurrently processed by an engine in the group as a fraction of the Maximum Batch Descriptors in Progress value specified in the ENGCAP register. The acceptable values are 0 (default), 1 (1/2 of max value), 2 (1/4 of the max value), and 3 (1/8 of the max value). It's visible only on platforms that support the capability.

/sys/bus/dsa/devices/group<m>.<n>/desc_progress_limit

Defined on file *sysfs-driver-dma-idxd*

Allows control of the number of work descriptors that can be concurrently processed by an engine in the group as a fraction of the Maximum Work Descriptors in Progress value specified in the ENGCAP register. The acceptable values are 0 (default), 1 (1/2 of max value), 2 (1/4 of the max value), and 3 (1/8 of the max value). It's visible only on platforms that support the capability.

/sys/bus/dsa/devices/group<m>.<n>/read_buffers_allowed

Defined on file *sysfs-driver-dma-idxd*

Indicates max number of read buffers that may be in use at one time by all engines in the group. See DSA spec v1.2 9.2.18 GRPCFG Read Buffers Allowed. It's not visible when the device does not support Read Buffer allocation control.

/sys/bus/dsa/devices/group<m>.<n>/read_buffers_reserved

Defined on file *sysfs-driver-dma-idxd*

Indicates the number of Read Buffers reserved for the use of engines in the group. See DSA spec v1.2 9.2.18 GRPCFG Read Buffers Reserved. It's not visible when the device does not support Read Buffer allocation control.

/sys/bus/dsa/devices/group<m>.<n>/use_read_buffer_limit

Defined on file *sysfs-driver-dma-idxd*

Enable the use of global read buffer limit for the group. See DSA spec v1.2 9.2.18 GRPCFG Use Global Read Buffer Limit. It's not visible when the device does not support Read Buffer allocation control.

/sys/bus/dsa/devices/wq<m>.<n>/ats_disable

Defined on file *sysfs-driver-dma-idxd*

Indicate whether ATS disable is turned on for the workqueue. 0 indicates ATS is on, and 1 indicates ATS is off for the workqueue.

/sys/bus/dsa/devices/wq<m>.<n>/block_on_fault

Defined on file *sysfs-driver-dma-idxd*

To indicate block on fault is allowed or not for the work queue to support on demand paging.

/sys/bus/dsa/devices/wq<m>.<n>/cdev_minor

Defined on file *sysfs-driver-dma-idxd*

The minor number assigned to this work queue by the character device driver.

/sys/bus/dsa/devices/wq<m>.<n>/driver_name

Defined on file *sysfs-driver-dma-idxd*

Name of driver to be bounded to the wq.

/sys/bus/dsa/devices/wq<m>.<n>/dsa<x>\!wq<m>.<n>/file<y>/cr_fault_failures

Defined on file *sysfs-driver-dma-idxd*

Show the number of Completion Record (CR) faults failures that this application has caused. The failure counter is incremented when the driver cannot fault in the address for the CR. Typically this is caused by a bad address programmed in the submitted descriptor or a malicious submitter is using bad CR address on purpose.

/sys/bus/dsa/devices/wq<m>.<n>/dsa<x>\!wq<m>.<n>/file<y>/cr_faults

Defined on file *sysfs-driver-dma-idxd*

Show the number of Completion Record (CR) faults this application has caused.

/sys/bus/dsa/devices/wq<m>.<n>/dsa<x>\!wq<m>.<n>/file<y>/pid

Defined on file *sysfs-driver-dma-idxd*

Show the process id of the application that opened the file. This is helpful information for a monitor daemon that wants to kill the application that opened the file.

/sys/bus/dsa/devices/wq<m>.<n>/enqcmds_retries

Defined on file *sysfs-driver-dma-idxd*

Indicate the number of retires for an enqcmds submission on a sharedwq. A max value to set attribute is capped at 64.

/sys/bus/dsa/devices/wq<m>.<n>/group_id

Defined on file *sysfs-driver-dma-idxd*

The group id that this work queue belongs to.

/sys/bus/dsa/devices/wq<m>.<n>/max_batch_size

Defined on file *sysfs-driver-dma-idxd*

The max batch size for this workqueue. Cannot exceed device max batch size. Configurable parameter. It's not visible when the device does not support batch.

/sys/bus/dsa/devices/wq<m>.<n>/max_transfer_size

Defined on file *sysfs-driver-dma-idxd*

The max transfer sized for this workqueue. Cannot exceed device max transfer size. Configurable parameter.

/sys/bus/dsa/devices/wq<m>.<n>/mode

Defined on file *sysfs-driver-dma-idxd*

The work queue mode type for this work queue.

/sys/bus/dsa/devices/wq<m>.<n>/occupancy

Defined on file *sysfs-driver-dma-idxd*

Show the current number of entries in this WQ if WQ Occupancy Support bit WQ capabilities is 1.

/sys/bus/dsa/devices/wq<m>.<n>/op_config

Defined on file *sysfs-driver-dma-idxd*

Shows the operation capability bits displayed in bitmap format presented by %*pb printk() output format specifier. The attribute can be configured when the WQ is disabled in order to configure the WQ to accept specific bits that correlates to the operations allowed. It's visible only on platforms that support the capability.

/sys/bus/dsa/devices/wq<m>.<n>/priority

Defined on file *sysfs-driver-dma-idxd*

The priority value of this work queue, it is a value relative to other work queue in the same group to control quality of service for dispatching work from multiple workqueues in the same group.

/sys/bus/dsa/devices/wq<m>.<n>/prs_disable

Defined on file *sysfs-driver-dma-idxd*

Controls whether PRS disable is turned on for the workqueue. 0 indicates PRS is on, and 1 indicates PRS is off for the workqueue. This option overrides block_on_fault attribute if set. It's visible only on platforms that support the capability.

/sys/bus/dsa/devices/wq<m>.<n>/size

Defined on file *sysfs-driver-dma-idxd*

The work queue size for this work queue.

/sys/bus/dsa/devices/wq<m>.<n>/state

Defined on file *sysfs-driver-dma-idxd*

The current state of the work queue.

/sys/bus/dsa/devices/wq<m>.<n>/threshold

Defined on file *sysfs-driver-dma-idxd*

The number of entries in this work queue that may be filled via a limited portal.

/sys/bus/dsa/devices/wq<m>.<n>/type

Defined on file *sysfs-driver-dma-idxd*

The type of this work queue, it can be ”kernel” type for work queue usages in the kernel space or ”user” type for work queue usages by applications in user space.

/sys/bus/firewire/devices/*/

Defined on file *sysfs-bus-firewire*

Attributes common to IEEE 1394 node devices and unit devices. Read-only. Mutable during the node device's lifetime. Immutable during the unit device's lifetime. See IEEE 1212 for semantic definitions.

These attributes are only created if the root directory of an IEEE 1394 node or the unit directory of an IEEE 1394 unit actually contains according entries.

hardware_version
Hexadecimal string representation of an u24.

hardware_version_name
Contents of a respective textual descriptor leaf.

model
Hexadecimal string representation of an u24.

model_name
Contents of a respective textual descriptor leaf.

specifier_id
Hexadecimal string representation of an u24. Mandatory in unit directories according to IEEE 1212.

vendor
Hexadecimal string representation of an u24. Mandatory in the root directory according to IEEE 1212.

vendor_name
Contents of a respective textual descriptor leaf.

version
Hexadecimal string representation of an u24. Mandatory in unit directories according to IEEE 1212.

/sys/bus/firewire/devices/fw[0-9]+/

Defined on file *sysfs-bus-firewire*

IEEE 1394 node device attributes. Read-only. Mutable during the node device's lifetime. See IEEE 1212 for semantic definitions.

config_rom
Contents of the Configuration ROM register. Binary attribute; an array of host-endian u32.

guid
The node's EUI-64 in the bus information block of Configuration ROM. Hexadecimal string representation of an u64.

/sys/bus/firewire/devices/fw[0-9]+/is_local

Defined on file *sysfs-bus-firewire*

IEEE 1394 node device attribute. Read-only and immutable. Values: 1: The sysfs entry represents a local node (a controller card).

0: The sysfs entry represents a remote node.

/sys/bus/firewire/devices/fw[0-9]+/units

Defined on file *sysfs-bus-firewire*

IEEE 1394 node device attribute. Read-only. Mutable during the node device's lifetime. See IEEE 1212 for semantic definitions.

units
Summary of all units present in an IEEE 1394 node. Contains space-separated tuples of specifier_id and version of each unit present in the node. Specifier_id and version are hexadecimal string representations of u24 of the respective unit directory entries. Specifier_id and version within each tuple are separated by a colon.

Users: udev rules to set ownership and access permissions or ACLs of /dev/fw[0-9]+ character device files

/sys/bus/firewire/devices/fw[0-9]+[.][0-9]+/

Defined on file *sysfs-bus-firewire*

IEEE 1394 unit device attributes. Read-only. Immutable during the unit device's lifetime. See IEEE 1212 for semantic definitions.

modalias
Same as MODALIAS in the uevent at device creation.

rom_index
Offset of the unit directory within the parent device's (node device's) Configuration ROM, in quadlets. Decimal string representation.

/sys/bus/firewire/drivers/sbp2/fw*/host*/target*/*:*:*:*/ieee1394_id

Defined on file *sysfs-bus-firewire*

SCSI target port identifier and logical unit identifier of a logical unit of an SBP-2 target. The identifiers are specified in SAM-2...SAM-4 annex A. They are persistent and world-wide unique properties the SBP-2 attached target.

Read-only attribute, immutable during the target's lifetime. Format, as exposed by firewire-sbp2 since 2.6.22, May 2007: Colon-separated hexadecimal string representations of

u64 EUI-64 : u24 directory_ID : u16 LUN

without 0x prefixes, without whitespace. The former sbp2 driver (removed in 2.6.37 after being superseded by firewire-sbp2) used a somewhat shorter format which was not as close to SAM.

Users: udev rules to create /dev/disk/by-id/ symlinks

/sys/bus/fsl-mc/autorescan

Defined on file *sysfs-bus-fsl-mc*

Writing a zero value to this attribute will disable the DPRC IRQs on which automatic rescan of the fsl-mc bus is performed. A non-zero value will enable the DPRC IRQs.

Users: Userspace drivers and management tools

/sys/bus/fsl-mc/rescan

Defined on file *sysfs-bus-fsl-mc*

Writing a non-zero value to this attribute will force a rescan of fsl-mc bus in the system and synchronize the objects under fsl-mc bus and the Management Complex firmware.

Users: Userspace drivers and management tools

/sys/bus/mhi/devices/.../oem_pk_hash

Defined on file *sysfs-bus-mhi*

The file holds the OEM PK Hash value of the endpoint device obtained using a BHI (Boot Host Interface) register read after at least one attempt to power up the device has been done. If read without having the device power on at least once, the file will read all 0's.

Users: Any userspace application or clients interested in device info.

/sys/bus/mhi/devices/.../serialnumber

Defined on file *sysfs-bus-mhi*

The file holds the serial number of the client device obtained using a BHI (Boot Host Interface) register read after at least one attempt to power up the device has been done. If read without having the device power on at least once, the file will read all 0's.

Users: Any userspace application or clients interested in device info.

/sys/bus/mhi/devices/.../soc_reset

Defined on file *sysfs-bus-mhi*

Initiates a SoC reset on the MHI controller. A SoC reset is a reset of last resort, and will require a complete re-init. This can be useful as a method of recovery if the device is non-responsive, or as a means of loading new firmware as a system administration task.

/sys/bus/nvmem/devices/.../nvmem

Defined on file *sysfs-bus-nvmem*

This file allows user to read/write the raw NVMEM contents. Permissions for write to this file depends on the nvmem provider configuration. Note: This file is only present if CONFIG_NVMEM_SYSFS is enabled

ex:

```
hexdump /sys/bus/nvmem/devices/qfprom0/nvmem

0000000 0000 0000 0000 0000 0000 0000 0000 0000
*
00000a0 db10 2240 0000 e000 0c00 0c00 0000 0c00
0000000 0000 0000 0000 0000 0000 0000 0000 0000
```

```
...
*
0001000
```

/sys/bus/pci/drivers/qla2xxx/.../devices/*

Defined on file *sysfs-driver-qla2xxx*

qla2xxx-udev.sh currently looks for uevent CHANGE events to signal a firmware-dump has been generated by the driver and is ready for retrieval.

Users: qla2xxx-udev.sh. Proposed changes should be mailed to linux-driver@qlogic.com

/sys/bus/platform/drivers/aspeed-vuart/*/lpc_address

Defined on file *sysfs-driver-aspeed-vuart*

Configures which IO port the host side of the UART will appear on the host <-> BMC LPC bus.

Users: OpenBMC. Proposed changes should be mailed to openbmc@lists.ozlabs.org

/sys/bus/platform/drivers/aspeed-vuart/*/sirq

Defined on file *sysfs-driver-aspeed-vuart*

Configures which interrupt number the host side of the UART will appear on the host <-> BMC LPC bus.

Users: OpenBMC. Proposed changes should be mailed to openbmc@lists.ozlabs.org

/sys/bus/platform/drivers/aspeed-vuart/*/sirq_polarity

Defined on file *sysfs-driver-aspeed-vuart*

Configures the polarity of the serial interrupt to the host via the BMC LPC bus. Set to 0 for active-low or 1 for active-high.

Users: OpenBMC. Proposed changes should be mailed to openbmc@lists.ozlabs.org

/sys/bus/usb/device/.../avoid_reset_quirk

Defined on file *sysfs-bus-usb*

Writing 1 to this file tells the kernel that this device will morph into another mode when it is reset. Drivers will not use reset for error handling for such devices.

Users:

usb_modeswitch

/sys/bus/usb/device/.../power/active_duration

Defined on file *sysfs-bus-usb*

If CONFIG_PM is enabled, then this file is present. When read, it returns the total time (in msec) that the USB device has been active, i.e. not in a suspended state. This file is read-only.

Tools can use this file and the connected_duration file to compute the percentage of time that a device has been active. For example:

```
echo $((100 * `cat active_duration` / `cat connected_duration`))
```

will give an integer percentage. Note that this does not account for counter wrap.

Users:

PowerTOP <powertop@lists.01.org> https://01.org/powertop/

/sys/bus/usb/device/.../power/connected_duration

Defined on file *sysfs-bus-usb*

If CONFIG_PM is enabled, then this file is present. When read, it returns the total time (in msec) that the USB device has been connected to the machine. This file is read-only.

Users:

PowerTOP <powertop@lists.01.org> https://01.org/powertop/

/sys/bus/usb/devices/.../bConfigurationValue

Defined on file *sysfs-bus-usb*

bConfigurationValue of the *active* configuration for the device. Writing 0 or -1 to bConfigurationValue will reset the active configuration (unconfigure the device). Writing another value will change the active configuration.

Note that some devices, in violation of the USB spec, have a configuration with a value equal to 0. Writing 0 to bConfigurationValue for these devices will install that configuration, rather then unconfigure the device.

Writing -1 will always unconfigure the device.

Users:

libusb

/sys/bus/usb/devices/.../busnum

Defined on file *sysfs-bus-usb*

Bus-number of the USB-bus the device is connected to.

Users:

libusb

/sys/bus/usb/devices/.../descriptors

Defined on file *sysfs-bus-usb*

Binary file containing cached descriptors of the device. The binary data consists of the device descriptor followed by the descriptors for each configuration of the device. Note that the wTotalLength of the config descriptors can not be trusted, as the device may have a smaller config descriptor than it advertises. The bLength field of each (sub) descriptor can be trusted, and can be used to seek forward one (sub) descriptor at a time until the next config descriptor is found. All descriptors read from this file are in bus-endian format

Users:

libusb

/sys/bus/usb/devices/.../devnum

Defined on file *sysfs-bus-usb*

Device address on the USB bus.

Users:

libusb

/sys/bus/usb/devices/.../power/autosuspend

Defined on file *sysfs-bus-usb*

Each USB device directory will contain a file named power/autosuspend. This file holds the time (in seconds) the device must be idle before it will be autosuspended. 0 means the device will be autosuspended as soon as possible. Negative values will prevent the device from being autosuspended at all, and writing a negative value will resume the device if it is already suspended.

The autosuspend delay for newly-created devices is set to the value of the usbcore.autosuspend module parameter.

/sys/bus/usb/devices/.../power/persist

Defined on file *sysfs-bus-usb*

USB device directories can contain a file named power/persist. The file holds a boolean value (0 or 1) indicating whether or not the "USB-Persist" facility is enabled for the device. For hubs this facility is always enabled and their device directories will not contain this file.

For more information, see /driver-api/usb/persist.

/sys/bus/usb/devices/.../speed

Defined on file *sysfs-bus-usb*

Speed the device is connected with to the usb-host in Mbit / second. IE one of 1.5 / 12 / 480 / 5000.

Users:

libusb

/sys/bus/usb/devices/<busnum>-<port[.port]>...:<config num>-<interface num>/supports_autosuspend

Defined on file *sysfs-bus-usb*

When read, this file returns 1 if the interface driver for this interface supports autosuspend. It also returns 1 if no driver has claimed this interface, as an unclaimed interface will not stop the device from being autosuspended if all other interface drivers are idle. The file returns 0 if autosuspend support has not been added to the driver.

Users:

USB PM tool git://git.moblin.org/users/sarah/usb-pm-tool/

/sys/bus/usb/drivers/usbtmc/*/interface_capabilities
/sys/bus/usb/drivers/usbtmc/*/device_capabilities

Defined on file *sysfs-driver-usb-usbtmc*

These files show the various USB TMC capabilities as described by the device itself. The full description of the bitfields can be found in the USB TMC documents from the USB-IF entitled "Universal Serial Bus Test and Measurement Class Specification (USBTMC) Revision 1.0" section 4.2.1.8.

The files are read only.

/sys/bus/usb/drivers/usbtmc/*/usb488_interface_capabilities
/sys/bus/usb/drivers/usbtmc/*/usb488_device_capabilities

Defined on file *sysfs-driver-usb-usbtmc*

These files show the various USB TMC capabilities as described by the device itself. The full description of the bitfields can be found in the USB TMC documents from the USB-IF entitled "Universal Serial Bus Test and Measurement Class, Subclass USB488 Specification (USBTMC-USB488) Revision 1.0" section 4.2.2.

The files are read only.

/sys/bus/vmbus/devices/<UUID>/channel_vp_mapping

Defined on file *sysfs-bus-vmbus*

The mapping of which primary/sub channels are bound to which Virtual Processors. Format: <channel's child_relid:the bound cpu's number>

Users: tools/hv/lsvmbus

/sys/bus/vmbus/devices/<UUID>/channels/<N>

Defined on file *sysfs-bus-vmbus*

Directory for per-channel information NN is the VMBUS relid associated with the channel.

/sys/bus/vmbus/devices/<UUID>/channels/<N>/cpu

Defined on file *sysfs-bus-vmbus*

VCPU (sub)channel is affinitized to

Users: tools/hv/lsvmbus and other debugging tools

/sys/bus/vmbus/devices/<UUID>/channels/<N>/events

Defined on file *sysfs-bus-vmbus*

Number of times we have signaled the host

Users: Debugging tools

/sys/bus/vmbus/devices/<UUID>/channels/<N>/in_mask

Defined on file *sysfs-bus-vmbus*

Host to guest channel interrupt mask

Users: Debugging tools

/sys/bus/vmbus/devices/<UUID>/channels/<N>/interrupts

Defined on file *sysfs-bus-vmbus*

Number of times we have taken an interrupt (incoming)

Users: Debugging tools

/sys/bus/vmbus/devices/<UUID>/channels/<N>/intr_in_full

Defined on file *sysfs-bus-vmbus*

Number of guest to host interrupts caused by the inbound ring buffer transitioning from full to not full while a packet is waiting for buffer space to become available

Users: Debugging tools

/sys/bus/vmbus/devices/<UUID>/channels/<N>/intr_out_empty

Defined on file *sysfs-bus-vmbus*

Number of guest to host interrupts caused by the outbound ring buffer transitioning from empty to not empty

Users: Debugging tools

/sys/bus/vmbus/devices/<UUID>/channels/<N>/latency

Defined on file *sysfs-bus-vmbus*

Channel signaling latency. This file is available only for performance critical channels (storage, network, etc.) that use the monitor page mechanism.

Users: Debugging tools

/sys/bus/vmbus/devices/<UUID>/channels/<N>/monitor_id

Defined on file *sysfs-bus-vmbus*

Monitor bit associated with channel. This file is available only for performance critical channels (storage, network, etc.) that use the monitor page mechanism.

Users: Debugging tools and userspace drivers

/sys/bus/vmbus/devices/<UUID>/channels/<N>/out_full_first

Defined on file *sysfs-bus-vmbus*

Number of write operations that were the first to encounter an outbound ring buffer full condition

Users: Debugging tools

/sys/bus/vmbus/devices/<UUID>/channels/<N>/out_full_total

Defined on file *sysfs-bus-vmbus*

Total number of write operations that encountered an outbound ring buffer full condition

Users: Debugging tools

/sys/bus/vmbus/devices/<UUID>/channels/<N>/out_mask

Defined on file *sysfs-bus-vmbus*

Guest to host channel interrupt mask

Users: Debugging tools

/sys/bus/vmbus/devices/<UUID>/channels/<N>/pending

Defined on file *sysfs-bus-vmbus*

Channel interrupt pending state. This file is available only for performance critical channels (storage, network, etc.) that use the monitor page mechanism.

Users: Debugging tools

/sys/bus/vmbus/devices/<UUID>/channels/<N>/read_avail

Defined on file *sysfs-bus-vmbus*

Bytes available to read

Users: Debugging tools

/sys/bus/vmbus/devices/<UUID>/channels/<N>/ring

Defined on file *sysfs-bus-vmbus*

Binary file created by uio_hv_generic for ring buffer

Users: Userspace drivers

/sys/bus/vmbus/devices/<UUID>/channels/<N>/subchannel_id

Defined on file *sysfs-bus-vmbus*

Subchannel ID associated with VMBUS channel

Users: Debugging tools and userspace drivers

/sys/bus/vmbus/devices/<UUID>/channels/<N>/write_avail

Defined on file *sysfs-bus-vmbus*

Bytes available to write

Users: Debugging tools

/sys/bus/vmbus/devices/<UUID>/class_id

Defined on file *sysfs-bus-vmbus*

The VMBus interface type GUID of the device

Users: tools/hv/lsvmbus

/sys/bus/vmbus/devices/<UUID>/device

Defined on file *sysfs-bus-vmbus*

The 16 bit device ID of the device

Users: tools/hv/lsvmbus and user level RDMA libraries

/sys/bus/vmbus/devices/<UUID>/device_id

Defined on file *sysfs-bus-vmbus*

The VMBus interface instance GUID of the device

Users: tools/hv/lsvmbus

/sys/bus/vmbus/devices/<UUID>/id

Defined on file *sysfs-bus-vmbus*

The VMBus child_relid of the device's primary channel

Users: tools/hv/lsvmbus

/sys/bus/vmbus/devices/<UUID>/numa_node

Defined on file *sysfs-bus-vmbus*

This NUMA node to which the VMBUS device is attached, or -1 if the node is unknown.

/sys/bus/vmbus/devices/<UUID>/vendor

Defined on file *sysfs-bus-vmbus*

The 16 bit vendor ID of the device

Users: tools/hv/lsvmbus and user level RDMA libraries

/sys/bus/vmbus/hibernation

Defined on file *sysfs-bus-vmbus*

Whether the host supports hibernation for the VM.

Users: Daemon that sets up swap partition/file for hibernation.

/sys/bus/w1/devices/.../eeprom

Defined on file *sysfs-driver-w1_ds28e04*

read/write the contents of the EEPROM memory of the DS28E04-100 see /w1/slaves/w1_ds28e04 for detailed information

Users: any user space application which wants to communicate with DS28E04-100

/sys/bus/w1/devices/.../offset

Defined on file *sysfs-driver-w1_ds2438*

write the contents to the offset register of the DS2438 see /w1/slaves/w1_ds2438 for detailed information

Users: any user space application which wants to communicate with DS2438

/sys/bus/w1/devices/.../page1

Defined on file *sysfs-driver-w1_ds2438*

read the contents of the page1 of the DS2438 see /w1/slaves/w1_ds2438 for detailed information

Users: any user space application which wants to communicate with DS2438

/sys/bus/w1/devices/.../pio

Defined on file *sysfs-driver-w1_ds28e04*

read/write the contents of the two PIO's of the DS28E04-100 see /w1/slaves/w1_ds28e04 for detailed information

Users: any user space application which wants to communicate with DS28E04-100

/sys/bus/w1/devices/.../w1_master_timeout_us

Defined on file *sysfs-bus-w1*

Bus scanning interval, microseconds component. Some of 1-Wire devices commonly associated with physical access control systems are attached/generate presence for as short as 100 ms - hence the tens-to-hundreds milliseconds scan intervals are required.

see /w1/w1-generic for detailed information.

Users: any user space application which wants to know bus scanning interval

/sys/bus/w1/devices/.../w1_seq

Defined on file *sysfs-driver-w1_ds28ea00*

Support for the DS28EA00 chain sequence function see /w1/slaves/w1_therm for detailed information

Users: any user space application which wants to communicate with DS28EA00

/sys/bus/wmi/devices/05901221-D566-11D1-B2F0-00A0C9062910[-X]/bmof

Defined on file *sysfs-platform-wmi-bmof*

Binary MOF metadata used to describe the details of available ACPI WMI interfaces.

See /wmi/devices/wmi-bmof for details.

/sys/bus/xen-backend/devices/*/devtype

Defined on file *sysfs-bus-xen-backend*

The type of the device. e.g., one of: 'vbd' (block), 'vif' (network), or 'vfb' (framebuffer).

/sys/bus/xen-backend/devices/*/nodename

Defined on file *sysfs-bus-xen-backend*

XenStore node (under /local/domain/NNN/) for this backend device.

/sys/bus/xen-backend/devices/*/state

Defined on file *sysfs-bus-xen-backend*

The state of the device. One of: 'Unknown', 'Initialising', 'Initialised', 'Connected', 'Closing', 'Closed', 'Reconfiguring', 'Reconfigured'.

/sys/bus/xen-backend/devices/vbd-*/mode

Defined on file *sysfs-bus-xen-backend*

Whether the block device is read-only ('r') or read-write ('w').

/sys/bus/xen-backend/devices/vbd-*/physical_device

Defined on file *sysfs-bus-xen-backend*

The major:minor number (in hexadecimal) of the physical device providing the storage for this backend block device.

/sys/bus/xen-backend/devices/vbd-*/statistics/f_req

Defined on file *sysfs-bus-xen-backend*

Number of flush requests from the frontend.

/sys/bus/xen-backend/devices/vbd-*/statistics/oo_req

Defined on file *sysfs-bus-xen-backend*

Number of requests delayed because the backend was too busy processing previous requests.

/sys/bus/xen-backend/devices/vbd-*/statistics/rd_req

Defined on file *sysfs-bus-xen-backend*

Number of read requests from the frontend.

/sys/bus/xen-backend/devices/vbd-*/statistics/rd_sect

Defined on file *sysfs-bus-xen-backend*

Number of sectors read by the frontend.

/sys/bus/xen-backend/devices/vbd-*/statistics/wr_req

Defined on file *sysfs-bus-xen-backend*

Number of write requests from the frontend.

/sys/bus/xen-backend/devices/vbd-*/statistics/wr_sect

Defined on file *sysfs-bus-xen-backend*

Number of sectors written by the frontend.

5.1.5 Symbols under /sys/class

/sys/class/backlight/<backlight>/actual_brightness

Defined on file *sysfs-class-backlight*

Show the actual brightness by querying the hardware.

Users: HAL

/sys/class/backlight/<backlight>/bl_power

Defined on file *sysfs-class-backlight*

Control BACKLIGHT power, values are FB_BLANK_* from fb.h

- FB_BLANK_UNBLANK (0) : power on.
- FB_BLANK_POWERDOWN (4) : power off

Users: HAL

/sys/class/backlight/<backlight>/brightness

Defined on file *sysfs-class-backlight*

Control the brightness for this <backlight>. Values are between 0 and max_brightness. This file will also show the brightness level stored in the driver, which may not be the actual brightness (see actual_brightness).

Users: HAL

/sys/class/backlight/<backlight>/max_brightness

Defined on file *sysfs-class-backlight*

Maximum brightness for <backlight>.

Users: HAL

/sys/class/backlight/<backlight>/type

Defined on file *sysfs-class-backlight*

The type of interface controlled by <backlight>. ”firmware”: The driver uses a standard firmware interface ”platform”: The driver uses a platform-specific interface ”raw”: The driver controls hardware registers directly

In the general case, when multiple backlight interfaces are available for a single device, firmware control should be preferred to platform control should be preferred to raw control.

Using a firmware interface reduces the probability of confusion with the hardware and the OS independently updating the backlight state. Platform interfaces are mostly a holdover from pre-standardisation of firmware interfaces.

/sys/class/infiniband/<device-name>/hw_counters/lifespan
/sys/class/infiniband/<device-name>/ports/<port-num>/hw_counters/lifespan

Defined on file *sysfs-class-infiniband*

The optional "hw_counters" subdirectory can be under either the parent device or the port subdirectories or both. If present, there are a list of counters provided by the hardware. They may match some of the counters in the counters directory, but they often include many other counters. In addition to the various counters, there will be a file named "lifespan" that configures how frequently the core should update the counters when they are being accessed (counters are not updated if they are not being accessed). The lifespan is in milliseconds and defaults to 10 unless set to something else by the driver. Users may echo a value between 0-10000 to the lifespan file to set the length of time between updates in milliseconds.

/sys/class/infiniband/<device>/fw_ver

Defined on file *sysfs-class-infiniband*

(RO) Display firmware version

/sys/class/infiniband/<device>/node_desc

Defined on file *sysfs-class-infiniband*

(RW) Update the node description with information such as the node's hostname, so that IB network management software can tie its view to the real world.

/sys/class/infiniband/<device>/node_type
/sys/class/infiniband/<device>/node_guid
/sys/class/infiniband/<device>/sys_image_guid

Defined on file *sysfs-class-infiniband*

node_type:	(RO) Node type (CA, RNIC, usNIC, usNIC UDP, switch or router)
node_guid:	(RO) Node GUID
sys_image_guid:	(RO) System image GUID

/sys/class/infiniband/<device>/ports/<port-num>/counters/VL15_dropped
/sys/class/infiniband/<device>/ports/<port-num>/counters/port_xmit_wait

Defined on file *sysfs-class-infiniband*

Errors info:

symbol_error: (RO) Total number of minor link errors detected on one or more physical lanes.

port_rcv_errors : (RO) Total number of packets containing an error that were received on the port.

port_rcv_remote_physical_errors : (RO) Total number of packets marked with the EBP delimiter received on the port.

port_rcv_switch_relay_errors : (RO) Total number of packets received on the port that were discarded because they could not be forwarded by the switch relay.

link_error_recovery: (RO) Total number of times the Port Training state machine has successfully completed the link error recovery process.

port_xmit_constraint_errors: (RO) Total number of packets not transmitted from the switch physical port due to outbound raw filtering or failing outbound partition or IP version check.

port_rcv_constraint_errors: (RO) Total number of packets received on the switch physical port that are discarded due to inbound raw filtering or failing inbound partition or IP version check.

local_link_integrity_errors: (RO) The number of times that the count of local physical errors exceeded the threshold specified by LocalPhyErrors

excessive_buffer_overrun_errors: (RO) This counter, indicates an input buffer overrun. It indicates possible misconfiguration of a port, either by the Subnet Manager (SM) or by user intervention. It can also indicate hardware issues or extremely poor link signal integrity

Data info:

port_xmit_data: (RO) Total number of data octets, divided by 4 (lanes), transmitted on all VLs. This is 64 bit counter

port_rcv_data: (RO) Total number of data octets, divided by 4 (lanes), received on all VLs. This is 64 bit counter.

port_xmit_packets: (RO) Total number of packets transmitted on all VLs from this port. This may include packets with errors. This is 64 bit counter.

port_rcv_packets: (RO) Total number of packets (this may include packets containing Errors. This is 64 bit counter.

link_downed: (RO) Total number of times the Port Training state machine has failed the link error recovery process and downed the link.

unicast_rcv_packets: (RO) Total number of unicast packets, including unicast packets containing errors.

unicast_xmit_packets: (RO) Total number of unicast packets transmitted on all VLs from the port. This may include unicast packets with errors.

multicast_rcv_packets: (RO) Total number of multicast packets, including multicast packets containing errors.

multicast_xmit_packets: (RO) Total number of multicast packets transmitted on all VLs from the port. This may include multicast packets with errors.

Misc info:

port_xmit_discards: (RO) Total number of outbound packets discarded by the port because the port is down or congested.

VL15_dropped: (RO) Number of incoming VL15 packets dropped due to resource limitations (e.g., lack of buffers) of the port.

port_xmit_wait: (RO) The number of ticks during which the port had data to transmit but no data was sent during the entire tick (either because of insufficient credits or because of lack of arbitration).

Each of these files contains the corresponding value from the port's Performance Management PortCounters attribute, as described in the InfiniBand Architecture Specification.

/sys/class/infiniband/<device>/ports/<port-num>/lid
/sys/class/infiniband/<device>/ports/<port-num>/rate
/sys/class/infiniband/<device>/ports/<port-num>/lid_mask_count
/sys/class/infiniband/<device>/ports/<port-num>/sm_sl
/sys/class/infiniband/<device>/ports/<port-num>/sm_lid
/sys/class/infiniband/<device>/ports/<port-num>/state
/sys/class/infiniband/<device>/ports/<port-num>/phys_state
/sys/class/infiniband/<device>/ports/<port-num>/cap_mask

Defined on file *sysfs-class-infiniband*

lid:	(RO) Port LID
rate:	(RO) Port data rate (active width * active speed)
lid_mask_count:	(RO) Port LID mask count
sm_sl:	(RO) Subnet manager SL for port's subnet
sm_lid:	(RO) Subnet manager LID for port's subnet
state:	(RO) Port state (DOWN, INIT, ARMED, ACTIVE or ACTIVE_DEFER)
phys_state:	(RO) Port physical state (Sleep, Polling, LinkUp, etc)
cap_mask:	(RO) Port capability mask. 2 bits here are settable- IsCommunicationManagementSupported (set when CM module is loaded) and IsSM (set via open of issmN file).

/sys/class/infiniband/<device>/ports/<port-num>/link_layer

Defined on file *sysfs-class-infiniband*

(RO) Link layer type information (Infiniband or Ethernet type)

/sys/class/infiniband/<hca>/ports/<port-number>/gid_attrs/ndevs/<gid-index>

Defined on file *sysfs-class-infiniband*

The net-device's name associated with the GID resides at index <gid-index>.

/sys/class/infiniband/<hca>/ports/<port-number>/gid_attrs/types/<gid-index>

Defined on file *sysfs-class-infiniband*

The RoCE type of the associated GID resides at index <gid-index>. This could either be "IB/RoCE v1" for IB and RoCE v1 based GIDs or "RoCE v2" for RoCE v2 based GIDs.

/sys/class/infiniband/bnxt_reX/hw_rev
/sys/class/infiniband/bnxt_reX/hca_type

Defined on file *sysfs-class-infiniband*

hw_rev:	(RO)	Hardware revision number
hca_type:	(RO)	Host channel adapter type

/sys/class/infiniband/cxgb4_X/hw_rev
/sys/class/infiniband/cxgb4_X/hca_type
/sys/class/infiniband/cxgb4_X/board_id

Defined on file *sysfs-class-infiniband*

hw_rev:	(RO) Hardware revision number
hca_type:	(RO) Driver short name. Should normally match the name in its bus driver structure (e.g. pci_driver::name)
board_id:	(RO) Manufacturing board id. (Vendor + device information)

sysfs interface for Intel IB driver qib

/sys/class/infiniband/hfi1_X/hw_rev

/sys/class/infiniband/hfi1_X/nfreectxts
/sys/class/infiniband/hfi1_X/tempsense

Defined on file *sysfs-class-infiniband*

hw_rev:	(RO) Hardware revision number
board_id:	(RO) Manufacturing board id
nctxts:	(RO) Total contexts available.
serial:	(RO) Board serial number
chip_reset:	(WO) Write ”reset” to this file to reset the chip if possible. Only allowed if no user contexts are open that use chip resources.
boardversion:	(RO) Human readable board info
nfreectxts:	(RO) The number of free user ports (contexts) available.
tempsense:	(RO) Thermal sense information

/sys/class/infiniband/hfi1_X/ports/<N>/CCMgtA/cc_settings_bin
/sys/class/infiniband/hfi1_X/ports/<N>/CCMgtA/cc_table_bin
/sys/class/infiniband/hfi1_X/ports/<N>/CCMgtA/cc_prescan

Defined on file *sysfs-class-infiniband*

Per-port congestion control.

cc_table_bin	(RO) CCA tables used by PSM2 Congestion control table size followed by table entries. Binary attribute.
cc_settings_bin	(RO) Congestion settings: port control, control map and an array of 16 entries for the congestion entries - increase, timer, event log trigger threshold and the minimum injection rate delay. Binary attribute.
cc_prescan	(RW) enable prescanning for faster BECN response. Write ”on” to enable and ”off” to disable.

/sys/class/infiniband/hfi1_X/ports/<N>/sc2vl/[0-31]
/sys/class/infiniband/hfi1_X/ports/<N>/sl2sc/[0-31]
/sys/class/infiniband/hfi1_X/ports/<N>/vl2mtu/[0-15]

Defined on file *sysfs-class-infiniband*

sc2vl/:	(RO) 32 files (0 - 31) used to translate sl->vl
sl2sc/:	(RO) 32 files (0 - 31) used to translate sl->sc
vl2mtu/:	(RO) 16 files (0 - 15) used to determine MTU for vl

/sys/class/infiniband/hfi1_X/sdma_<N>/cpu_list
/sys/class/infiniband/hfi1_X/sdma_<N>/vl

Defined on file *sysfs-class-infiniband*

sdma<N>/ contains one directory per sdma engine (0 - 15)

cpu_list:	(RW) List of cpus for user-process to sdma engine assignment.
vl:	(RO) Displays the virtual lane (vl) the sdma engine maps to.

This interface gives the user control on the affinity settings for the device. As an example, to set an sdma engine irq affinity and thread affinity of a user processes to use the sdma engine, which is "near" in terms of NUMA configuration, or physical cpu location, the user will do:

```
echo "3" > /proc/irq/<N>/smp_affinity_list
echo "4-7" > /sys/devices/.../sdma3/cpu_list
cat /sys/devices/.../sdma3/vl
0
echo "8" > /proc/irq/<M>/smp_affinity_list
echo "9-12" > /sys/devices/.../sdma4/cpu_list
cat /sys/devices/.../sdma4/vl
1
```

to make sure that when a process runs on cpus 4,5,6, or 7, and uses vl=0, then sdma engine 3 is selected by the driver, and also the interrupt of the sdma engine 3 is steered to cpu 3. Similarly, when a process runs on cpus 9,10,11, or 12 and sets vl=1, then engine 4 will be selected and the irq of the sdma engine 4 is steered to cpu 8. This assumes that in the above N is the irq number of "sdma3", and M is irq number of "sdma4" in the /proc/interrupts file.

sysfs interface for QLogic qedr NIC Driver

/sys/class/infiniband/mlx4_X/hw_rev
/sys/class/infiniband/mlx4_X/hca_type
/sys/class/infiniband/mlx4_X/board_id

Defined on file *sysfs-class-infiniband*

hw_rev:	(RO) Hardware revision number
hca_type:	(RO) Host channel adapter type
board_id:	(RO) Manufacturing board ID

/sys/class/infiniband/mlx4_X/iov/<pci-slot-num>/ports/<m>/smi_enabled
/sys/class/infiniband/mlx4_X/iov/<pci-slot-num>/ports/<m>/enable_smi_admin

Defined on file *sysfs-class-infiniband*

Enabling QP0 on VFs for selected VF/port. By default, no VFs are enabled for QP0 operation.

smi_enabled:	(RO)	Indicates whether smi is currently enabled for the indicated VF/port
enable_smi_admin:	(RW)	Used by the admin to request that smi capability be enabled or disabled for the indicated VF/port. 0 = disable, 1 = enable.

The requested enablement will occur at the next reset of the VF (e.g. driver restart on the VM which owns the VF).

sysfs interface for Chelsio T4/T5 RDMA driver (cxgb4)

/sys/class/infiniband/mlx4_X/iov/ports/<port-num>/gids/<n>
/sys/class/infiniband/mlx4_X/iov/ports/<port-num>/admin_guids/<n>
/sys/class/infiniband/mlx4_X/iov/ports/<port-num>/pkeys/<n>
/sys/class/infiniband/mlx4_X/iov/ports/<port-num>/mcgs/
/sys/class/infiniband/mlx4_X/iov/ports/<pci-slot-num>/ports/<m>/gid_idx/0
/sys/class/infiniband/mlx4_X/iov/ports/<pci-slot-num>/ports/<m>/pkey_idx/<n>

Defined on file *sysfs-class-infiniband*

The sysfs iov directory is used to manage and examine the port P_Key and guid paravirtualization. This directory is added only for the master -- slaves do not have it.

Under iov/ports, the administrator may examine the gid and P_Key tables as they are present in the device (and as are seen in the ”network view” presented to the SM).

The ”pkeys” and ”gids” subdirectories contain one file for each entry in the port's P_Key or GID table respectively. For example, ports/1/pkeys/10 contains the value at index 10 in port 1's P_Key table.

gids/<n>:	(RO) The physical port gids n = 0..127
admin_guids/<n>:	(RW) Allows examining or changing the administrative state of a given GUID n = 0..127
pkeys/<n>:	(RO) Displays the contents of the physical key table n = 0..126
mcgs/:	(RO) Multicast group table
<m>/gid_idx/0:	(RO) Display the GID mapping m = 1..2
<m>/pkey_idx/<n>:	(RW) Writable except for RoCE pkeys. m = 1..2, n = 0..126 Under the iov/<pci slot number> directories, the admin may map the index numbers in the physical tables (as under iov/ports) to the paravirtualized index numbers that guests see. For example, if the administrator, for port 1 on guest 2 maps physical pkey index 10 to virtual index 1, then that guest, whenever it uses its pkey index 1, will actually be using the real pkey index 10.

hw_rev:	(RO)	Hardware revision number
hca_type:	(RO)	Host channel adapter type
board_id:	(RO)	Display PVRDMA manufacturing board ID

sysfs interface for Broadcom NetXtreme-E RoCE driver

/sys/class/infiniband_mad/abi_version

Defined on file *sysfs-class-infiniband*

(RO) Value is incremented if any changes are made that break userspace ABI compatibility of umad & issm devices.

/sys/class/infiniband_mad/umad<N>/ibdev
/sys/class/infiniband_mad/umad<N>/port
/sys/class/infiniband_mad/issm<N>/ibdev
/sys/class/infiniband_mad/issm<N>/port

Defined on file *sysfs-class-infiniband*

Each port of each InfiniBand device has a "umad" device and an "issm" device attached. For example, a two-port HCA will have two umad devices and two issm devices, while a switch will have one device of each type (for switch port 0).

ibdev:	(RO) Show Infiniband (IB) device name
port:	(RO) Display port number

/sys/class/infiniband_srp/srp-<hca>-<port_number>/add_target

Defined on file *sysfs-driver-ib_srp*

Interface for making ib_srp connect to a new target. One can request ib_srp to connect to a new target by writing a comma-separated list of login parameters to this sysfs attribute. The supported parameters are:

- id_ext, a 16-digit hexadecimal number specifying the eight byte identifier extension in the 16-byte SRP target port identifier. The target port identifier is sent by ib_srp to the target in the SRP_LOGIN_REQ request.

- ioc_guid, a 16-digit hexadecimal number specifying the eight byte I/O controller GUID portion of the 16-byte target port identifier.
- dgid, a 32-digit hexadecimal number specifying the destination GID.
- pkey, a four-digit hexadecimal number specifying the InfiniBand partition key.
- service_id, a 16-digit hexadecimal number specifying the InfiniBand service ID used to establish communication with the SRP target. How to find out the value of the service ID is specified in the documentation of the SRP target.
- max_sect, a decimal number specifying the maximum number of 512-byte sectors to be transferred via a single SCSI command.
- max_cmd_per_lun, a decimal number specifying the maximum number of outstanding commands for a single LUN.
- io_class, a hexadecimal number specifying the SRP I/O class. Must be either 0xff00 (rev 10) or 0x0100 (rev 16a). The I/O class defines the format of the SRP initiator and target port identifiers.
- initiator_ext, a 16-digit hexadecimal number specifying the identifier extension portion of the SRP initiator port identifier. This data is sent by the initiator to the target in the SRP_LOGIN_REQ request.
- cmd_sg_entries, a number in the range 1..255 that specifies the maximum number of data buffer descriptors stored in the SRP_CMD information unit itself. With allow_ext_sg=0 the parameter cmd_sg_entries defines the maximum S/G list length for a single SRP_CMD, and commands whose S/G list length exceeds this limit after S/G list collapsing will fail.
- allow_ext_sg, whether ib_srp is allowed to include a partial memory descriptor list in an SRP_CMD instead of the entire list. If a partial memory descriptor list has been included in an SRP_CMD the remaining memory descriptors are communicated from initiator to target via an additional RDMA transfer. Setting allow_ext_sg to 1 increases the maximum amount of data that can be transferred between initiator and target via a single SCSI command. Since not all SRP target implementations support partial memory descriptor lists the default value for this option is 0.
- sg_tablesize, a number in the range 1..2048 specifying the maximum S/G list length the SCSI layer is allowed to pass to ib_srp. Specifying a value that exceeds cmd_sg_entries is only safe with partial memory descriptor list support enabled (allow_ext_sg=1).
- comp_vector, a number in the range 0..n-1 specifying the MSI-X completion vector of the first RDMA channel. Some HCA's allocate multiple (n) MSI-X vectors per HCA port. If the IRQ affinity masks of these interrupts have been configured such that each MSI-X interrupt is handled by a different CPU then the comp_vector parameter can be used to spread the SRP completion workload over multiple CPU's.
- tl_retry_count, a number in the range 2..7 specifying the IB RC retry count.
- queue_size, the maximum number of commands that the initiator is allowed to queue per SCSI host. The default value for this parameter is 62. The lowest supported value is 2.
- max_it_iu_size, a decimal number specifying the maximum initiator to target information unit length.

/sys/class/infiniband_srp/srp-<hca>-<port_number>/ibdev

Defined on file *sysfs-driver-ib_srp*

HCA name (<hca>).

/sys/class/infiniband_srp/srp-<hca>-<port_number>/port

Defined on file *sysfs-driver-ib_srp*

HCA port number (<port_number>).

/sys/class/infiniband_verbs/abi_version

Defined on file *sysfs-class-infiniband*

(RO) Value is incremented if any changes are made that break userspace ABI compatibility of uverbs devices.

sysfs interface for Mellanox IB HCA low-level driver (mthca)

/sys/class/infiniband_verbs/uverbs<N>/ibdev
/sys/class/infiniband_verbs/uverbs<N>/abi_version

Defined on file *sysfs-class-infiniband*

ibdev:	(RO) Display Infiniband (IB) device name
abi_version:	(RO) Show ABI version of IB device specific interfaces.

/sys/class/rfkill

Defined on file *sysfs-class-rfkill*

The rfkill class subsystem folder. Each registered rfkill driver is represented by an rfkillX subfolder (X being an integer >= 0).

/sys/class/rfkill/rfkill[0-9]+/hard

Defined on file *sysfs-class-rfkill*

Current hardblock state. This file is read only. Values: A numeric value.

0: inactive
The transmitter is (potentially) active.

1: active
The transmitter is forced off by something outside of the driver's control.

/sys/class/rfkill/rfkill[0-9]+/name

Defined on file *sysfs-class-rfkill*

Name assigned by driver to this key (interface or driver name). Values: arbitrary string.

/sys/class/rfkill/rfkill[0-9]+/persistent

Defined on file *sysfs-class-rfkill*

Whether the soft blocked state is initialised from non-volatile storage at startup. Values: A numeric value:

- 0: false
- 1: true

/sys/class/rfkill/rfkill[0-9]+/soft

Defined on file *sysfs-class-rfkill*

Current softblock state. This file is read and write. Values: A numeric value.

0: inactive
The transmitter is (potentially) active.

1: active
The transmitter is turned off by software.

/sys/class/rfkill/rfkill[0-9]+/state

Defined on file *sysfs-class-rfkill*

Current state of the transmitter. This file was scheduled to be removed in 2014, but due to its large number of users it will be sticking around for a bit longer. Despite it being marked as stable, the newer ”hard” and ”soft” interfaces should be preferred, since it is not possible to express the 'soft and hard block' state of the rfkill driver through this interface. There will likely be another attempt to remove it in the future. Values: A numeric value.

0: RFKILL_STATE_SOFT_BLOCKED
transmitter is turned off by software

1: RFKILL_STATE_UNBLOCKED
transmitter is (potentially) active

2: RFKILL_STATE_HARD_BLOCKED
transmitter is forced off by something outside of the driver's control.

/sys/class/rfkill/rfkill[0-9]+/type

Defined on file *sysfs-class-rfkill*

Driver type string (”wlan”, ”bluetooth”, etc). Values: See include/linux/rfkill.h.

/sys/class/scsi_host/host<n>/allow_ext_sg

Defined on file *sysfs-driver-ib_srp*

Whether ib_srp is allowed to include a partial memory descriptor list in an SRP_CMD when communicating with an SRP target.

/sys/class/scsi_host/host<n>/ch_count

Defined on file *sysfs-driver-ib_srp*

Number of RDMA channels used for communication with the SRP target.

/sys/class/scsi_host/host<n>/cmd_sg_entries

Defined on file *sysfs-driver-ib_srp*

Maximum number of data buffer descriptors that may be sent to the target in a single SRP_CMD request.

/sys/class/scsi_host/host<n>/comp_vector

Defined on file *sysfs-driver-ib_srp*

Completion vector used for the first RDMA channel.

/sys/class/scsi_host/host<n>/dgid

Defined on file *sysfs-driver-ib_srp*

InfiniBand destination GID used for communication with the SRP target. Differs from orig_dgid if port redirection has happened.

/sys/class/scsi_host/host<n>/id_ext

Defined on file *sysfs-driver-ib_srp*

Eight-byte identifier extension portion of the 16-byte target port identifier.

/sys/class/scsi_host/host<n>/ioc_guid

Defined on file *sysfs-driver-ib_srp*

Eight-byte I/O controller GUID portion of the 16-byte target port identifier.

/sys/class/scsi_host/host<n>/local_ib_device

Defined on file *sysfs-driver-ib_srp*

Name of the InfiniBand HCA used for communicating with the SRP target.

/sys/class/scsi_host/host<n>/local_ib_port

Defined on file *sysfs-driver-ib_srp*

Number of the HCA port used for communicating with the SRP target.

/sys/class/scsi_host/host<n>/orig_dgid

Defined on file *sysfs-driver-ib_srp*

InfiniBand destination GID specified in the parameters written to the add_target sysfs attribute.

/sys/class/scsi_host/host<n>/pkey

Defined on file *sysfs-driver-ib_srp*

A 16-bit number representing the InfiniBand partition key used for communication with the SRP target.

/sys/class/scsi_host/host<n>/req_lim

Defined on file *sysfs-driver-ib_srp*

Number of requests ib_srp can send to the target before it has to wait for more credits. For more information see also the SRP credit algorithm in the SRP specification.

/sys/class/scsi_host/host<n>/service_id

Defined on file *sysfs-driver-ib_srp*

InfiniBand service ID used for establishing communication with the SRP target.

/sys/class/scsi_host/host<n>/sgid

Defined on file *sysfs-driver-ib_srp*

InfiniBand GID of the source port used for communication with the SRP target.

/sys/class/scsi_host/host<n>/zero_req_lim

Defined on file *sysfs-driver-ib_srp*

Number of times the initiator had to wait before sending a request to the target because it ran out of credits. For more information see also the SRP credit algorithm in the SRP specification.

/sys/class/srp_remote_ports/port-<h>:<n>/delete

Defined on file *sysfs-transport-srp*

Instructs an SRP initiator to disconnect from a target and to remove all LUNs imported from that target.

/sys/class/srp_remote_ports/port-<h>:<n>/dev_loss_tmo

Defined on file *sysfs-transport-srp*

Number of seconds the SCSI layer will wait after a transport layer error has been observed before removing a target port. Zero means immediate removal. Setting this attribute to "off" will disable the dev_loss timer.

/sys/class/srp_remote_ports/port-<h>:<n>/fast_io_fail_tmo

Defined on file *sysfs-transport-srp*

Number of seconds the SCSI layer will wait after a transport layer error has been observed before failing I/O. Zero means failing I/O immediately. Setting this attribute to "off" will disable the fast_io_fail timer.

/sys/class/srp_remote_ports/port-<h>:<n>/port_id

Defined on file *sysfs-transport-srp*

16-byte local SRP port identifier in hexadecimal format. An example: 4c:49:4e:55:58:20:56:49:4f:00:00:00:00:00:00:00.

/sys/class/srp_remote_ports/port-<h>:<n>/reconnect_delay

Defined on file *sysfs-transport-srp*

Number of seconds the SCSI layer will wait after a reconnect attempt failed before retrying. Setting this attribute to "off" will disable time-based reconnecting.

/sys/class/srp_remote_ports/port-<h>:<n>/roles

Defined on file *sysfs-transport-srp*

Role of the remote port. Either "SRP Initiator" or "SRP Target".

/sys/class/srp_remote_ports/port-<h>:<n>/state

Defined on file *sysfs-transport-srp*

State of the transport layer used for communication with the remote port. "running" if the transport layer is operational; "blocked" if a transport layer error has been encountered but the fast_io_fail_tmo timer has not yet fired; "fail-fast" after the fast_io_fail_tmo timer has fired and before the "dev_loss_tmo" timer has fired; "lost" after the "dev_loss_tmo" timer has fired and before the port is finally removed.

/sys/class/tpm/tpmX/device/

Defined on file *sysfs-class-tpm*

The device/ directory under a specific TPM instance exposes the properties of that TPM chip

/sys/class/tpm/tpmX/device/active

Defined on file *sysfs-class-tpm*

The "active" property prints a '1' if the TPM chip is accepting commands. An inactive TPM chip still contains all the state of an active chip (Storage Root Key, NVRAM, etc), and can be visible

to the OS, but will only accept a restricted set of commands. See the TPM Main Specification part 2, Structures, section 17 for more information on which commands are available.

/sys/class/tpm/tpmX/device/cancel

Defined on file *sysfs-class-tpm*

The ”cancel” property allows you to cancel the currently pending TPM command. Writing any value to cancel will call the TPM vendor specific cancel operation.

/sys/class/tpm/tpmX/device/caps

Defined on file *sysfs-class-tpm*

The ”caps” property contains TPM manufacturer and version info.

Example output:

```
Manufacturer: 0x53544d20
TCG version: 1.2
Firmware version: 8.16
```

Manufacturer is a hex dump of the 4 byte manufacturer info space in a TPM. TCG version shows the TCG TPM spec level that the chip supports. Firmware version is that of the chip and is manufacturer specific.

/sys/class/tpm/tpmX/device/durations

Defined on file *sysfs-class-tpm*

The ”durations” property shows the 3 vendor-specific values used to wait for a short, medium and long TPM command. All TPM commands are categorized as short, medium or long in execution time, so that the driver doesn't have to wait any longer than necessary before starting to poll for a result.

Example output:

```
3015000 4508000 180995000 [original]
```

Here the short, medium and long durations are displayed in usecs. ”[original]” indicates that the values are displayed unmodified from when they were queried from the chip. Durations can be modified in the case where a buggy chip reports them in msec instead of usec and they need to be scaled to be displayed in usecs. In this case ”[adjusted]” will be displayed in place of ”[original]”.

/sys/class/tpm/tpmX/device/enabled

Defined on file *sysfs-class-tpm*

The ”enabled” property prints a '1' if the TPM chip is enabled, meaning that it should be visible to the OS. This property may be visible but produce a '0' after some operation that disables the TPM.

/sys/class/tpm/tpmX/device/owned

Defined on file *sysfs-class-tpm*

The "owned" property produces a '1' if the TPM_TakeOwnership ordinal has been executed successfully in the chip. A '0' indicates that ownership hasn't been taken.

/sys/class/tpm/tpmX/device/pcrs

Defined on file *sysfs-class-tpm*

The "pcrs" property will dump the current value of all Platform Configuration Registers in the TPM. Note that since these values may be constantly changing, the output is only valid for a snapshot in time.

Example output:

```
PCR-00: 3A 3F 78 0F 11 A4 B4 99 69 FC AA 80 CD 6E 39 57 C3 3B 22 75
PCR-01: 3A 3F 78 0F 11 A4 B4 99 69 FC AA 80 CD 6E 39 57 C3 3B 22 75
PCR-02: 3A 3F 78 0F 11 A4 B4 99 69 FC AA 80 CD 6E 39 57 C3 3B 22 75
PCR-03: 3A 3F 78 0F 11 A4 B4 99 69 FC AA 80 CD 6E 39 57 C3 3B 22 75
PCR-04: 3A 3F 78 0F 11 A4 B4 99 69 FC AA 80 CD 6E 39 57 C3 3B 22 75
...
```

The number of PCRs and hex bytes needed to represent a PCR value will vary depending on TPM chip version. For TPM 1.1 and 1.2 chips, PCRs represent SHA-1 hashes, which are 20 bytes long. Use the "caps" property to determine TPM version.

/sys/class/tpm/tpmX/device/pubek

Defined on file *sysfs-class-tpm*

The "pubek" property will return the TPM's public endorsement key if possible. If the TPM has had ownership established and is version 1.2, the pubek will not be available without the owner's authorization. Since the TPM driver doesn't store any secrets, it can't authorize its own request for the pubek, making it unaccessible. The public endorsement key is gener- ated at TPM manufacture time and exists for the life of the chip.

Example output:

```
Algorithm: 00 00 00 01
Encscheme: 00 03
Sigscheme: 00 01
Parameters: 00 00 08 00 00 00 00 02 00 00 00 00

```

Possible values:

```
Algorithm:    TPM_ALG_RSA                     (1)
Encscheme:    TPM_ES_RSAESPKCSv15             (2)
              TPM_ES_RSAESOAEP_SHA1_MGF1      (3)
Sigscheme:    TPM_SS_NONE                     (1)
Parameters, a byte string of 3 u32 values:
      Key Length (bits):      00 00 08 00     (2048)
      Num primes:             00 00 00 02     (2)
      Exponent Size:          00 00 00 00     (0 means the
                                               default exp)
Modulus Length: 256 (bytes)
Modulus:      The 256 byte Endorsement Key modulus
```

/sys/class/tpm/tpmX/device/temp_deactivated

Defined on file *sysfs-class-tpm*

The ”temp_deactivated” property returns a '1' if the chip has been temporarily deactivated, usually until the next power cycle. Whether a warm boot (reboot) will clear a TPM chip from a temp_deactivated state is platform specific.

/sys/class/tpm/tpmX/device/timeouts

Defined on file *sysfs-class-tpm*

The ”timeouts” property shows the 4 vendor-specific values for the TPM's interface spec timeouts. The use of these timeouts is defined by the TPM interface spec that the chip conforms to.

Example output:

```
750000 750000 750000 750000 [original]
```

The four timeout values are shown in usecs, with a trailing ”[original]” or ”[adjusted]” depending on whether the values were scaled by the driver to be reported in usec from msecs.

/sys/class/tpm/tpmX/pcr-<H>/<N>

Defined on file *sysfs-class-tpm*

produces output in compact hex representation for PCR number N from hash bank H. N is the numeric value of the PCR number and H is the crypto string representation of the hash

Example output:

```
cat /sys/class/tpm/tpm0/pcr-sha256/7
2ED93F199692DC6788EFA6A1FE74514AB9760B2A6CEEAEF6C808C13E4ABB0D42
```

/sys/class/tpm/tpmX/tpm_version_major

Defined on file *sysfs-class-tpm*

The "tpm_version_major" property shows the TCG spec major version implemented by the TPM device.

Example output:

```
2
```

/sys/class/ubi/

Defined on file *sysfs-class-ubi*

The ubi/ class sub-directory belongs to the UBI subsystem and provides general UBI information, per-UBI device information and per-UBI volume information.

/sys/class/ubi/ubiX/avail_eraseblocks

Defined on file *sysfs-class-ubi*

Amount of available logical eraseblock. For example, one may create a new UBI volume which has this amount of logical eraseblocks.

/sys/class/ubi/ubiX/bad_peb_count

Defined on file *sysfs-class-ubi*

Count of bad physical eraseblocks on the underlying MTD device.

/sys/class/ubi/ubiX/bgt_enabled

Defined on file *sysfs-class-ubi*

Contains ASCII "0n" if the UBI background thread is disabled, and ASCII "1n" if it is enabled.

/sys/class/ubi/ubiX/dev

Defined on file *sysfs-class-ubi*

Major and minor numbers of the character device corresponding to this UBI device (in <major>:<minor> format).

/sys/class/ubi/ubiX/eraseblock_size

Defined on file *sysfs-class-ubi*

Maximum logical eraseblock size this UBI device may provide. UBI volumes may have smaller logical eraseblock size because of their alignment.

/sys/class/ubi/ubiX/max_ec

Defined on file *sysfs-class-ubi*

Maximum physical eraseblock erase counter value.

/sys/class/ubi/ubiX/max_vol_count

Defined on file *sysfs-class-ubi*

Maximum number of volumes which this UBI device may have.

/sys/class/ubi/ubiX/min_io_size

Defined on file *sysfs-class-ubi*

Minimum input/output unit size. All the I/O may only be done in fractions of the contained number.

/sys/class/ubi/ubiX/mtd_num

Defined on file *sysfs-class-ubi*

Number of the underlying MTD device.

/sys/class/ubi/ubiX/reserved_for_bad

Defined on file *sysfs-class-ubi*

Number of physical eraseblocks reserved for bad block handling.

/sys/class/ubi/ubiX/ro_mode

Defined on file *sysfs-class-ubi*

Contains ASCII "1n" if the read-only flag is set on this device, and "0n" if it is cleared. UBI devices mark themselves as read-only when they detect an unrecoverable error.

/sys/class/ubi/ubiX/total_eraseblocks

Defined on file *sysfs-class-ubi*

Total number of good (not marked as bad) physical eraseblocks on the underlying MTD device.

/sys/class/ubi/ubiX/ubiX_Y/

Defined on file *sysfs-class-ubi*

The /sys/class/ubi/ubiX/ubiX_0/, /sys/class/ubi/ubiX/ubiX_1/, etc directories describe UBI volumes on UBI device X (volumes 0, 1, etc).

/sys/class/ubi/ubiX/ubiX_Y/alignment

Defined on file *sysfs-class-ubi*

Volume alignment - the value the logical eraseblock size of this volume has to be aligned on. For example, 2048 means that logical eraseblock size is multiple of 2048. In other words, volume logical eraseblock size is UBI device logical eraseblock size aligned to the alignment value.

/sys/class/ubi/ubiX/ubiX_Y/corrupted

Defined on file *sysfs-class-ubi*

Contains ASCII "0n" if the UBI volume is OK, and ASCII "1n" if it is corrupted (e.g., due to an interrupted volume update).

/sys/class/ubi/ubiX/ubiX_Y/data_bytes

Defined on file *sysfs-class-ubi*

The amount of data this volume contains. This value makes sense only for static volumes, and for dynamic volume it equivalent to the total volume size in bytes.

/sys/class/ubi/ubiX/ubiX_Y/dev

Defined on file *sysfs-class-ubi*

Major and minor numbers of the character device corresponding to this UBI volume (in <major>:<minor> format).

/sys/class/ubi/ubiX/ubiX_Y/name

Defined on file *sysfs-class-ubi*

Volume name.

/sys/class/ubi/ubiX/ubiX_Y/reserved_ebs

Defined on file *sysfs-class-ubi*

Count of physical eraseblock reserved for this volume. Equivalent to the volume size in logical eraseblocks.

/sys/class/ubi/ubiX/ubiX_Y/type

Defined on file *sysfs-class-ubi*

Volume type. Contains ASCII ”dynamicn” for dynamic volumes and ”staticn” for static volumes.

/sys/class/ubi/ubiX/ubiX_Y/upd_marker

Defined on file *sysfs-class-ubi*

Contains ASCII ”0n” if the update marker is not set for this volume, and ”1n” if it is set. The update marker is set when volume update starts, and cleaned when it ends. So the presence of the update marker indicates that the volume is being updated at the moment of the update was interrupted. The later may be checked using the ”corrupted” sysfs file.

/sys/class/ubi/ubiX/ubiX_Y/usable_eb_size

Defined on file *sysfs-class-ubi*

Logical eraseblock size of this volume. Equivalent to logical eraseblock size of the device aligned on the volume alignment value.

/sys/class/ubi/ubiX/volumes_count

Defined on file *sysfs-class-ubi*

Count of volumes on this UBI device.

/sys/class/ubi/version

Defined on file *sysfs-class-ubi*

This file contains version of the latest supported UBI on-media format. Currently it is 1, and there is no plan to change this. However, if in the future UBI needs on-flash format changes which cannot be done in a compatible manner, a new format version will be added. So this is a mechanism for possible future backward-compatible (but forward-incompatible) improvements.

/sys/class/ubiX/

Defined on file *sysfs-class-ubi*

The /sys/class/ubi0, /sys/class/ubi1, etc directories describe UBI devices (UBI device 0, 1, etc). They contain general UBI device information and per UBI volume information (each UBI device may have many UBI volumes)

/sys/class/udc/<udc>/a_alt_hnp_support

Defined on file *sysfs-class-udc*

Indicates if an OTG A-Host supports HNP at an alternate port.

/sys/class/udc/<udc>/a_hnp_support

Defined on file *sysfs-class-udc*

Indicates if an OTG A-Host supports HNP at this port.

/sys/class/udc/<udc>/b_hnp_enable

Defined on file *sysfs-class-udc*

Indicates if an OTG A-Host enabled HNP support.

/sys/class/udc/<udc>/current_speed

Defined on file *sysfs-class-udc*

Indicates the current negotiated speed at this port.

/sys/class/udc/<udc>/function

Defined on file *sysfs-class-udc*

Prints out name of currently running USB Gadget Driver.

/sys/class/udc/<udc>/is_a_peripheral

Defined on file *sysfs-class-udc*

Indicates that this port is the default Host on an OTG session but HNP was used to switch roles.

/sys/class/udc/<udc>/is_otg

Defined on file *sysfs-class-udc*

Indicates that this port support OTG.

/sys/class/udc/<udc>/maximum_speed

Defined on file *sysfs-class-udc*

Indicates the maximum USB speed supported by this port.

/sys/class/udc/<udc>/soft_connect

Defined on file *sysfs-class-udc*

Allows users to disconnect data pullup resistors thus causing a logical disconnection from the USB Host.

/sys/class/udc/<udc>/srp

Defined on file *sysfs-class-udc*

Allows users to manually start Session Request Protocol.

/sys/class/udc/<udc>/state

Defined on file *sysfs-class-udc*

Indicates current state of the USB Device Controller. Valid states are: 'not-attached', 'attached', 'powered', 'reconnecting', 'unauthenticated', 'default', 'addressed', 'configured', and 'suspended'; however not all USB Device Controllers support reporting all states.

5.1.6 Symbols under /sys/devices

/sys/devices/*/dev

Defined on file *sysfs-devices*

Major and minor numbers of the character device corresponding to the device (in <major>:<minor> format).

/sys/devices/*/devspec

Defined on file *sysfs-devices*

If CONFIG_OF is enabled, then this file is present. When read, it returns full name of the device node.

/sys/devices/*/obppath

Defined on file *sysfs-devices*

If CONFIG_OF is enabled, then this file is present. When read, it returns full name of the device node.

/sys/devices/*/of_node

Defined on file *sysfs-devices*

Any device associated with a device-tree node will have an of_path symlink pointing to the corresponding device node in /sys/firmware/devicetree/

/sys/devices/pciXXXX:XX/0000:XX:XX.X/dma/dma<n>chan<n>/quickdata/cap

Defined on file *sysfs-driver-dma-ioatdma*

Capabilities the DMA supports.Currently there are DMA_PQ, DMA_PQ_VAL, DMA_XOR,DMA_XOR_VAL,DMA_INTERRUPT.

/sys/devices/pciXXXX:XX/0000:XX:XX.X/dma/dma<n>chan<n>/quickdata/intr_coalesce

Defined on file *sysfs-driver-dma-ioatdma*

Tune-able interrupt delay value per channel basis.

/sys/devices/pciXXXX:XX/0000:XX:XX.X/dma/dma<n>chan<n>/quickdata/ring_active

Defined on file *sysfs-driver-dma-ioatdma*

The number of descriptors active in the ring.

/sys/devices/pciXXXX:XX/0000:XX:XX.X/dma/dma<n>chan<n>/quickdata/ring_size

Defined on file *sysfs-driver-dma-ioatdma*

Descriptor ring size, total number of descriptors available.

/sys/devices/pciXXXX:XX/0000:XX:XX.X/dma/dma<n>chan<n>/quickdata/version

Defined on file *sysfs-driver-dma-ioatdma*

Version of ioatdma device.

/sys/devices/platform/firmware\:zynqmp-firmware/feature_config_id

Defined on file *sysfs-driver-firmware-zynqmp*

This sysfs interface allows user to configure features at runtime. The user can enable or disable features running at firmware as well as the user can configure the parameters of the features at runtime. The supported features are over temperature and external watchdog. Here, the external watchdog is completely different than the /dev/watchdog as the external watchdog is running on the firmware and it is used to monitor the health of firmware not APU(Linux). Also, the external watchdog is interfaced outside of the zynqmp soc.

The supported config ids are for the feature configuration is, 1. PM_FEATURE_OVERTEMP_STATUS = 1, the user can enable or disable the over temperature feature. 2. PM_FEATURE_OVERTEMP_VALUE = 2, the user can configure the over temperature limit in Degree Celsius. 3. PM_FEATURE_EXTWDT_STATUS = 3, the user can enable or disable the external watchdog feature. 4. PM_FEATURE_EXTWDT_VALUE = 4, the user can configure the external watchdog feature.

Usage:

Select over temperature config ID to enable/disable feature # echo 1 > /sys/devices/platform/firmware:zynqmp-firmware/feature_config_id

Check over temperature config ID is selected or not # cat /sys/devices/platform/firmware:zynqmp-firmware/feature_config_id The expected result is 1.

Select over temperature config ID to configure OT limit # echo 2 > /sys/devices/platform/firmware:zynqmp-firmware/feature_config_id

Check over temperature config ID is selected or not # cat /sys/devices/platform/firmware:zynqmp-firmware/feature_config_id The expected result is 2.

Select external watchdog config ID to enable/disable feature # echo 3 > /sys/devices/platform/firmware:zynqmp-firmware/feature_config_id

Check external watchdog config ID is selected or not # cat /sys/devices/platform/firmware:zynqmp-firmware/feature_config_id The expected result is 3.

Select external watchdog config ID to configure time interval # echo 4 > /sys/devices/platform/firmware:zynqmp-firmware/feature_config_id

Check external watchdog config ID is selected or not # cat /sys/devices/platform/firmware:zynqmp-firmware/feature_config_id The expected result is 4.

Users: Xilinx

/sys/devices/platform/firmware\:zynqmp-firmware/feature_config_value

Defined on file *sysfs-driver-firmware-zynqmp*

This sysfs interface allows to configure features at runtime. The user can enable or disable features running at firmware. Also, the user can configure the parameters of the features at runtime. The supported features are over temperature and external watchdog. Here, the external watchdog is completely different than the /dev/watchdog as the external watchdog is running on the firmware and it is used to monitor the health of firmware not APU(Linux). Also, the external watchdog is interfaced outside of the zynqmp soc.

By default the features are disabled in the firmware. The user can enable features by querying appropriate config id of the features.

The default limit for the over temperature is 90 Degree Celsius. The default timer interval for the external watchdog is 570ms.

The supported config ids are for the feature configuration is, 1. PM_FEATURE_OVERTEMP_STATUS = 1, the user can enable or disable the over temperature feature. 2. PM_FEATURE_OVERTEMP_VALUE = 2, the user can configure the over temperature limit in Degree Celsius. 3. PM_FEATURE_EXTWDT_STATUS = 3, the user can enable or disable the external watchdog feature. 4. PM_FEATURE_EXTWDT_VALUE = 4, the user can configure the external watchdog feature.

Usage:

Enable over temperature feature # echo 1 > /sys/devices/platform/firmware:zynqmp-firmware/feature_config_id # echo 1 > /sys/devices/platform/firmware:zynqmp-firmware/feature_config_value

Check whether the over temperature feature is enabled or not # cat /sys/devices/platform/firmware:zynqmp-firmware/feature_config_value The expected result is 1.

Disable over temperature feature # echo 1 > /sys/devices/platform/firmware:zynqmp-firmware/feature_config_id # echo 0 > /sys/devices/platform/firmware:zynqmp-firmware/feature_config_value

Check whether the over temperature feature is disabled or not # cat /sys/devices/platform/firmware:zynqmp-firmware/feature_config_value The expected result is 0.

Configure over temperature limit to 50 Degree Celsius # echo 2 > /sys/devices/platform/firmware:zynqmp-firmware/feature_config_id # echo 50 > /sys/devices/platform/firmware:zynqmp-firmware/feature_config_value

Check whether the over temperature limit is configured or not # cat /sys/devices/platform/firmware:zynqmp-firmware/feature_config_value The expected result

is 50.

Enable external watchdog feature # echo 3 > /sys/devices/platform/firmware:zynqmp-firmware/feature_config_id # echo 1 > /sys/devices/platform/firmware:zynqmp-firmware/feature_config_value

Check whether the external watchdog feature is enabled or not # cat /sys/devices/platform/firmware:zynqmp-firmware/feature_config_value The expected result is 1.

Disable external watchdog feature # echo 3 > /sys/devices/platform/firmware:zynqmp-firmware/feature_config_id # echo 0 > /sys/devices/platform/firmware:zynqmp-firmware/feature_config_value

Check whether the external watchdog feature is disabled or not # cat /sys/devices/platform/firmware:zynqmp-firmware/feature_config_value The expected result is 0.

Configure external watchdog timer interval to 500ms # echo 4 > /sys/devices/platform/firmware:zynqmp-firmware/feature_config_id # echo 500 > /sys/devices/platform/firmware:zynqmp-firmware/feature_config_value

Check whether the external watchdog timer interval is configured or not # cat /sys/devices/platform/firmware:zynqmp-firmware/feature_config_value The expected result is 500.

Users: Xilinx

/sys/devices/platform/firmware\:zynqmp-firmware/ggs*

Defined on file *sysfs-driver-firmware-zynqmp*

Read/Write PMU global general storage register value, GLOBAL_GEN_STORAGE{0:3}. Global general storage register that can be used by system to pass information between masters.

The register is reset during system or power-on resets. Three registers are used by the FSBL and other Xilinx software products: GLOBAL_GEN_STORAGE{4:6}.

Usage:

```
# cat /sys/devices/platform/firmware\:zynqmp-firmware/ggs0
# echo <value> > /sys/devices/platform/firmware\:zynqmp-firmware/ggs0
```

Example:

```
# cat /sys/devices/platform/firmware\:zynqmp-firmware/ggs0
# echo 0x1234ABCD > /sys/devices/platform/firmware\:zynqmp-firmware/ggs0
```

Users: Xilinx

/sys/devices/platform/firmware\:zynqmp-firmware/health_status

Defined on file *sysfs-driver-firmware-zynqmp*

This sysfs interface allows to set the health status. If PMUFW is compiled with CHECK_HEALTHY_BOOT, it will check the healthy bit on FPD WDT expiration. If healthy bit is

set by a user application running in Linux, PMUFW will do APU only restart. If healthy bit is not set during FPD WDT expiration, PMUFW will do system restart.

Usage:

Set healthy bit:

```
# echo 1 > /sys/devices/platform/firmware\:zynqmp-firmware/health_status
```

Unset healthy bit:

```
# echo 0 > /sys/devices/platform/firmware\:zynqmp-firmware/health_status
```

Users: Xilinx

/sys/devices/platform/firmware\:zynqmp-firmware/pggs*

Defined on file *sysfs-driver-firmware-zynqmp*

Read/Write PMU persistent global general storage register value, PERS_GLOB_GEN_STORAGE{0:3}. Persistent global general storage register that can be used by system to pass information between masters.

This register is only reset by the power-on reset and maintains its value through a system reset. Four registers are used by the FSBL and other Xilinx software products: PERS_GLOB_GEN_STORAGE{4:7}. Register is reset only by a POR reset.

Usage:

```
# cat /sys/devices/platform/firmware\:zynqmp-firmware/pggs0
# echo <value> > /sys/devices/platform/firmware\:zynqmp-firmware/pggs0
```

Example:

```
# cat /sys/devices/platform/firmware\:zynqmp-firmware/pggs0
# echo 0x1234ABCD > /sys/devices/platform/firmware\:zynqmp-firmware/pggs0
```

Users: Xilinx

/sys/devices/platform/firmware\:zynqmp-firmware/shutdown_scope

Defined on file *sysfs-driver-firmware-zynqmp*

This sysfs interface allows to set the shutdown scope for the next shutdown request. When the next shutdown is performed, the platform specific portion of PSCI-system_off can use the chosen shutdown scope.

Following are available shutdown scopes(subtypes):

subsystem:
Only the APU along with all of its peripherals not used by other processing units will be shut down. This may result in the FPD power domain being shut down provided that no other processing unit uses FPD peripherals or DRAM.

ps_only:
The complete PS will be shut down, including the RPU, PMU, etc. Only the PL domain (FPGA) remains untouched.

system:
The complete system/device is shut down.

Usage:

```
# cat /sys/devices/platform/firmware\:zynqmp-firmware/shutdown_scope
# echo <scope> > /sys/devices/platform/firmware\:zynqmp-firmware/shutdown_scope
```

Example:

```
# cat /sys/devices/platform/firmware\:zynqmp-firmware/shutdown_scope
# echo "subsystem" > /sys/devices/platform/firmware\:zynqmp-firmware/shutdown_
↪scope
```

Users: Xilinx

/sys/devices/platform/mlxplat/i2c_mlxcpld.*/i2c-*/i2c-*/i2c-*/*-0032/mlxreg-io.*/hwmon/hwmon*/agb_spi_burn_en
/sys/devices/platform/mlxplat/i2c_mlxcpld.*/i2c-*/i2c-*/i2c-*/*-0032/mlxreg-io.*/hwmon/hwmon*/fpga_spi_burn_en

Defined on file *sysfs-driver-mlxreg-io*

These files allow gearboxes and FPGA SPI flash burning. The attributes are set 1 to enable burning, 0 - to disable. If the system is in locked-down mode writing these files will not be allowed. The purpose of these files to allow line card Gearboxes and FPGA burning during production flow.

The file is read/write.

/sys/devices/platform/mlxplat/i2c_mlxcpld.*/i2c-*/i2c-*/i2c-*/*-0032/mlxreg-io.*/hwmon/hwmon*/cpld1_pn
/sys/devices/platform/mlxplat/i2c_mlxcpld.*/i2c-*/i2c-*/i2c-*/*-0032/mlxreg-io.*/hwmon/hwmon*/cpld1_version
/sys/devices/platform/mlxplat/i2c_mlxcpld.*/i2c-*/i2c-*/i2c-*/*-0032/mlxreg-io.*/hwmon/hwmon*/cpld1_version_min

Defined on file *sysfs-driver-mlxreg-io*

These files show with which CPLD major and minor versions and part number has been burned CPLD device on line card.

The files are read only.

/sys/devices/platform/mlxplat/i2c_mlxcpld.*/i2c-*/i2c-*/i2c-*/*-0032/mlxreg-io.*/hwmon/hwmon*/cpld_upgrade_en
/sys/devices/platform/mlxplat/i2c_mlxcpld.*/i2c-*/i2c-*/i2c-*/*-0032/mlxreg-io.*/hwmon/hwmon*/fpga_upgrade_en

Defined on file *sysfs-driver-mlxreg-io*

These files allow CPLD and FPGA burning. Value 1 in file means burning is enabled, 0 - otherwise. If the system is in locked-down mode writing these files will not be allowed. The purpose of these files to allow line card CPLD and FPGA upgrade through the JTAG daisy-chain.

The files are read/write.

/sys/devices/platform/mlxplat/i2c_mlxcpld.*/i2c-*/i2c-*/i2c-*/*-0032/mlxreg-io.*/hwmon/hwmon*/fpga1_pn
/sys/devices/platform/mlxplat/i2c_mlxcpld.*/i2c-*/i2c-*/i2c-*/*-0032/mlxreg-io.*/hwmon/hwmon*/fpga1_version
/sys/devices/platform/mlxplat/i2c_mlxcpld.*/i2c-*/i2c-*/i2c-*/*-0032/mlxreg-io.*/hwmon/hwmon*/fpga1_version_min

Defined on file *sysfs-driver-mlxreg-io*

These files show with which FPGA major and minor versions and part number has been burned FPGA device on line card.

The files are read only.

/sys/devices/platform/mlxplat/i2c_mlxcpld.*/i2c-*/i2c-*/i2c-*/*-0032/mlxreg-io.*/hwmon/hwmon*/max_power
/sys/devices/platform/mlxplat/i2c_mlxcpld.*/i2c-*/i2c-*/i2c-*/*-0032/mlxreg-io.*/hwmon/hwmon*/config

Defined on file *sysfs-driver-mlxreg-io*

These files provide the maximum powered required for line card feeding and line card configuration Id.

The files are read only.

/sys/devices/platform/mlxplat/i2c_mlxcpld.*/i2c-*/i2c-*/i2c-*/*-0032/mlxreg-io.*/hwmon/hwmon*/qsfp_pwr_en
/sys/devices/platform/mlxplat/i2c_mlxcpld.*/i2c-*/i2c-*/i2c-*/*-0032/mlxreg-io.*/hwmon/hwmon*/pwr_en

Defined on file *sysfs-driver-mlxreg-io*

These files allow to power on/off all QSFP ports and whole line card. The attributes are set 1 for power on, 0 - for power off.

The files are read/write.

/sys/devices/platform/mlxplat/i2c_mlxcpld.*/i2c-*/i2c-*/i2c-*/*-0032/mlxreg-io.*/hwmon/hwmon*/reset_aux_pwr_or_ref
/sys/devices/platform/mlxplat/i2c_mlxcpld.*/i2c-*/i2c-*/i2c-*/*-0032/mlxreg-io.*/hwmon/hwmon*/reset_dc_dc_pwr_fail
/sys/devices/platform/mlxplat/i2c_mlxcpld.*/i2c-*/i2c-*/i2c-*/*-0032/mlxreg-io.*/hwmon/hwmon*/reset_fpga_not_done
/sys/devices/platform/mlxplat/i2c_mlxcpld.*/i2c-*/i2c-*/i2c-*/*-0032/mlxreg-io.*/hwmon/hwmon*/reset_from_chassis
/sys/devices/platform/mlxplat/i2c_mlxcpld.*/i2c-*/i2c-*/i2c-*/*-0032/mlxreg-io.*/hwmon/hwmon*/reset_line_card
/sys/devices/platform/mlxplat/i2c_mlxcpld.*/i2c-*/i2c-*/i2c-*/*-0032/mlxreg-io.*/hwmon/hwmon*/reset_pwr_off_from_chassis

Defined on file *sysfs-driver-mlxreg-io*

These files show the line reset cause, as following: power auxiliary outage or power refresh, DC-to-DC power failure, FPGA reset failed, line card reset failed, power off from chassis. Value 1 in file means this is reset cause, 0 - otherwise. Only one of the above causes could be 1 at the same time, representing only last reset cause.

The files are read only.

/sys/devices/platform/mlxplat/i2c_mlxcpld.*/i2c-*/i2c-*/i2c-*/*-0032/mlxreg-io.*/hwmon/hwmon*/vpd_wp

Defined on file *sysfs-driver-mlxreg-io*

This file allow to overwrite line card VPD hardware write protection mode. When attribute is set 1 - write protection is disabled, when 0 - enabled. Default is 0. If the system is in locked-down mode writing this file will not be allowed. The purpose if this file is to allow line card VPD burning during production flow.

The file is read/write.

/sys/devices/platform/mlxplat/mlxreg-io/hwmon/hwmon*/asic2_health

Defined on file *sysfs-driver-mlxreg-io*

This file shows 2-nd ASIC health status. The possible values are: 0 - health failed, 2 - health OK, 3 - ASIC in booting state.

The file is read only.

/sys/devices/platform/mlxplat/mlxreg-io/hwmon/hwmon*/asic_health

Defined on file *sysfs-driver-mlxreg-io*

This file shows ASIC health status. The possible values are: 0 - health failed, 2 - health OK, 3 - ASIC in booting state.

The files are read only.

/sys/devices/platform/mlxplat/mlxreg-io/hwmon/hwmon*/asic_pg_fail

Defined on file *sysfs-driver-mlxreg-io*

This file shows ASIC Power Good status. Value 1 in file means ASIC Power Good failed, 0 - otherwise.

The file is read only.

/sys/devices/platform/mlxplat/mlxreg-io/hwmon/hwmon*/asic_reset
/sys/devices/platform/mlxplat/mlxreg-io/hwmon/hwmon*/asic2_reset

Defined on file *sysfs-driver-mlxreg-io*

These files allow to each of ASICs by writing 1.

The files are write only.

/sys/devices/platform/mlxplat/mlxreg-io/hwmon/hwmon*/bios_active_image
/sys/devices/platform/mlxplat/mlxreg-io/hwmon/hwmon*/bios_auth_fail
/sys/devices/platform/mlxplat/mlxreg-io/hwmon/hwmon*/bios_upgrade_fail

Defined on file *sysfs-driver-mlxreg-io*

The files represent BIOS statuses:

bios_active_image: location of current active BIOS image: 0: Top, 1: Bottom. The reported value should correspond to value expected by OS in case of BIOS safe mode is 0. This bit is related to Intel top-swap feature of DualBios on the same flash.

bios_auth_fail: BIOS upgrade is failed because provided BIOS image is not signed correctly.

bios_upgrade_fail: BIOS upgrade is failed by some other reason not because authentication. For example due to physical SPI flash problem.

The files are read only.

/sys/devices/platform/mlxplat/mlxreg-io/hwmon/hwmon*/clk_brd1_boot_fail
/sys/devices/platform/mlxplat/mlxreg-io/hwmon/hwmon*/clk_brd2_boot_fail
/sys/devices/platform/mlxplat/mlxreg-io/hwmon/hwmon*/clk_brd_fail

Defined on file *sysfs-driver-mlxreg-io*

These files are related to clock boards status in system. - clk_brd1_boot_fail: warning about 1-st clock board failed to boot from CI. - clk_brd2_boot_fail: warning about 2-nd clock board failed to boot from CI. - clk_brd_fail: error about common clock board boot failure.

The files are read only.

/sys/devices/platform/mlxplat/mlxreg-io/hwmon/hwmon*/clk_brd_prog_en

Defined on file *sysfs-driver-mlxreg-io*

This file enables programming of clock boards. Default is 0 (programming disabled). If the system is in locked-down mode writing this file will not be allowed.

The file is read/write.

/sys/devices/platform/mlxplat/mlxreg-io/hwmon/hwmon*/comm_chnl_ready

Defined on file *sysfs-driver-mlxreg-io*

This file is used to indicate remote end (for example BMC) that system host CPU is ready for sending telemetry data to remote end. For indication the file should be written 1.

The file is write only.

/sys/devices/platform/mlxplat/mlxreg-io/hwmon/hwmon*/config1
/sys/devices/platform/mlxplat/mlxreg-io/hwmon/hwmon*/config2

Defined on file *sysfs-driver-mlxreg-io*

These files show system static topology identification like system's static I2C topology, number and type of FPGA devices within the system and so on.

The files are read only.

/sys/devices/platform/mlxplat/mlxreg-io/hwmon/hwmon*/config3

Defined on file *sysfs-driver-mlxreg-io*

The file indicates COME module hardware configuration. The value is pushed by hardware through GPIO pins. The purpose is to expose some minor BOM changes for the same system SKU.

The file is read only.

/sys/devices/platform/mlxplat/mlxreg-io/hwmon/hwmon*/cpld1_pn
/sys/devices/platform/mlxplat/mlxreg-io/hwmon/hwmon*/cpld2_pn
/sys/devices/platform/mlxplat/mlxreg-io/hwmon/hwmon*/cpld3_pn
/sys/devices/platform/mlxplat/mlxreg-io/hwmon/hwmon*/cpld4_pn
/sys/devices/platform/mlxplat/mlxreg-io/hwmon/hwmon*/cpld1_version_min
/sys/devices/platform/mlxplat/mlxreg-io/hwmon/hwmon*/cpld2_version_min
/sys/devices/platform/mlxplat/mlxreg-io/hwmon/hwmon*/cpld3_version_min
/sys/devices/platform/mlxplat/mlxreg-io/hwmon/hwmon*/cpld4_version_min

Defined on file *sysfs-driver-mlxreg-io*

These files show with which CPLD part numbers and minor versions have been burned CPLD devices equipped on a system.

The files are read only.

/sys/devices/platform/mlxplat/mlxreg-io/hwmon/hwmon*/cpld1_version
/sys/devices/platform/mlxplat/mlxreg-io/hwmon/hwmon*/cpld2_version

Defined on file *sysfs-driver-mlxreg-io*

These files show with which CPLD versions have been burned on carrier and switch boards.

The files are read only.

/sys/devices/platform/mlxplat/mlxreg-io/hwmon/hwmon*/cpld3_version

Defined on file *sysfs-driver-mlxreg-io*

These files show with which CPLD versions have been burned on LED or Gearbox board.

The files are read only.

/sys/devices/platform/mlxplat/mlxreg-io/hwmon/hwmon*/cpld4_version

Defined on file *sysfs-driver-mlxreg-io*

These files show with which CPLD versions have been burned on LED board.

The files are read only.

/sys/devices/platform/mlxplat/mlxreg-io/hwmon/hwmon*/cpld5_pn
/sys/devices/platform/mlxplat/mlxreg-io/hwmon/hwmon*/cpld5_version
/sys/devices/platform/mlxplat/mlxreg-io/hwmon/hwmon*/cpld5_version_min

Defined on file *sysfs-driver-mlxreg-io*

These files show with which CPLD part numbers, version and minor versions have been burned the 5-th CPLD device equipped on a system.

The files are read only.

/sys/devices/platform/mlxplat/mlxreg-io/hwmon/hwmon*/erot1_ap_reset
/sys/devices/platform/mlxplat/mlxreg-io/hwmon/hwmon*/erot2_ap_reset

Defined on file *sysfs-driver-mlxreg-io*

These files aim to monitor the status of the External Root of Trust (EROT) processor's RESET output to the Application Processor (AP). By reading this file, could be determined if the EROT has invalidated or revoked AP Firmware, at which point it will hold the AP in RESET until a valid firmware is loaded. This protects the AP from running an unauthorized firmware. In the normal flow, the AP reset should be released after the EROT validates the integrity of the FW, and it should be done so as quickly as possible so that the AP boots before the CPU starts to communicate to each ASIC.

The files are read only.

/sys/devices/platform/mlxplat/mlxreg-io/hwmon/hwmon*/erot1_recovery
/sys/devices/platform/mlxplat/mlxreg-io/hwmon/hwmon*/erot2_recovery
/sys/devices/platform/mlxplat/mlxreg-io/hwmon/hwmon*/erot1_reset
/sys/devices/platform/mlxplat/mlxreg-io/hwmon/hwmon*/erot2_reset

Defined on file *sysfs-driver-mlxreg-io*

These files aim to perform External Root of Trust (EROT) recovery sequence after EROT device failure. These EROT devices protect ASICs from unauthorized access and in normal flow their reset should be released with system power – earliest power up stage, so that EROTs can begin boot and authentication process before CPU starts to communicate to ASICs. Issuing a reset

to the EROT while asserting the recovery signal will cause the EROT Application Processor to enter recovery mode so that the EROT FW can be updated/recovered. For reset/recovery the related file should be toggled by 1/0.

The files are read/write.

/sys/devices/platform/mlxplat/mlxreg-io/hwmon/hwmon*/erot1_wp
/sys/devices/platform/mlxplat/mlxreg-io/hwmon/hwmon*/erot2_wp

Defined on file *sysfs-driver-mlxreg-io*

These files allow access to External Root of Trust (EROT) for reset and recovery sequence after EROT device failure. Default is 0 (programming disabled). If the system is in locked-down mode writing this file will not be allowed.

The files are read/write.

/sys/devices/platform/mlxplat/mlxreg-io/hwmon/hwmon*/fan_dir

Defined on file *sysfs-driver-mlxreg-io*

This file shows the system fans direction: forward direction - relevant bit is set 0; reversed direction - relevant bit is set 1.

The files are read only.

/sys/devices/platform/mlxplat/mlxreg-io/hwmon/hwmon*/jtag_cap

Defined on file *sysfs-driver-mlxreg-io*

This file indicates the available method of CPLD/FPGA devices field update through the JTAG chain:

b00 - field update through LPC bus register memory space. b01 - Reserved. b10 - Reserved. b11 - field update through CPU GPIOs bit-banging.

The file is read only.

/sys/devices/platform/mlxplat/mlxreg-io/hwmon/hwmon*/jtag_enable

Defined on file *sysfs-driver-mlxreg-io*

These files enable and disable the access to the JTAG domain. By default access to the JTAG domain is disabled.

The file is read/write.

/sys/devices/platform/mlxplat/mlxreg-io/hwmon/hwmon*/lc1_enable
/sys/devices/platform/mlxplat/mlxreg-io/hwmon/hwmon*/lc2_enable
/sys/devices/platform/mlxplat/mlxreg-io/hwmon/hwmon*/lc3_enable
/sys/devices/platform/mlxplat/mlxreg-io/hwmon/hwmon*/lc4_enable
/sys/devices/platform/mlxplat/mlxreg-io/hwmon/hwmon*/lc5_enable
/sys/devices/platform/mlxplat/mlxreg-io/hwmon/hwmon*/lc6_enable
/sys/devices/platform/mlxplat/mlxreg-io/hwmon/hwmon*/lc7_enable
/sys/devices/platform/mlxplat/mlxreg-io/hwmon/hwmon*/lc8_enable

Defined on file *sysfs-driver-mlxreg-io*

These files allow line cards enable state control. Expected behavior: When lc{n}_enable is written 1, related line card is released from the reset state, when 0 - is hold in reset state.

The files are read/write.

/sys/devices/platform/mlxplat/mlxreg-io/hwmon/hwmon*/lc1_pwr
/sys/devices/platform/mlxplat/mlxreg-io/hwmon/hwmon*/lc2_pwr
/sys/devices/platform/mlxplat/mlxreg-io/hwmon/hwmon*/lc3_pwr
/sys/devices/platform/mlxplat/mlxreg-io/hwmon/hwmon*/lc4_pwr
/sys/devices/platform/mlxplat/mlxreg-io/hwmon/hwmon*/lc5_pwr
/sys/devices/platform/mlxplat/mlxreg-io/hwmon/hwmon*/lc6_pwr
/sys/devices/platform/mlxplat/mlxreg-io/hwmon/hwmon*/lc7_pwr
/sys/devices/platform/mlxplat/mlxreg-io/hwmon/hwmon*/lc8_pwr

Defined on file *sysfs-driver-mlxreg-io*

These files switching line cards power on and off. Expected behavior: When lc{n}_pwr is written 1, related line card is powered on, when written 0 - powered off.

The files are read/write.

/sys/devices/platform/mlxplat/mlxreg-io/hwmon/hwmon*/lc1_rst_mask
/sys/devices/platform/mlxplat/mlxreg-io/hwmon/hwmon*/lc2_rst_mask
/sys/devices/platform/mlxplat/mlxreg-io/hwmon/hwmon*/lc3_rst_mask
/sys/devices/platform/mlxplat/mlxreg-io/hwmon/hwmon*/lc4_rst_mask
/sys/devices/platform/mlxplat/mlxreg-io/hwmon/hwmon*/lc5_rst_mask
/sys/devices/platform/mlxplat/mlxreg-io/hwmon/hwmon*/lc6_rst_mask
/sys/devices/platform/mlxplat/mlxreg-io/hwmon/hwmon*/lc7_rst_mask
/sys/devices/platform/mlxplat/mlxreg-io/hwmon/hwmon*/lc8_rst_mask

Defined on file *sysfs-driver-mlxreg-io*

These files clear line card reset bit enforced by ASIC, when it sets it due to some abnormal ASIC behavior. Expected behavior: When lc{n}_rst_mask is written 1, related line card reset bit is cleared, when written 0 - no effect.

The files are write only.

/sys/devices/platform/mlxplat/mlxreg-io/hwmon/hwmon*/lid_open

Defined on file *sysfs-driver-mlxreg-io*

1 - indicates that system lid is opened, otherwise 0.

The file is read only.

/sys/devices/platform/mlxplat/mlxreg-io/hwmon/hwmon*/mac_reset

Defined on file *sysfs-driver-mlxreg-io*

This file allows to reset ASIC MT52132 when attribute is set 0 due to some abnormal ASIC behavior. Expected behavior: When mac_reset is written 1, the ASIC MT52132 is released from the reset state, when 0 - is hold in reset state.

The files are read/write.

/sys/devices/platform/mlxplat/mlxreg-io/hwmon/hwmon*/os_started

Defined on file *sysfs-driver-mlxreg-io*

This file, when written 1, indicates to programmable devices that OS is taking control over it.

The file is read/write.

/sys/devices/platform/mlxplat/mlxreg-io/hwmon/hwmon*/pcie_asic_reset_dis

Defined on file *sysfs-driver-mlxreg-io*

This file allows to retain ASIC up during PCIe root complex reset, when attribute is set 1.

The file is read/write.

/sys/devices/platform/mlxplat/mlxreg-io/hwmon/hwmon*/phy_reset

Defined on file *sysfs-driver-mlxreg-io*

This file allows to reset PHY 88E1548 when attribute is set 0 due to some abnormal PHY behavior. Expected behavior: When phy_reset is written 1, all PHY 88E1548 are released from the reset state, when 0 - are hold in reset state.

The files are read/write.

/sys/devices/platform/mlxplat/mlxreg-io/hwmon/hwmon*/pm_mgmt_en

Defined on file *sysfs-driver-mlxreg-io*

This file assigns power management control ownership. When power management control is provided by hardware, hardware will automatically power off one or more line previously powered line cards in case system power budget is getting insufficient. It could be in case when some of power units lost power good state. When pm_mgmt_en is written 1, power management control by software is enabled, 0 - power management control by hardware. Note that for any setting of pm_mgmt_en attribute hardware will not allow to power on any new line card in case system power budget is insufficient. Same in case software will try to power on several line cards at once - hardware will power line cards while system has enough power budget. Default is 0.

The file is read/write.

/sys/devices/platform/mlxplat/mlxreg-io/hwmon/hwmon*/psu1_on

Defined on file *sysfs-driver-mlxreg-io*

These files allow asserting system power cycling, switching power supply units on and off and system's main power domain shutdown. Expected behavior: When pwr_cycle is written 1: auxiliary power domain will go down and after short period (about 1 second) up. When psu1_on or psu2_on is written 1, related unit will be disconnected from the power source, when written 0 - connected. If both are written 1 - power supplies main power domain will go down. When pwr_down is written 1, system's main power domain will go down.

The files are write only.

/sys/devices/platform/mlxplat/mlxreg-io/hwmon/hwmon*/psu3_on
/sys/devices/platform/mlxplat/mlxreg-io/hwmon/hwmon*/psu4_on

Defined on file *sysfs-driver-mlxreg-io*

These files switching power supply units on and off. Expected behavior: When psu3_on or psu4_on is written 1, related unit will be disconnected from the power source, when written 0 - connected.

The files are write only.

/sys/devices/platform/mlxplat/mlxreg-io/hwmon/hwmon*/pwr_converter_prog_en

Defined on file *sysfs-driver-mlxreg-io*

This file enables programming of power converters. Default is 0 (programming disabled). If the system is in locked-down mode writing this file will not be allowed.

The file is read/write.

/sys/devices/platform/mlxplat/mlxreg-io/hwmon/hwmon*/qsfp_pwr_good

Defined on file *sysfs-driver-mlxreg-io*

This file shows QSFP ports power status. The value is set to 0 when one of any QSFP ports is plugged. The value is set to 1 when there are no any QSFP ports are plugged. The possible values are: 0 - Power good, 1 - Not power good.

The files are read only.

/sys/devices/platform/mlxplat/mlxreg-io/hwmon/hwmon*/reset_ac_ok_fail

Defined on file *sysfs-driver-mlxreg-io*

This file shows the system reset cause due to AC power failure. Value 1 in file means this is reset cause, 0 - otherwise.

The file is read only.

/sys/devices/platform/mlxplat/mlxreg-io/hwmon/hwmon*/reset_ac_pwr_fail
/sys/devices/platform/mlxplat/mlxreg-io/hwmon/hwmon*/reset_platform
/sys/devices/platform/mlxplat/mlxreg-io/hwmon/hwmon*/reset_soc
/sys/devices/platform/mlxplat/mlxreg-io/hwmon/hwmon*/reset_sw_pwr_off

Defined on file *sysfs-driver-mlxreg-io*

These files show the system reset causes, as following: reset due to AC power failure, reset invoked from software by assertion reset signal through CPLD. reset caused by signal asserted by SOC through ACPI register, reset invoked from software by assertion power off signal through CPLD.

The files are read only.

/sys/devices/platform/mlxplat/mlxreg-io/hwmon/hwmon*/reset_aux_pwr_or_ref
/sys/devices/platform/mlxplat/mlxreg-io/hwmon/hwmon*/reset_asic_thermal
/sys/devices/platform/mlxplat/mlxreg-io/hwmon/hwmon*/reset_hotswap_or_halt
/sys/devices/platform/mlxplat/mlxreg-io/hwmon/hwmon*/reset_hotswap_or_wd
/sys/devices/platform/mlxplat/mlxreg-io/hwmon/hwmon*/reset_fw_reset
/sys/devices/platform/mlxplat/mlxreg-io/hwmon/hwmon*/reset_long_pb
/sys/devices/platform/mlxplat/mlxreg-io/hwmon/hwmon*/reset_main_pwr_fail
/sys/devices/platform/mlxplat/mlxreg-io/hwmon/hwmon*/reset_short_pb
/sys/devices/platform/mlxplat/mlxreg-io/hwmon/hwmon*/reset_sw_reset

Defined on file *sysfs-driver-mlxreg-io*

These files show the system reset cause, as following: power auxiliary outage or power refresh, ASIC thermal shutdown, halt, hotswap, watchdog, firmware reset, long press power button, short press power button, software reset. Value 1 in file means this is reset cause, 0 - otherwise. Only one of the above causes could be 1 at the same time, representing only last reset cause.

The files are read only.

/sys/devices/platform/mlxplat/mlxreg-io/hwmon/hwmon*/reset_comex_pwr_fail
/sys/devices/platform/mlxplat/mlxreg-io/hwmon/hwmon*/reset_from_comex
/sys/devices/platform/mlxplat/mlxreg-io/hwmon/hwmon*/reset_system
/sys/devices/platform/mlxplat/mlxreg-io/hwmon/hwmon*/reset_voltmon_upgrade_fail

Defined on file *sysfs-driver-mlxreg-io*

These files show the system reset cause, as following: ComEx power fail, reset from ComEx, system platform reset, reset due to voltage monitor devices upgrade failure, Value 1 in file means this is reset cause, 0 - otherwise. Only one bit could be 1 at the same time, representing only the last reset cause.

The files are read only.

/sys/devices/platform/mlxplat/mlxreg-io/hwmon/hwmon*/reset_comex_thermal
/sys/devices/platform/mlxplat/mlxreg-io/hwmon/hwmon*/reset_comex_wd
/sys/devices/platform/mlxplat/mlxreg-io/hwmon/hwmon*/reset_from_asic
/sys/devices/platform/mlxplat/mlxreg-io/hwmon/hwmon*/reset_reload_bios
/sys/devices/platform/mlxplat/mlxreg-io/hwmon/hwmon*/reset_sff_wd
/sys/devices/platform/mlxplat/mlxreg-io/hwmon/hwmon*/reset_swb_wd

Defined on file *sysfs-driver-mlxreg-io*

These files show the system reset cause, as following: COMEX thermal shutdown; wathchdog power off or reset was derived by one of the next components: COMEX, switch board or by Small Form Factor mezzanine, reset requested from ASIC, reset caused by BIOS reload. Value

1 in file means this is reset cause, 0 - otherwise. Only one of the above causes could be 1 at the same time, representing only last reset cause.

The files are read only.

/sys/devices/platform/mlxplat/mlxreg-io/hwmon/hwmon*/reset_long_pwr_pb

Defined on file *sysfs-driver-mlxreg-io*

This file if set 1 indicates that system has been reset by long press of power button.

The file is read only.

/sys/devices/platform/mlxplat/mlxreg-io/hwmon/hwmon*/reset_pwr_converter_fail

Defined on file *sysfs-driver-mlxreg-io*

This file shows the system reset cause due to power converter devices failure. Value 1 in file means this is reset cause, 0 - otherwise.

The file is read only.

/sys/devices/platform/mlxplat/mlxreg-io/hwmon/hwmon*/reset_swb_dc_dc_pwr_fail

Defined on file *sysfs-driver-mlxreg-io*

This file shows 1 in case the system reset happened due to the failure of any DC-DC power converter devices equipped on the switch board.

The file is read only.

/sys/devices/platform/mlxplat/mlxreg-io/hwmon/hwmon*/select_iio

Defined on file *sysfs-driver-mlxreg-io*

This file allows iio devices selection.

Attribute select_iio can be written with 0 or with 1. It selects which one of iio devices can be accessed.

The file is read/write.

/sys/devices/platform/mlxplat/mlxreg-io/hwmon/hwmon*/shutdown_unlock

Defined on file *sysfs-driver-mlxreg-io*

This file allows to unlock ASIC after thermal shutdown event. When system thermal shutdown is enforced by ASIC, ASIC is getting locked and after system boot it will not be available. Software can decide to unlock it by setting this attribute to 1 and then perform system power cycle by setting pwr_cycle attribute to 1 (power cycle of main power domain). Before setting shutdown_unlock to 1 it is recommended to validate that system reboot cause is reset_asic_thermal or reset_thermal_spc_or_pciesw. In case shutdown_unlock is not set 1, the only way to release ASIC from locking - is full system power cycle through the external power distribution unit. Default is 1.

The file is read/write.

/sys/devices/platform/mlxplat/mlxreg-io/hwmon/hwmon*/spi_chnl_select

Defined on file *sysfs-driver-mlxreg-io*

This file allows SPI chip selection for External Root of Trust (EROT) device Out-of-Band recovery. File can be written with 0 or with 1. It selects which EROT can be accessed through SPI device.

The file is read/write.

/sys/devices/platform/mlxplat/mlxreg-io/hwmon/hwmon*/ufm_version

Defined on file *sysfs-driver-mlxreg-io*

This file exposes the firmware version of burnable voltage regulator devices.

The file is read only.

/sys/devices/platform/mlxplat/mlxreg-io/hwmon/hwmon*/voltreg_update_status

Defined on file *sysfs-driver-mlxreg-io*

This file exposes the configuration update status of burnable voltage regulator devices. The status values are as following: 0 - OK; 1 - CRC failure; 2 = I2C failure; 3 - in progress.

The file is read only.

/sys/devices/platform/mlxplat/mlxreg-io/hwmon/hwmon*/vpd_wp

Defined on file *sysfs-driver-mlxreg-io*

This file allows to overwrite system VPD hardware write protection when attribute is set 1.

The file is read/write.

/sys/devices/system/cpu/cpuX/topology/book_id

Defined on file *sysfs-devices-system-cpu*

the book ID of cpuX. Typically it is the hardware platform's identifier (rather than the kernel's). The actual value is architecture and platform dependent. it's only used on s390. Values: integer

/sys/devices/system/cpu/cpuX/topology/book_siblings

Defined on file *sysfs-devices-system-cpu*

internal kernel map of cpuX's hardware threads within the same book_id. it's only used on s390. Values: hexadecimal bitmask.

/sys/devices/system/cpu/cpuX/topology/book_siblings_list

Defined on file *sysfs-devices-system-cpu*

human-readable list of cpuX's hardware threads within the same book_id. The format is like 0-3, 8-11, 14,17. it's only used on s390. Values: decimal list.

/sys/devices/system/cpu/cpuX/topology/cluster_cpus

Defined on file *sysfs-devices-system-cpu*

internal kernel map of CPUs within the same cluster. Values: hexadecimal bitmask.

/sys/devices/system/cpu/cpuX/topology/cluster_cpus_list

Defined on file *sysfs-devices-system-cpu*

human-readable list of CPUs within the same cluster. The format is like 0-3, 8-11, 14,17. Values: decimal list.

/sys/devices/system/cpu/cpuX/topology/cluster_id

Defined on file *sysfs-devices-system-cpu*

the cluster ID of cpuX. Typically it is the hardware platform's identifier (rather than the kernel's). The actual value is architecture and platform dependent. Values: integer

/sys/devices/system/cpu/cpuX/topology/core_cpus

Defined on file *sysfs-devices-system-cpu*

internal kernel map of CPUs within the same core. (deprecated name: "thread_siblings") Values: hexadecimal bitmask.

/sys/devices/system/cpu/cpuX/topology/core_cpus_list

Defined on file *sysfs-devices-system-cpu*

human-readable list of CPUs within the same core. The format is like 0-3, 8-11, 14,17. (deprecated name: "thread_siblings_list"). Values: decimal list.

/sys/devices/system/cpu/cpuX/topology/core_id

Defined on file *sysfs-devices-system-cpu*

the CPU core ID of cpuX. Typically it is the hardware platform's identifier (rather than the kernel's). The actual value is architecture and platform dependent. Values: integer

/sys/devices/system/cpu/cpuX/topology/die_cpus

Defined on file *sysfs-devices-system-cpu*

internal kernel map of CPUs within the same die. Values: hexadecimal bitmask.

/sys/devices/system/cpu/cpuX/topology/die_cpus_list

Defined on file *sysfs-devices-system-cpu*

human-readable list of CPUs within the same die. The format is like 0-3, 8-11, 14,17. Values: decimal list.

/sys/devices/system/cpu/cpuX/topology/die_id

Defined on file *sysfs-devices-system-cpu*

the CPU die ID of cpuX. Typically it is the hardware platform's identifier (rather than the kernel's). The actual value is architecture and platform dependent. Values: integer

/sys/devices/system/cpu/cpuX/topology/drawer_id

Defined on file *sysfs-devices-system-cpu*

the drawer ID of cpuX. Typically it is the hardware platform's identifier (rather than the kernel's). The actual value is architecture and platform dependent. it's only used on s390. Values: integer

/sys/devices/system/cpu/cpuX/topology/drawer_siblings

Defined on file *sysfs-devices-system-cpu*

internal kernel map of cpuX's hardware threads within the same drawer_id. it's only used on s390. Values: hexadecimal bitmask.

/sys/devices/system/cpu/cpuX/topology/drawer_siblings_list

Defined on file *sysfs-devices-system-cpu*

human-readable list of cpuX's hardware threads within the same drawer_id. The format is like 0-3, 8-11, 14,17. it's only used on s390. Values: decimal list.

/sys/devices/system/cpu/cpuX/topology/package_cpus

Defined on file *sysfs-devices-system-cpu*

internal kernel map of the CPUs sharing the same physical_package_id. (deprecated name: "core_siblings"). Values: hexadecimal bitmask.

/sys/devices/system/cpu/cpuX/topology/package_cpus_list

Defined on file *sysfs-devices-system-cpu*

human-readable list of CPUs sharing the same physical_package_id. The format is like 0-3, 8-11, 14,17. (deprecated name: "core_siblings_list") Values: decimal list.

/sys/devices/system/cpu/cpuX/topology/physical_package_id

Defined on file *sysfs-devices-system-cpu*

physical package id of cpuX. Typically corresponds to a physical socket number, but the actual value is architecture and platform dependent. Values: integer

/sys/devices/system/cpu/cpuX/topology/ppin

Defined on file *sysfs-devices-system-cpu*

per-socket protected processor inventory number Values: hexadecimal.

/sys/devices/system/cpu/cpu[0-9]+/dscr

Defined on file *sysfs-devices-system-cpu*

Default value for the Data Stream Control Register (DSCR) on a CPU. This default value is used when the kernel is executing and for any process that has not set the DSCR itself. If a process ever sets the DSCR (via direct access to the SPR) that value will be persisted for that process and used on any CPU where it executes (overriding the value described here). If set by a process it will be inherited by child processes. Values: 64 bit unsigned integer (bit field)

/sys/devices/system/cpu/dscr_default

Defined on file *sysfs-devices-system-cpu*

Writes are equivalent to writing to /sys/devices/system/cpu/cpuN/dscr on all CPUs. Reads return the last written value or 0. This value is not a global default: it is a way to set all per-CPU defaults at the same time. Values: 64 bit unsigned integer (bit field)

/sys/devices/system/node/has_cpu

Defined on file *sysfs-devices-node*

Nodes that have one or more CPUs.

/sys/devices/system/node/has_high_memory

Defined on file *sysfs-devices-node*

Nodes that have regular or high memory. Depends on CONFIG_HIGHMEM.

/sys/devices/system/node/has_normal_memory

Defined on file *sysfs-devices-node*

Nodes that have regular memory.

/sys/devices/system/node/nodeX

Defined on file *sysfs-devices-node*

When CONFIG_NUMA is enabled, this is a directory containing information on node X such as what CPUs are local to the node. Each file is detailed next.

/sys/devices/system/node/nodeX/accessY/

Defined on file *sysfs-devices-node*

The node's relationship to other nodes for access class "Y".

/sys/devices/system/node/nodeX/accessY/initiators/

Defined on file *sysfs-devices-node*

The directory containing symlinks to memory initiator nodes that have class "Y" access to this target node's memory. CPUs and other memory initiators in nodes not in the list accessing this node's memory may have different performance.

/sys/devices/system/node/nodeX/accessY/initiators/read_bandwidth

Defined on file *sysfs-devices-node*

This node's read bandwidth in MB/s when accessed from nodes found in this access class's linked initiators.

/sys/devices/system/node/nodeX/accessY/initiators/read_latency

Defined on file *sysfs-devices-node*

This node's read latency in nanoseconds when accessed from nodes found in this access class's linked initiators.

/sys/devices/system/node/nodeX/accessY/initiators/write_bandwidth

Defined on file *sysfs-devices-node*

This node's write bandwidth in MB/s when accessed from found in this access class's linked initiators.

/sys/devices/system/node/nodeX/accessY/initiators/write_latency

Defined on file *sysfs-devices-node*

This node's write latency in nanoseconds when access from nodes found in this class's linked initiators.

/sys/devices/system/node/nodeX/accessY/targets/

Defined on file *sysfs-devices-node*

The directory containing symlinks to memory targets that this initiator node has class "Y" access.

/sys/devices/system/node/nodeX/compact

Defined on file *sysfs-devices-node*

When this file is written to, all memory within that node will be compacted. When it completes, memory will be freed into blocks which have as many contiguous pages as possible

/sys/devices/system/node/nodeX/cpulist

Defined on file *sysfs-devices-node*

The CPUs associated to the node.

/sys/devices/system/node/nodeX/cpumap

Defined on file *sysfs-devices-node*

The node's cpumap.

/sys/devices/system/node/nodeX/distance

Defined on file *sysfs-devices-node*

Distance between the node and all the other nodes in the system.

/sys/devices/system/node/nodeX/hugepages/hugepages-<size>/

Defined on file *sysfs-devices-node*

The node's huge page size control/query attributes. See *HugeTLB Pages*

/sys/devices/system/node/nodeX/meminfo

Defined on file *sysfs-devices-node*

Provides information about the node's distribution and memory utilization. Similar to /proc/meminfo, see /filesystems/proc

/sys/devices/system/node/nodeX/memory_failure/delayed

Defined on file *sysfs-devices-node*

Of the raw poisoned pages on a NUMA node, how many pages are delayed by memory error recovery attempt. Delayed poisoned pages usually will be retried by kernel.

/sys/devices/system/node/nodeX/memory_failure/failed

Defined on file *sysfs-devices-node*

Of the raw poisoned pages on a NUMA node, how many pages are failed by memory error recovery attempt. This usually means a key recovery operation failed.

/sys/devices/system/node/nodeX/memory_failure/ignored

Defined on file *sysfs-devices-node*

Of the raw poisoned pages on a NUMA node, how many pages are ignored by memory error recovery attempt, usually because support for this type of pages is unavailable, and kernel gives up the recovery.

/sys/devices/system/node/nodeX/memory_failure/recovered

Defined on file *sysfs-devices-node*

Of the raw poisoned pages on a NUMA node, how many pages are recovered by memory error recovery attempt.

/sys/devices/system/node/nodeX/memory_failure/total

Defined on file *sysfs-devices-node*

The total number of raw poisoned pages (pages containing corrupted data due to memory errors) on a NUMA node.

/sys/devices/system/node/nodeX/memory_side_cache/indexY/

Defined on file *sysfs-devices-node*

The directory containing attributes for the memory-side cache level 'Y'.

/sys/devices/system/node/nodeX/memory_side_cache/indexY/indexing

Defined on file *sysfs-devices-node*

The caches associativity indexing: 0 for direct mapped, non-zero if indexed.

/sys/devices/system/node/nodeX/memory_side_cache/indexY/line_size

Defined on file *sysfs-devices-node*

The number of bytes accessed from the next cache level on a cache miss.

/sys/devices/system/node/nodeX/memory_side_cache/indexY/size

Defined on file *sysfs-devices-node*

The size of this memory side cache in bytes.

/sys/devices/system/node/nodeX/memory_side_cache/indexY/write_policy

Defined on file *sysfs-devices-node*

The cache write policy: 0 for write-back, 1 for write-through, other or unknown.

/sys/devices/system/node/nodeX/numastat

Defined on file *sysfs-devices-node*

The node's hit/miss statistics, in units of pages. See *Numa policy hit/miss statistics*

/sys/devices/system/node/nodeX/vmstat

Defined on file *sysfs-devices-node*

The node's zoned virtual memory statistics. This is a superset of numastat.

/sys/devices/system/node/nodeX/x86/sgx_total_bytes

Defined on file *sysfs-devices-node*

The total amount of SGX physical memory in bytes.

/sys/devices/system/node/online

Defined on file *sysfs-devices-node*

Nodes that are online.

/sys/devices/system/node/possible

Defined on file *sysfs-devices-node*

Nodes that could be possibly become online at some point.

/sys/devices/system/xen_memory/xen_memory0/info/current_kb

Defined on file *sysfs-devices-system-xen_memory*

Current size (in KiB) of this domain's memory reservation.

/sys/devices/system/xen_memory/xen_memory0/info/high_kb

Defined on file *sysfs-devices-system-xen_memory*

Amount (in KiB) of high memory in the balloon.

/sys/devices/system/xen_memory/xen_memory0/info/low_kb

Defined on file *sysfs-devices-system-xen_memory*

Amount (in KiB) of low (or normal) memory in the balloon.

/sys/devices/system/xen_memory/xen_memory0/max_retry_count

Defined on file *sysfs-devices-system-xen_memory*

The maximum number of times the balloon driver will attempt to increase the balloon before giving up. See also 'retry_count' below. A value of zero means retry forever and is the default one.

/sys/devices/system/xen_memory/xen_memory0/max_schedule_delay

Defined on file *sysfs-devices-system-xen_memory*

The limit that 'schedule_delay' (see below) will be increased to. The default value is 32 seconds.

/sys/devices/system/xen_memory/xen_memory0/retry_count

Defined on file *sysfs-devices-system-xen_memory*

The current number of times that the balloon driver has attempted to increase the size of the balloon. The default value is one. With max_retry_count being zero (unlimited), this means that the driver will attempt to retry with a 'schedule_delay' delay.

/sys/devices/system/xen_memory/xen_memory0/schedule_delay

Defined on file *sysfs-devices-system-xen_memory*

The time (in seconds) to wait between attempts to increase the balloon. Each time the balloon cannot be increased, 'schedule_delay' is increased (until 'max_schedule_delay' is reached at which point it will use the max value).

/sys/devices/system/xen_memory/xen_memory0/scrub_pages

Defined on file *sysfs-devices-system-xen_memory*

Control scrubbing pages before returning them to Xen for others domains use. Can be set with xen_scrub_pages cmdline parameter. Default value controlled with CONFIG_XEN_SCRUB_PAGES_DEFAULT.

/sys/devices/system/xen_memory/xen_memory0/target

Defined on file *sysfs-devices-system-xen_memory*

The target number of pages to adjust this domain's memory reservation to.

/sys/devices/system/xen_memory/xen_memory0/target_kb

Defined on file *sysfs-devices-system-xen_memory*

As target above, except the value is in KiB.

5.1.7 Symbols under /sys/firmware

/sys/firmware/acpi/pm_profile

Defined on file *sysfs-acpi-pmprofile*

The ACPI pm_profile sysfs interface exposes the preferred power management (and performance) profile of the platform as provided in the ACPI FADT Preferred_PM_Profile field.

The integer value is directly passed as retrieved from the FADT.

Values: For the possible values refer to the Preferred_PM_Profile field
definition in Table 5.9 ”FADT Format”, Section 5.2.9 ”Fixed ACPI Description Table (FADT)” of the ACPI specification.

As of ACPI 6.5, the following values are defined:

0	Unspecified
1	Desktop
2	Mobile
3	Workstation
4	Enterprise Server
5	SOHO Server
6	Appliance PC
7	Performance Server
8	Tablet
>8	Reserved

/sys/firmware/efi/vars

Defined on file *sysfs-firmware-efi-vars*

This directory exposes interfaces for interactive with EFI variables. For more information on EFI variables, see 'Variable Services' in the UEFI specification (section 7.2 in specification version 2.3 Errata D).

In summary, EFI variables are named, and are classified into separate namespaces through the use of a vendor GUID. They also have an arbitrary binary value associated with them.

The efivars module enumerates these variables and creates a separate directory for each one found. Each directory has a name of the form ”<key>-<vendor guid>” and contains the following files:

attributes:	A read-only text file enumerating the EFI variable flags. Potential values include: EFI_VARIABLE_NON_VOLATILE EFI_VARIABLE_BOOTSERVICE_ACCESS EFI_VARIABLE_RUNTIME_ACCESS EFI_VARIABLE_HARDWARE_ERROR_RECORD EFI_VARIABLE_AUTHENTICATED_WRITE_ACCESS See the EFI documentation for an explanation of each of these variables.
data:	A read-only binary file that can be read to attain the value of the EFI variable
guid:	The vendor GUID of the variable. This should always match the GUID in the variable's name.
raw_var:	A binary file that can be read to obtain a structure that contains everything there is to know about the variable. For structure definition see ”struct efi_variable” in the kernel sources. This file can also be written to in order to update the value of a variable. For this to work however, all fields of the ”struct efi_variable” passed must match byte for byte with the structure read out of the file, save for the value portion. **Note** the efi_variable structure read/written with this file contains a 'long' type that may change widths depending on your underlying architecture.
size:	As ASCII representation of the size of the variable's value.

In addition, two other magic binary files are provided in the top-level directory and are used for adding and removing variables:

new_var:	Takes a ”struct efi_variable” and instructs the EFI firmware to create a new variable.
del_var:	Takes a ”struct efi_variable” and instructs the EFI firmware to remove any variable that has a matching vendor GUID and variable key name.

/sys/firmware/opal/dump

Defined on file *sysfs-firmware-opal-dump*

This directory exposes interfaces for interacting with the FSP and platform dumps through OPAL firmware interface.

This is only for the powerpc/powernv platform.

initiate_dump:	When '1' is written to it, we will initiate a dump. Read this file for supported commands.
0xXX-0xYYYY:	A directory for dump of type 0xXX and id 0xYYYY (in hex). The name of this directory should not be relied upon to be in this format, only that it's unique among all dumps. For determining the type and ID of the dump, use the id and type files. Do not rely on any particular size of dump type or dump id.

Each dump has the following files:

id:	An ASCII representation of the dump ID in hex (e.g. '0x01')
type:	An ASCII representation of the type of dump in the format "0x%x %s" with the ID in hex and a description of the dump type (or 'unknown'). Type '0xffffffff unknown' is used when we could not get the type from firmware. e.g. '0x02 System/Platform Dump'
dump:	A binary file containing the dump. The size of the dump is the size of this file.
acknowledge:	When 'ack' is written to this, we will acknowledge that we've retrieved the dump to the service processor. It will then remove it, making the dump inaccessible. Reading this file will get a list of supported actions.

/sys/firmware/opal/elog

Defined on file *sysfs-firmware-opal-elog*

This directory exposes error log entries retrieved through the OPAL firmware interface.

Each error log is identified by a unique ID and will exist until explicitly acknowledged to firmware.

Each log entry has a directory in */sys/firmware/opal/elog*.

Log entries may be purged by the service processor before retrieved by firmware or retrieved/acknowledged by Linux if there is no room for more log entries.

In the event that Linux has retrieved the log entries but not explicitly acknowledged them to firmware and the service processor needs more room for log entries, the only remaining copy of a log message may be in Linux.

Typically, a user space daemon will monitor for new entries, read them out and acknowledge them.

The service processor may be able to store more log entries than firmware can, so after you acknowledge an event from Linux you may instantly get another one from the queue that was generated some time in the past.

The raw log format is a binary format. We currently do not parse this at all in kernel, leaving it up to user space to solve the problem. In future, we may do more parsing in kernel and add more files to make it easier for simple user space processes to extract more information.

For each log entry (directory), there are the following files:

id:	An ASCII representation of the ID of the error log, in hex - e.g. "0x01".
type:	An ASCII representation of the type id and description of the type of error log. Currently just "0x00 PEL" - platform error log. In the future there may be additional types.
raw:	A read-only binary file that can be read to get the raw log entry. These are <16kb, often just hundreds of bytes and "average" 2kb.
acknowledge:	Writing 'ack' to this file will acknowledge the error log to firmware (and in turn the service processor, if applicable). Shortly after acknowledging it, the log entry will be removed from sysfs. Reading this file will list the supported operations (currently just acknowledge).

5.1.8 Symbols under /sys/fs

/sys/fs/o2cb/

Defined on file *o2cb*

Ocfs2-tools looks at 'interface-revision' for versioning information. Each logmask/ file controls a set of debug prints and can be written into with the strings "allow", "deny", or "off". Reading the file returns the current state.

Users: ocfs2-tools. It's sufficient to mail proposed changes to ocfs2-devel@lists.linux.dev.

/sys/fs/orangefs/acache/*

Defined on file *sysfs-fs-orangefs*

Attribute cache configurable settings.

/sys/fs/orangefs/capcache/*

Defined on file *sysfs-fs-orangefs*

Capability cache configurable settings.

/sys/fs/orangefs/ccache/*

Defined on file *sysfs-fs-orangefs*

Credential cache configurable settings.

/sys/fs/orangefs/ncache/*

Defined on file *sysfs-fs-orangefs*

Name cache configurable settings.

/sys/fs/orangefs/op_timeout_secs

Defined on file *sysfs-fs-orangefs*

Service operation timeout in seconds.

/sys/fs/orangefs/perf_counter_reset

Defined on file *sysfs-fs-orangefs*

echo a 0 or a 1 into perf_counter_reset to reset all the counters in /sys/fs/orangefs/perf_counters except ones with PINT_PERF_PRESERVE set.

/sys/fs/orangefs/perf_counters/*

Defined on file *sysfs-fs-orangefs*

Counters and settings for various caches. Read only.

/sys/fs/orangefs/perf_history_size

Defined on file *sysfs-fs-orangefs*

The perf_counters cache statistics have N, or perf_history_size, samples. The default is one.

Every perf_time_interval_secs the (first) samples are reset.

If N is greater than one, the "current" set of samples is reset, and the samples from the other N-1 intervals remain available.

/sys/fs/orangefs/perf_time_interval_secs

Defined on file *sysfs-fs-orangefs*

Length of perf counter intervals in seconds.

/sys/fs/orangefs/slot_timeout_secs

Defined on file *sysfs-fs-orangefs*

"Slot" timeout in seconds. A "slot" is an indexed buffer in the shared memory segment used for communication between the kernel module and userspace. Slots are requested and waited for, the wait times out after slot_timeout_secs.

5.1.9 Symbols under /sys/hypervisor

/sys/hypervisor/compilation/compile_date

Defined on file *sysfs-hypervisor-xen*

If running under Xen: Contains the build time stamp of the Xen hypervisor Might return "<denied>" in case of special security settings in the hypervisor.

/sys/hypervisor/compilation/compiled_by

Defined on file *sysfs-hypervisor-xen*

If running under Xen: Contains information who built the Xen hypervisor Might return "<denied>" in case of special security settings in the hypervisor.

/sys/hypervisor/compilation/compiler

Defined on file *sysfs-hypervisor-xen*

If running under Xen: Compiler which was used to build the Xen hypervisor Might return "<denied>" in case of special security settings in the hypervisor.

/sys/hypervisor/properties/capabilities

Defined on file *sysfs-hypervisor-xen*

If running under Xen: Space separated list of supported guest system types. Each type is in the format: <class>-<major>.<minor>-<arch> With:

<class>:	"xen" -- x86: paravirtualized, arm: standard "hvm" -- x86 only: fully virtualized
<major>:	major guest interface version
<minor>:	minor guest interface version
<arch>:	architecture, e.g.: "x86_32": 32 bit x86 guest without PAE "x86_32p": 32 bit x86 guest with PAE "x86_64": 64 bit x86 guest "armv7l": 32 bit arm guest "aarch64": 64 bit arm guest

/sys/hypervisor/properties/changeset

Defined on file *sysfs-hypervisor-xen*

If running under Xen: Changeset of the hypervisor (git commit) Might return "<denied>" in case of special security settings in the hypervisor.

/sys/hypervisor/properties/features

Defined on file *sysfs-hypervisor-xen*

If running under Xen: Features the Xen hypervisor supports for the guest as defined in include/xen/interface/features.h printed as a hex value.

/sys/hypervisor/properties/pagesize

Defined on file *sysfs-hypervisor-xen*

If running under Xen: Default page size of the hypervisor printed as a hex value. Might return "0" in case of special security settings in the hypervisor.

/sys/hypervisor/properties/virtual_start

Defined on file *sysfs-hypervisor-xen*

If running under Xen: Virtual address of the hypervisor as a hex value.

/sys/hypervisor/start_flags/*

Defined on file *sysfs-hypervisor-xen*

If running under Xen: All bits in Xen's start-flags are represented as boolean files, returning '1' if set, '0' otherwise. This takes the place of the defunct /proc/xen/capabilities, which would

contain ”control_d” on dom0, and be empty otherwise. This flag is now exposed as ”initdomain” in addition to the ”privileged” flag; all other possible flags are accessible as ”unknownXX”.

/sys/hypervisor/type

Defined on file *sysfs-hypervisor-xen*

If running under Xen: Type of hypervisor: ”xen”: Xen hypervisor

/sys/hypervisor/uuid

Defined on file *sysfs-hypervisor-xen*

If running under Xen: UUID of the guest as known to the Xen hypervisor.

/sys/hypervisor/version/extra

Defined on file *sysfs-hypervisor-xen*

If running under Xen: The Xen version is in the format <major>.<minor><extra> This is the <extra> part of it. Might return ”<denied>” in case of special security settings in the hypervisor.

/sys/hypervisor/version/major

Defined on file *sysfs-hypervisor-xen*

If running under Xen: The Xen version is in the format <major>.<minor><extra> This is the <major> part of it.

/sys/hypervisor/version/minor

Defined on file *sysfs-hypervisor-xen*

If running under Xen: The Xen version is in the format <major>.<minor><extra> This is the <minor> part of it.

5.1.10 Symbols under /sys/kernel

/sys/kernel/notes

Defined on file *sysfs-kernel-notes*

The */sys/kernel/notes* file contains the binary representation of the running vmlinux's .notes section.

5.1.11 Symbols under /sys/module

/sys/module/<MODULENAME>

Defined on file *sysfs-module*

The name of the module that is in the kernel. This module name will always show up if the module is loaded as a dynamic module. If it is built directly into the kernel, it will only show up if it has a version or at least one parameter.

Note: The conditions of creation in the built-in case are not by design and may be removed in the future.

/sys/module/<MODULENAME>/parameters

Defined on file *sysfs-module*

This directory contains individual files that are each individual parameters of the module that are able to be changed at runtime. See the individual module documentation as to the contents of these parameters and what they accomplish.

Note: The individual parameter names and values are not considered stable, only the fact that they will be placed in this location within sysfs. See the individual driver documentation for details as to the stability of the different parameters.

/sys/module/<MODULENAME>/refcnt

Defined on file *sysfs-module*

If the module is able to be unloaded from the kernel, this file will contain the current reference count of the module.

Note: If the module is built into the kernel, or if the CONFIG_MODULE_UNLOAD kernel configuration value is not enabled, this file will not be present.

/sys/module/<MODULENAME>/srcversion

Defined on file *sysfs-module*

If the module source has MODULE_VERSION, this file will contain the checksum of the source code.

/sys/module/<MODULENAME>/version

Defined on file *sysfs-module*

If the module source has MODULE_VERSION, this file will contain the version of the source code.

5.1.12 A notification mechanism for thermal related events

A notification mechanism for thermal related events

Defined on file *thermal-notification*

This interface enables notification for thermal related events. The notification is in the form of a netlink event.

5.1.13 Audit Login Session ID

Audit Login Session ID

Defined on file *procfs-audit_loginuid*

The /proc/$pid/sessionid pseudofile is read to get the audit login session ID of process $pid as a decimal unsigned int (%u, u32). It is set automatically, serially assigned with each new login.

Users: audit and login applications

5.1.14 Audit Login UID

Audit Login UID

Defined on file *procfs-audit_loginuid*

The /proc/$pid/loginuid pseudofile is written to set and read to get the audit login UID of process $pid as a decimal unsigned int (%u, u32). If it is unset, permissions are not needed to set it. The accessor must have CAP_AUDIT_CONTROL in the initial user namespace to write it if it has been set. It cannot be written again if AUDIT_FEATURE_LOGINUID_IMMUTABLE is enabled. It cannot be unset if AUDIT_FEATURE_ONLY_UNSET_LOGINUID is enabled.

Users: audit and login applications

5.1.15 The kernel syscall interface

The kernel syscall interface

Defined on file *syscalls*

This interface matches much of the POSIX interface and is based on it and other Unix based interfaces. It will only be added to over time, and not have things removed from it.

Note that this interface is different for every architecture that Linux supports. Please see the architecture-specific documentation for details on the syscall numbers that are to be mapped to each syscall.

5.1.16 vDSO

vDSO

Defined on file *vdso*

On some architectures, when the kernel loads any userspace program it maps an ELF DSO into that program's address space. This DSO is called the vDSO and it often contains useful and highly-optimized alternatives to real syscalls.

These functions are called just like ordinary C function according to your platform's ABI. Call them from a sensible context. (For example, if you set CS on x86 to something strange, the vDSO functions are within their rights to crash.) In addition, if you pass a bad pointer to a vDSO function, you might get SIGSEGV instead of -EFAULT.

To find the DSO, parse the auxiliary vector passed to the program's entry point. The AT_SYSINFO_EHDR entry will point to the vDSO.

The vDSO uses symbol versioning; whenever you request a symbol from the vDSO, specify the version you are expecting.

Programs that dynamically link to glibc will use the vDSO automatically. Otherwise, you can use the reference parser in tools/testing/selftests/vDSO/parse_vdso.c.

Unless otherwise noted, the set of symbols with any given version and the ABI of those symbols is considered stable. It may vary across architectures, though.

Note:
As of this writing, this ABI documentation as been confirmed for x86_64. The maintainers of the other vDSO-using architectures should confirm that it is correct for their architecture.

5.1.17 File stable/firewire-cdev

Has the following ABI:

- */dev/fw[0-9]+*

5.1.18 File stable/o2cb

Has the following ABI:

- */sys/fs/o2cb/*

5.1.19 File stable/procfs-audit_loginuid

Has the following ABI:

- *Audit Login UID*
- *Audit Login Session ID*

5.1.20 File stable/syscalls

Has the following ABI:

- *The kernel syscall interface*

5.1.21 File stable/sysfs-acpi-pmprofile

Has the following ABI:

- */sys/firmware/acpi/pm_profile*

5.1.22 File stable/sysfs-block

Has the following ABI:

- */sys/block/<disk>/alignment_offset*
- */sys/block/<disk>/discard_alignment*
- */sys/block/<disk>/diskseq*
- */sys/block/<disk>/inflight*
- */sys/block/<disk>/integrity/device_is_integrity_capable*

5.1.23 File stable/sysfs-bus-firewire

Has the following ABI:

- */sys/bus/firewire/devices/fw[0-9]+/*
- */sys/bus/firewire/devices/fw[0-9]+/units*
- */sys/bus/firewire/devices/fw[0-9]+/is_local*
- */sys/bus/firewire/devices/fw[0-9]+[.][0-9]+/*
- */sys/bus/firewire/devices/*/*
- */sys/bus/firewire/drivers/sbp2/fw*/host*/target*/*:*:*:*/ieee1394_id*

5.1.24 File stable/sysfs-bus-fsl-mc

Has the following ABI:

- */sys/bus/fsl-mc/rescan*
- */sys/bus/fsl-mc/autorescan*

5.1.25 File stable/sysfs-bus-mhi

Has the following ABI:

- */sys/bus/mhi/devices/.../serialnumber*
- */sys/bus/mhi/devices/.../oem_pk_hash*
- */sys/bus/mhi/devices/.../soc_reset*

5.1.26 File stable/sysfs-bus-nvmem

Has the following ABI:

- */sys/bus/nvmem/devices/.../nvmem*

5.1.27 File stable/sysfs-bus-usb

Has the following ABI:

- */sys/bus/usb/devices/.../power/persist*
- */sys/bus/usb/devices/.../power/autosuspend*
- */sys/bus/usb/device/.../power/connected_duration*
- */sys/bus/usb/device/.../power/active_duration*

- */sys/bus/vmbus/devices/<UUID>/channels/<N>/monitor_id*
- */sys/bus/vmbus/devices/<UUID>/channels/<N>/ring*
- */sys/bus/vmbus/devices/<UUID>/channels/<N>/intr_in_full*
- */sys/bus/vmbus/devices/<UUID>/channels/<N>/intr_out_empty*
- */sys/bus/vmbus/devices/<UUID>/channels/<N>/out_full_first*
- */sys/bus/vmbus/devices/<UUID>/channels/<N>/out_full_total*

5.1.29 File stable/sysfs-bus-w1

Has the following ABI:

- */sys/bus/w1/devices/.../w1_master_timeout_us*

5.1.30 File stable/sysfs-bus-xen-backend

Has the following ABI:

- */sys/bus/xen-backend/devices/*/devtype*
- */sys/bus/xen-backend/devices/*/nodename*
- */sys/bus/xen-backend/devices/vbd-*/physical_device*
- */sys/bus/xen-backend/devices/vbd-*/mode*
- */sys/bus/xen-backend/devices/vbd-*/statistics/f_req*
- */sys/bus/xen-backend/devices/vbd-*/statistics/oo_req*
- */sys/bus/xen-backend/devices/vbd-*/statistics/rd_req*
- */sys/bus/xen-backend/devices/vbd-*/statistics/rd_sect*
- */sys/bus/xen-backend/devices/vbd-*/statistics/wr_req*
- */sys/bus/xen-backend/devices/vbd-*/statistics/wr_sect*
- */sys/bus/xen-backend/devices/*/state*

5.1.31 File stable/sysfs-class-backlight

Has the following ABI:

- */sys/class/backlight/<backlight>/bl_power*
- */sys/class/backlight/<backlight>/brightness*
- */sys/class/backlight/<backlight>/actual_brightness*
- */sys/class/backlight/<backlight>/max_brightness*
- */sys/class/backlight/<backlight>/type*

5.1.32 File stable/sysfs-class-infiniband

sysfs interface common for all infiniband devices

Has the following ABI:

- */sys/class/infiniband/<device>/node_type*
- */sys/class/infiniband/<device>/node_guid*
- */sys/class/infiniband/<device>/sys_image_guid*
- */sys/class/infiniband/<device>/node_desc*

5.1.33 File stable/sysfs-class-rfkill

rfkill - radio frequency (RF) connector kill switch support

For details to this subsystem look at /driver-api/rfkill.

For the deprecated `/sys/class/rfkill/*/claim` knobs of this interface look in *removed/sysfs-class-rfkill*.

Has the following ABI:

- */sys/class/rfkill*
- */sys/class/rfkill/rfkill[0-9]+/name*
- */sys/class/rfkill/rfkill[0-9]+/type*
- */sys/class/rfkill/rfkill[0-9]+/persistent*
- */sys/class/rfkill/rfkill[0-9]+/state*
- */sys/class/rfkill/rfkill[0-9]+/hard*
- */sys/class/rfkill/rfkill[0-9]+/soft*

5.1.34 File stable/sysfs-class-tpm

Has the following ABI:

- */sys/class/tpm/tpmX/device/*
- */sys/class/tpm/tpmX/device/active*
- */sys/class/tpm/tpmX/device/cancel*
- */sys/class/tpm/tpmX/device/caps*
- */sys/class/tpm/tpmX/device/durations*
- */sys/class/tpm/tpmX/device/enabled*
- */sys/class/tpm/tpmX/device/owned*
- */sys/class/tpm/tpmX/device/pcrs*
- */sys/class/tpm/tpmX/device/pubek*
- */sys/class/tpm/tpmX/device/temp_deactivated*
- */sys/class/tpm/tpmX/device/timeouts*
- */sys/class/tpm/tpmX/tpm_version_major*

- */sys/class/tpm/tpmX/pcr-<H>/<N>*

5.1.35 File stable/sysfs-class-ubi

Has the following ABI:

- */sys/class/ubi/*
- */sys/class/ubi/version*
- */sys/class/ubiX/*
- */sys/class/ubi/ubiX/avail_eraseblocks*
- */sys/class/ubi/ubiX/bad_peb_count*
- */sys/class/ubi/ubiX/bgt_enabled*
- */sys/class/ubi/ubiX/dev*
- */sys/class/ubi/ubiX/eraseblock_size*
- */sys/class/ubi/ubiX/max_ec*
- */sys/class/ubi/ubiX/max_vol_count*
- */sys/class/ubi/ubiX/min_io_size*
- */sys/class/ubi/ubiX/mtd_num*
- */sys/class/ubi/ubiX/reserved_for_bad*
- */sys/class/ubi/ubiX/ro_mode*
- */sys/class/ubi/ubiX/total_eraseblocks*
- */sys/class/ubi/ubiX/volumes_count*
- */sys/class/ubi/ubiX/ubiX_Y/*
- */sys/class/ubi/ubiX/ubiX_Y/alignment*
- */sys/class/ubi/ubiX/ubiX_Y/corrupted*
- */sys/class/ubi/ubiX/ubiX_Y/data_bytes*
- */sys/class/ubi/ubiX/ubiX_Y/dev*
- */sys/class/ubi/ubiX/ubiX_Y/name*
- */sys/class/ubi/ubiX/ubiX_Y/reserved_ebs*
- */sys/class/ubi/ubiX/ubiX_Y/type*
- */sys/class/ubi/ubiX/ubiX_Y/upd_marker*
- */sys/class/ubi/ubiX/ubiX_Y/usable_eb_size*

5.1.36 File stable/sysfs-class-udc

Has the following ABI:

- */sys/class/udc/<udc>/a_alt_hnp_support*
- */sys/class/udc/<udc>/a_hnp_support*
- */sys/class/udc/<udc>/b_hnp_enable*
- */sys/class/udc/<udc>/current_speed*
- */sys/class/udc/<udc>/is_a_peripheral*
- */sys/class/udc/<udc>/is_otg*
- */sys/class/udc/<udc>/maximum_speed*
- */sys/class/udc/<udc>/soft_connect*
- */sys/class/udc/<udc>/srp*
- */sys/class/udc/<udc>/state*
- */sys/class/udc/<udc>/function*

5.1.37 File stable/sysfs-devices

Note:
This documents additional properties of any device beyond what is documented in *Rules on how to access information in sysfs*

Has the following ABI:

- */sys/devices/*/of_node*
- */sys/devices/*/devspec*
- */sys/devices/*/obppath*
- */sys/devices/*/dev*

5.1.38 File stable/sysfs-devices-node

Has the following ABI:

- */sys/devices/system/node/possible*
- */sys/devices/system/node/online*
- */sys/devices/system/node/has_normal_memory*
- */sys/devices/system/node/has_cpu*
- */sys/devices/system/node/has_high_memory*
- */sys/devices/system/node/nodeX*
- */sys/devices/system/node/nodeX/cpumap*
- */sys/devices/system/node/nodeX/cpulist*

- */sys/devices/system/node/nodeX/meminfo*
- */sys/devices/system/node/nodeX/numastat*
- */sys/devices/system/node/nodeX/distance*
- */sys/devices/system/node/nodeX/vmstat*
- */sys/devices/system/node/nodeX/compact*
- */sys/devices/system/node/nodeX/hugepages/hugepages-<size>/*
- */sys/devices/system/node/nodeX/accessY/*
- */sys/devices/system/node/nodeX/accessY/initiators/*
- */sys/devices/system/node/nodeX/accessY/targets/*
- */sys/devices/system/node/nodeX/accessY/initiators/read_bandwidth*
- */sys/devices/system/node/nodeX/accessY/initiators/read_latency*
- */sys/devices/system/node/nodeX/accessY/initiators/write_bandwidth*
- */sys/devices/system/node/nodeX/accessY/initiators/write_latency*
- */sys/devices/system/node/nodeX/memory_side_cache/indexY/*
- */sys/devices/system/node/nodeX/memory_side_cache/indexY/indexing*
- */sys/devices/system/node/nodeX/memory_side_cache/indexY/line_size*
- */sys/devices/system/node/nodeX/memory_side_cache/indexY/size*
- */sys/devices/system/node/nodeX/memory_side_cache/indexY/write_policy*
- */sys/devices/system/node/nodeX/x86/sgx_total_bytes*
- */sys/devices/system/node/nodeX/memory_failure/total*
- */sys/devices/system/node/nodeX/memory_failure/ignored*
- */sys/devices/system/node/nodeX/memory_failure/failed*
- */sys/devices/system/node/nodeX/memory_failure/delayed*
- */sys/devices/system/node/nodeX/memory_failure/recovered*

5.1.39 File stable/sysfs-devices-system-cpu

Has the following ABI:

- */sys/devices/system/cpu/dscr_default*
- */sys/devices/system/cpu/cpu[0-9]+/dscr*
- */sys/devices/system/cpu/cpuX/topology/physical_package_id*
- */sys/devices/system/cpu/cpuX/topology/die_id*
- */sys/devices/system/cpu/cpuX/topology/core_id*
- */sys/devices/system/cpu/cpuX/topology/cluster_id*
- */sys/devices/system/cpu/cpuX/topology/book_id*

- */sys/devices/system/cpu/cpuX/topology/drawer_id*
- */sys/devices/system/cpu/cpuX/topology/core_cpus*
- */sys/devices/system/cpu/cpuX/topology/core_cpus_list*
- */sys/devices/system/cpu/cpuX/topology/package_cpus*
- */sys/devices/system/cpu/cpuX/topology/package_cpus_list*
- */sys/devices/system/cpu/cpuX/topology/die_cpus*
- */sys/devices/system/cpu/cpuX/topology/ppin*
- */sys/devices/system/cpu/cpuX/topology/die_cpus_list*
- */sys/devices/system/cpu/cpuX/topology/cluster_cpus*
- */sys/devices/system/cpu/cpuX/topology/cluster_cpus_list*
- */sys/devices/system/cpu/cpuX/topology/book_siblings*
- */sys/devices/system/cpu/cpuX/topology/book_siblings_list*
- */sys/devices/system/cpu/cpuX/topology/drawer_siblings*
- */sys/devices/system/cpu/cpuX/topology/drawer_siblings_list*

5.1.40 File stable/sysfs-devices-system-xen_memory

Has the following ABI:

- */sys/devices/system/xen_memory/xen_memory0/max_retry_count*
- */sys/devices/system/xen_memory/xen_memory0/max_schedule_delay*
- */sys/devices/system/xen_memory/xen_memory0/retry_count*
- */sys/devices/system/xen_memory/xen_memory0/schedule_delay*
- */sys/devices/system/xen_memory/xen_memory0/target*
- */sys/devices/system/xen_memory/xen_memory0/target_kb*
- */sys/devices/system/xen_memory/xen_memory0/info/current_kb*
- */sys/devices/system/xen_memory/xen_memory0/info/high_kb*
- */sys/devices/system/xen_memory/xen_memory0/info/low_kb*
- */sys/devices/system/xen_memory/xen_memory0/scrub_pages*

5.1.41 File stable/sysfs-driver-aspeed-vuart

Has the following ABI:

- */sys/bus/platform/drivers/aspeed-vuart/*/lpc_address*
- */sys/bus/platform/drivers/aspeed-vuart/*/sirq*
- */sys/bus/platform/drivers/aspeed-vuart/*/sirq_polarity*

5.1.42 File stable/sysfs-driver-dma-idxd

Has the following ABI:

- */sys/bus/dsa/devices/dsa<m>/version*
- */sys/bus/dsa/devices/dsa<m>/cdev_major*
- */sys/bus/dsa/devices/dsa<m>/errors*
- */sys/bus/dsa/devices/dsa<m>/max_batch_size*
- */sys/bus/dsa/devices/dsa<m>/max_work_queues_size*
- */sys/bus/dsa/devices/dsa<m>/max_engines*
- */sys/bus/dsa/devices/dsa<m>/max_groups*
- */sys/bus/dsa/devices/dsa<m>/max_read_buffers*
- */sys/bus/dsa/devices/dsa<m>/max_transfer_size*
- */sys/bus/dsa/devices/dsa<m>/max_work_queues*
- */sys/bus/dsa/devices/dsa<m>/numa_node*
- */sys/bus/dsa/devices/dsa<m>/op_cap*
- */sys/bus/dsa/devices/dsa<m>/pasid_enabled*
- */sys/bus/dsa/devices/dsa<m>/state*
- */sys/bus/dsa/devices/dsa<m>/group<m>.<n>*
- */sys/bus/dsa/devices/dsa<m>/engine<m>.<n>*
- */sys/bus/dsa/devices/dsa<m>/wq<m>.<n>*
- */sys/bus/dsa/devices/dsa<m>/configurable*
- */sys/bus/dsa/devices/dsa<m>/read_buffer_limit*
- */sys/bus/dsa/devices/dsa<m>/cmd_status*
- */sys/bus/dsa/devices/dsa<m>/iaa_cap*
- */sys/bus/dsa/devices/dsa<m>/event_log_size*
- */sys/bus/dsa/devices/wq<m>.<n>/block_on_fault*
- */sys/bus/dsa/devices/wq<m>.<n>/group_id*
- */sys/bus/dsa/devices/wq<m>.<n>/size*
- */sys/bus/dsa/devices/wq<m>.<n>/type*

- */sys/hypervisor/version/major*
- */sys/hypervisor/version/minor*
- */sys/hypervisor/start_flags/**

5.1.58 File stable/sysfs-kernel-notes

Has the following ABI:

- */sys/kernel/notes*

5.1.59 File stable/sysfs-module

The /sys/module tree consists of the following structure:

Has the following ABI:

- */sys/module/<MODULENAME>*
- */sys/module/<MODULENAME>/parameters*
- */sys/module/<MODULENAME>/refcnt*
- */sys/module/<MODULENAME>/srcversion*

- */sys/module/<MODULENAME>/version*

5.1.60 File stable/sysfs-platform-wmi-bmof

Has the following ABI:

- */sys/bus/wmi/devices/05901221-D566-11D1-B2F0-00A0C9062910[-X]/bmof*

5.1.61 File stable/sysfs-transport-srp

Has the following ABI:

- */sys/class/srp_remote_ports/port-<h>:<n>/delete*
- */sys/class/srp_remote_ports/port-<h>:<n>/dev_loss_tmo*
- */sys/class/srp_remote_ports/port-<h>:<n>/fast_io_fail_tmo*
- */sys/class/srp_remote_ports/port-<h>:<n>/port_id*
- */sys/class/srp_remote_ports/port-<h>:<n>/reconnect_delay*
- */sys/class/srp_remote_ports/port-<h>:<n>/roles*
- */sys/class/srp_remote_ports/port-<h>:<n>/state*

5.1.62 File stable/thermal-notification

Has the following ABI:

- *A notification mechanism for thermal related events*

5.1.63 File stable/vdso

Has the following ABI:

- *vDSO*

5.2 ABI testing symbols

Documents interfaces that are felt to be stable, as the main development of this interface has been completed.

The interface can be changed to add new features, but the current interface will not break by doing this, unless grave errors or security problems are found in them.

Userspace programs can start to rely on these interfaces, but they must be aware of changes that can occur before these interfaces move to be marked stable.

Programs that use these interfaces are strongly encouraged to add their name to the description of these interfaces, so that the kernel developers can easily notify them if any changes occur.

5.2.1 .../XXXXXXX.ipa/endpoint_id/

.../XXXXXXX.ipa/endpoint_id/

Defined on file *sysfs-devices-platform-soc-ipa*

The .../XXXXXXX.ipa/endpoint_id/ directory contains attributes that define IDs associated with IPA endpoints. The "rx" or "tx" in an endpoint name is from the perspective of the AP. An endpoint ID is a small unsigned integer.

5.2.2 .../XXXXXXX.ipa/endpoint_id/modem_rx

.../XXXXXXX.ipa/endpoint_id/modem_rx

Defined on file *sysfs-devices-platform-soc-ipa*

The .../XXXXXXX.ipa/endpoint_id/modem_rx file contains the ID of the AP endpoint on which packets originating from the embedded modem are received.

5.2.3 .../XXXXXXX.ipa/endpoint_id/modem_tx

.../XXXXXXX.ipa/endpoint_id/modem_tx

Defined on file *sysfs-devices-platform-soc-ipa*

The .../XXXXXXX.ipa/endpoint_id/modem_tx file contains the ID of the AP endpoint on which packets destined for the embedded modem are sent.

5.2.4 .../XXXXXXX.ipa/endpoint_id/monitor_rx

.../XXXXXXX.ipa/endpoint_id/monitor_rx

Defined on file *sysfs-devices-platform-soc-ipa*

The .../XXXXXXX.ipa/endpoint_id/monitor_rx file contains the ID of the AP endpoint on which IPA "monitor" data is received. The monitor endpoint supplies replicas of packets that enter the IPA hardware for processing. Each replicated packet is preceded by a fixed-size "ODL" header (see .../XXXXXXX.ipa/feature/monitor, above). Large packets are truncated, to reduce the bandwidth required to provide the monitor function.

5.2.5 .../XXXXXXX.ipa/feature/

.../XXXXXXX.ipa/feature/

Defined on file *sysfs-devices-platform-soc-ipa*

The .../XXXXXXX.ipa/feature/ directory contains a set of attributes describing features implemented by the IPA hardware.

5.2.6 .../XXXXXXX.ipa/feature/rx_offload

.../XXXXXXX.ipa/feature/rx_offload

Defined on file *sysfs-devices-platform-soc-ipa*

The .../XXXXXXX.ipa/feature/rx_offload file contains a string indicating the type of receive checksum offload that is supported by the hardware. The possible values are "MAPv4" or "MAPv5".

5.2.7 .../XXXXXXX.ipa/feature/tx_offload

.../XXXXXXX.ipa/feature/tx_offload

Defined on file *sysfs-devices-platform-soc-ipa*

The .../XXXXXXX.ipa/feature/tx_offload file contains a string indicating the type of transmit checksum offload that is supported by the hardware. The possible values are "MAPv4" or "MAPv5".

5.2.8 .../XXXXXXX.ipa/modem/

.../XXXXXXX.ipa/modem/

Defined on file *sysfs-devices-platform-soc-ipa*

The .../XXXXXXX.ipa/modem/ directory contains attributes describing properties of the modem embedded in the SoC.

5.2.9 .../XXXXXXX.ipa/modem/rx_endpoint_id

.../XXXXXXX.ipa/modem/rx_endpoint_id

Defined on file *sysfs-devices-platform-soc-ipa*

The .../XXXXXXX.ipa/modem/rx_endpoint_id file duplicates the value found in .../XXXXXXX.ipa/endpoint_id/modem_rx.

5.2.10 .../XXXXXXX.ipa/modem/tx_endpoint_id

.../XXXXXXX.ipa/modem/tx_endpoint_id

Defined on file *sysfs-devices-platform-soc-ipa*

The .../XXXXXXX.ipa/modem/tx_endpoint_id file duplicates the value found in .../XXXXXXX.ipa/endpoint_id/modem_tx.

5.2.11 .../XXXXXXX.ipa/version

.../XXXXXXX.ipa/version

Defined on file *sysfs-devices-platform-soc-ipa*

The .../XXXXXXX.ipa/version file contains the IPA hardware version, as a period-separated set of two or three integers (e.g., "3.5.1" or "4.2").

5.2.12 Symbols under /config/acpi

/config/acpi

Defined on file *configfs-acpi*

This represents the ACPI subsystem entry point directory. It contains sub-groups corresponding to ACPI configurable options.

/config/acpi/table

Defined on file *configfs-acpi*

This group contains the configuration for user defined ACPI tables. The attributes of a user define table are:

aml

- a binary attribute that the user can use to fill in the ACPI aml definitions. Once the aml data is written to this file and the file is closed the table will be loaded and ACPI devices will be enumerated. To check if the operation is successful the user must check the error code for close(). If the operation is successful, subsequent writes to this attribute will fail.

The rest of the attributes are read-only and are valid only after the table has been loaded by filling the aml entry:

signature

- ASCII table signature

length

- length of table in bytes, including the header

revision

- ACPI Specification minor version number

oem_id

- ASCII OEM identification

oem_table_id

- ASCII OEM table identification

oem_revision

- OEM revision number

asl_compiler_id

- ASCII ASL compiler vendor ID

asl_compiler_revision

- ASL compiler version

5.2.13 Symbols under /config/iio

/config/iio

Defined on file *configfs-iio*

This represents Industrial IO configuration entry point directory. It contains sub-groups corresponding to IIO objects.

/config/iio/devices

Defined on file *configfs-iio*

Industrial IO software devices directory.

/config/iio/devices/dummy

Defined on file *configfs-iio*

Dummy IIO devices directory. Creating a directory here will result in creating a dummy IIO device in the IIO subsystem.

/config/iio/triggers

Defined on file *configfs-iio*

Industrial IO software triggers directory.

/config/iio/triggers/hrtimers

Defined on file *configfs-iio*

High resolution timers directory. Creating a directory here will result in creating a hrtimer trigger in the IIO subsystem.

5.2.14 Symbols under /config/pcie-gadget

/config/pcie-gadget

Defined on file *configfs-spear-pcie-gadget*

Interface is used to configure selected dual mode PCIe controller as device and then program its various registers to configure it as a particular device type. This interfaces can be used to show spear's PCIe device capability.

Nodes are only visible when configfs is mounted. To mount configfs in /config directory use:

```
# mount -t configfs none /config/
```

For nth PCIe Device Controller */config/pcie-gadget*.n/:

link	used to enable ltssm and read its status.
int_type	used to configure and read type of supported interrupt
no_of_msi	used to configure number of MSI vector needed and to read no of MSI granted.
inta	write 1 to assert INTA and 0 to de-assert.
send_msi	write MSI vector to be sent.
vendor_id	used to write and read vendor id (hex)
device_id	used to write and read device id (hex)
bar0_size	used to write and read bar0_size
bar0_address	used to write and read bar0 mapped area in hex.
bar0_rw_offset	used to write and read offset of bar0 where bar0_data will be written or read.
bar0_data	used to write and read data at bar0_rw_offset.

5.2.15 Symbols under /config/rdma_cm

/config/rdma_cm

Defined on file *configfs-rdma_cm*

Interface is used to configure RDMA-cable HCAs in respect to RDMA-CM attributes.

Attributes are visible only when configfs is mounted. To mount configfs in /config directory use:
mount -t configfs none /config/

In order to set parameters related to a specific HCA, a directory for this HCA has to be created:
mkdir -p /config/rdma_cm/<hca>

/config/rdma_cm/<hca>/ports/<port-num>/default_roce_mode

Defined on file *configfs-rdma_cm*

RDMA-CM based connections from HCA <hca> at port <port-num> will be initiated with this RoCE type as default. The possible RoCE types are either "IB/RoCE v1" or "RoCE v2". This parameter has RW access.

/config/rdma_cm/<hca>/ports/<port-num>/default_roce_tos

Defined on file *configfs-rdma_cm*

RDMA-CM QPs from HCA <hca> at port <port-num> will be created with this TOS as default. This can be overridden by using the rdma_set_option API. The possible RoCE TOS values are 0-255.

5.2.16 Symbols under /config/stp-policy

/config/stp-policy

Defined on file *configfs-stp-policy*

This group contains policies mandating Master/Channel allocation for software sources wishing to send trace data over an STM device.

/config/stp-policy/<device>.<policy>

Defined on file *configfs-stp-policy*

This group is the root of a policy; its name is a concatenation of an stm device name to which this policy applies and an arbitrary string. If <device> part doesn't match an existing stm device, mkdir will fail with ENODEV; if that device already has a policy assigned to it, mkdir will fail with EBUSY.

/config/stp-policy/<device>.<policy>/<node>

Defined on file *configfs-stp-policy*

Policy node is a string identifier that software clients will use to request a master/channel to be allocated and assigned to them.

/config/stp-policy/<device>.<policy>/<node>/channels

Defined on file *configfs-stp-policy*

Range of channels from which to allocate for users of this node. Write two numbers: the first channel and the last channel number.

/config/stp-policy/<device>.<policy>/<node>/masters

Defined on file *configfs-stp-policy*

Range of masters from which to allocate for users of this node. Write two numbers: the first master and the last master number.

/config/stp-policy/<device>.<policy>/device

Defined on file *configfs-stp-policy*

STM device to which this policy applies, read only. Same as the <device> component of its parent directory.

/config/stp-policy/<device>:p_sys-t.<policy>/<node>/clocksync_interval

Defined on file *configfs-stp-policy-p_sys-t*

Time interval in milliseconds. Send a CLOCKSYNC packet if this many milliseconds have passed since the previous CLOCKSYNC packet from this source. Zero is the default and stands for "never send the CLOCKSYNC". It makes sense to use this option with sources that generate constant and/or periodic data, like stm_heartbeat.

/config/stp-policy/<device>:p_sys-t.<policy>/<node>/do_len

Defined on file *configfs-stp-policy-p_sys-t*

Include payload length in the MIPI SyS-T header, boolean. If enabled, the SyS-T protocol encoder will include payload length in each packet's metadata. This is normally redundant if the underlying transport protocol supports marking message boundaries (which STP does), so this is off by default.

/config/stp-policy/<device>:p_sys-t.<policy>/<node>/ts_interval

Defined on file *configfs-stp-policy-p_sys-t*

Time interval in milliseconds. Include a timestamp in the MIPI SyS-T packet metadata, if this many milliseconds have passed since the previous packet from this source. Zero is the default and stands for "never send the timestamp".

/config/stp-policy/<device>:p_sys-t.<policy>/<node>/uuid

Defined on file *configfs-stp-policy-p_sys-t*

UUID source identifier string, RW. Default value is randomly generated at the mkdir <node> time. Data coming from trace sources that use this <node> will be tagged with this UUID in the MIPI SyS-T packet stream, to allow the decoder to discern between different sources within the same master/channel range, and identify the higher level decoders that may be needed for each source.

5.2.17 Symbols under /config/usb-gadget

/config/usb-gadget

Defined on file *configfs-usb-gadget*

This group contains sub-groups corresponding to created USB gadgets.

/config/usb-gadget/gadget

Defined on file *configfs-usb-gadget*

The attributes of a gadget:

UDC	bind a gadget to UDC/unbind a gadget; write UDC's name found in /sys/class/udc/* to bind a gadget, empty string "" to unbind.
max_speed	maximum speed the driver supports. Valid names are super-speed-plus, super-speed, high-speed, full-speed, and low-speed.
bDeviceClass	USB device class code
bDeviceSubClass	USB device subclass code
bDeviceProtocol	USB device protocol code
bMaxPacketSize0	maximum endpoint 0 packet size
bcdDevice	bcd device release number
bcdUSB	bcd USB specification version number
idProduct	product ID
idVendor	vendor ID

/config/usb-gadget/gadget/configs

Defined on file *configfs-usb-gadget*

This group contains a USB gadget's configurations

/config/usb-gadget/gadget/configs/config

Defined on file *configfs-usb-gadget*

The attributes of a configuration:

bmAttributes	configuration characteristics
MaxPower	maximum power consumption from the bus

/config/usb-gadget/gadget/configs/config/strings

Defined on file *configfs-usb-gadget*

This group contains subdirectories for language-specific strings for this configuration.

/config/usb-gadget/gadget/configs/config/strings/language

Defined on file *configfs-usb-gadget*

The attributes:

configuration	configuration description

/config/usb-gadget/gadget/functions

Defined on file *configfs-usb-gadget*

This group contains functions available to this USB gadget.

/config/usb-gadget/gadget/functions/<func>.<inst>/interface.<n>

Defined on file *configfs-usb-gadget*

This group contains ”Feature Descriptors” specific for one gadget's USB interface or one interface group described by an IAD.

The attributes:

compatible_id	8-byte string for ”Compatible ID”
sub_compatible_id	8-byte string for ”Sub Compatible ID”

/config/usb-gadget/gadget/functions/<func>.<inst>/interface.<n>/<property>

Defined on file *configfs-usb-gadget*

This group contains ”Extended Property Descriptors” specific for one gadget's USB interface or one interface group described by an IAD.

The attributes:

type	value 1..7 for interpreting the data • 1: unicode string • 2: unicode string with environment variable • 3: binary • 4: little-endian 32-bit • 5: big-endian 32-bit • 6: unicode string with a symbolic link • 7: multiple unicode strings
data	blob of data to be interpreted depending on type

/config/usb-gadget/gadget/functions/Loopback.name

Defined on file *configfs-usb-gadget-loopback*

The attributes:

qlen	depth of loopback queue
buflen	buffer length

/config/usb-gadget/gadget/functions/SourceSink.name

Defined on file *configfs-usb-gadget-sourcesink*

The attributes:

pattern	0 (all zeros), 1 (mod63), 2 (none)
isoc_interval	1..16
isoc_maxpacket	0 - 1023 (fs), 0 - 1024 (hs/ss)
isoc_mult	0..2 (hs/ss only)
isoc_maxburst	0..15 (ss only)
buflen	buffer length
bulk_qlen	depth of queue for bulk
iso_qlen	depth of queue for iso

/config/usb-gadget/gadget/functions/acm.name

Defined on file *configfs-usb-gadget-acm*

This item contains just one readonly attribute: port_num. It contains the port number of the /dev/ttyGS<n> device associated with acm function's instance "name".

/config/usb-gadget/gadget/functions/ecm.name

Defined on file *configfs-usb-gadget-ecm*

The attributes:

ifname

- network device interface name associated with this function instance

qmult

- queue length multiplier for high and super speed

host_addr

- MAC address of host's end of this Ethernet over USB link

dev_addr

- MAC address of device's end of this Ethernet over USB link

/config/usb-gadget/gadget/functions/eem.name

Defined on file *configfs-usb-gadget-eem*

The attributes:

ifname	network device interface name associated with this function instance
qmult	queue length multiplier for high and super speed
host_addr	MAC address of host's end of this Ethernet over USB link
dev_addr	MAC address of device's end of this Ethernet over USB link

/config/usb-gadget/gadget/functions/ffs.name

Defined on file *configfs-usb-gadget-ffs*

The purpose of this directory is to create and remove it.

A corresponding USB function instance is created/removed. There are no attributes here.

All parameters are set through FunctionFS.

/config/usb-gadget/gadget/functions/geth.name

Defined on file *configfs-usb-gadget-subset*

The attributes:

ifname	network device interface name associated with this function instance
qmult	queue length multiplier for high and super speed
host_addr	MAC address of host's end of this Ethernet over USB link
dev_addr	MAC address of device's end of this Ethernet over USB link

/config/usb-gadget/gadget/functions/gser.name

Defined on file *configfs-usb-gadget-serial*

This item contains just one readonly attribute: port_num. It contains the port number of the /dev/ttyGS<n> device associated with gser function's instance "name".

/config/usb-gadget/gadget/functions/hid.name

Defined on file *configfs-usb-gadget-hid*

The attributes:

protocol	HID protocol to use
report_desc	blob corresponding to HID report descriptors except the data passed through /dev/hidg<N>
report_length	HID report length
subclass	HID device subclass to use

/config/usb-gadget/gadget/functions/mass_storage.name

Defined on file *configfs-usb-gadget-mass-storage*

The attributes:

stall	Set to permit function to halt bulk endpoints. Disabled on some USB devices known not to work correctly. You should set it to true.
num_buffers	Number of pipeline buffers. Valid numbers are 2..4. Available only if CONFIG_USB_GADGET_DEBUG_FILES is set.

/config/usb-gadget/gadget/functions/mass_storage.name/lun.name

Defined on file *configfs-usb-gadget-mass-storage*

The attributes:

file	The path to the backing file for the LUN. Required if LUN is not marked as removable.
ro	Flag specifying access to the LUN shall be read-only. This is implied if CD-ROM emulation is enabled as well as when it was impossible to open "filename" in R/W mode.
removable	Flag specifying that LUN shall be indicated as being removable.
cdrom	Flag specifying that LUN shall be reported as being a CD-ROM.
nofua	Flag specifying that FUA flag in SCSI WRITE(10,12)
forced_eject	This write-only file is useful only when the function is active. It causes the backing file to be forcibly detached from the LUN, regardless of whether the host has allowed it. Any non-zero number of bytes written will result in ejection.

/config/usb-gadget/gadget/functions/midi.name

Defined on file *configfs-usb-gadget-midi*

The attributes:

index	index value for the USB MIDI adapter
id	ID string for the USB MIDI adapter
buflen	MIDI buffer length
qlen	USB read request queue length
in_ports	number of MIDI input ports
out_ports	number of MIDI output ports

/config/usb-gadget/gadget/functions/midi2.name

Defined on file *configfs-usb-gadget-midi2*

The attributes:

process_ump	Flag to process UMP Stream messages (0 or 1)
static_block	Flag for static blocks (0 or 1)
iface_name	MIDI interface name string

/config/usb-gadget/gadget/functions/midi2.name/ep.number

Defined on file *configfs-usb-gadget-midi2*

This group contains a UMP Endpoint configuration. A new Endpoint starts from 0, and can be up to 3.

The attributes:

protocol_caps	MIDI protocol capabilities (1, 2 or 3 for both)
protocol	Default MIDI protocol (1 or 2)
ep_name	UMP Endpoint name string
product_id	Product ID string
manufacturer	Manufacture ID (24 bit)
family	Device family ID (16 bit)
model	Device model ID (16 bit)
sw_revision	Software Revision (32 bit)

/config/usb-gadget/gadget/functions/midi2.name/ep.number/block.number

Defined on file *configfs-usb-gadget-midi2*

This group contains a UMP Function Block configuration. A new block starts from 0, and can be up to 31.

The attributes:

name	Function Block name string
direction	1: input, 2: output, 3: bidirectional
first_group	The first UMP Group number (0-15)
num_groups	The number of groups in this FB (1-16)
midi1_first_group	The first UMP Group number for MIDI 1.0 (0-15)
midi1_num_groups	The number of groups for MIDI 1.0 (0-16)
ui_hint	0: unknown, 1: receiver, 2: sender, 3: both
midi_ci_verison	Supported MIDI-CI version number (8 bit)
is_midi1	Legacy MIDI 1.0 device (0, 1 or 2)
sysex8_streams	Max number of SysEx8 streams (8 bit)
active	Active FB flag (0 or 1)

/config/usb-gadget/gadget/functions/ncm.name

Defined on file *configfs-usb-gadget-ncm*

The attributes:

ifname - network device interface name associated with
this function instance

qmult - queue length multiplier for high and
super speed

host_addr - MAC address of host's end of this
Ethernet over USB link

dev_addr - MAC address of device's end of this
Ethernet over USB link

/config/usb-gadget/gadget/functions/obex.name

Defined on file *configfs-usb-gadget-obex*

This item contains just one readonly attribute: port_num. It contains the port number of the /dev/ttyGS<n> device associated with obex function's instance "name".

/config/usb-gadget/gadget/functions/phonet.name

Defined on file *configfs-usb-gadget-phonet*

This item contains just one readonly attribute: ifname. It contains the network interface name assigned during network device registration.

/config/usb-gadget/gadget/functions/printer.name

Defined on file *configfs-usb-gadget-printer*

The attributes:

pnp_string	Data to be passed to the host in pnp string
q_len	Number of requests per endpoint

/config/usb-gadget/gadget/functions/rndis.name

Defined on file *configfs-usb-gadget-rndis*

The attributes:

ifname	network device interface name associated with this function instance
qmult	queue length multiplier for high and super speed
host_addr	MAC address of host's end of this Ethernet over USB link
dev_addr	MAC address of device's end of this Ethernet over USB link
class	USB interface class, default is 02 (hex)
subclass	USB interface subclass, default is 06 (hex)
protocol	USB interface protocol, default is 00 (hex)

/config/usb-gadget/gadget/functions/tcm.name

Defined on file *configfs-usb-gadget-tcm*

There are no attributes because all the configuration is performed in the "target" subsystem of configfs.

/config/usb-gadget/gadget/functions/uac1.name

Defined on file *configfs-usb-gadget-uac1*

The attributes:

c_chmask	capture channel mask
c_srate	list of capture sampling rates (comma-separated)
c_ssize	capture sample size (bytes)
c_mute_present	capture mute control enable
c_volume_present	capture volume control enable
c_volume_min	capture volume control min value (in 1/256 dB)
c_volume_max	capture volume control max value (in 1/256 dB)
c_volume_res	capture volume control resolution (in 1/256 dB)
p_chmask	playback channel mask
p_srate	list of playback sampling rates (comma-separated)
p_ssize	playback sample size (bytes)
p_mute_present	playback mute control enable
p_volume_present	playback volume control enable
p_volume_min	playback volume control min value (in 1/256 dB)
p_volume_max	playback volume control max value (in 1/256 dB)
p_volume_res	playback volume control resolution (in 1/256 dB)
req_number	the number of pre-allocated requests for both capture and playback
function_name	name of the interface

/config/usb-gadget/gadget/functions/uac1_legacy.name

Defined on file *configfs-usb-gadget-uac1_legacy*

The attributes:

audio_buf_size - audio buffer size fn_cap - capture pcm device file name fn_cntl - control device file name fn_play - playback pcm device file name req_buf_size - ISO OUT endpoint request buffer size req_count - ISO OUT endpoint request count

/config/usb-gadget/gadget/functions/uac2.name

Defined on file *configfs-usb-gadget-uac2*

The attributes:

c_chmask	capture channel mask
c_srate	list of capture sampling rates (comma-separated)
c_ssize	capture sample size (bytes)
c_hs_bint	capture bInterval for HS/SS (1-4: fixed, 0: auto)
c_sync	capture synchronization type (async/adaptive)
c_mute_present	capture mute control enable
c_volume_present	capture volume control enable
c_volume_min	capture volume control min value (in 1/256 dB)
c_volume_max	capture volume control max value (in 1/256 dB)
c_volume_res	capture volume control resolution (in 1/256 dB)
fb_max	maximum extra bandwidth in async mode
p_chmask	playback channel mask
p_srate	list of playback sampling rates (comma-separated)
p_ssize	playback sample size (bytes)
p_hs_bint	playback bInterval for HS/SS (1-4: fixed, 0: auto)
p_mute_present	playback mute control enable
p_volume_present	playback volume control enable
p_volume_min	playback volume control min value (in 1/256 dB)
p_volume_max	playback volume control max value (in 1/256 dB)
p_volume_res	playback volume control resolution (in 1/256 dB)
req_number	the number of pre-allocated requests for both capture and playback
function_name	name of the interface
c_terminal_type	code of the capture terminal type
p_terminal_type	code of the playback terminal type

/config/usb-gadget/gadget/functions/uvc.name

Defined on file *configfs-usb-gadget-uvc*

UVC function directory

streaming_maxburst	0..15 (ss only)
streaming_maxpacket	1..1023 (fs), 1..3072 (hs/ss)
streaming_interval	1..16
function_name	string [32]

/config/usb-gadget/gadget/functions/uvc.name/control

Defined on file *configfs-usb-gadget-uvc*

Control descriptors

All attributes read only except enable_interrupt_ep:

bInterfaceNumber	USB interface number for this streaming interface
enable_interrupt_ep	flag to enable the interrupt endpoint for the VC interface

/config/usb-gadget/gadget/functions/uvc.name/control/class

Defined on file *configfs-usb-gadget-uvc*

Class descriptors

/config/usb-gadget/gadget/functions/uvc.name/control/class/fs

Defined on file *configfs-usb-gadget-uvc*

Full speed control class descriptors

/config/usb-gadget/gadget/functions/uvc.name/control/class/ss

Defined on file *configfs-usb-gadget-uvc*

Super speed control class descriptors

/config/usb-gadget/gadget/functions/uvc.name/control/extensions

Defined on file *configfs-usb-gadget-uvc*

Extension unit descriptors

/config/usb-gadget/gadget/functions/uvc.name/control/extensions/name

Defined on file *configfs-usb-gadget-uvc*

Extension Unit (XU) Descriptor

bLength, bUnitID and iExtension are read-only. All others are read-write.

bLength	size of the descriptor in bytes
bUnitID	non-zero ID of this unit
guidExtensionCode	Vendor-specific code identifying the XU
bNumControls	number of controls in this XU
bNrInPins	number of input pins for this unit
baSourceID	list of the IDs of the units or terminals to which this XU is connected
bControlSize	size of the bmControls field in bytes
bmControls	list of bitmaps detailing which vendor specific controls are supported
iExtension	index of a string descriptor that describes this extension unit

/config/usb-gadget/gadget/functions/uvc.name/control/header

Defined on file *configfs-usb-gadget-uvc*

Control header descriptors

/config/usb-gadget/gadget/functions/uvc.name/control/header/name

Defined on file *configfs-usb-gadget-uvc*

Specific control header descriptors

dwClockFrequency bcdUVC

/config/usb-gadget/gadget/functions/uvc.name/control/processing

Defined on file *configfs-usb-gadget-uvc*

Processing unit descriptors

/config/usb-gadget/gadget/functions/uvc.name/control/processing/default

Defined on file *configfs-usb-gadget-uvc*

Default processing unit descriptors

All attributes read only except bmControls, which is read/write:

iProcessing	index of string descriptor
bmControls	bitmap specifying which controls are supported for the video stream
wMaxMultiplier	maximum digital magnification x100
bSourceID	id of the terminal to which this unit is connected
bUnitID	a non-zero id of this unit

/config/usb-gadget/gadget/functions/uvc.name/control/terminal

Defined on file *configfs-usb-gadget-uvc*

Terminal descriptors

/config/usb-gadget/gadget/functions/uvc.name/control/terminal/camera

Defined on file *configfs-usb-gadget-uvc*

Camera terminal descriptors

/config/usb-gadget/gadget/functions/uvc.name/control/terminal/camera/default

Defined on file *configfs-usb-gadget-uvc*

Default camera terminal descriptors

All attributes read only except bmControls, which is read/write:

bmControls	bitmap specifying which controls are supported for the video stream
wOcularFocalLength	the value of Locular
wObjectiveFocalLengthMax	the value of Lmin
wObjectiveFocalLengthMin	the value of Lmax
iTerminal	index of string descriptor
bAssocTerminal	id of the output terminal to which this terminal is connected
wTerminalType	terminal type
bTerminalID	a non-zero id of this terminal

/config/usb-gadget/gadget/functions/uvc.name/control/terminal/output

Defined on file *configfs-usb-gadget-uvc*

Output terminal descriptors

/config/usb-gadget/gadget/functions/uvc.name/control/terminal/output/default

Defined on file *configfs-usb-gadget-uvc*

Default output terminal descriptors

All attributes read only except bSourceID:

iTerminal	index of string descriptor
bSourceID	id of the terminal to which this terminal is connected
bAssocTerminal	id of the input terminal to which this output terminal is associated
wTerminalType	terminal type
bTerminalID	a non-zero id of this terminal

/config/usb-gadget/gadget/functions/uvc.name/streaming

Defined on file *configfs-usb-gadget-uvc*

Streaming descriptors

All attributes read only:

bInterfaceNumber	USB interface number for this streaming interface

/config/usb-gadget/gadget/functions/uvc.name/streaming/class

Defined on file *configfs-usb-gadget-uvc*

Streaming class descriptors

/config/usb-gadget/gadget/functions/uvc.name/streaming/class/fs

Defined on file *configfs-usb-gadget-uvc*

Full speed streaming class descriptors

/config/usb-gadget/gadget/functions/uvc.name/streaming/class/hs

Defined on file *configfs-usb-gadget-uvc*

High speed streaming class descriptors

/config/usb-gadget/gadget/functions/uvc.name/streaming/class/ss

Defined on file *configfs-usb-gadget-uvc*

Super speed streaming class descriptors

/config/usb-gadget/gadget/functions/uvc.name/streaming/color_matching

Defined on file *configfs-usb-gadget-uvc*

Color matching descriptors

/config/usb-gadget/gadget/functions/uvc.name/streaming/color_matching/default

Defined on file *configfs-usb-gadget-uvc*

Default color matching descriptors

All attributes read/write:

bMatrixCoefficients	matrix used to compute luma and chroma values from the color primaries
bTransferCharacteristics	optoelectronic transfer characteristic of the source picture, also called the gamma function
bColorPrimaries	color primaries and the reference white

/config/usb-gadget/gadget/functions/uvc.name/streaming/color_matching/name

Defined on file *configfs-usb-gadget-uvc*

Additional color matching descriptors

All attributes read/write:

bMatrixCoefficients	matrix used to compute luma and chroma values from the color primaries
bTransferCharacteristics	optoelectronic transfer characteristic of the source picture, also called the gamma function
bColorPrimaries	color primaries and the reference white

/config/usb-gadget/gadget/functions/uvc.name/streaming/header

Defined on file *configfs-usb-gadget-uvc*

Streaming header descriptors

/config/usb-gadget/gadget/functions/uvc.name/streaming/header/name

Defined on file *configfs-usb-gadget-uvc*

Specific streaming header descriptors

All attributes read only:

bTriggerUsage	how the host software will respond to a hardware trigger interrupt event
bTriggerSupport	flag specifying if hardware triggering is supported
bStillCaptureMethod	method of still image capture supported
bTerminalLink	id of the output terminal to which the video endpoint of this interface is connected
bmInfo	capabilities of this video streaming interface

/config/usb-gadget/gadget/functions/uvc.name/streaming/mjpeg

Defined on file *configfs-usb-gadget-uvc*

MJPEG format descriptors

/config/usb-gadget/gadget/functions/uvc.name/streaming/mjpeg/name

Defined on file *configfs-usb-gadget-uvc*

Specific MJPEG format descriptors

All attributes read only, except bmaControls and bDefaultFrameIndex:

bFormatIndex	unique id for this format descriptor; only defined after parent header is linked into the streaming class; read-only
bmaControls	this format's data for bmaControls in the streaming header
bmInterlaceFlags	specifies interlace information, read-only
bAspectRatioY	the X dimension of the picture aspect ratio, read-only
bAspectRatioX	the Y dimension of the picture aspect ratio, read-only
bmFlags	characteristics of this format, read-only
bDefaultFrameIndex	optimum frame index for this stream

/config/usb-gadget/gadget/functions/uvc.name/streaming/mjpeg/name/name

Defined on file *configfs-usb-gadget-uvc*

Specific MJPEG frame descriptors

bFrameIndex	unique id for this framedescriptor; only defined after parent format is linked into the streaming header; read-only
dwFrameInterval	indicates how frame interval can be programmed; a number of values separated by newline can be specified
dwDefaultFrameInterval	the frame interval the device would like to use as default
dwMaxVideoFrameBufferSize	the maximum number of bytes the compressor will produce for a video frame or still image
dwMaxBitRate	the maximum bit rate at the shortest frame interval in bps
dwMinBitRate	the minimum bit rate at the longest frame interval in bps
wHeight	height of decoded bitmap frame in px
wWidth	width of decoded bitmam frame in px
bmCapabilities	still image support, fixed frame-rate support

/config/usb-gadget/gadget/functions/uvc.name/streaming/uncompressed

Defined on file *configfs-usb-gadget-uvc*

Uncompressed format descriptors

/config/usb-gadget/gadget/functions/uvc.name/streaming/uncompressed/name

Defined on file *configfs-usb-gadget-uvc*

Specific uncompressed format descriptors

bFormatIndex	unique id for this format descriptor; only defined after parent header is linked into the streaming class; read-only
bmaControls	this format's data for bmaControls in the streaming header
bmInterlaceFlags	specifies interlace information, read-only
bAspectRatioY	the X dimension of the picture aspect ratio, read-only
bAspectRatioX	the Y dimension of the picture aspect ratio, read-only
bDefaultFrameIndex	optimum frame index for this stream
bBitsPerPixel	number of bits per pixel used to specify color in the decoded video frame
guidFormat	globally unique id used to identify stream-encoding format

/config/usb-gadget/gadget/functions/uvc.name/streaming/uncompressed/name/name

Defined on file *configfs-usb-gadget-uvc*

Specific uncompressed frame descriptors

bFrameIndex	unique id for this framedescriptor; only defined after parent format is linked into the streaming header; read-only
dwFrameInterval	indicates how frame interval can be programmed; a number of values separated by newline can be specified
dwDefaultFrameInterval	the frame interval the device would like to use as default
dwMaxVideoFrameBufferSize	the maximum number of bytes the compressor will produce for a video frame or still image
dwMaxBitRate	the maximum bit rate at the shortest frame interval in bps
dwMinBitRate	the minimum bit rate at the longest frame interval in bps
wHeight	height of decoded bitmap frame in px
wWidth	width of decoded bitmam frame in px
bmCapabilities	still image support, fixed frame-rate support

/config/usb-gadget/gadget/os_desc

Defined on file *configfs-usb-gadget*

This group contains ”OS String” extension handling attributes.

use	flag turning ”OS Descriptors” support on/off
b_vendor_code	one-byte value used for custom per-device and per-interface requests
qw_sign	an identifier to be reported as ”OS String” proper

/config/usb-gadget/gadget/strings

Defined on file *configfs-usb-gadget*

This group contains subdirectories for language-specific strings for this gadget.

/config/usb-gadget/gadget/strings/language

Defined on file *configfs-usb-gadget*

The attributes:

serialnumber	gadget's serial number (string)
product	gadget's product description
manufacturer	gadget's manufacturer description

/config/usb-gadget/gadget/webusb

Defined on file *configfs-usb-gadget*

This group contains ”WebUSB” extension handling attributes.

use	flag turning ”WebUSB” support on/off
bcdVersion	bcd WebUSB specification version number
bVendorCode	one-byte value used for custom per-device
landingPage	UTF-8 encoded URL of the device's landing page

5.2.18 Symbols under /dev/gpiochip

/dev/gpiochip[0-9]+

Defined on file *gpio-cdev*

The character device files /dev/gpiochip* are the interface between GPIO chips and userspace.

The ioctl(2)-based ABI is defined and documented in [include/uapi]<linux/gpio.h>.

The following file operations are supported:

open(2)
Currently the only useful flags are O_RDWR.

ioctl(2)
Initiate various actions.

See the inline documentation in [include/uapi]<linux/gpio.h> for descriptions of all ioctls.

close(2)
Stops and free up the I/O contexts that was associated with the file descriptor.

Users: TBD

5.2.19 Symbols under /dev/kmsg

/dev/kmsg

Defined on file *dev-kmsg*

The */dev/kmsg* character device node provides userspace access to the kernel's printk buffer.

Injecting messages:

Every write() to the opened device node places a log entry in the kernel's printk buffer.

The logged line can be prefixed with a <N> syslog prefix, which carries the syslog priority and facility. The single decimal prefix number is composed of the 3 lowest bits being the syslog priority and the next 8 bits the syslog facility number.

If no prefix is given, the priority number is the default kernel log priority and the facility number is set to LOG_USER (1). It is not possible to inject messages from userspace with the facility number LOG_KERN (0), to make sure that the origin of the messages can always be reliably determined.

Accessing the buffer:

Every read() from the opened device node receives one record of the kernel's printk buffer.

The first read() directly following an open() always returns first message in the buffer; there is no kernel-internal persistent state; many readers can concurrently open the device and read from it, without affecting other readers.

Every read() will receive the next available record. If no more records are available read() will block, or if O_NONBLOCK is used -EAGAIN returned.

Messages in the record ring buffer get overwritten as whole, there are never partial messages received by read().

In case messages get overwritten in the circular buffer while the device is kept open, the next read() will return -EPIPE, and the seek position be updated to the next available record. Subsequent reads() will return available records again.

Unlike the classic syslog() interface, the 64 bit record sequence numbers allow to calculate the amount of lost messages, in case the buffer gets overwritten. And they allow to reconnect to the buffer and reconstruct the read position if needed, without limiting the interface to a single reader.

The device supports seek with the following parameters:

SEEK_SET, 0
seek to the first entry in the buffer

SEEK_END, 0
seek after the last entry in the buffer

SEEK_DATA, 0
: seek after the last record available at the time the last SYSLOG_ACTION_CLEAR was issued.

Other seek operations or offsets are not supported because of the special behavior this device has. The device allows to read or write only whole variable length messages (records) that are stored in a ring buffer.

Because of the non-standard behavior also the error values are non-standard. -ESPIPE is returned for non-zero offset. -EINVAL is returned for other operations, e.g. SEEK_CUR. This behavior and values are historical and could not be modified without the risk of breaking userspace.

The output format consists of a prefix carrying the syslog prefix including priority and facility, the 64 bit message sequence number and the monotonic timestamp in microseconds, and a flag field. All fields are separated by a ','.

Future extensions might add more comma separated values before the terminating ';'. Unknown fields and values should be gracefully ignored.

The human readable text string starts directly after the ';' and is terminated by a 'n'. Untrusted values derived from hardware or other facilities are printed, therefore all non-printable characters and '' itself in the log message are escaped by "x00" C-style hex encoding.

A line starting with ' ', is a continuation line, adding key/value pairs to the log message, which provide the machine readable context of the message, for reliable processing in userspace.

Example:

```
7,160,424069,-;pci_root PNP0A03:00: host bridge window [io  0x0000-0x0cf7]␣
↪(ignored)
 SUBSYSTEM=acpi
 DEVICE=+acpi:PNP0A03:00
6,339,5140900,-;NET: Registered protocol family 10
30,340,5690716,-;udevd[80]: starting version 181
```

The DEVICE= key uniquely identifies devices the following way:

b12:8	block dev_t
c127:3	char dev_t
n8	netdev ifindex
+sound:card0	subsystem:devname

The flags field carries '-' by default. A 'c' indicates a fragment of a line. Note, that these hints about continuation lines are not necessarily correct, and the stream could be interleaved with unrelated messages, but merging the lines in the output usually produces better human readable results. A similar logic is used internally when messages are printed to the console, /proc/kmsg or the syslog() syscall.

By default, kernel tries to avoid fragments by concatenating when it can and fragments are rare; however, when extended console support is enabled, the in-kernel concatenation is disabled and */dev/kmsg* output will contain more fragments. If the log consumer performs concatenation, the end result should be the same. In the future, the in-kernel concatenation may be removed entirely and */dev/kmsg* users are recommended to implement fragment handling.

Users: dmesg(1), userspace kernel log consumers

5.2.20 Symbols under /dev/rtcX

/dev/rtcX

Defined on file *rtc-cdev*

The ioctl interface to drivers for real-time clocks (RTCs). Following actions are supported:

- RTC_RD_TIME, RTC_SET_TIME: Read or set the RTC time. Time format is a Gregorian calendar date and 24 hour wall clock time.
- RTC_AIE_ON, RTC_AIE_OFF: Enable or disable the alarm interrupt for RTCs that support alarms
- RTC_ALM_READ, RTC_ALM_SET: Read or set the alarm time for RTCs that support alarms. Can be set upto 24 hours in the future. Requires a separate RTC_AIE_ON call to enable the alarm interrupt. (Prefer to use RTC_WKALM_*)
- RTC_WKALM_RD, RTC_WKALM_SET: For RTCs that support a more powerful interface, which can issue alarms beyond 24 hours and enable IRQs in the same request.
- RTC_PIE_ON, RTC_PIE_OFF: Enable or disable the periodic interrupt for RTCs that support periodic interrupts.
- RTC_UIE_ON, RTC_UIE_OFF: Enable or disable the update interrupt for RTCs that support it.
- RTC_IRQP_READ, RTC_IRQP_SET: Read or set the frequency for periodic interrupts for RTCs that support periodic interrupts. Requires a separate RTC_PIE_ON call to enable the periodic interrupts.
- RTC_VL_READ: Read the voltage inputs status of the RTC when supported. The value is a bit field of RTC_VL_*, giving the status of the main and backup voltages.
- RTC_VL_CLEAR: Clear the voltage status of the RTC. Some RTCs need user interaction when the backup power provider is replaced or charged to be able to clear the status.

The ioctl() calls supported by the older /dev/rtc interface are also supported by the newer RTC class framework. However, because the chips and systems are not standardized, some PC/AT functionality might not be provided. And in the same way, some newer features -- including those enabled by ACPI -- are exposed by the RTC class framework, but can't be supported by the older driver.

5.2.21 Symbols under /dev/wmi

/dev/wmi/dell-smbios

Defined on file *dell-smbios-wmi*

Perform SMBIOS calls on supported Dell machines. through the Dell ACPI-WMI interface.

IOCTL's and buffer formats are defined in: <uapi/linux/wmi.h>

1) To perform an SMBIOS call from userspace, you'll need to first determine the minimum size of the calling interface buffer for your machine. Platforms that contain larger buffers

can return larger objects from the system firmware. Commonly this size is either 4k or 32k.

To determine the size of the buffer read() a u64 dword from the WMI character device */dev/wmi/dell-smbios*.

2) After you've determined the minimum size of the calling interface buffer, you can allocate a structure that represents the structure documented above.

3) In the 'length' object store the size of the buffer you determined above and allocated.

4) In this buffer object, prepare as necessary for the SMBIOS call you're interested in. Typically SMBIOS buffers have ”class”, ”select”, and ”input” defined to values that coincide with the data you are interested in. Documenting class/select/input values is outside of the scope of this documentation. Check with the libsmbios project for further documentation on these values.

6) Run the call by using ioctl() as described in the header.

7) The output will be returned in the buffer object.

8) Be sure to free up your allocated object.

5.2.22 Symbols under /kvd

/kvd/

Defined on file *devlink-resource-mlxsw*

The main database in the Spectrum device is a centralized KVD database used for many of the tables used to configure the chip including L2 FDB, L3 LPM, ECMP and more. The KVD is divided into two sections, the first is hash-based table and the second is a linear access table. The division between the linear and hash-based sections is static and require reload before the changes take effect.

5.2.23 Symbols under /kvd/hash_double

/kvd/hash_double

Defined on file *devlink-resource-mlxsw*

The hash based section of the KVD is managed by the switch device. Used in case the key is larger than 64 bit.

5.2.24 Symbols under /kvd/hash_single

/kvd/hash_single

Defined on file *devlink-resource-mlxsw*

The hash based section of the KVD is managed by the switch device. Used in case the key size is smaller or equal to 64bit.

5.2.25 Symbols under /kvd/linear

/kvd/linear

Defined on file *devlink-resource-mlxsw*

The linear section of the KVD is managed by software as a flat memory accessed using an index.

5.2.26 Symbols under /proc

/proc/*/attr/current

Defined on file *procfs-attr-current*

The current security information used by a Linux security module (LSM) that is active on the system. The details of permissions required to read from this interface and hence obtain the security state of the task identified is LSM dependent. A process cannot write to this interface unless it refers to itself. The other details of permissions required to write to this interface and hence change the security state of the task identified are LSM dependent. The format of the data used by this interface is LSM dependent. SELinux, Smack and AppArmor provide this interface.

Users: SELinux user-space Smack user-space AppArmor user-space

/proc/*/attr/exec

Defined on file *procfs-attr-exec*

The security information to be used on the process by a Linux security module (LSM) active on the system after a subsequent exec() call. The details of permissions required to read from this interface and hence obtain the security state of the task identified is LSM dependent. A process cannot write to this interface unless it refers to itself. The other details of permissions required to write to this interface and hence change the security state of the task identified are LSM dependent. The format of the data used by this interface is LSM dependent. SELinux and AppArmor provide this interface.

Users: SELinux user-space AppArmor user-space

/proc/*/attr/prev

Defined on file *procfs-attr-prev*

The security information used on the process by a Linux security module (LSM) active on the system prior to the most recent exec() call. The details of permissions required to read from this interface is LSM dependent. A process cannot write to this interface unless it refers to itself. The other details of permissions required to write to this interface are LSM dependent. The format of the data used by this interface is LSM dependent. SELinux and AppArmor provide this interface.

Users: SELinux user-space AppArmor user-space

5.2.27 Symbols under /proc/diskstats

/proc/diskstats

Defined on file *procfs-diskstats*

The */proc/diskstats* file displays the I/O statistics of block devices. Each line contains the following 14 fields:

1	major number
2	minor number
3	device name
4	reads completed successfully
5	reads merged
6	sectors read
7	time spent reading (ms)
8	writes completed
9	writes merged
10	sectors written
11	time spent writing (ms)
12	I/Os currently in progress
13	time spent doing I/Os (ms)
14	weighted time spent doing I/Os (ms)

Kernel 4.18+ appends four more fields for discard tracking putting the total at 18:

15	discards completed successfully
16	discards merged
17	sectors discarded
18	time spent discarding

Kernel 5.5+ appends two more fields for flush requests:

19	flush requests completed successfully
20	time spent flushing

For more details refer to *I/O statistics fields*

5.2.28 Symbols under /proc/pid

/proc/pid/smaps_rollup

Defined on file *procfs-smaps_rollup*

This file provides pre-summed memory information for a process. The format is almost identical to /proc/pid/smaps, except instead of an entry for each VMA in a process, smaps_rollup has a single entry (tagged "[rollup]") for which each field is the sum of the corresponding fields from all the maps in /proc/pid/smaps. Additionally, the fields Pss_Anon, Pss_File and Pss_Shmem are not present in /proc/pid/smaps. These fields represent the sum of the Pss field of each type (anon, file, shmem). For more details, see /filesystems/proc and the procfs man page.

Typical output looks like this:

```
00100000-ff709000 ---p 00000000 00:00 0          [rollup]
Size:               1192 kB
KernelPageSize:        4 kB
MMUPageSize:           4 kB
Rss:                 884 kB
Pss:                 385 kB
Pss_Dirty:            68 kB
Pss_Anon:            301 kB
Pss_File:             80 kB
Pss_Shmem:             4 kB
Shared_Clean:        696 kB
Shared_Dirty:          0 kB
Private_Clean:       120 kB
Private_Dirty:        68 kB
Referenced:          884 kB
Anonymous:            68 kB
LazyFree:              0 kB
AnonHugePages:         0 kB
ShmemPmdMapped:        0 kB
Shared_Hugetlb:        0 kB
Private_Hugetlb:       0 kB
Swap:                  0 kB
SwapPss:               0 kB
Locked:              385 kB
```

5.2.29 Symbols under /sys

/sys/.../<device>/<UUID>/

Defined on file *sysfs-bus-vfio-mdev*

This directory represents device directory of mediated device. It contains all the attributes related to mediated device.

/sys/.../<device>/<UUID>/mdev_type

Defined on file *sysfs-bus-vfio-mdev*

This is symbolic link pointing to supported type, <type-id> directory of which this mediated device is created.

/sys/.../<device>/<UUID>/remove

Defined on file *sysfs-bus-vfio-mdev*

Writing '1' to this file destroys the mediated device. The vendor driver can fail the remove() callback if that device is active and the vendor driver doesn't support hot unplug. Example:

```
# echo 1 > /sys/bus/mdev/devices/<UUID>/remove
```

/sys/.../<device>/mdev_supported_types/

Defined on file *sysfs-bus-vfio-mdev*

This directory contains list of directories of currently supported mediated device types and their details for <device>. Supported type attributes are defined by the vendor driver who registers with Mediated device framework. Each supported type is a directory whose name is created by adding the device driver string as a prefix to the string provided by the vendor driver.

/sys/.../<device>/mdev_supported_types/<type-id>/

Defined on file *sysfs-bus-vfio-mdev*

This directory gives details of supported type, like name, description, available_instances, device_api etc. 'device_api' and 'available_instances' are mandatory attributes to be provided by vendor driver. 'name', 'description' and other vendor driver specific attributes are optional.

/sys/.../<device>/vfio-dev/vfioX/

Defined on file *sysfs-devices-vfio-dev*

This directory is created when the device is bound to a vfio driver. The layout under this directory matches what exists for a standard 'struct device'. 'X' is a unique index marking this device in vfio.

/sys/.../events/illuminance_threshY_falling_value
/sys/.../events/illuminance_threshY_raising_value

Defined on file *sysfs-bus-iio-light-lm3533-als*

Specifies the value of threshold that the device is comparing against for the events enabled by in_illuminance0_thresh_either_en (0..255), where Y in 0..3.

Note that threshY_falling must be less than or equal to threshY_raising.

These thresholds correspond to the eight zone-boundary registers (boundaryY_{low,high}) and define the five light zones.

/sys/.../events/in_accel_gesture_doubletap_tap2_min_delay

Defined on file *sysfs-bus-iio*

Specifies the minimum quiet time in seconds between the two taps of a double tap.

/sys/.../events/in_accel_gesture_doubletap_tap2_min_delay_available

Defined on file *sysfs-bus-iio*

Lists all available delay values between two taps in the double tap. Units in seconds.

/sys/.../events/in_accel_gesture_singletap_en
/sys/.../events/in_accel_gesture_doubletap_en

Defined on file *sysfs-bus-iio*

Device generates an event on a single or double tap.

/sys/.../events/in_accel_gesture_singletap_reset_timeout
/sys/.../events/in_accel_gesture_doubletap_reset_timeout

Defined on file *sysfs-bus-iio*

Specifies the timeout value in seconds for the tap detector to not to look for another tap event after the event as occurred. Basically the minimum quiet time between the two single-tap's or two double-tap's.

/sys/.../events/in_accel_gesture_singletap_value
/sys/.../events/in_accel_gesture_doubletap_value

Defined on file *sysfs-bus-iio*

Specifies the threshold value that the device is comparing against to generate the tap gesture event. The lower threshold value increases the sensitivity of tap detection. Units and the exact meaning of value are device-specific.

/sys/.../events/in_accel_gesture_tap_maxtomin_time

Defined on file *sysfs-bus-iio*

Specifies the maximum time difference allowed between upper and lower peak of tap to consider it as the valid tap event. Units in seconds.

/sys/.../events/in_accel_gesture_tap_maxtomin_time_available

Defined on file *sysfs-bus-iio*

Lists all available time values between upper peak to lower peak. Units in seconds.

/sys/.../events/in_accel_gesture_tap_reset_timeout_available

Defined on file *sysfs-bus-iio*

Lists all available tap reset timeout values. Units in seconds.

/sys/.../events/in_accel_gesture_tap_value_available

Defined on file *sysfs-bus-iio*

Lists all available threshold values which can be used to modify the sensitivity of the tap detection.

/sys/.../events/in_accel_gesture_tap_wait_dur

Defined on file *sysfs-bus-iio*

Timeout value in seconds for tap gesture confirmation.

/sys/.../events/in_accel_gesture_tap_wait_dur_available

Defined on file *sysfs-bus-iio*

List of available timeout value for tap gesture confirmation.

/sys/.../events/in_accel_gesture_tap_wait_timeout

Defined on file *sysfs-bus-iio*

Enable tap gesture confirmation with timeout.

/sys/.../events/in_accel_raw_mag_value
/sys/.../events/in_accel_x_raw_mag_rising_value
/sys/.../events/in_accel_y_raw_mag_rising_value
/sys/.../events/in_accel_z_raw_mag_rising_value

Defined on file *sysfs-bus-iio*

The value to which the magnitude of the channel is compared. If number or direction is not specified, applies to all channels of this type.

/sys/.../events/in_accel_scale
/sys/.../events/in_accel_peak_scale
/sys/.../events/in_anglvel_scale
/sys/.../events/in_magn_scale
/sys/.../events/in_rot_from_north_magnetic_scale
/sys/.../events/in_rot_from_north_true_scale
/sys/.../events/in_voltage_scale
/sys/.../events/in_voltage_supply_scale
/sys/.../events/in_temp_scale
/sys/.../events/in_illuminance_scale
/sys/.../events/in_proximity_scale

Defined on file *sysfs-bus-iio*

Specifies the conversion factor from the standard units to device specific units used to set the event trigger threshold.

/sys/.../events/in_accel_thresh_rising_high_pass_filter_3db
/sys/.../events/in_anglvel_thresh_rising_high_pass_filter_3db
/sys/.../events/in_magn_thresh_rising_high_pass_filter_3db

Defined on file *sysfs-bus-iio*

If a high pass filter can be applied to the event generation this property gives its 3db frequency in Hz. A value of zero disables the filter.

/sys/.../events/in_accel_thresh_rising_low_pass_filter_3db
/sys/.../events/in_anglvel_thresh_rising_low_pass_filter_3db
/sys/.../events/in_magn_thresh_rising_low_pass_filter_3db

Defined on file *sysfs-bus-iio*

If a low pass filter can be applied to the event generation this property gives its 3db frequency in Hz. A value of zero disables the filter.

/sys/.../events/in_accel_thresh_rising_value
/sys/.../events/in_accel_thresh_falling_value
/sys/.../events/in_accel_x_raw_thresh_rising_value
/sys/.../events/in_accel_x_raw_thresh_falling_value
/sys/.../events/in_accel_y_raw_thresh_rising_value
/sys/.../events/in_accel_y_raw_thresh_falling_value
/sys/.../events/in_accel_z_raw_thresh_rising_value
/sys/.../events/in_accel_z_raw_thresh_falling_value
/sys/.../events/in_anglvel_x_raw_thresh_rising_value
/sys/.../events/in_anglvel_x_raw_thresh_falling_value
/sys/.../events/in_anglvel_y_raw_thresh_rising_value
/sys/.../events/in_anglvel_y_raw_thresh_falling_value
/sys/.../events/in_anglvel_z_raw_thresh_rising_value
/sys/.../events/in_anglvel_z_raw_thresh_falling_value
/sys/.../events/in_magn_x_raw_thresh_rising_value
/sys/.../events/in_magn_x_raw_thresh_falling_value
/sys/.../events/in_magn_y_raw_thresh_rising_value
/sys/.../events/in_magn_y_raw_thresh_falling_value
/sys/.../events/in_magn_z_raw_thresh_rising_value
/sys/.../events/in_magn_z_raw_thresh_falling_value
/sys/.../events/in_rot_from_north_magnetic_raw_thresh_rising_value
/sys/.../events/in_rot_from_north_magnetic_raw_thresh_falling_value
/sys/.../events/in_rot_from_north_true_raw_thresh_rising_value
/sys/.../events/in_rot_from_north_true_raw_thresh_falling_value
/sys/.../events/in_rot_from_north_magnetic_tilt_comp_raw_thresh_rising_value
/sys/.../events/in_rot_from_north_magnetic_tilt_comp_raw_thresh_falling_value

/sys/.../events/in_capacitanceY_thresh_falling_value
/sys/.../events/in_capacitanceY_thresh_adaptive_rising_value
/sys/.../events/in_capacitanceY_thresh_falling_rising_value

Defined on file *sysfs-bus-iio*

Specifies the value of threshold that the device is comparing against for the events enabled by <type>Y[_name]_thresh[_rising|falling]_en.

If separate attributes exist for the two directions, but direction is not specified for this attribute, then a single threshold value applies to both directions.

The raw or input element of the name indicates whether the value is in raw device units or in processed units (as _raw and _input do on sysfs direct channel read attributes).

/sys/.../events/in_proximity0_thresh_falling_hysteresis
/sys/.../events/in_proximity0_thresh_rising_hysteresis
/sys/.../events/in_proximity0_thresh_either_hysteresis

Defined on file *sysfs-bus-iio*

Specifies the hysteresis of threshold that the device is comparing against for the events enabled by <type>Y[_name]_thresh[_(rising|falling)]_hysteresis. If separate attributes exist for the two directions, but direction is not specified for this attribute, then a single hysteresis value applies to both directions.

For falling events the hysteresis is added to the _value attribute for this event to get the upper threshold for when the event goes back to normal, for rising events the hysteresis is subtracted from the _value attribute. E.g. if in_voltage0_raw_thresh_rising_value is set to 1200 and in_voltage0_raw_thresh_rising_hysteresis is set to 50. The event will get activated once in_voltage0_raw goes above 1200 and will become deactivated again once the value falls below 1150.

/sys/.../events/in_activity_jogging_thresh_falling_period
/sys/.../events/in_activity_running_thresh_rising_period
/sys/.../events/in_activity_running_thresh_falling_period
/sys/.../events/in_illuminance_thresh_either_period

Defined on file *sysfs-bus-iio*

Period of time (in seconds) for which the condition must be met before an event is generated. If direction is not specified then this period applies to both directions.

/sys/.../events/in_activity_still_thresh_rising_en
/sys/.../events/in_activity_still_thresh_falling_en
/sys/.../events/in_activity_walking_thresh_rising_en
/sys/.../events/in_activity_walking_thresh_falling_en
/sys/.../events/in_activity_jogging_thresh_rising_en
/sys/.../events/in_activity_jogging_thresh_falling_en
/sys/.../events/in_activity_running_thresh_rising_en
/sys/.../events/in_activity_running_thresh_falling_en

Defined on file *sysfs-bus-iio*

Enables or disables activity events. Depending on direction an event is generated when sensor ENTERS or LEAVES a given state.

/sys/.../events/in_activity_still_thresh_rising_value
/sys/.../events/in_activity_still_thresh_falling_value
/sys/.../events/in_activity_walking_thresh_rising_value
/sys/.../events/in_activity_walking_thresh_falling_value
/sys/.../events/in_activity_jogging_thresh_rising_value
/sys/.../events/in_activity_jogging_thresh_falling_value
/sys/.../events/in_activity_running_thresh_rising_value
/sys/.../events/in_activity_running_thresh_falling_value

Defined on file *sysfs-bus-iio*

Confidence value (in units as percentage) to be used for deciding when an event should be generated. E.g for running: If the confidence value reported by the sensor is greater than in_activity_running_thresh_rising_value then the sensor ENTERS running state. Conversely, if the confidence value reported by the sensor is lower than in_activity_running_thresh_falling_value then the sensor is LEAVING running state.

/sys/.../events/in_capacitanceY_adaptive_thresh_rising_en
/sys/.../events/in_capacitanceY_adaptive_thresh_falling_en

Defined on file *sysfs-bus-iio*

Adaptive thresholds are similar to normal fixed thresholds but the value is expressed as an offset from a value which provides a low frequency approximation of the channel itself. Thus these detect if a rapid change occurs in the specified direction which crosses tracking value + offset. Tracking value calculation is devices specific.

/sys/.../events/in_illuminance0_threshY_hysteresis

Defined on file *sysfs-bus-iio-light-lm3533-als*

Get the hysteresis for thresholds Y, that is, threshY_hysteresis = threshY_raising - threshY_falling

/sys/.../events/in_illuminance0_thresh_either_en

Defined on file *sysfs-bus-iio-light-lm3533-als*

Event generated when channel passes one of the four thresholds in each direction (rising|falling) and a zone change occurs. The corresponding light zone can be read from in_illuminance0_zone.

/sys/.../events/in_proximity_thresh_either_runningcount

Defined on file *sysfs-bus-iio*

Number of conditions that must occur, during a running period, before an event is generated.

/sys/.../events/in_proximity_thresh_either_runningperiod

Defined on file *sysfs-bus-iio*

A running period of time (in seconds) for which in_proximity_thresh_either_runningcount amount of conditions must occur before an event is generated. If direction is not specified then this period applies to both directions.

/sys/.../events/in_steps_change_en

Defined on file *sysfs-bus-iio*

Event generated when channel passes a threshold on the absolute change in value. E.g. for steps: a step change event is generated each time the user takes N steps, where N is set using in_steps_change_value.

/sys/.../events/in_steps_change_value

Defined on file *sysfs-bus-iio*

Specifies the value of change threshold that the device is comparing against for the events enabled by <type>[Y][_name]_roc[_rising|falling|]_en. E.g. for steps: if set to 3, a step change event will be generated every 3 steps.

/sys/.../iio:deviceX/bufferY/in_pressure_type
/sys/.../iio:deviceX/bufferY/in_rot_quaternion_type
/sys/.../iio:deviceX/bufferY/in_proximity_type

Defined on file *sysfs-bus-iio*

Description of the scan element data storage within the buffer and hence the form in which it is read from user-space. Form is [be|le]:[s|u]bits/storagebits[>>shift]. be or le specifies big or little endian. s or u specifies if signed (2's complement) or unsigned. bits is the number of bits of data and storagebits is the space (after padding) that it occupies in the buffer. shift if specified, is the shift that needs to be applied prior to masking out unused bits. Some devices put their data in the middle of the transferred elements with additional information on both sides. Note that some devices will have additional information in the unused bits so to get a clean value, the bits value must be used to mask the buffer output value appropriately. The storagebits value also specifies the data alignment. So s48/64>>2 will be a signed 48 bit integer stored in a 64 bit location aligned to a 64 bit boundary. To obtain the clean value, shift right 2 and apply a mask to zero the top 16 bits of the result. For other storage combinations this attribute will be extended appropriately.

/sys/.../iio:deviceX/events/in_tempY_roc_rising_en
/sys/.../iio:deviceX/events/in_tempY_roc_falling_en

Defined on file *sysfs-bus-iio*

Event generated when channel passes a threshold on the rate of change (1st differential) in the specified (_rising|_falling) direction. If the direction is not specified, then either the device will report an event which ever direction a single threshold value is passed in (e.g. <type>[Y][_name]_<raw|input>_roc_value) or <type>[Y][_name]_<raw|input>_roc_rising_value and <type>[Y][_name]_<raw|input>_roc_falling_va may take different values, but the device can only enable both rate of change thresholds or neither.

Note the driver will assume the last p events requested are to be enabled where p is however many it supports (which may vary depending on the exact set requested. So if you want to be sure you have set what you think you have, check the contents of these attributes after everything is configured. Drivers may have to buffer any parameters so that they are consistent when a given event type is enabled a future point (and not those for whatever event was previously enabled).

/sys/.../iio:deviceX/events/in_tempY_thresh_rising_en
/sys/.../iio:deviceX/events/in_tempY_thresh_falling_en
/sys/.../iio:deviceX/events/in_capacitanceY_thresh_rising_en
/sys/.../iio:deviceX/events/in_capacitanceY_thresh_falling_en

Defined on file *sysfs-bus-iio*

Event generated when channel passes a threshold in the specified (_rising|_falling) direction. If the direction is not specified, then either the device will report an event which ever direction a single threshold value is passed in (e.g. <type>[Y][_name]_<raw|input>_thresh_value) or <type>[Y][_name]_<raw|input>_thresh_rising_value and <type>[Y][_name]_<raw|input>_thresh_fal may take different values, but the device can only enable both thresholds or neither.

Note the driver will assume the last p events requested are to be enabled where p is how many it supports (which may vary depending on the exact set requested. So if you want to be sure you have set what you think you have, check the contents of these attributes after everything is configured. Drivers may have to buffer any parameters so that they are consistent when a given event type is enabled at a future point (and not those for whatever event was previously enabled).

/sys/.../iio:deviceX/in_accelX_power_mode

Defined on file *sysfs-bus-iio*

Specifies the chip power mode. low_noise: reduce noise level from ADC, low_power: enable low current consumption. For a list of available output power modes read in_accel_power_mode_available.

/sys/.../iio:deviceX/in_activity_still_input
/sys/.../iio:deviceX/in_activity_walking_input
/sys/.../iio:deviceX/in_activity_jogging_input
/sys/.../iio:deviceX/in_activity_running_input

Defined on file *sysfs-bus-iio*

This attribute is used to read the confidence for an activity expressed in units as percentage.

/sys/.../iio:deviceX/in_anglvel_z_quadrature_correction_raw

Defined on file *sysfs-bus-iio*

This attribute is used to read the amount of quadrature error present in the device at a given time.

/sys/.../iio:deviceX/in_capacitableY_calibbias_calibration
/sys/.../iio:deviceX/in_capacitableY_calibscale_calibration

Defined on file *sysfs-bus-iio-cdc-ad7746*

Write 1 to trigger a calibration of the calibbias or calibscale. For calibscale, a full scale capacitance should be connected to the capacitance input and a calibscale_calibration then started. For calibbias see the device datasheet section on "capacitive system offset calibration".

/sys/.../iio:deviceX/in_capacitanceY-capacitanceZ_raw

Defined on file *sysfs-bus-iio*

Raw differential capacitance measurement equivalent to channel Y - channel Z where these channel numbers apply to the physically equivalent inputs when non differential readings are separately available. In differential only parts, then all that is required is a consistent labeling. Units after application of scale and offset are nanofarads.

/sys/.../iio:deviceX/in_capacitanceY-capacitanceZ_zeropoint

Defined on file *sysfs-bus-iio*

For differential channels, this an offset that is applied equally to both inputs. As the reading is of the difference between the two inputs, this should not be applied to the _raw reading by userspace (unlike _offset) and unlike calibbias it does not affect the differential value measured because the effect of _zeropoint cancels out across the two inputs that make up the differential pair. It's purpose is to bring the individual signals, before the differential is measured, within the measurement range of the device. The naming is chosen because if the separate inputs that make the differential pair are drawn on a graph in their _raw units, this is the value that the zero point on the measurement axis represents. It is expressed with the same scaling as _raw.

/sys/.../iio:deviceX/in_distance_input
/sys/.../iio:deviceX/in_distance_raw

Defined on file *sysfs-bus-iio*

This attribute is used to read the measured distance to an object or the distance covered by the user since the last reboot while activated. Units after application of scale are meters.

/sys/.../iio:deviceX/in_energy_en
/sys/.../iio:deviceX/in_distance_en
/sys/.../iio:deviceX/in_velocity_sqrt(x^2+y^2+z^2)_en
/sys/.../iio:deviceX/in_steps_en

Defined on file *sysfs-bus-iio*

Activates a device feature that runs in firmware/hardware. E.g. for steps: the pedometer saves power while not used; when activated, it will count the steps taken by the user in firmware and export them through in_steps_input.

/sys/.../iio:deviceX/in_energy_input
/sys/.../iio:deviceX/in_energy_raw

Defined on file *sysfs-bus-iio*

This attribute is used to read the energy value reported by the device (e.g.: human activity sensors report energy burnt by the user). Units after application of scale are Joules.

/sys/.../iio:deviceX/in_illuminance_input
/sys/.../iio:deviceX/in_illuminance_raw
/sys/.../iio:deviceX/in_illuminanceY_input
/sys/.../iio:deviceX/in_illuminanceY_raw
/sys/.../iio:deviceX/in_illuminanceY_mean_raw
/sys/.../iio:deviceX/in_illuminance_ir_raw
/sys/.../iio:deviceX/in_illuminance_clear_raw

Defined on file *sysfs-bus-iio*

Illuminance measurement, units after application of scale and offset are lux.

/sys/.../iio:deviceX/in_intensityY_raw
/sys/.../iio:deviceX/in_intensityY_ir_raw
/sys/.../iio:deviceX/in_intensityY_both_raw
/sys/.../iio:deviceX/in_intensityY_uv_raw
/sys/.../iio:deviceX/in_intensityY_uva_raw
/sys/.../iio:deviceX/in_intensityY_uvb_raw
/sys/.../iio:deviceX/in_intensityY_duv_raw

Defined on file *sysfs-bus-iio*

Unit-less light intensity. Modifiers both and ir indicate that measurements contain visible and infrared light components or just infrared light, respectively. Modifier uv indicates that measurements contain ultraviolet light components. Modifiers uva, uvb and duv indicate that measurements contain A, B or deep (C) ultraviolet light components respectively.

/sys/.../iio:deviceX/in_intensity_integration_time
/sys/.../iio:deviceX/in_intensity_red_integration_time
/sys/.../iio:deviceX/in_intensity_green_integration_time
/sys/.../iio:deviceX/in_intensity_blue_integration_time
/sys/.../iio:deviceX/in_intensity_clear_integration_time
/sys/.../iio:deviceX/in_illuminance_integration_time

Defined on file *sysfs-bus-iio*

This attribute is used to get/set the integration time in seconds. If shared across all channels of a given type, <type>_integration_time is used.

/sys/.../iio:deviceX/in_proximity_raw
/sys/.../iio:deviceX/in_proximity_input
/sys/.../iio:deviceX/in_proximityY_raw

Defined on file *sysfs-bus-iio*

Proximity measurement indicating that some object is near the sensor, usually by observing reflectivity of infrared or ultrasound emitted.

Often these sensors are unit less and as such conversion to SI units is not possible. Higher proximity measurements indicate closer objects, and vice versa. Units after application of scale and offset are meters.

/sys/.../iio:deviceX/in_steps_debounce_count

Defined on file *sysfs-bus-iio*

Specifies the number of steps that must occur within in_steps_filter_debounce_time for the pedometer to decide the consumer is making steps.

/sys/.../iio:deviceX/in_steps_debounce_time

Defined on file *sysfs-bus-iio*

Specifies number of seconds in which we compute the steps that occur in order to decide if the consumer is making steps.

/sys/.../iio:deviceX/in_steps_input

Defined on file *sysfs-bus-iio*

This attribute is used to read the number of steps taken by the user since the last reboot while activated.

/sys/.../iio:deviceX/in_uvindex_input

Defined on file *sysfs-bus-iio*

UV light intensity index measuring the human skin's response to different wavelength of sunlight weighted according to the standardised CIE Erythemal Action Spectrum. UV index values range from 0 (low) to >=11 (extreme).

/sys/.../iio:deviceX/in_velocity_sqrt(x^2+y^2+z^2)_input
/sys/.../iio:deviceX/in_velocity_sqrt(x^2+y^2+z^2)_raw

Defined on file *sysfs-bus-iio*

This attribute is used to read the current speed value of the user (which is the norm or magnitude of the velocity vector). Units after application of scale are m/s.

/sys/.../iio:deviceX/in_velocity_sqrt(x^2+y^2+z^2)_integration_time

Defined on file *sysfs-bus-iio*

Number of seconds in which to compute speed.

/sys/.../iio:deviceX/out_voltageY_powerdown_mode_available
/sys/.../iio:deviceX/out_voltage_powerdown_mode_available
/sys/.../iio:deviceX/out_altvoltageY_powerdown_mode_available
/sys/.../iio:deviceX/out_altvoltage_powerdown_mode_available

Defined on file *sysfs-bus-iio*

Lists all available output power down modes. If Y is not present the mode is shared across all outputs.

/sys/.../iio:deviceX/scan_elements/in_accel_type_available

Defined on file *sysfs-bus-iio*

If the type parameter can take one of a small set of values, this attribute lists them.

/sys/.../in_accel_filter_high_pass_3db_frequency
/sys/.../in_anglvel_filter_high_pass_3db_frequency
/sys/.../in_magn_filter_high_pass_3db_frequency

Defined on file *sysfs-bus-iio*

If a known or controllable high pass filter is applied to the underlying data channel, then this parameter gives the 3dB frequency of the filter in Hz.

/sys/.../in_accel_filter_low_pass_3db_frequency
/sys/.../in_magn_filter_low_pass_3db_frequency
/sys/.../in_anglvel_filter_low_pass_3db_frequency

Defined on file *sysfs-bus-iio*

If a known or controllable low pass filter is applied to the underlying data channel, then this parameter gives the 3dB frequency of the filter in Hz.

/sys/.../in_capacitanceY_adaptive_thresh_rising_timeout
/sys/.../in_capacitanceY_adaptive_thresh_falling_timeout

Defined on file *sysfs-bus-iio*

When adaptive thresholds are used, the tracking signal may adjust too slowly to step changes in the raw signal. Thus these specify the time in seconds for which the difference between the slow tracking signal and the raw signal is allowed to remain out-of-range before a reset event occurs in which the tracking signal is made equal to the raw signal, allowing slow tracking to resume and the adaptive threshold event detection to function as expected.

/sys/.../mdev_supported_types/<type-id>/available_instances

Defined on file *sysfs-bus-vfio-mdev*

Reading this attribute will show the number of mediated devices of type <type-id> that can be created. This is a readonly file.

Users:

Userspace applications interested in creating mediated device of that type. Userspace application should check the number of available instances could be created before creating mediated device of this type.

/sys/.../mdev_supported_types/<type-id>/create

Defined on file *sysfs-bus-vfio-mdev*

Writing UUID to this file will create mediated device of type <type-id> for parent device <device>. This is a write-only file. For example:

```
# echo "83b8f4f2-509f-382f-3c1e-e6bfe0fa1001" >       \
     /sys/devices/foo/mdev_supported_types/foo-1/create
```

/sys/.../mdev_supported_types/<type-id>/description

Defined on file *sysfs-bus-vfio-mdev*

Reading this attribute will show description of the type of mediated device that will get created of type <type-id>. This is optional attribute. For example: "2 heads, 512M FB, 2560x1600 maximum resolution"

Users:

Userspace applications interested in knowing the details of a particular <type-id> that can help in understanding the features provided by that type of mediated device.

/sys/.../mdev_supported_types/<type-id>/device_api

Defined on file *sysfs-bus-vfio-mdev*

Reading this attribute will show VFIO device API supported by this type. For example, "vfio-pci" for a PCI device, "vfio-platform" for platform device.

/sys/.../mdev_supported_types/<type-id>/devices/

Defined on file *sysfs-bus-vfio-mdev*

This directory contains symbolic links pointing to mdev devices sysfs entries which are created of this <type-id>.

/sys/.../mdev_supported_types/<type-id>/name

Defined on file *sysfs-bus-vfio-mdev*

Reading this attribute will show human readable name of the mediated device that will get created of type <type-id>. This is optional attribute. For example: "Grid M60-0Q"

Users:

Userspace applications interested in knowing the name of a particular <type-id> that can help in understanding the type of mediated device.

/sys/.../uevent

Defined on file *sysfs-uevent*

Enable passing additional variables for synthetic uevents that are generated by writing /sys/.../uevent file.

Recognized extended format is:

```
ACTION [UUID [KEY=VALUE ...]
```

The ACTION is compulsory - it is the name of the uevent action (`add`, `change`, `remove`). There is no change compared to previous functionality here. The rest of the extended format is optional.

You need to pass UUID first before any KEY=VALUE pairs. The UUID must be in `xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxx` format where 'x' is a hex digit. The UUID is considered to be a transaction identifier so it's possible to use the same UUID value for one or more synthetic uevents in which case we logically group these uevents together for any userspace listeners. The UUID value appears in uevent as `SYNTH_UUID=xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxx` environment variable.

If UUID is not passed in, the generated synthetic uevent gains `SYNTH_UUID=0` environment variable automatically.

The KEY=VALUE pairs can contain alphanumeric characters only.

It's possible to define zero or more pairs - each pair is then delimited by a space character ' '. Each pair appears in synthetic uevent as `SYNTH_ARG_KEY=VALUE`. That means the KEY name gains `SYNTH_ARG_` prefix to avoid possible collisions with existing variables.

Example of valid sequence written to the uevent file:

```
add fe4d7c9d-b8c6-4a70-9ef1-3d8a58d18eed A=1 B=abc
```

This generates synthetic uevent including these variables:

```
ACTION=add
SYNTH_ARG_A=1
SYNTH_ARG_B=abc
SYNTH_UUID=fe4d7c9d-b8c6-4a70-9ef1-3d8a58d18eed
```

Users:

udev, userspace tools generating synthetic uevents

5.2.30 Symbols under /sys/block

/sys/block/*/device/cdl_enable

Defined on file *sysfs-block-device*

(RW) For a device supporting the command duration limits feature, write to the file to turn on or off the feature. By default this feature is turned off. Writing ”1” to this file enables the use of command duration limits for read and write commands in the kernel and turns on the feature on the device. Writing ”0” disables the feature.

/sys/block/*/device/cdl_supported

Defined on file *sysfs-block-device*

(RO) Indicates if the device supports the command duration limits feature found in some ATA and SCSI devices.

/sys/block/*/device/ncq_prio_enable

Defined on file *sysfs-block-device*

(RW) Write to the file to turn on or off the SATA NCQ (native command queueing) priority support. By default this feature is turned off. If the device does not support the SATA NCQ priority feature, writing "1" to this file results in an error (see ncq_prio_supported).

/sys/block/*/device/ncq_prio_supported

Defined on file *sysfs-block-device*

(RO) Indicates if the device supports the SATA NCQ (native command queueing) priority feature.

/sys/block/*/device/sas_ncq_prio_enable

Defined on file *sysfs-block-device*

(RW) This is the equivalent of the ncq_prio_enable attribute file for SATA devices connected to a SAS host-bus-adapter (HBA) implementing support for the SATA NCQ priority feature. This file does not exist if the HBA driver does not implement support for the SATA NCQ priority feature, regardless of the device support for this feature (see sas_ncq_prio_supported).

/sys/block/*/device/sas_ncq_prio_supported

Defined on file *sysfs-block-device*

(RO) This is the equivalent of the ncq_prio_supported attribute file for SATA devices connected to a SAS host-bus-adapter (HBA) implementing support for the SATA NCQ priority feature. This file does not exist if the HBA driver does not implement support for the SATA NCQ priority feature, regardless of the device support for this feature.

/sys/block/*/device/sw_activity

Defined on file *sysfs-block-device*

(RW) Used by drivers which support software controlled activity LEDs.

It has the following valid values:

0	OFF - the LED is not activated on activity
1	BLINK_ON - the LED blinks on every 10ms when activity is detected.
2	BLINK_OFF - the LED is on when idle, and blinks off every 10ms when activity is detected.

Note that the user must turn sw_activity OFF it they wish to control the activity LED via the em_message file.

/sys/block/*/device/unload_heads

Defined on file *sysfs-block-device*

(RW) Hard disk shock protection

Writing an integer value to this file will take the heads of the respective drive off the platter and block all I/O operations for the specified number of milliseconds.

- If the device does not support the unload heads feature, access is denied with -EOPNOTSUPP.
- The maximal value accepted for a timeout is 30000 milliseconds.
- A previously set timeout can be cancelled and disk can resume normal operation immediately by specifying a timeout of 0.
- Some hard drives only comply with an earlier version of the ATA standard, but support the unload feature nonetheless. There is no safe way Linux can detect these devices, so this is not enabled by default. If it is known that your device does support the unload feature, then you can tell the kernel to enable it by writing -1. It can be disabled again by writing -2.
- Values below -2 are rejected with -EINVAL

For more information, see *Hard disk shock protection*

/sys/block/<device>/iosched/target_latency

Defined on file *sysfs-cfq-target-latency*

The */sys/block/<device>/iosched/target_latency* only exists when the user sets cfq to /sys/block/<device>/scheduler. It contains an estimated latency time for the cfq. cfq will use it to calculate the time slice used for every task.

/sys/block/<disk>/bcache/btree_cache_size

Defined on file *sysfs-block-bcache*

Number of btree buckets/nodes that are currently cached in memory; cache dynamically grows and shrinks in response to memory pressure from the rest of the system.

/sys/block/<disk>/bcache/btree_written

Defined on file *sysfs-block-bcache*

For a cache, sum of all btree writes in human readable units.

/sys/block/<disk>/bcache/bucket_size

Defined on file *sysfs-block-bcache*

For a cache, bucket size in human readable units, as set at cache creation time; should match the erase block size of the SSD for optimal performance.

/sys/block/<disk>/bcache/bypassed

Defined on file *sysfs-block-bcache*

Sum of all reads and writes that have bypassed the cache (due to the sequential cutoff). Expressed as bytes in human readable units.

/sys/block/<disk>/bcache/cache

Defined on file *sysfs-block-bcache*

For a backing device that has cache, a symlink to the bcache/ dir of that cache.

/sys/block/<disk>/bcache/cache_hit_ratio

Defined on file *sysfs-block-bcache*

For backing devices: cache hits as a percentage.

/sys/block/<disk>/bcache/cache_hits

Defined on file *sysfs-block-bcache*

For backing devices: integer number of full cache hits, counted per bio. A partial cache hit counts as a miss.

/sys/block/<disk>/bcache/cache_misses

Defined on file *sysfs-block-bcache*

For backing devices: integer number of cache misses.

/sys/block/<disk>/bcache/clear_stats

Defined on file *sysfs-block-bcache*

Writing to this file resets all the statistics for the device.

/sys/block/<disk>/bcache/discard

Defined on file *sysfs-block-bcache*

For a cache, a boolean allowing discard/TRIM to be turned off or back on if the device supports it.

/sys/block/<disk>/bcache/nbuckets

Defined on file *sysfs-block-bcache*

For a cache, the number of usable buckets.

/sys/block/<disk>/bcache/sequential_cutoff

Defined on file *sysfs-block-bcache*

For backing devices: Threshold past which sequential IO will skip the cache. Read and written as bytes in human readable units (i.e. echo 10M > sequntial_cutoff).

/sys/block/<disk>/bcache/synchronous

Defined on file *sysfs-block-bcache*

For a cache, a boolean that allows synchronous mode to be switched on and off. In synchronous mode all writes are ordered such that the cache can reliably recover from unclean shutdown; if disabled bcache will not generally wait for writes to complete but if the cache is not shut down cleanly all data will be discarded from the cache. Should not be turned off with writeback caching enabled.

/sys/block/<disk>/bcache/tree_depth

Defined on file *sysfs-block-bcache*

For a cache, height of the btree excluding leaf nodes (i.e. a one node tree will have a depth of 0).

/sys/block/<disk>/bcache/unregister

Defined on file *sysfs-block-bcache*

A write to this file causes the backing device or cache to be unregistered. If a backing device had dirty data in the cache, writeback mode is automatically disabled and all dirty data is flushed before the device is unregistered. Caches unregister all associated backing devices before unregistering themselves.

/sys/block/<disk>/bcache/writeback

Defined on file *sysfs-block-bcache*

For backing devices: When on, writeback caching is enabled and writes will be buffered in the cache. When off, caching is in writethrough mode; reads and writes will be added to the cache but no write buffering will take place.

/sys/block/<disk>/bcache/writeback_delay

Defined on file *sysfs-block-bcache*

For backing devices: In writeback mode, when dirty data is written to the cache and the cache held no dirty data for that backing device, writeback from cache to backing device starts after this delay, expressed as an integer number of seconds.

/sys/block/<disk>/bcache/writeback_percent

Defined on file *sysfs-block-bcache*

For backing devices: If nonzero, writeback from cache to backing device only takes place when more than this percentage of the cache is used, allowing more write coalescing to take place and reducing total number of writes sent to the backing device. Integer between 0 and 40.

/sys/block/<disk>/bcache/writeback_running

Defined on file *sysfs-block-bcache*

For backing devices: when off, dirty data will not be written from the cache to the backing device. The cache will still be used to buffer writes until it is mostly full, at which point writes transparently revert to writethrough mode. Intended only for benchmarking/testing.

/sys/block/<disk>/bcache/written

Defined on file *sysfs-block-bcache*

For a cache, total amount of data in human readable units written to the cache, excluding all metadata.

/sys/block/dm-<num>/dm/name

Defined on file *sysfs-block-dm*

Device-mapper device name. Read-only string containing mapped device name.

Users: util-linux, device-mapper udev rules

/sys/block/dm-<num>/dm/rq_based_seq_io_merge_deadline

Defined on file *sysfs-block-dm*

Allow control over how long a request that is a reasonable merge candidate can be queued on the request queue. The resolution of this deadline is in microseconds (ranging from 1 to 100000 usecs). Setting this attribute to 0 (the default) will disable request-based DM's merge heuristic and associated extra accounting. This attribute is not applicable to bio-based DM devices so it will only ever report 0 for them.

/sys/block/dm-<num>/dm/suspended

Defined on file *sysfs-block-dm*

Device-mapper device suspend state. Contains the value 1 while the device is suspended. Otherwise it contains 0. Read-only attribute.

Users: util-linux, device-mapper udev rules

/sys/block/dm-<num>/dm/use_blk_mq

Defined on file *sysfs-block-dm*

Request-based Device-mapper blk-mq I/O path mode. Contains the value 1 if the device is using blk-mq. Otherwise it contains 0. Read-only attribute.

/sys/block/dm-<num>/dm/uuid

Defined on file *sysfs-block-dm*

Device-mapper device UUID. Read-only string containing DM-UUID or empty string if DM-UUID is not set.

Users: util-linux, device-mapper udev rules

/sys/block/etherd*/firmware-version

Defined on file *sysfs-block-aoe*

(RO) Version of the firmware in the target.

/sys/block/etherd*/mac

Defined on file *sysfs-block-aoe*

(RO) The ethernet address of the remote Ata over Ethernet (AoE) device.

/sys/block/etherd*/netif

Defined on file *sysfs-block-aoe*

(RO) The names of the network interfaces on the localhost (comma separated) through which we are communicating with the remote AoE device.

/sys/block/etherd*/payload

Defined on file *sysfs-block-aoe*

(RO) The amount of user data transferred (in bytes) inside each AoE command on the network, network headers excluded.

/sys/block/etherd*/state

Defined on file *sysfs-block-aoe*

(RO) Device status. The state attribute is ”up” when the device is ready for I/O and ”down” if detected but unusable. The ”down,closewait” state shows that the device is still open and cannot come up again until it has been closed. The ”up,kickme” state means that the driver wants to send more commands to the target but found out there were already the max number of commands waiting for a response. It will retry again after being kicked by the periodic timer handler routine.

/sys/block/loopX/loop/autoclear

Defined on file *sysfs-block-loop*

(RO) Shows if the device is in autoclear mode or not (”1” or ”0”). Autoclear (if set) indicates that the loopback device will self-distruct after last close.

/sys/block/loopX/loop/backing_file

Defined on file *sysfs-block-loop*

(RO) The path of the backing file that the loop device maps its data blocks to.

/sys/block/loopX/loop/dio

Defined on file *sysfs-block-loop*

(RO) Shows if direct IO is being used to access backing file or not (”1 or ”0”).

/sys/block/loopX/loop/offset

Defined on file *sysfs-block-loop*

(RO) Start offset (in bytes).

/sys/block/loopX/loop/partscan

Defined on file *sysfs-block-loop*

(RO) Shows if automatic partition scanning is enabled for the device or not (”1” or ”0”). This can be requested individually per loop device during its setup by setting LO_FLAGS_PARTSCAN in in the ioctl request. By default, no partition tables are scanned.

/sys/block/loopX/loop/sizelimit

Defined on file *sysfs-block-loop*

(RO) The size (in bytes) that the block device maps, starting from the offset.

/sys/block/rnbd<N>/rnbd/access_mode

Defined on file *sysfs-block-rnbd*

Contains the device access mode: ro, rw or migration.

/sys/block/rnbd<N>/rnbd/mapping_path

Defined on file *sysfs-block-rnbd*

Contains the path that was passed as ”device_path” to the map_device operation.

/sys/block/rnbd<N>/rnbd/nr_poll_queues

Defined on file *sysfs-block-rnbd*

Contains the number of poll-mode queues

/sys/block/rnbd<N>/rnbd/remap_device

Defined on file *sysfs-block-rnbd*

Remap the disconnected device if the session is not destroyed yet.

/sys/block/rnbd<N>/rnbd/resize

Defined on file *sysfs-block-rnbd*

Write the number of sectors to change the size of the disk.

/sys/block/rnbd<N>/rnbd/session

Defined on file *sysfs-block-rnbd*

RNBD uses RTRS session to transport the data between client and server. The entry "session" contains the name of the session, that was used to establish the RTRS session. It's the same name that was passed as server parameter to the map_device entry.

/sys/block/rnbd<N>/rnbd/state

Defined on file *sysfs-block-rnbd*

The file contains the current state of the block device. The state file returns "open" when the device is successfully mapped from the server and accepting I/O requests. When the connection to the server gets disconnected in case of an error (e.g. link failure), the state file returns "closed" and all I/O requests submitted to it will fail with -EIO.

/sys/block/rnbd<N>/rnbd/unmap_device

Defined on file *sysfs-block-rnbd*

To unmap a volume, "normal" or "force" has to be written to: */sys/block/rnbd<N>/rnbd/unmap_device*

When "normal" is used, the operation will fail with EBUSY if any process is using the device. When "force" is used, the device is also unmapped when device is in use. All I/Os that are in progress will fail.

Example:

```
# echo "normal" > /sys/block/rnbd0/rnbd/unmap_device
```

/sys/block/rssd*/status

Defined on file *sysfs-block-rssd*

This is a read-only file. Indicates the status of the device.

/sys/block/zram<id>/backing_dev

Defined on file *sysfs-block-zram*

The backing_dev file is read-write and set up backing device for zram to write incompressible pages. For using, user should enable CONFIG_ZRAM_WRITEBACK.

/sys/block/zram<id>/bd_stat

Defined on file *sysfs-block-zram*

The bd_stat file is read-only and represents backing device's statistics (bd_count, bd_reads, bd_writes) in a format similar to block layer statistics file format.

/sys/block/zram<id>/comp_algorithm

Defined on file *sysfs-block-zram*

The comp_algorithm file is read-write and lets to show available and selected compression algorithms, change compression algorithm selection.

/sys/block/zram<id>/compact

Defined on file *sysfs-block-zram*

The compact file is write-only and trigger compaction for allocator zrm uses. The allocator moves some objects so that it could free fragment space.

/sys/block/zram<id>/debug_stat

Defined on file *sysfs-block-zram*

The debug_stat file is read-only and represents various device's debugging info useful for kernel developers. Its format is not documented intentionally and may change anytime without any notice.

/sys/block/zram<id>/disksize

Defined on file *sysfs-block-zram*

The disksize file is read-write and specifies the disk size which represents the limit on the *uncompressed* worth of data that can be stored in this disk. Unit: bytes

/sys/block/zram<id>/idle

Defined on file *sysfs-block-zram*

idle file is write-only and mark zram slot as idle. If system has mounted debugfs, user can see which slots are idle via /sys/kernel/debug/zram/zram<id>/block_state

/sys/block/zram<id>/initstate

Defined on file *sysfs-block-zram*

The initstate file is read-only and shows the initialization state of the device.

/sys/block/zram<id>/io_stat

Defined on file *sysfs-block-zram*

The io_stat file is read-only and accumulates device's I/O statistics not accounted by block layer. For example, failed_reads, failed_writes, etc. File format is similar to block layer statistics file format.

/sys/block/zram<id>/max_comp_streams

Defined on file *sysfs-block-zram*

The max_comp_streams file is read-write and specifies the number of backend's zcomp_strm compression streams (number of concurrent compress operations).

/sys/block/zram<id>/mem_limit

Defined on file *sysfs-block-zram*

The mem_limit file is write-only and specifies the maximum amount of memory ZRAM can use to store the compressed data. The limit could be changed in run time and "0" means disable the limit. No limit is the initial state. Unit: bytes

/sys/block/zram<id>/mem_used_max

Defined on file *sysfs-block-zram*

The mem_used_max file is write-only and is used to reset the counter of maximum memory zram have consumed to store compressed data. For resetting the value, you should write "0". Otherwise, you could see -EINVAL. Unit: bytes

/sys/block/zram<id>/mm_stat

Defined on file *sysfs-block-zram*

The mm_stat file is read-only and represents device's mm statistics (orig_data_size, compr_data_size, etc.) in a format similar to block layer statistics file format.

/sys/block/zram<id>/recomp_algorithm

Defined on file *sysfs-block-zram*

The recomp_algorithm file is read-write and allows to set or show secondary compression algorithms.

/sys/block/zram<id>/recompress

Defined on file *sysfs-block-zram*

The recompress file is write-only and triggers re-compression with secondary compression algorithms.

/sys/block/zram<id>/reset

Defined on file *sysfs-block-zram*

The reset file is write-only and allows resetting the device. The reset operation frees all the memory associated with this device.

/sys/block/zram<id>/writeback

Defined on file *sysfs-block-zram*

The writeback file is write-only and trigger idle and/or huge page writeback to backing device.

/sys/block/zram<id>/writeback_limit

Defined on file *sysfs-block-zram*

The writeback_limit file is read-write and specifies the maximum amount of writeback ZRAM can do. The limit could be changed in run time.

/sys/block/zram<id>/writeback_limit_enable

Defined on file *sysfs-block-zram*

The writeback_limit_enable file is read-write and specifies eanbe of writeback_limit feature. "1" means eable the feature. No limit "0" is the initial state.

5.2.31 Symbols under /sys/bus

/sys/bus/*/drivers/ufshcd/*/auto_hibern8

Defined on file *sysfs-driver-ufs*

This file contains the auto-hibernate idle timer setting of a UFS host controller. A value of '0' means auto-hibernate is not enabled. Otherwise the value is the number of microseconds of idle time before the UFS host controller will autonomously put the link into hibernate state. That will save power at the expense of increased latency. Note that the hardware supports 10-bit values with a power-of-ten multiplier which allows a maximum value of 102300000. Refer to the UFS Host Controller Interface specification for more details.

/sys/bus/.../drivers/intel-m10-bmc/.../bmc_version

Defined on file *sysfs-driver-intel-m10-bmc*

Read only. Returns the hardware build version of Intel MAX10 BMC chip. Format: "0x%x".

/sys/bus/.../drivers/intel-m10-bmc/.../bmcfw_version

Defined on file *sysfs-driver-intel-m10-bmc*

Read only. Returns the firmware version of Intel MAX10 BMC chip. Format: "0x%x".

/sys/bus/.../drivers/intel-m10-bmc/.../mac_address

Defined on file *sysfs-driver-intel-m10-bmc*

Read only. Returns the first MAC address in a block of sequential MAC addresses assigned to the board that is managed by the Intel MAX10 BMC. It is stored in FLASH storage and is mirrored in the MAX10 BMC register space. Format: "%02x:%02x:%02x:%02x:%02x:%02x".

/sys/bus/.../drivers/intel-m10-bmc/.../mac_count

Defined on file *sysfs-driver-intel-m10-bmc*

Read only. Returns the number of sequential MAC addresses assigned to the board managed by the Intel MAX10 BMC. This value is stored in FLASH and is mirrored in the MAX10 BMC register space. Format: "%u".

/sys/bus/acpi/devices/.../adr

Defined on file *sysfs-bus-acpi*

This attribute contains the output of the device object's _ADR control method, which is present for ACPI device objects representing devices having standard enumeration algorithms, such as PCI.

/sys/bus/acpi/devices/.../description

Defined on file *sysfs-bus-acpi*

This attribute contains the output of the device object's _STR control method, if present.

/sys/bus/acpi/devices/.../eject

Defined on file *sysfs-bus-acpi*

Writing 1 to this attribute will trigger hot removal of this device object. This file exists for every device object that has _EJ0 method.

/sys/bus/acpi/devices/.../hid

Defined on file *sysfs-bus-acpi*

This attribute indicates the hardware ID (_HID) of the device object. For example, PNP0103. This file is present for device objects having the _HID control method.

/sys/bus/acpi/devices/.../hrv

Defined on file *sysfs-bus-acpi*

(RO) Allows users to read the hardware version of non-PCI hardware, if the _HRV control method is present. It is mostly useful for non-PCI devices because lspci can list the hardware version for PCI devices.

/sys/bus/acpi/devices/.../modalias

Defined on file *sysfs-bus-acpi*

This attribute indicates the PNP IDs of the device object. That is acpi:HHHHHHHH:[CCCCCCC:]. Where each HHHHHHHH or CCCCCCCC contains device object's PNPID (_HID or _CID).

/sys/bus/acpi/devices/.../path

Defined on file *sysfs-bus-acpi*

This attribute indicates the full path of ACPI namespace object associated with the device object. For example, _SB_.PCI0.

This file is not present for device objects representing fixed ACPI hardware features (like power and sleep buttons).

/sys/bus/acpi/devices/.../status

Defined on file *sysfs-bus-acpi*

(RO) Returns the ACPI device status: enabled, disabled or functioning or present, if the method _STA is present.

The return value is a decimal integer representing the device's status bitmap:

Bit [0]	Set if the device is present.
Bit [1]	Set if the device is enabled and decoding its resources.
Bit [2]	Set if the device should be shown in the UI.
Bit [3]	Set if the device is functioning properly (cleared if device failed its diagnostics).
Bit [4]	Set if the battery is present.
Bits [31:5]	Reserved (must be cleared)

If bit [0] is clear, then bit 1 must also be clear (a device that is not present cannot be enabled).

Bit 0 can be clear (not present) with bit [3] set (device is functional). This case is used to indicate a valid device for which no device driver should be loaded.

More special cases are covered in the ACPI specification.

/sys/bus/acpi/devices/.../uid

Defined on file *sysfs-bus-acpi*

This attribute contains the output of the device object's _UID control method, if present.

/sys/bus/acpi/intel-rapid-start/wakeup_events

Defined on file *sysfs-driver-intel-rapid-start*

An integer representing a set of wakeup events as follows: 1: Wake to enter hibernation when the wakeup timer expires 2: Wake to enter hibernation when the battery reaches a critical level

These values are ORed together. For example, a value of 3 indicates that the system will wake to enter hibernation when either the wakeup timer expires or the battery reaches a critical level.

/sys/bus/acpi/intel-rapid-start/wakeup_time

Defined on file *sysfs-driver-intel-rapid-start*

An integer representing the length of time the system will remain asleep before waking up to enter hibernation. This value is in minutes.

/sys/bus/amba/devices/.../driver_override

Defined on file *sysfs-bus-amba*

This file allows the driver for a device to be specified which will override standard OF, ACPI, ID table, and name matching. When specified, only a driver with a name matching the value written to driver_override will have an opportunity to bind to the device. The override is specified by writing a string to the driver_override file (echo vfio-amba > driver_override) and may be cleared with an empty string (echo > driver_override). This returns the device to standard matching rules binding. Writing to driver_override does not automatically unbind the device from its current driver or make any attempt to automatically load the specified driver. If no driver with a matching name is currently loaded in the kernel, the device will not bind to any driver. This also allows devices to opt-out of driver binding using a driver_override name such as "none". Only a single driver may be specified in the override, there is no support for parsing delimiters.

/sys/bus/auxiliary/devices/intel_vsec.sdsi.X

Defined on file *sysfs-driver-intel_sdsi*

This directory contains interface files for accessing Intel On Demand (formerly Software Defined Silicon or SDSi) features on a CPU. X represents the socket instance (though not the socket ID). The socket ID is determined by reading the registers file and decoding it per the specification.

Some files communicate with On Demand hardware through a mailbox. Should the operation fail, one of the following error codes may be returned:

Error Code	Cause
EIO	General mailbox failure. Log may indicate cause.
EBUSY	Mailbox is owned by another agent.
EPERM	On Demand capability is not enabled in hardware.
EPROTO	Failure in mailbox protocol detected by driver. See log for details.
EOVERFLOW	For provision commands, the size of the data exceeds what may be written.
ESPIPE	Seeking is not allowed.
ETIMEDOUT	Failure to complete mailbox transaction in time.

/sys/bus/auxiliary/devices/intel_vsec.sdsi.X/guid

Defined on file *sysfs-driver-intel_sdsi*

(RO) The GUID for the registers file. The GUID identifies the layout of the registers file in this directory. Information about the register layouts for a particular GUID is available at http://github.com/intel/intel-sdsi

/sys/bus/auxiliary/devices/intel_vsec.sdsi.X/meter_certificate

Defined on file *sysfs-driver-intel_sdsi*

(RO) Used to read back the current meter certificate for the CPU from Intel On Demand hardware. The meter certificate contains utilization metrics of On Demand enabled features. Mailbox command.

/sys/bus/auxiliary/devices/intel_vsec.sdsi.X/provision_akc

Defined on file *sysfs-driver-intel_sdsi*

(WO) Used to write an Authentication Key Certificate (AKC) to the On Demand NVRAM for the CPU. The AKC is used to authenticate a Capability Activation Payload. Mailbox command.

/sys/bus/auxiliary/devices/intel_vsec.sdsi.X/provision_cap

Defined on file *sysfs-driver-intel_sdsi*

(WO) Used to write a Capability Activation Payload (CAP) to the On Demand NVRAM for the CPU. CAPs are used to activate a given CPU feature. A CAP is validated by On Demand hardware using a previously provisioned AKC file. Upon successful authentication, the CPU configuration is updated. A cold reboot is required to fully activate the feature. Mailbox command.

/sys/bus/auxiliary/devices/intel_vsec.sdsi.X/registers

Defined on file *sysfs-driver-intel_sdsi*

(RO) Contains information needed by applications to provision a CPU and monitor status information. The layout of this file is determined by the GUID in this directory. Information about the layout for a particular GUID is available at http://github.com/intel/intel-sdsi

/sys/bus/auxiliary/devices/intel_vsec.sdsi.X/state_certificate

Defined on file *sysfs-driver-intel_sdsi*

(RO) Used to read back the current state certificate for the CPU from On Demand hardware. The state certificate contains information about the current licenses on the CPU. Mailbox command.

/sys/bus/bcma/devices/.../class

Defined on file *sysfs-bus-bcma*

Each BCMA core is identified by few fields, including class it belongs to. See include/linux/bcma/bcma.h for possible values.

/sys/bus/bcma/devices/.../id

Defined on file *sysfs-bus-bcma*

There are a few types of BCMA cores, they can be identified by id field.

/sys/bus/bcma/devices/.../manuf

Defined on file *sysfs-bus-bcma*

Each BCMA core has its manufacturer id. See include/linux/bcma/bcma.h for possible values.

/sys/bus/bcma/devices/.../rev

Defined on file *sysfs-bus-bcma*

BCMA cores of the same type can still slightly differ depending on their revision. Use it for detailed programming.

/sys/bus/cdx/devices/.../class

Defined on file *sysfs-bus-cdx*

This file contains the class of the CDX device, in hexadecimal. Class is 24 bit identifier specifies the functionality of the device.

/sys/bus/cdx/devices/.../device

Defined on file *sysfs-bus-cdx*

Device ID for this CDX device, in hexadecimal. Device ID is 16 bit identifier to identify a device type within the range of a device manufacturer. Combination of Vendor ID and Device ID identifies a device.

/sys/bus/cdx/devices/.../enable

Defined on file *sysfs-bus-cdx*

CDX bus should be disabled before updating the devices in FPGA. Writing n/0/off will attempt to disable the CDX bus and. writing y/1/on will attempt to enable the CDX bus. Reading this file gives the current state of the bus, 1 for enabled and 0 for disabled.

For example:

```
# echo 1 > /sys/bus/cdx/.../enable
```

/sys/bus/cdx/devices/.../modalias

Defined on file *sysfs-bus-cdx*

This attribute indicates the CDX ID of the device. That is in the format: cdx:vXXXXdXXXXsvXXXXsdXXXXcXXXXXX, where:

- vXXXX contains the vendor ID;
- dXXXX contains the device ID;
- svXXXX contains the subsystem vendor ID;
- sdXXXX contains the subsystem device ID;
- cXXXXXX contains the device class.

/sys/bus/cdx/devices/.../remove

Defined on file *sysfs-bus-cdx*

Writing y/1/on to this file removes the corresponding device from the CDX bus. If the device is to be reconfigured reconfigured in the Hardware, the device can be removed, so that the device driver does not access the device while it is being reconfigured.

For example:

```
# echo 1 > /sys/bus/cdx/devices/.../remove
```

/sys/bus/cdx/devices/.../reset

Defined on file *sysfs-bus-cdx*

Writing y/1/on to this file resets the CDX device or all devices on the bus. On resetting the device, the corresponding driver is notified twice, once before the device is being reset, and again after the reset has been complete.

For example:

```
# echo 1 > /sys/bus/cdx/.../reset
```

/sys/bus/cdx/devices/.../resource<N>

Defined on file *sysfs-bus-cdx*

The resource binary file contains the content of the memory regions. These files can be m'maped from userspace.

/sys/bus/cdx/devices/.../revision

Defined on file *sysfs-bus-cdx*

This file contains the revision field of the CDX device, in hexadecimal. Revision is 8 bit revision identifier of the device.

/sys/bus/cdx/devices/.../subsystem_device

Defined on file *sysfs-bus-cdx*

Subsystem Device ID for this CDX device, in hexadecimal Subsystem Device ID is 16 bit identifier specific to the card manufacturer.

/sys/bus/cdx/devices/.../subsystem_vendor

Defined on file *sysfs-bus-cdx*

Subsystem Vendor ID for this CDX device, in hexadecimal. Subsystem Vendor ID is 16 bit identifier specific to the card manufacturer.

/sys/bus/cdx/devices/.../vendor

Defined on file *sysfs-bus-cdx*

Vendor ID for this CDX device, in hexadecimal. Vendor ID is 16 bit identifier which is specific to the device manufacturer. Combination of Vendor ID and Device ID identifies a device.

/sys/bus/cdx/rescan

Defined on file *sysfs-bus-cdx*

Writing y/1/on to this file will cause rescan of the bus and devices on the CDX bus. Any new devices are scanned and added to the list of Linux devices and any devices removed are also deleted from Linux.

For example:

```
# echo 1 > /sys/bus/cdx/rescan
```

/sys/bus/coreboot

Defined on file *sysfs-bus-coreboot*

The coreboot bus provides a variety of virtual devices used to access data structures created by the Coreboot BIOS.

/sys/bus/coreboot/devices/cbmem-<id>

Defined on file *sysfs-bus-coreboot*

CBMEM is a downwards-growing memory region created by Coreboot, and contains tagged data structures to be shared with payloads in the boot process and the OS. Each CBMEM entry is given a directory in /sys/bus/coreboot/devices based on its id. A list of ids known to Coreboot can be found in the coreboot source tree at `src/commonlib/bsd/include/commonlib/bsd/cbmem_id.h`.

/sys/bus/coreboot/devices/cbmem-<id>/address

Defined on file *sysfs-bus-coreboot*

This is the physical memory address that the CBMEM entry's data begins at, in hexadecimal (e.g., `0x76ffe000`).

/sys/bus/coreboot/devices/cbmem-<id>/mem

Defined on file *sysfs-bus-coreboot*

A file exposing read/write access to the entry's data. Note that this file does not support mmap(), as coreboot does not guarantee that the data will be page-aligned.

The mode of this file is 0600. While there shouldn't be anything security-sensitive contained in CBMEM, read access requires root privileges given this is exposing a small subset of physical memory.

/sys/bus/coreboot/devices/cbmem-<id>/size

Defined on file *sysfs-bus-coreboot*

This is the size of the CBMEM entry's data, in hexadecimal (e.g., `0x1234`).

/sys/bus/coresight/devices/<cti-name>/channels/chan_clear

Defined on file *sysfs-bus-coresight-devices-cti*

(Write) Deactivate a single channel.

/sys/bus/coresight/devices/<cti-name>/channels/chan_free

Defined on file *sysfs-bus-coresight-devices-cti*

(Read) show channels with no attached trigger signals.

/sys/bus/coresight/devices/<cti-name>/channels/chan_gate_disable

Defined on file *sysfs-bus-coresight-devices-cti*

(Write) Disable CTIGATE for single channel.

/sys/bus/coresight/devices/<cti-name>/channels/chan_gate_enable

Defined on file *sysfs-bus-coresight-devices-cti*

(RW) Enable CTIGATE for single channel (Write) or list enabled channels through the gate (R).

/sys/bus/coresight/devices/<cti-name>/channels/chan_inuse

Defined on file *sysfs-bus-coresight-devices-cti*

(Read) show channels with at least one attached trigger signal.

/sys/bus/coresight/devices/<cti-name>/channels/chan_pulse

Defined on file *sysfs-bus-coresight-devices-cti*

(Write) Pulse a single channel - activate for a single clock cycle.

/sys/bus/coresight/devices/<cti-name>/channels/chan_set

Defined on file *sysfs-bus-coresight-devices-cti*

(Write) Activate a single channel.

/sys/bus/coresight/devices/<cti-name>/channels/chan_xtrigs_in

Defined on file *sysfs-bus-coresight-devices-cti*

(Read) Read to see input triggers connected to selected view channel.

/sys/bus/coresight/devices/<cti-name>/channels/chan_xtrigs_out

Defined on file *sysfs-bus-coresight-devices-cti*

(Read) Read to see output triggers connected to selected view channel.

/sys/bus/coresight/devices/<cti-name>/channels/chan_xtrigs_reset

Defined on file *sysfs-bus-coresight-devices-cti*

(Write) Clear all channel / trigger programming.

/sys/bus/coresight/devices/<cti-name>/channels/chan_xtrigs_sel

Defined on file *sysfs-bus-coresight-devices-cti*

(RW) Write channel number to select a channel to view, read to see selected channel number.

/sys/bus/coresight/devices/<cti-name>/channels/trig_filter_enable

Defined on file *sysfs-bus-coresight-devices-cti*

(RW) Enable or disable trigger output signal filtering.

/sys/bus/coresight/devices/<cti-name>/channels/trigin_attach

Defined on file *sysfs-bus-coresight-devices-cti*

(Write) Attach a CTI input trigger to a CTM channel.

/sys/bus/coresight/devices/<cti-name>/channels/trigin_detach

Defined on file *sysfs-bus-coresight-devices-cti*

(Write) Detach a CTI input trigger from a CTM channel.

/sys/bus/coresight/devices/<cti-name>/channels/trigout_attach

Defined on file *sysfs-bus-coresight-devices-cti*

(Write) Attach a CTI output trigger to a CTM channel.

/sys/bus/coresight/devices/<cti-name>/channels/trigout_detach

Defined on file *sysfs-bus-coresight-devices-cti*

(Write) Detach a CTI output trigger from a CTM channel.

/sys/bus/coresight/devices/<cti-name>/channels/trigout_filtered

Defined on file *sysfs-bus-coresight-devices-cti*

(Read) List of output triggers filtered across all connections.

/sys/bus/coresight/devices/<cti-name>/ctmid

Defined on file *sysfs-bus-coresight-devices-cti*

(Read) Display the associated CTM ID

/sys/bus/coresight/devices/<cti-name>/enable

Defined on file *sysfs-bus-coresight-devices-cti*

(RW) Enable/Disable the CTI hardware.

/sys/bus/coresight/devices/<cti-name>/nr_trigger_cons

Defined on file *sysfs-bus-coresight-devices-cti*

(Read) Number of devices connected to triggers on this CTI

/sys/bus/coresight/devices/<cti-name>/powered

Defined on file *sysfs-bus-coresight-devices-cti*

(Read) Indicate if the CTI hardware is powered.

/sys/bus/coresight/devices/<cti-name>/regs/appclear

Defined on file *sysfs-bus-coresight-devices-cti*

(Write) Write APPCLEAR register to deactivate channel.

/sys/bus/coresight/devices/<cti-name>/regs/apppulse

Defined on file *sysfs-bus-coresight-devices-cti*

(Write) Write APPPULSE to pulse a channel active for one clock cycle.

/sys/bus/coresight/devices/<cti-name>/regs/appset

Defined on file *sysfs-bus-coresight-devices-cti*

(RW) Set CTIAPPSET register to activate channel. Read back to determine current value of register.

/sys/bus/coresight/devices/<cti-name>/regs/asicctl

Defined on file *sysfs-bus-coresight-devices-cti*

(RW) Read or write ASICCTL register.

/sys/bus/coresight/devices/<cti-name>/regs/chinstatus

Defined on file *sysfs-bus-coresight-devices-cti*

(Read) Read current status of channel inputs.

/sys/bus/coresight/devices/<cti-name>/regs/choutstatus

Defined on file *sysfs-bus-coresight-devices-cti*

(Read) read current status of channel outputs.

/sys/bus/coresight/devices/<cti-name>/regs/gate

Defined on file *sysfs-bus-coresight-devices-cti*

(RW) Read or write CTIGATE register.

/sys/bus/coresight/devices/<cti-name>/regs/inen

Defined on file *sysfs-bus-coresight-devices-cti*

(RW) Read or write the CTIINEN register selected by inout_sel.

/sys/bus/coresight/devices/<cti-name>/regs/inout_sel

Defined on file *sysfs-bus-coresight-devices-cti*

(RW) Select the index for inen and outen registers.

/sys/bus/coresight/devices/<cti-name>/regs/intack

Defined on file *sysfs-bus-coresight-devices-cti*

(Write) Write the INTACK register.

/sys/bus/coresight/devices/<cti-name>/regs/outen

Defined on file *sysfs-bus-coresight-devices-cti*

(RW) Read or write the CTIOUTEN register selected by inout_sel.

/sys/bus/coresight/devices/<cti-name>/regs/triginstatus

Defined on file *sysfs-bus-coresight-devices-cti*

(Read) read current status of input trigger signals

/sys/bus/coresight/devices/<cti-name>/regs/trigoutstatus

Defined on file *sysfs-bus-coresight-devices-cti*

(Read) read current status of output trigger signals.

/sys/bus/coresight/devices/<cti-name>/triggers<N>/in_signals

Defined on file *sysfs-bus-coresight-devices-cti*

(Read) Input trigger signals from connected device <N>

/sys/bus/coresight/devices/<cti-name>/triggers<N>/in_types

Defined on file *sysfs-bus-coresight-devices-cti*

(Read) Functional types for the input trigger signals from connected device <N>

/sys/bus/coresight/devices/<cti-name>/triggers<N>/name

Defined on file *sysfs-bus-coresight-devices-cti*

(Read) Name of connected device <N>

/sys/bus/coresight/devices/<cti-name>/triggers<N>/out_signals

Defined on file *sysfs-bus-coresight-devices-cti*

(Read) Output trigger signals to connected device <N>

/sys/bus/coresight/devices/<cti-name>/triggers<N>/out_types

Defined on file *sysfs-bus-coresight-devices-cti*

(Read) Functional types for the output trigger signals to connected device <N>

/sys/bus/coresight/devices/<memory_map>.[etm|ptm]/addr_acctype

Defined on file *sysfs-bus-coresight-devices-etm3x*

(RW) Used in conjunction with @addr_idx. Specifies characteristics about the address comparator being configure, for example the access type, the kind of instruction to trace, processor contect ID to trigger on, etc. Individual fields in the access type register may vary on the version of the trace entity.

/sys/bus/coresight/devices/<memory_map>.[etm|ptm]/addr_idx

Defined on file *sysfs-bus-coresight-devices-etm3x*

Select which address comparator or pair (of comparators) to work with.

/sys/bus/coresight/devices/<memory_map>.[etm|ptm]/addr_range

Defined on file *sysfs-bus-coresight-devices-etm3x*

(RW) Used in conjunction with @addr_idx. Specifies the range of addresses to trigger on. Inclusion or exclusion is specified in the corresponding access type register.

/sys/bus/coresight/devices/<memory_map>.[etm|ptm]/addr_single

Defined on file *sysfs-bus-coresight-devices-etm3x*

(RW) Used in conjunction with @addr_idx. Specifies the single address to trigger on, highly influenced by the configuration options of the corresponding access type register.

/sys/bus/coresight/devices/<memory_map>.[etm|ptm]/addr_start

Defined on file *sysfs-bus-coresight-devices-etm3x*

(RW) Used in conjunction with @addr_idx. Specifies the single address to start tracing on, highly influenced by the configuration options of the corresponding access type register.

/sys/bus/coresight/devices/<memory_map>.[etm|ptm]/addr_stop

Defined on file *sysfs-bus-coresight-devices-etm3x*

(RW) Used in conjunction with @addr_idx. Specifies the single address to stop tracing on, highly influenced by the configuration options of the corresponding access type register.

/sys/bus/coresight/devices/<memory_map>.[etm|ptm]/cntr_event

Defined on file *sysfs-bus-coresight-devices-etm3x*

(RW) Used in conjunction with cntr_idx, give access to the counter event register.

/sys/bus/coresight/devices/<memory_map>.[etm|ptm]/cntr_idx

Defined on file *sysfs-bus-coresight-devices-etm3x*

(RW) Specifies the counter to work on.

/sys/bus/coresight/devices/<memory_map>.[etm|ptm]/cntr_rld_event

Defined on file *sysfs-bus-coresight-devices-etm3x*

(RW) Used in conjunction with cntr_idx, give access to the counter reload event register.

/sys/bus/coresight/devices/<memory_map>.[etm|ptm]/cntr_rld_val

Defined on file *sysfs-bus-coresight-devices-etm3x*

(RW) Used in conjunction with cntr_idx, give access to the counter reload value register.

/sys/bus/coresight/devices/<memory_map>.[etm|ptm]/cntr_val

Defined on file *sysfs-bus-coresight-devices-etm3x*

(RW) Used in conjunction with cntr_idx, give access to the counter value register.

/sys/bus/coresight/devices/<memory_map>.[etm|ptm]/cpu

Defined on file *sysfs-bus-coresight-devices-etm3x*

(RO) Holds the cpu number this tracer is affined to.

/sys/bus/coresight/devices/<memory_map>.[etm|ptm]/ctxid_idx

Defined on file *sysfs-bus-coresight-devices-etm3x*

(RW) Specifies the index of the context ID register to be selected.

/sys/bus/coresight/devices/<memory_map>.[etm|ptm]/ctxid_mask

Defined on file *sysfs-bus-coresight-devices-etm3x*

(RW) Mask to apply to all the context ID comparator.

/sys/bus/coresight/devices/<memory_map>.[etm|ptm]/ctxid_pid

Defined on file *sysfs-bus-coresight-devices-etm3x*

(RW) Used with the ctxid_idx, specify with context ID to trigger on.

/sys/bus/coresight/devices/<memory_map>.[etm|ptm]/curr_seq_state

Defined on file *sysfs-bus-coresight-devices-etm3x*

(Read) Holds the current state of the sequencer.

/sys/bus/coresight/devices/<memory_map>.[etm|ptm]/enable_event

Defined on file *sysfs-bus-coresight-devices-etm3x*

(RW) Defines which event triggers a trace.

/sys/bus/coresight/devices/<memory_map>.[etm|ptm]/enable_source

Defined on file *sysfs-bus-coresight-devices-etm3x*

(RW) Enable/disable tracing on this specific trace entiry. Enabling a source implies the source has been configured properly and a sink has been identidifed for it. The path of coresight components linking the source to the sink is configured and managed automatically by the coresight framework.

/sys/bus/coresight/devices/<memory_map>.[etm|ptm]/etmsr

Defined on file *sysfs-bus-coresight-devices-etm3x*

(RW) Gives access to the ETM status register, which holds programming information and status on certains events.

/sys/bus/coresight/devices/<memory_map>.[etm|ptm]/fifofull_level

Defined on file *sysfs-bus-coresight-devices-etm3x*

(RW) Number of byte left in the fifo before considering it full. Depending on the tracer's version, can also hold threshold for data suppression.

/sys/bus/coresight/devices/<memory_map>.[etm|ptm]/mgmt/etmccer

Defined on file *sysfs-bus-coresight-devices-etm3x*

(RO) Print the content of the ETM Configuration Code Extension register (0x1e8). The value is read directly from the HW.

/sys/bus/coresight/devices/<memory_map>.[etm|ptm]/mgmt/etmccr

Defined on file *sysfs-bus-coresight-devices-etm3x*

(RO) Print the content of the ETM Configuration Code register (0x004). The value is read directly from the HW.

/sys/bus/coresight/devices/<memory_map>.[etm|ptm]/mgmt/etmcr

Defined on file *sysfs-bus-coresight-devices-etm3x*

(RO) Print the content of the ETM Main Control register (0x000). The value is read directly from the HW.

/sys/bus/coresight/devices/<memory_map>.[etm|ptm]/mgmt/etmidr

Defined on file *sysfs-bus-coresight-devices-etm3x*

(RO) Print the content of the ETM ID register (0x1e4). The value is read directly from the HW.

/sys/bus/coresight/devices/<memory_map>.[etm|ptm]/mgmt/etmscr

Defined on file *sysfs-bus-coresight-devices-etm3x*

(RO) Print the content of the ETM System Configuration register (0x014). The value is read directly from the HW.

/sys/bus/coresight/devices/<memory_map>.[etm|ptm]/mgmt/etmtecr1

Defined on file *sysfs-bus-coresight-devices-etm3x*

(RO) Print the content of the ETM Enable Control #1 register (0x024). The value is read directly from the HW.

/sys/bus/coresight/devices/<memory_map>.[etm|ptm]/mgmt/etmtecr2

Defined on file *sysfs-bus-coresight-devices-etm3x*

(RO) Print the content of the ETM Enable Control #2 register (0x01c). The value is read directly from the HW.

/sys/bus/coresight/devices/<memory_map>.[etm|ptm]/mgmt/etmteevr

Defined on file *sysfs-bus-coresight-devices-etm3x*

(RO) Print the content of the ETM Trace Enable Event register (0x020). The value is read directly from the HW.

/sys/bus/coresight/devices/<memory_map>.[etm|ptm]/mgmt/etmtraceidr

Defined on file *sysfs-bus-coresight-devices-etm3x*

(RO) Print the content of the ETM Trace ID register (0x200). The value is read directly from the HW.

/sys/bus/coresight/devices/<memory_map>.[etm|ptm]/mgmt/etmtsscr

Defined on file *sysfs-bus-coresight-devices-etm3x*

(RO) Print the content of the ETM Trace Start/Stop Control register (0x018). The value is read directly from the HW.

/sys/bus/coresight/devices/<memory_map>.[etm|ptm]/mode

Defined on file *sysfs-bus-coresight-devices-etm3x*

(RW) Interface with the driver's 'mode' field, controlling various aspect of the trace entity such as time stamping, context ID size and cycle accurate tracing. Driver specific and bound to change depending on the driver.

/sys/bus/coresight/devices/<memory_map>.[etm|ptm]/nr_addr_cmp

Defined on file *sysfs-bus-coresight-devices-etm3x*

(Read) Provides the number of address comparators pairs accessible on a trace unit, as specified by bit 3:0 of register ETMCCR.

/sys/bus/coresight/devices/<memory_map>.[etm|ptm]/nr_cntr

Defined on file *sysfs-bus-coresight-devices-etm3x*

(Read) Provides the number of counters accessible on a trace unit, as specified by bit 15:13 of register ETMCCR.

/sys/bus/coresight/devices/<memory_map>.[etm|ptm]/nr_ctxid_cmp

Defined on file *sysfs-bus-coresight-devices-etm3x*

(Read) Provides the number of context ID comparator available on a trace unit, as specified by bit 25:24 of register ETMCCR.

/sys/bus/coresight/devices/<memory_map>.[etm|ptm]/reset

Defined on file *sysfs-bus-coresight-devices-etm3x*

(Write) Cancels all configuration on a trace unit and set it back to its boot configuration.

/sys/bus/coresight/devices/<memory_map>.[etm|ptm]/seq_12_event

Defined on file *sysfs-bus-coresight-devices-etm3x*

(RW) Defines the event that causes the sequencer to transition from state 1 to state 2.

/sys/bus/coresight/devices/<memory_map>.[etm|ptm]/seq_13_event

Defined on file *sysfs-bus-coresight-devices-etm3x*

(RW) Defines the event that causes the sequencer to transition from state 1 to state 3.

/sys/bus/coresight/devices/<memory_map>.[etm|ptm]/seq_21_event

Defined on file *sysfs-bus-coresight-devices-etm3x*

(RW) Defines the event that causes the sequencer to transition from state 2 to state 1.

/sys/bus/coresight/devices/<memory_map>.[etm|ptm]/seq_23_event

Defined on file *sysfs-bus-coresight-devices-etm3x*

(RW) Defines the event that causes the sequencer to transition from state 2 to state 3.

/sys/bus/coresight/devices/<memory_map>.[etm|ptm]/seq_31_event

Defined on file *sysfs-bus-coresight-devices-etm3x*

(RW) Defines the event that causes the sequencer to transition from state 3 to state 1.

/sys/bus/coresight/devices/<memory_map>.[etm|ptm]/seq_32_event

Defined on file *sysfs-bus-coresight-devices-etm3x*

(RW) Defines the event that causes the sequencer to transition from state 3 to state 2.

/sys/bus/coresight/devices/<memory_map>.[etm|ptm]/sync_freq

Defined on file *sysfs-bus-coresight-devices-etm3x*

(RW) Holds the trace synchronization frequency value - must be programmed with the various implementation behavior in mind.

/sys/bus/coresight/devices/<memory_map>.[etm|ptm]/timestamp_event

Defined on file *sysfs-bus-coresight-devices-etm3x*

(RW) Defines an event that requests the insertion of a timestamp into the trace stream.

/sys/bus/coresight/devices/<memory_map>.[etm|ptm]/traceid

Defined on file *sysfs-bus-coresight-devices-etm3x*

(RO) Holds the trace ID that will appear in the trace stream coming from this trace entity.

/sys/bus/coresight/devices/<memory_map>.[etm|ptm]/trigger_event

Defined on file *sysfs-bus-coresight-devices-etm3x*

(RW) Define the event that controls the trigger.

/sys/bus/coresight/devices/<memory_map>.etb/enable_sink

Defined on file *sysfs-bus-coresight-devices-etb10*

(RW) Add/remove a sink from a trace path. There can be multiple source for a single sink.

ex:

```
echo 1 > /sys/bus/coresight/devices/20010000.etb/enable_sink
```

/sys/bus/coresight/devices/<memory_map>.etb/mgmt/ctl

Defined on file *sysfs-bus-coresight-devices-etb10*

(Read) Shows the value held by the ETB Control register. The value is read directly from HW register CTL, 0x020.

/sys/bus/coresight/devices/<memory_map>.etb/mgmt/ffcr

Defined on file *sysfs-bus-coresight-devices-etb10*

(Read) Shows the value held by the ETB Formatter and Flush Control register. The value is read directly from HW register FFCR, 0x304.

/sys/bus/coresight/devices/<memory_map>.etb/mgmt/ffsr

Defined on file *sysfs-bus-coresight-devices-etb10*

(Read) Shows the value held by the ETB Formatter and Flush Status register. The value is read directly from HW register FFSR, 0x300.

/sys/bus/coresight/devices/<memory_map>.etb/mgmt/rdp

Defined on file *sysfs-bus-coresight-devices-etb10*

(Read) Defines the depth, in words, of the trace RAM in powers of 2. The value is read directly from HW register RDP, 0x004.

/sys/bus/coresight/devices/<memory_map>.etb/mgmt/rrp

Defined on file *sysfs-bus-coresight-devices-etb10*

(Read) Shows the value held by the ETB RAM Read Pointer register that is used to read entries from the Trace RAM over the APB interface. The value is read directly from HW register RRP, 0x014.

/sys/bus/coresight/devices/<memory_map>.etb/mgmt/rwp

Defined on file *sysfs-bus-coresight-devices-etb10*

(Read) Shows the value held by the ETB RAM Write Pointer register that is used to sets the write pointer to write entries from the CoreSight bus into the Trace RAM. The value is read directly from HW register RWP, 0x018.

/sys/bus/coresight/devices/<memory_map>.etb/mgmt/sts

Defined on file *sysfs-bus-coresight-devices-etb10*

(Read) Shows the value held by the ETB status register. The value is read directly from HW register STS, 0x00C.

/sys/bus/coresight/devices/<memory_map>.etb/mgmt/trg

Defined on file *sysfs-bus-coresight-devices-etb10*

(Read) Similar to ”trigger_cntr” above except that this value is read directly from HW register TRG, 0x01C.

/sys/bus/coresight/devices/<memory_map>.etb/trigger_cntr

Defined on file *sysfs-bus-coresight-devices-etb10*

(RW) Disables write access to the Trace RAM by stopping the formatter after a defined number of words have been stored following the trigger event. The number of 32-bit words written into the Trace RAM following the trigger event is equal to the value stored in this register+1 (from ARM ETB-TRM).

/sys/bus/coresight/devices/<memory_map>.funnel/funnel_ctrl

Defined on file *sysfs-bus-coresight-devices-funnel*

(RW) Enables the slave ports and defines the hold time of the slave ports.

/sys/bus/coresight/devices/<memory_map>.funnel/priority

Defined on file *sysfs-bus-coresight-devices-funnel*

(RW) Defines input port priority order.

/sys/bus/coresight/devices/<memory_map>.stm/enable_source

Defined on file *sysfs-bus-coresight-devices-stm*

(RW) Enable/disable tracing on this specific trace macrocell. Enabling the trace macrocell implies it has been configured properly and a sink has been identified for it. The path of coresight components linking the source to the sink is configured and managed automatically by the coresight framework.

/sys/bus/coresight/devices/<memory_map>.stm/hwevent_enable

Defined on file *sysfs-bus-coresight-devices-stm*

(RW) Provides access to the HW event enable register, used in conjunction with HW event bank select register.

/sys/bus/coresight/devices/<memory_map>.stm/hwevent_select

Defined on file *sysfs-bus-coresight-devices-stm*

(RW) Gives access to the HW event block select register (STMHEBSR) in order to configure up to 256 channels. Used in conjunction with "hwevent_enable" register as described above.

/sys/bus/coresight/devices/<memory_map>.stm/port_enable

Defined on file *sysfs-bus-coresight-devices-stm*

(RW) Provides access to the stimulus port enable register (STMSPER). Used in conjunction with "port_select" described below.

/sys/bus/coresight/devices/<memory_map>.stm/port_select

Defined on file *sysfs-bus-coresight-devices-stm*

(RW) Used to determine which bank of stimulus port bit in register STMSPER (see above) apply to.

/sys/bus/coresight/devices/<memory_map>.stm/status

Defined on file *sysfs-bus-coresight-devices-stm*

(Read) List various control and status registers. The specific layout and content is driver specific.

/sys/bus/coresight/devices/<memory_map>.stm/traceid

Defined on file *sysfs-bus-coresight-devices-stm*

(RW) Holds the trace ID that will appear in the trace stream coming from this trace entity.

/sys/bus/coresight/devices/<memory_map>.tmc/buf_mode_preferred

Defined on file *sysfs-bus-coresight-devices-tmc*

(RW) Current Coresight TMC-ETR buffer mode selected. But user could only provide a mode which is supported for a given ETR device. This file is available only for TMC ETR devices.

/sys/bus/coresight/devices/<memory_map>.tmc/buf_modes_available

Defined on file *sysfs-bus-coresight-devices-tmc*

(Read) Shows all supported Coresight TMC-ETR buffer modes available for the users to configure explicitly. This file is avaialble only for TMC ETR devices.

/sys/bus/coresight/devices/<memory_map>.tmc/buffer_size

Defined on file *sysfs-bus-coresight-devices-tmc*

(RW) Size of the trace buffer for TMC-ETR when used in SYSFS mode. Writable only for TMC-ETR configurations. The value should be aligned to the kernel pagesize.

/sys/bus/coresight/devices/<memory_map>.tmc/mgmt/ctl

Defined on file *sysfs-bus-coresight-devices-tmc*

(Read) Shows the value held by the TMC Control register. The value is read directly from HW register CTL, 0x020.

/sys/bus/coresight/devices/<memory_map>.tmc/mgmt/devid

Defined on file *sysfs-bus-coresight-devices-tmc*

(Read) Indicates the capabilities of the Coresight TMC. The value is read directly from the DEVID register, 0xFC8,

/sys/bus/coresight/devices/<memory_map>.tmc/mgmt/ffcr

Defined on file *sysfs-bus-coresight-devices-tmc*

(Read) Shows the value held by the TMC Formatter and Flush Control register. The value is read directly from HW register FFCR, 0x304.

/sys/bus/coresight/devices/<memory_map>.tmc/mgmt/ffsr

Defined on file *sysfs-bus-coresight-devices-tmc*

(Read) Shows the value held by the TMC Formatter and Flush Status register. The value is read directly from HW register FFSR, 0x300.

/sys/bus/coresight/devices/<memory_map>.tmc/mgmt/mode

Defined on file *sysfs-bus-coresight-devices-tmc*

(Read) Shows the value held by the TMC Mode register, which indicate the mode the device has been configured to enact. The The value is read directly from the MODE register, 0x028.

/sys/bus/coresight/devices/<memory_map>.tmc/mgmt/rrp

Defined on file *sysfs-bus-coresight-devices-tmc*

(Read) Shows the value held by the TMC RAM Read Pointer register that is used to read entries from the Trace RAM over the APB interface. The value is read directly from HW register RRP, 0x014.

/sys/bus/coresight/devices/<memory_map>.tmc/mgmt/rsz

Defined on file *sysfs-bus-coresight-devices-tmc*

(Read) Defines the size, in 32-bit words, of the local RAM buffer. The value is read directly from HW register RSZ, 0x004.

/sys/bus/coresight/devices/<memory_map>.tmc/mgmt/rwp

Defined on file *sysfs-bus-coresight-devices-tmc*

(Read) Shows the value held by the TMC RAM Write Pointer register that is used to sets the write pointer to write entries from the CoreSight bus into the Trace RAM. The value is read directly from HW register RWP, 0x018.

/sys/bus/coresight/devices/<memory_map>.tmc/mgmt/sts

Defined on file *sysfs-bus-coresight-devices-tmc*

(Read) Shows the value held by the TMC status register. The value is read directly from HW register STS, 0x00C.

/sys/bus/coresight/devices/<memory_map>.tmc/mgmt/trg

Defined on file *sysfs-bus-coresight-devices-tmc*

(Read) Similar to ”trigger_cntr” above except that this value is read directly from HW register TRG, 0x01C.

/sys/bus/coresight/devices/<memory_map>.tmc/trigger_cntr

Defined on file *sysfs-bus-coresight-devices-tmc*

(RW) Disables write access to the Trace RAM by stopping the formatter after a defined number of words have been stored following the trigger event. Additional interface for this driver are expected to be added as it matures.

/sys/bus/coresight/devices/<tpdm-name>/dsb_edge/ctrl_idx

Defined on file *sysfs-bus-coresight-devices-tpdm*

(RW) Set/Get the index number of the edge detection for the DSB subunit TPDM. Since there are at most 256 edge detections, this value ranges from 0 to 255.

/sys/bus/coresight/devices/<tpdm-name>/dsb_edge/ctrl_mask

Defined on file *sysfs-bus-coresight-devices-tpdm*

Write a data to mask the edge detection corresponding to the index number. Before writing data to this sysfs file, "ctrl_idx" should be written first to configure the index number of the edge detection which needs to be masked.

Accepts only one of the 2 values - 0 or 1.

/sys/bus/coresight/devices/<tpdm-name>/dsb_edge/ctrl_val

Defined on file *sysfs-bus-coresight-devices-tpdm*

Write a data to control the edge detection corresponding to the index number. Before writing data to this sysfs file, "ctrl_idx" should be written first to configure the index number of the edge detection which needs to be controlled.

Accepts only one of the following values. 0 - Rising edge detection 1 - Falling edge detection 2 - Rising and falling edge detection (toggle detection)

/sys/bus/coresight/devices/<tpdm-name>/dsb_edge/edcmr[0:7]

Defined on file *sysfs-bus-coresight-devices-tpdm*

Read a set of the edge control mask of the DSB in TPDM.

/sys/bus/coresight/devices/<tpdm-name>/dsb_edge/edcr[0:15]

Defined on file *sysfs-bus-coresight-devices-tpdm*

Read a set of the edge control value of the DSB in TPDM.

/sys/bus/coresight/devices/<tpdm-name>/dsb_mode

Defined on file *sysfs-bus-coresight-devices-tpdm*

(RW) Set/Get the programming mode of the DSB for tpdm.

Accepts the value needs to be greater than 0. What data bits do is listed below. Bit[0:1] : Test mode control bit for choosing the inputs. Bit[3] : Set to 0 for low performance mode. Set to 1 for high performance mode. Bit[4:8] : Select byte lane for high performance mode.

/sys/bus/coresight/devices/<tpdm-name>/dsb_msr/msr[0:31]

Defined on file *sysfs-bus-coresight-devices-tpdm*

(RW) Set/Get the MSR(mux select register) for the DSB subunit TPDM.

/sys/bus/coresight/devices/<tpdm-name>/dsb_patt/enable_ts

Defined on file *sysfs-bus-coresight-devices-tpdm*

(Write) Set the pattern timestamp of DSB tpdm. Read the pattern timestamp of DSB tpdm.

Accepts only one of the 2 values - 0 or 1. 0 : Disable DSB pattern timestamp. 1 : Enable DSB pattern timestamp.

/sys/bus/coresight/devices/<tpdm-name>/dsb_patt/set_type

Defined on file *sysfs-bus-coresight-devices-tpdm*

(Write) Set the pattern type of DSB tpdm. Read the pattern type of DSB tpdm.

Accepts only one of the 2 values - 0 or 1. 0 : Set the DSB pattern type to value. 1 : Set the DSB pattern type to toggle.

/sys/bus/coresight/devices/<tpdm-name>/dsb_patt/tpmr[0:7]

Defined on file *sysfs-bus-coresight-devices-tpdm*

(RW) Set/Get the mask of the pattern for the DSB subunit TPDM.

/sys/bus/coresight/devices/<tpdm-name>/dsb_patt/tpr[0:7]

Defined on file *sysfs-bus-coresight-devices-tpdm*

(RW) Set/Get the value of the pattern for the DSB subunit TPDM.

/sys/bus/coresight/devices/<tpdm-name>/dsb_trig_patt/xpmr[0:7]

Defined on file *sysfs-bus-coresight-devices-tpdm*

(RW) Set/Get the mask of the trigger pattern for the DSB subunit TPDM.

/sys/bus/coresight/devices/<tpdm-name>/dsb_trig_patt/xpr[0:7]

Defined on file *sysfs-bus-coresight-devices-tpdm*

(RW) Set/Get the value of the trigger pattern for the DSB subunit TPDM.

/sys/bus/coresight/devices/<tpdm-name>/dsb_trig_ts

Defined on file *sysfs-bus-coresight-devices-tpdm*

(RW) Set/Get the trigger timestamp of the DSB for tpdm.

Accepts only one of the 2 values - 0 or 1. 0 : Set the DSB trigger type to false 1 : Set the DSB trigger type to true

/sys/bus/coresight/devices/<tpdm-name>/dsb_trig_type

Defined on file *sysfs-bus-coresight-devices-tpdm*

(RW) Set/Get the trigger type of the DSB for tpdm.

Accepts only one of the 2 values - 0 or 1. 0 : Set the DSB trigger type to false 1 : Set the DSB trigger type to true

/sys/bus/coresight/devices/<tpdm-name>/integration_test

Defined on file *sysfs-bus-coresight-devices-tpdm*

(Write) Run integration test for tpdm. Integration test will generate test data for tpdm. It can help to make sure that the trace path is enabled and the link configurations are fine.

Accepts only one of the 2 values - 1 or 2. 1 : Generate 64 bits data 2 : Generate 32 bits data

/sys/bus/coresight/devices/<tpdm-name>/reset_dataset

Defined on file *sysfs-bus-coresight-devices-tpdm*

(Write) Reset the dataset of the tpdm.

Accepts only one value - 1. 1 : Reset the dataset of the tpdm

/sys/bus/coresight/devices/etm<N>/addr_cmp_view

Defined on file *sysfs-bus-coresight-devices-etm4x*

(Read) Print the current settings for the selected address comparator.

/sys/bus/coresight/devices/etm<N>/addr_exlevel_s_ns

Defined on file *sysfs-bus-coresight-devices-etm4x*

(RW) Set the Exception Level matching bits for secure and non-secure exception levels.

/sys/bus/coresight/devices/etm<N>/addr_idx

Defined on file *sysfs-bus-coresight-devices-etm4x*

(RW) Select which address comparator or pair (of comparators) to work with.

/sys/bus/coresight/devices/etm<N>/addr_instdatatype

Defined on file *sysfs-bus-coresight-devices-etm4x*

(RW) Controls what type of comparison the trace unit performs.

/sys/bus/coresight/devices/etm<N>/addr_range

Defined on file *sysfs-bus-coresight-devices-etm4x*

(RW) Used to setup address range comparator values.

/sys/bus/coresight/devices/etm<N>/addr_single

Defined on file *sysfs-bus-coresight-devices-etm4x*

(RW) Used to setup single address comparator values.

/sys/bus/coresight/devices/etm<N>/bb_ctrl

Defined on file *sysfs-bus-coresight-devices-etm4x*

(RW) Controls which regions in the memory map are enabled to use branch broadcasting.

/sys/bus/coresight/devices/etm<N>/cntr_ctrl

Defined on file *sysfs-bus-coresight-devices-etm4x*

(RW) Controls the operation of the selected counter.

/sys/bus/coresight/devices/etm<N>/cntr_idx

Defined on file *sysfs-bus-coresight-devices-etm4x*

(RW) Select which counter unit to work with.

/sys/bus/coresight/devices/etm<N>/cntr_val

Defined on file *sysfs-bus-coresight-devices-etm4x*

(RW) This sets or returns the current count value of the specific counter.

/sys/bus/coresight/devices/etm<N>/cntrldvr

Defined on file *sysfs-bus-coresight-devices-etm4x*

(RW) This sets or returns the reload count value of the specific counter.

/sys/bus/coresight/devices/etm<N>/cpu

Defined on file *sysfs-bus-coresight-devices-etm4x*

(Read) The CPU this tracing entity is associated with.

/sys/bus/coresight/devices/etm<N>/ctxid_idx

Defined on file *sysfs-bus-coresight-devices-etm4x*

(RW) Select which context ID comparator to work with.

/sys/bus/coresight/devices/etm<N>/ctxid_masks

Defined on file *sysfs-bus-coresight-devices-etm4x*

(RW) Mask for all 8 context ID comparator value registers (if implemented).

/sys/bus/coresight/devices/etm<N>/ctxid_pid

Defined on file *sysfs-bus-coresight-devices-etm4x*

(RW) Get/Set the context ID comparator value to trigger on.

/sys/bus/coresight/devices/etm<N>/cyc_threshold

Defined on file *sysfs-bus-coresight-devices-etm4x*

(RW) Sets the threshold value for cycle counting.

/sys/bus/coresight/devices/etm<N>/enable_source

Defined on file *sysfs-bus-coresight-devices-etm4x*

(RW) Enable/disable tracing on this specific trace entiry. Enabling a source implies the source has been configured properly and a sink has been identidifed for it. The path of coresight components linking the source to the sink is configured and managed automatically by the coresight framework.

/sys/bus/coresight/devices/etm<N>/event

Defined on file *sysfs-bus-coresight-devices-etm4x*

(RW) Controls the tracing of arbitrary events from bank 0 to 3.

/sys/bus/coresight/devices/etm<N>/event_instren

Defined on file *sysfs-bus-coresight-devices-etm4x*

(RW) Controls the behavior of the events in bank 0 to 3.

/sys/bus/coresight/devices/etm<N>/event_ts

Defined on file *sysfs-bus-coresight-devices-etm4x*

(RW) Controls the insertion of global timestamps in the trace streams.

/sys/bus/coresight/devices/etm<N>/event_vinst

Defined on file *sysfs-bus-coresight-devices-etm4x*

(RW) Controls instruction trace filtering.

/sys/bus/coresight/devices/etm<N>/mgmt/trcauthstatus

Defined on file *sysfs-bus-coresight-devices-etm4x*

(Read) Print the content of the Authentication Status Register (0xFB8). The value is taken directly from the HW.

/sys/bus/coresight/devices/etm<N>/mgmt/trcconfig

Defined on file *sysfs-bus-coresight-devices-etm4x*

(Read) Print the content of the trace configuration register (0x010) as currently set by SW.

/sys/bus/coresight/devices/etm<N>/mgmt/trcdevarch

Defined on file *sysfs-bus-coresight-devices-etm4x*

(Read) Print the content of the Device Architecture Register (offset 0xFBC). The value is taken directly read from the HW.

/sys/bus/coresight/devices/etm<N>/mgmt/trcdevid

Defined on file *sysfs-bus-coresight-devices-etm4x*

(Read) Print the content of the Device ID Register (0xFC8). The value is taken directly from the HW.

/sys/bus/coresight/devices/etm<N>/mgmt/trcdevtype

Defined on file *sysfs-bus-coresight-devices-etm4x*

(Read) Print the content of the Device Type Register (0xFCC). The value is taken directly from the HW.

/sys/bus/coresight/devices/etm<N>/mgmt/trclsr

Defined on file *sysfs-bus-coresight-devices-etm4x*

(Read) Print the content of the SW Lock Status Register (0xFB4). The value is taken directly from the HW.

/sys/bus/coresight/devices/etm<N>/mgmt/trcoslsr

Defined on file *sysfs-bus-coresight-devices-etm4x*

(Read) Print the content of the OS Lock Status Register (0x304). The value it taken directly from the HW.

/sys/bus/coresight/devices/etm<N>/mgmt/trcpdcr

Defined on file *sysfs-bus-coresight-devices-etm4x*

(Read) Print the content of the Power Down Control Register (0x310). The value is taken directly from the HW.

/sys/bus/coresight/devices/etm<N>/mgmt/trcpdsr

Defined on file *sysfs-bus-coresight-devices-etm4x*

(Read) Print the content of the Power Down Status Register (0x314). The value is taken directly from the HW.

/sys/bus/coresight/devices/etm<N>/mgmt/trcpidr0

Defined on file *sysfs-bus-coresight-devices-etm4x*

(Read) Print the content of the Peripheral ID0 Register (0xFE0). The value is taken directly from the HW.

/sys/bus/coresight/devices/etm<N>/mgmt/trcpidr1

Defined on file *sysfs-bus-coresight-devices-etm4x*

(Read) Print the content of the Peripheral ID1 Register (0xFE4). The value is taken directly from the HW.

/sys/bus/coresight/devices/etm<N>/mgmt/trcpidr2

Defined on file *sysfs-bus-coresight-devices-etm4x*

(Read) Print the content of the Peripheral ID2 Register (0xFE8). The value is taken directly from the HW.

/sys/bus/coresight/devices/etm<N>/mgmt/trcpidr3

Defined on file *sysfs-bus-coresight-devices-etm4x*

(Read) Print the content of the Peripheral ID3 Register (0xFEC). The value is taken directly from the HW.

/sys/bus/coresight/devices/etm<N>/mgmt/trctraceid

Defined on file *sysfs-bus-coresight-devices-etm4x*

(Read) Print the content of the trace ID register (0x040).

/sys/bus/coresight/devices/etm<N>/mode

Defined on file *sysfs-bus-coresight-devices-etm4x*

(RW) Controls various modes supported by this ETM, for example P0 instruction tracing, branch broadcast, cycle counting and context ID tracing.

/sys/bus/coresight/devices/etm<N>/nr_addr_cmp

Defined on file *sysfs-bus-coresight-devices-etm4x*

(Read) Indicates the number of address comparator pairs that are available for tracing.

/sys/bus/coresight/devices/etm<N>/nr_cntr

Defined on file *sysfs-bus-coresight-devices-etm4x*

(Read) Indicates the number of counters that are available for tracing.

/sys/bus/coresight/devices/etm<N>/nr_ext_inp

Defined on file *sysfs-bus-coresight-devices-etm4x*

(Read) Indicates how many external inputs are implemented.

/sys/bus/coresight/devices/etm<N>/nr_pe_cmp

Defined on file *sysfs-bus-coresight-devices-etm4x*

(Read) Indicates the number of PE comparator inputs that are available for tracing.

/sys/bus/coresight/devices/etm<N>/nr_resource

Defined on file *sysfs-bus-coresight-devices-etm4x*

(Read) Indicates the number of resource selection pairs that are available for tracing.

/sys/bus/coresight/devices/etm<N>/nr_ss_cmp

Defined on file *sysfs-bus-coresight-devices-etm4x*

(Read) Indicates the number of single-shot comparator controls that are available for tracing.

/sys/bus/coresight/devices/etm<N>/nrseqstate

Defined on file *sysfs-bus-coresight-devices-etm4x*

(Read) Indicates the number of sequencer states that are implemented.

/sys/bus/coresight/devices/etm<N>/ns_exlevel_vinst

Defined on file *sysfs-bus-coresight-devices-etm4x*

(RW) In non-secure state, each bit controls whether instruction tracing is enabled for the corresponding exception level.

/sys/bus/coresight/devices/etm<N>/numcidc

Defined on file *sysfs-bus-coresight-devices-etm4x*

(Read) Indicates the number of Context ID comparators that are available for tracing.

/sys/bus/coresight/devices/etm<N>/numvmidc

Defined on file *sysfs-bus-coresight-devices-etm4x*

(Read) Indicates the number of VMID comparators that are available for tracing.

/sys/bus/coresight/devices/etm<N>/pe

Defined on file *sysfs-bus-coresight-devices-etm4x*

(RW) Controls which PE to trace.

/sys/bus/coresight/devices/etm<N>/res_ctrl

Defined on file *sysfs-bus-coresight-devices-etm4x*

(RW) Controls the selection of the resources in the trace unit.

/sys/bus/coresight/devices/etm<N>/res_idx

Defined on file *sysfs-bus-coresight-devices-etm4x*

(RW) Select which resource selection unit to work with.

/sys/bus/coresight/devices/etm<N>/reset

Defined on file *sysfs-bus-coresight-devices-etm4x*

(Write) Cancels all configuration on a trace unit and set it back to its boot configuration.

/sys/bus/coresight/devices/etm<N>/s_exlevel_vinst

Defined on file *sysfs-bus-coresight-devices-etm4x*

(RW) In Secure state, each bit controls whether instruction tracing is enabled for the corresponding exception level.

/sys/bus/coresight/devices/etm<N>/seq_event

Defined on file *sysfs-bus-coresight-devices-etm4x*

(RW) Moves the sequencer state to a specific state.

/sys/bus/coresight/devices/etm<N>/seq_idx

Defined on file *sysfs-bus-coresight-devices-etm4x*

(RW) Select which sequensor.

/sys/bus/coresight/devices/etm<N>/seq_reset_event

Defined on file *sysfs-bus-coresight-devices-etm4x*

(RW) Moves the sequencer to state 0 when a programmed event occurs.

/sys/bus/coresight/devices/etm<N>/seq_state

Defined on file *sysfs-bus-coresight-devices-etm4x*

(RW) Use this to set, or read, the sequencer state.

/sys/bus/coresight/devices/etm<N>/sshot_ctrl

Defined on file *sysfs-bus-coresight-devices-etm4x*

(RW) Access the selected single shot control register.

/sys/bus/coresight/devices/etm<N>/sshot_idx

Defined on file *sysfs-bus-coresight-devices-etm4x*

(RW) Select the single shot control register to access.

/sys/bus/coresight/devices/etm<N>/sshot_pe_ctrl

Defined on file *sysfs-bus-coresight-devices-etm4x*

(RW) Access the selected single show PE comparator control register.

/sys/bus/coresight/devices/etm<N>/sshot_status

Defined on file *sysfs-bus-coresight-devices-etm4x*

(Read) Print the current value of the selected single shot status register.

/sys/bus/coresight/devices/etm<N>/syncfreq

Defined on file *sysfs-bus-coresight-devices-etm4x*

(RW) Controls how often trace synchronization requests occur.

/sys/bus/coresight/devices/etm<N>/trcidr/trcidr0

Defined on file *sysfs-bus-coresight-devices-etm4x*

(Read) Returns the tracing capabilities of the trace unit (0x1E0). The value is taken directly from the HW.

/sys/bus/coresight/devices/etm<N>/trcidr/trcidr1

Defined on file *sysfs-bus-coresight-devices-etm4x*

(Read) Returns the tracing capabilities of the trace unit (0x1E4). The value is taken directly from the HW.

/sys/bus/coresight/devices/etm<N>/trcidr/trcidr10

Defined on file *sysfs-bus-coresight-devices-etm4x*

(Read) Returns the number of P1 right-hand keys that the trace unit can use (0x188). The value is taken directly from the HW.

/sys/bus/coresight/devices/etm<N>/trcidr/trcidr11

Defined on file *sysfs-bus-coresight-devices-etm4x*

(Read) Returns the number of special P1 right-hand keys that the trace unit can use (0x18C). The value is taken directly from the HW.

/sys/bus/coresight/devices/etm<N>/trcidr/trcidr12

Defined on file *sysfs-bus-coresight-devices-etm4x*

(Read) Returns the number of conditional P1 right-hand keys that the trace unit can use (0x190). The value is taken directly from the HW.

/sys/bus/coresight/devices/etm<N>/trcidr/trcidr13

Defined on file *sysfs-bus-coresight-devices-etm4x*

(Read) Returns the number of special conditional P1 right-hand keys that the trace unit can use (0x194). The value is taken directly from the HW.

/sys/bus/coresight/devices/etm<N>/trcidr/trcidr2

Defined on file *sysfs-bus-coresight-devices-etm4x*

(Read) Returns the maximum size of the data value, data address, VMID, context ID and instruction address in the trace unit (0x1E8). The value is taken directly from the HW.

/sys/bus/coresight/devices/etm<N>/trcidr/trcidr3

Defined on file *sysfs-bus-coresight-devices-etm4x*

(Read) Returns the value associated with various resources available to the trace unit. See the Trace Macrocell architecture specification for more details (0x1E8). The value is taken directly from the HW.

/sys/bus/coresight/devices/etm<N>/trcidr/trcidr4

Defined on file *sysfs-bus-coresight-devices-etm4x*

(Read) Returns how many resources the trace unit supports (0x1F0). The value is taken directly from the HW.

/sys/bus/coresight/devices/etm<N>/trcidr/trcidr5

Defined on file *sysfs-bus-coresight-devices-etm4x*

(Read) Returns how many resources the trace unit supports (0x1F4). The value is taken directly from the HW.

/sys/bus/coresight/devices/etm<N>/trcidr/trcidr8

Defined on file *sysfs-bus-coresight-devices-etm4x*

(Read) Returns the maximum speculation depth of the instruction trace stream. (0x180). The value is taken directly from the HW.

/sys/bus/coresight/devices/etm<N>/trcidr/trcidr9

Defined on file *sysfs-bus-coresight-devices-etm4x*

(Read) Returns the number of P0 right-hand keys that the trace unit can use (0x184). The value is taken directly from the HW.

/sys/bus/coresight/devices/etm<N>/ts_source

Defined on file *sysfs-bus-coresight-devices-etm4x*

(Read) When FEAT_TRF is implemented, value of TRFCR_ELx.TS used for trace session. Otherwise -1 indicates an unknown time source. Check trcidr0.tssize to see if a global timestamp is available.

/sys/bus/coresight/devices/etm<N>/vinst_pe_cmp_start_stop

Defined on file *sysfs-bus-coresight-devices-etm4x*

(RW) Access the start stop control register for PE input comparators.

/sys/bus/coresight/devices/etm<N>/vmid_idx

Defined on file *sysfs-bus-coresight-devices-etm4x*

(RW) Select which virtual machine ID comparator to work with.

/sys/bus/coresight/devices/etm<N>/vmid_masks

Defined on file *sysfs-bus-coresight-devices-etm4x*

(RW) Mask for all 8 virtual machine ID comparator value registers (if implemented).

/sys/bus/coresight/devices/etm<N>/vmid_val

Defined on file *sysfs-bus-coresight-devices-etm4x*

(RW) Get/Set the virtual machine ID comparator value to trigger on.

/sys/bus/coresight/devices/trbe<cpu>/align

Defined on file *sysfs-bus-coresight-devices-trbe*

(Read) Shows the TRBE write pointer alignment. This value is fetched from the TRBIDR register.

/sys/bus/coresight/devices/trbe<cpu>/flag

Defined on file *sysfs-bus-coresight-devices-trbe*

(Read) Shows if TRBE updates in the memory are with access and dirty flag updates as well. This value is fetched from the TRBIDR register.

/sys/bus/coresight/devices/ultra_smb<N>/enable_sink

Defined on file *sysfs-bus-coresight-devices-ultra_smb*

(RW) Add/remove a SMB device from a trace path. There can be multiple sources for a single SMB device.

/sys/bus/coresight/devices/ultra_smb<N>/mgmt/buf_size

Defined on file *sysfs-bus-coresight-devices-ultra_smb*

(RO) Shows the buffer size of each UltraSoc SMB device.

/sys/bus/coresight/devices/ultra_smb<N>/mgmt/buf_status

Defined on file *sysfs-bus-coresight-devices-ultra_smb*

(RO) Shows the value of UltraSoc SMB status register. BIT(0) is zero means buffer is empty.

/sys/bus/coresight/devices/ultra_smb<N>/mgmt/read_pos

Defined on file *sysfs-bus-coresight-devices-ultra_smb*

(RO) Shows the value of UltraSoc SMB Read Pointer register.

/sys/bus/coresight/devices/ultra_smb<N>/mgmt/write_pos

Defined on file *sysfs-bus-coresight-devices-ultra_smb*

(RO) Shows the value of UltraSoc SMB Write Pointer register.

/sys/bus/counter/devices/counterX/cascade_counts_enable

Defined on file *sysfs-bus-counter*

Indicates the cascading of Counts on Counter X.

Valid attribute values are boolean.

/sys/bus/counter/devices/counterX/cascade_counts_enable_component_id
/sys/bus/counter/devices/counterX/external_input_phase_clock_select_component_id
/sys/bus/counter/devices/counterX/countY/capture_component_id
/sys/bus/counter/devices/counterX/countY/ceiling_component_id
/sys/bus/counter/devices/counterX/countY/floor_component_id
/sys/bus/counter/devices/counterX/countY/count_mode_component_id
/sys/bus/counter/devices/counterX/countY/direction_component_id
/sys/bus/counter/devices/counterX/countY/enable_component_id
/sys/bus/counter/devices/counterX/countY/error_noise_component_id
/sys/bus/counter/devices/counterX/countY/prescaler_component_id
/sys/bus/counter/devices/counterX/countY/preset_component_id
/sys/bus/counter/devices/counterX/countY/preset_enable_component_id
/sys/bus/counter/devices/counterX/countY/signalZ_action_component_id
/sys/bus/counter/devices/counterX/countY/num_overflows_component_id
/sys/bus/counter/devices/counterX/signalY/cable_fault_component_id
/sys/bus/counter/devices/counterX/signalY/cable_fault_enable_component_id
/sys/bus/counter/devices/counterX/signalY/filter_clock_prescaler_component_id
/sys/bus/counter/devices/counterX/signalY/index_polarity_component_id
/sys/bus/counter/devices/counterX/signalY/polarity_component_id
/sys/bus/counter/devices/counterX/signalY/synchronous_mode_component_id
/sys/bus/counter/devices/counterX/signalY/frequency_component_id

Defined on file *sysfs-bus-counter*

Read-only attribute that indicates the component ID of the respective extension or Synapse.

/sys/bus/counter/devices/counterX/countY/capture

Defined on file *sysfs-bus-counter*

Historical capture of the Count Y count data.

/sys/bus/counter/devices/counterX/countY/ceiling

Defined on file *sysfs-bus-counter*

Count value ceiling for Count Y. This is the upper limit for the respective counter.

/sys/bus/counter/devices/counterX/countY/count

Defined on file *sysfs-bus-counter*

Count data of Count Y represented as a string.

/sys/bus/counter/devices/counterX/countY/count_mode

Defined on file *sysfs-bus-counter*

Count mode for channel Y. The ceiling and floor values for Count Y are used by the count mode where required. The following count modes are available:

normal:
Counting is continuous in either direction.

range limit:
An upper or lower limit is set, mimicking limit switches in the mechanical counterpart. The upper limit is set to the Count Y ceiling value, while the lower limit is set to the Count Y floor value. The counter freezes at count = ceiling when counting up, and at count = floor when counting down. At either of these limits, the counting is resumed only when the count direction is reversed.

non-recycle:
The counter is disabled whenever a counter overflow or underflow takes place. The counter is re-enabled when a new count value is loaded to the counter via a preset operation or direct write.

modulo-n:
A count value boundary is set between the Count Y floor value and the Count Y ceiling value. The counter is reset to the Count Y floor value at count = ceiling when counting up, while the counter is set to the Count Y ceiling value at count = floor when counting down; the counter does not freeze at the boundary points, but counts continuously throughout.

interrupt on terminal count:
The output signal is initially low, and will remain low until the counter reaches zero. The output signal then goes high and remains high until a new preset value is set.

hardware retriggerable one-shot:
The output signal is initially high. The output signal will go low by a trigger input signal, and will remain low until the counter reaches zero. The output will then go high and remain high until the next trigger. A trigger results in loading the counter to the preset value and setting the output signal low, thus starting the one-shot pulse.

rate generator:
The output signal is initially high. When the counter has decremented to 1, the output signal goes low for one clock pulse. The output signal then goes high again, the counter is reloaded to the preset value, and the process repeats in a periodic manner as such.

square wave mode:
The output signal is initially high.

If the initial count is even, the counter is decremented by two on succeeding clock pulses. When the count expires, the output signal changes value and the counter is reloaded to the preset value. The process repeats in periodic manner as such.

If the initial count is odd, the initial count minus one (an even number) is loaded and then is decremented by two on succeeding clock pulses. One clock pulse after the count expires, the output signal goes low and the counter is reloaded to the preset value minus one. Succeeding clock pulses decrement the count by two. When the count expires, the output goes high again and the counter is reloaded to the preset value minus one. The process repeats in a periodic manner as such.

software triggered strobe:
The output signal is initially high. When the count expires, the output will go low for one clock pulse and then go high again. The counting sequence is ”triggered” by setting the preset value.

hardware triggered strobe:
The output signal is initially high. Counting is started by a trigger input signal. When the count expires, the output signal will go low for one clock pulse and then go high again. A trigger results in loading the counter to the preset value.

/sys/bus/counter/devices/counterX/countY/count_mode_available
/sys/bus/counter/devices/counterX/countY/error_noise_available
/sys/bus/counter/devices/counterX/countY/function_available
/sys/bus/counter/devices/counterX/countY/prescaler_available
/sys/bus/counter/devices/counterX/countY/signalZ_action_available

Defined on file *sysfs-bus-counter*

Discrete set of available values for the respective Count Y configuration are listed in this file. Values are delimited by newline characters.

/sys/bus/counter/devices/counterX/countY/direction

Defined on file *sysfs-bus-counter*

Read-only attribute that indicates the count direction of Count Y. Two count directions are available: forward and backward.

Some counter devices are able to determine the direction of their counting. For example, quadrature encoding counters can determine the direction of movement by evaluating the leading phase of the respective A and B quadrature encoding signals. This attribute exposes such count directions.

/sys/bus/counter/devices/counterX/countY/enable

Defined on file *sysfs-bus-counter*

Whether channel Y counter is enabled. Valid attribute values are boolean.

This attribute is intended to serve as a pause/unpause mechanism for Count Y. Suppose a counter device is used to count the total movement of a conveyor belt: this attribute allows an operator to temporarily pause the counter, service the conveyor belt, and then finally unpause the counter to continue where it had left off.

/sys/bus/counter/devices/counterX/countY/error_noise

Defined on file *sysfs-bus-counter*

Read-only attribute that indicates whether excessive noise is present at the channel Y counter inputs.

/sys/bus/counter/devices/counterX/countY/floor

Defined on file *sysfs-bus-counter*

Count value floor for Count Y. This is the lower limit for the respective counter.

/sys/bus/counter/devices/counterX/countY/function

Defined on file *sysfs-bus-counter*

Count function mode of Count Y; count function evaluation is triggered by conditions specified by the Count Y signalZ_action attributes. The following count functions are available:

increase:
Accumulated count is incremented.

decrease:
Accumulated count is decremented.

pulse-direction:
Rising edges on signal A updates the respective count. The input level of signal B determines direction.

quadrature x1 a:
If direction is forward, rising edges on quadrature pair signal A updates the respective count; if the direction is backward, falling edges on quadrature pair signal A updates the respective count. Quadrature encoding determines the direction.

quadrature x1 b:
If direction is forward, rising edges on quadrature pair signal B updates the respective count; if the direction is backward, falling edges on quadrature pair signal B updates the respective count. Quadrature encoding determines the direction.

quadrature x2 a:
Any state transition on quadrature pair signal A updates the respective count. Quadrature encoding determines the direction.

quadrature x2 b:
Any state transition on quadrature pair signal B updates the respective count. Quadrature encoding determines the direction.

quadrature x4:
Any state transition on either quadrature pair signals updates the respective count. Quadrature encoding determines the direction.

/sys/bus/counter/devices/counterX/countY/name

Defined on file *sysfs-bus-counter*

Read-only attribute that indicates the device-specific name of Count Y. If possible, this should match the name of the respective channel as it appears in the device datasheet.

/sys/bus/counter/devices/counterX/countY/num_overflows

Defined on file *sysfs-bus-counter*

This attribute indicates the number of overflows of count Y.

/sys/bus/counter/devices/counterX/countY/prescaler

Defined on file *sysfs-bus-counter*

Configure the prescaler value associated with Count Y. On the FlexTimer, the counter clock source passes through a prescaler (i.e. a counter). This acts like a clock divider.

/sys/bus/counter/devices/counterX/countY/preset

Defined on file *sysfs-bus-counter*

If the counter device supports preset registers -- registers used to load counter channels to a set count upon device-defined preset operation trigger events -- the preset count for channel Y is provided by this attribute.

/sys/bus/counter/devices/counterX/countY/preset_enable

Defined on file *sysfs-bus-counter*

Whether channel Y counter preset operation is enabled. Valid attribute values are boolean.

/sys/bus/counter/devices/counterX/countY/signalZ_action

Defined on file *sysfs-bus-counter*

Action mode of Count Y for Signal Z. This attribute indicates the condition of Signal Z that triggers the count function evaluation for Count Y. The following action modes are available:

none:
Signal does not trigger the count function. In Pulse-Direction count function mode, this Signal is evaluated as Direction.

rising edge:
Low state transitions to high state.

falling edge:
High state transitions to low state.

both edges:
Any state transition.

/sys/bus/counter/devices/counterX/countY/spike_filter_ns

Defined on file *sysfs-bus-counter*

If the counter device supports programmable spike filter this attribute indicates the value in nanoseconds where noise pulses shorter or equal to configured value are ignored. Value 0 means filter is disabled.

/sys/bus/counter/devices/counterX/events_queue_size

Defined on file *sysfs-bus-counter*

Size of the Counter events queue in number of struct counter_event data structures. The number of elements will be rounded-up to a power of 2.

/sys/bus/counter/devices/counterX/external_input_phase_clock_select

Defined on file *sysfs-bus-counter*

Selects the external clock pin for phase counting mode of Counter X.

MTCLKA-MTCLKB:
MTCLKA and MTCLKB pins are selected for the external phase clock.

MTCLKC-MTCLKD:
MTCLKC and MTCLKD pins are selected for the external phase clock.

/sys/bus/counter/devices/counterX/external_input_phase_clock_select_available

Defined on file *sysfs-bus-counter*

Discrete set of available values for the respective device configuration are listed in this file.

/sys/bus/counter/devices/counterX/name

Defined on file *sysfs-bus-counter*

Read-only attribute that indicates the device-specific name of the Counter. This should match the name of the device as it appears in its respective datasheet.

/sys/bus/counter/devices/counterX/num_counts

Defined on file *sysfs-bus-counter*

Read-only attribute that indicates the total number of Counts belonging to the Counter.

/sys/bus/counter/devices/counterX/num_signals

Defined on file *sysfs-bus-counter*

Read-only attribute that indicates the total number of Signals belonging to the Counter.

/sys/bus/counter/devices/counterX/signalY/cable_fault

Defined on file *sysfs-bus-counter*

Read-only attribute that indicates whether a differential encoder cable fault (not connected or loose wires) is detected for the respective channel of Signal Y. Valid attribute values are boolean. Detection must first be enabled via the corresponding cable_fault_enable attribute.

/sys/bus/counter/devices/counterX/signalY/cable_fault_enable

Defined on file *sysfs-bus-counter*

Whether detection of differential encoder cable faults for the respective channel of Signal Y is enabled. Valid attribute values are boolean.

/sys/bus/counter/devices/counterX/signalY/filter_clock_prescaler

Defined on file *sysfs-bus-counter*

Filter clock factor for input Signal Y. This prescaler value affects the inputs of both quadrature pair signals.

/sys/bus/counter/devices/counterX/signalY/frequency

Defined on file *sysfs-bus-counter*

Read-only attribute that indicates the signal Y frequency, in Hz.

/sys/bus/counter/devices/counterX/signalY/index_polarity

Defined on file *sysfs-bus-counter*

Active level of index input Signal Y; irrelevant in non-synchronous load mode.

/sys/bus/counter/devices/counterX/signalY/index_polarity_available
/sys/bus/counter/devices/counterX/signalY/synchronous_mode_available

Defined on file *sysfs-bus-counter*

Discrete set of available values for the respective Signal Y configuration are listed in this file.

/sys/bus/counter/devices/counterX/signalY/name

Defined on file *sysfs-bus-counter*

Read-only attribute that indicates the device-specific name of Signal Y. If possible, this should match the name of the respective signal as it appears in the device datasheet.

/sys/bus/counter/devices/counterX/signalY/polarity

Defined on file *sysfs-bus-counter*

Active level of Signal Y. The following polarity values are available:

positive:
Signal high state considered active level (rising edge).

negative:
Signal low state considered active level (falling edge).

/sys/bus/counter/devices/counterX/signalY/signal

Defined on file *sysfs-bus-counter*

Signal level state of Signal Y. The following signal level states are available:

low:
Low level state.

high:
High level state.

/sys/bus/counter/devices/counterX/signalY/synchronous_mode

Defined on file *sysfs-bus-counter*

Configure the counter associated with Signal Y for non-synchronous or synchronous load mode. Synchronous load mode cannot be selected in non-quadrature (Pulse-Direction) clock mode.

non-synchronous:
A logic low level is the active level at this index input. The index function (as enabled via preset_enable) is performed directly on the active level of the index input.

synchronous:
Intended for interfacing with encoder Index output in quadrature clock mode. The active level is configured via index_polarity. The index function (as enabled via preset_enable) is performed synchronously with the quadrature clock on the active level of the index input.

/sys/bus/css/devices/.../driver_override

Defined on file *sysfs-bus-css*

This file allows the driver for a device to be specified. When specified, only a driver with a name matching the value written to driver_override will have an opportunity to bind to the device. The override is specified by writing a string to the driver_override file (echo vfio-ccw > driver_override) and may be cleared with an empty string (echo > driver_override). This returns the device to standard matching rules binding. Writing to driver_override does not automatically unbind the device from its current driver or make any attempt to automatically load the specified driver. If no driver with a matching name is currently loaded in the kernel, the device will not bind to any driver. This also allows devices to opt-out of driver binding using a driver_override name such as "none". Only a single driver may be specified in the override, there is no support for parsing delimiters.

Note that unlike the mechanism of the same name for pci, this file does not allow to override basic matching rules. I.e., the driver must still match the subchannel type of the device.

/sys/bus/css/devices/.../modalias

Defined on file *sysfs-bus-css*

Contains the module alias as reported with uevents. It is of the format css:t<type> and present for all subchannel types.

/sys/bus/css/devices/.../type

Defined on file *sysfs-bus-css*

Contains the subchannel type, as reported by the hardware. This attribute is present for all subchannel types.

/sys/bus/css/drivers/io_subchannel/.../chpids

Defined on file *sysfs-bus-css*

Contains the ids of the channel paths used by this subchannel, as reported by the channel subsystem during subchannel recognition.

Note: This is an I/O-subchannel specific attribute.

Users: s390-tools, HAL

/sys/bus/css/drivers/io_subchannel/.../pimpampom

Defined on file *sysfs-bus-css*

Contains the PIM/PAM/POM values, as reported by the channel subsystem when last queried by the common I/O layer (this implies that this attribute is not necessarily in sync with the values current in the channel subsystem).

Note: This is an I/O-subchannel specific attribute.

Users: s390-tools, HAL

/sys/bus/cxl/devices/*/devtype

Defined on file *sysfs-bus-cxl*

(RO) CXL device objects export the devtype attribute which mirrors the same value communicated in the DEVTYPE environment variable for uevents for devices on the "cxl" bus.

/sys/bus/cxl/devices/*/modalias

Defined on file *sysfs-bus-cxl*

(RO) CXL device objects export the modalias attribute which mirrors the same value communicated in the MODALIAS environment variable for uevents for devices on the "cxl" bus.

/sys/bus/cxl/devices/decoderX.Y

Defined on file *sysfs-bus-cxl*

(RO) CXL decoder objects are enumerated from either a platform firmware description, or a CXL HDM decoder register set in a PCIe device (see CXL 2.0 section 8.2.5.12 CXL HDM Decoder Capability Structure). The 'X' in decoderX.Y represents the cxl_port container of this decoder, and 'Y' represents the instance id of a given decoder resource.

/sys/bus/cxl/devices/decoderX.Y/cap_{pmem,ram,type2,type3}

Defined on file *sysfs-bus-cxl*

(RO) When a CXL decoder is of devtype "cxl_decoder_root", it represents a fixed memory window identified by platform firmware. A fixed window may only support a subset of memory types. The 'cap_*' attributes indicate whether persistent memory, volatile memory, accelerator memory, and / or expander memory may be mapped behind this decoder's memory window.

/sys/bus/cxl/devices/decoderX.Y/create_{pmem,ram}_region

Defined on file *sysfs-bus-cxl*

(RW) Write a string in the form 'regionZ' to start the process of defining a new persistent, or volatile memory region (interleave-set) within the decode range bounded by root decoder 'decoderX.Y'. The value written must match the current value returned from reading this attribute. An atomic compare exchange operation is done on write to assign the requested id to a region and allocate the region-id for the next creation attempt. EBUSY is returned if the region name written does not match the current cached value.

/sys/bus/cxl/devices/decoderX.Y/delete_region

Defined on file *sysfs-bus-cxl*

(WO) Write a string in the form 'regionZ' to delete that region, provided it is currently idle / not bound to a driver.

/sys/bus/cxl/devices/decoderX.Y/dpa_resource

Defined on file *sysfs-bus-cxl*

(RO) When a CXL decoder is of devtype "cxl_decoder_endpoint", and its 'dpa_size' attribute is non-zero, this attribute indicates the device physical address (DPA) base address of the allocation.

/sys/bus/cxl/devices/decoderX.Y/dpa_size

Defined on file *sysfs-bus-cxl*

(RW) When a CXL decoder is of devtype "cxl_decoder_endpoint" it translates from a host physical address range, to a device local address range. The range, base address plus length in bytes, of DPA allocated to this decoder is conveyed in these 2 attributes. Allocations can be mutated as long as the decoder is in the disabled state. A write to 'dpa_size' releases the previous DPA allocation and then attempts to allocate from the free capacity in the device partition referred to by 'decoderX.Y/mode'. Allocate and free requests can only be performed on the highest instance number disabled decoder with non-zero size. I.e. allocations are enforced to occur in increasing 'decoderX.Y/id' order and frees are enforced to occur in decreasing 'decoderX.Y/id' order.

/sys/bus/cxl/devices/decoderX.Y/interleave_granularity

Defined on file *sysfs-bus-cxl*

(RO) The number of consecutive bytes of host physical address space this decoder claims at address N before the decode rotates to the next target in the interleave at address N + interleave_granularity (assuming N is aligned to interleave_granularity).

/sys/bus/cxl/devices/decoderX.Y/interleave_ways

Defined on file *sysfs-bus-cxl*

(RO) The number of targets across which this decoder's host physical address (HPA) memory range is interleaved. The device maps every Nth block of HPA (of size == 'interleave_granularity') to consecutive DPA addresses. The decoder's position in the interleave is

determined by the device's (endpoint or switch) switch ancestry. For root decoders their interleave is specified by platform firmware and they only specify a downstream target order for host bridges.

/sys/bus/cxl/devices/decoderX.Y/locked

Defined on file *sysfs-bus-cxl*

(RO) CXL HDM decoders have the capability to lock the configuration until the next device reset. For decoders of devtype "cxl_decoder_root" there is no standard facility to unlock them. For decoders of devtype "cxl_decoder_switch" a secondary bus reset, of the PCIe bridge that provides the bus for this decoders uport, unlocks / resets the decoder.

/sys/bus/cxl/devices/decoderX.Y/mode

Defined on file *sysfs-bus-cxl*

(RW) When a CXL decoder is of devtype "cxl_decoder_endpoint" it translates from a host physical address range, to a device local address range. Device-local address ranges are further split into a 'ram' (volatile memory) range and 'pmem' (persistent memory) range. The 'mode' attribute emits one of 'ram', 'pmem', 'mixed', or 'none'. The 'mixed' indication is for error cases when a decoder straddles the volatile/persistent partition boundary, and 'none' indicates the decoder is not actively decoding, or no DPA allocation policy has been set.

'mode' can be written, when the decoder is in the 'disabled' state, with either 'ram' or 'pmem' to set the boundaries for the next allocation.

/sys/bus/cxl/devices/decoderX.Y/qos_class

Defined on file *sysfs-bus-cxl*

(RO) For CXL host platforms that support "QoS Telemmetry" this root-decoder-only attribute conveys a platform specific cookie that identifies a QoS performance class for the CXL Window. This class-id can be compared against a similar "qos_class" published for each memory-type that an endpoint supports. While it is not required that endpoints map their local memory-class to a matching platform class, mismatches are not recommended and there are platform specific side-effects that may result.

/sys/bus/cxl/devices/decoderX.Y/target_list

Defined on file *sysfs-bus-cxl*

(RO) Display a comma separated list of the current decoder target configuration. The list is ordered by the current configured interleave order of the decoder's dport instances. Each entry in the list is a dport id.

/sys/bus/cxl/devices/decoderX.Y/target_type

Defined on file *sysfs-bus-cxl*

(RO) When a CXL decoder is of devtype "cxl_decoder_switch", it can optionally decode either accelerator memory (type-2) or expander memory (type-3). The 'target_type' attribute indicates

the current setting which may dynamically change based on what memory regions are activated in this decode hierarchy.

/sys/bus/cxl/devices/decoderX.Y/{start,size}

Defined on file *sysfs-bus-cxl*

(RO) The 'start' and 'size' attributes together convey the physical address base and number of bytes mapped in the decoder's decode window. For decoders of devtype "cxl_decoder_root" the address range is fixed. For decoders of devtype "cxl_decoder_switch" the address is bounded by the decode range of the cxl_port ancestor of the decoder's cxl_port, and dynamically updates based on the active memory regions in that address space.

/sys/bus/cxl/devices/endpointX/CDAT

Defined on file *sysfs-bus-cxl*

(RO) If this sysfs entry is not present no DOE mailbox was found to support CDAT data. If it is present and the length of the data is 0 reading the CDAT data failed. Otherwise the CDAT data is reported.

/sys/bus/cxl/devices/memX/firmware/

Defined on file *sysfs-bus-cxl*

(RW) Firmware uploader mechanism. The different files under this directory can be used to upload and activate new firmware for CXL devices. The interfaces under this are documented in sysfs-class-firmware.

/sys/bus/cxl/devices/memX/firmware_version

Defined on file *sysfs-bus-cxl*

(RO) "FW Revision" string as reported by the Identify Memory Device Output Payload in the CXL-2.0 specification.

/sys/bus/cxl/devices/memX/numa_node

Defined on file *sysfs-bus-cxl*

(RO) If NUMA is enabled and the platform has affinitized the host PCI device for this memory device, emit the CPU node affinity for this device.

/sys/bus/cxl/devices/memX/pmem/qos_class

Defined on file *sysfs-bus-cxl*

(RO) For CXL host platforms that support "QoS Telemmetry" this attribute conveys a comma delimited list of platform specific cookies that identifies a QoS performance class for the persistent partition of the CXL mem device. These class-ids can be compared against a similar "qos_class"

published for a root decoder. While it is not required that the endpoints map their local memory-class to a matching platform class, mismatches are not recommended and there are platform specific performance related side-effects that may result. First class-id is displayed.

/sys/bus/cxl/devices/memX/pmem/size

Defined on file *sysfs-bus-cxl*

(RO) "Persistent Only Capacity" as bytes. Represents the identically named field in the Identify Memory Device Output Payload in the CXL-2.0 specification.

/sys/bus/cxl/devices/memX/ram/qos_class

Defined on file *sysfs-bus-cxl*

(RO) For CXL host platforms that support "QoS Telemmetry" this attribute conveys a comma delimited list of platform specific cookies that identifies a QoS performance class for the volatile partition of the CXL mem device. These class-ids can be compared against a similar "qos_class" published for a root decoder. While it is not required that the endpoints map their local memory-class to a matching platform class, mismatches are not recommended and there are platform specific performance related side-effects that may result. First class-id is displayed.

/sys/bus/cxl/devices/memX/ram/size

Defined on file *sysfs-bus-cxl*

(RO) "Volatile Only Capacity" as bytes. Represents the identically named field in the Identify Memory Device Output Payload in the CXL-2.0 specification.

/sys/bus/cxl/devices/memX/security/sanitize

Defined on file *sysfs-bus-cxl*

(WO) Write a boolean 'true' string value to this attribute to sanitize the device to securely re-purpose or decommission it. This is done by ensuring that all user data and meta-data, whether it resides in persistent capacity, volatile capacity, or the LSA, is made permanently unavailable by whatever means is appropriate for the media type. This functionality requires the device to be disabled, that is, not actively decoding any HPA ranges. This permits avoiding explicit global CPU cache management, relying instead for it to be done when a region transitions between software programmed and hardware committed states. If this file is not present, then there is no hardware support for the operation.

What /sys/bus/cxl/devices/memX/security/erase (WO) Write a boolean 'true' string value to this attribute to secure erase user data by changing the media encryption keys for all user data areas of the device. This functionality requires the device to be disabled, that is, not actively decoding any HPA ranges. This permits avoiding explicit global CPU cache management, relying instead for it to be done when a region transitions between software programmed and hardware committed states. If this file is not present, then there is no hardware support for the operation.

/sys/bus/cxl/devices/memX/security/state

Defined on file *sysfs-bus-cxl*

(RO) Reading this file will display the CXL security state for that device. Such states can be: 'disabled', 'sanitize', when a sanitization is currently underway; or those available only for persistent memory: 'locked', 'unlocked' or 'frozen'. This sysfs entry is select/poll capable from userspace to notify upon completion of a sanitize operation.

/sys/bus/cxl/devices/memX/serial

Defined on file *sysfs-bus-cxl*

(RO) 64-bit serial number per the PCIe Device Serial Number capability. Mandatory for CXL devices, see CXL 2.0 8.1.12.2 Memory Device PCIe Capabilities and Extended Capabilities.

/sys/bus/cxl/devices/memX/trigger_poison_list

Defined on file *sysfs-bus-cxl*

(WO) When a boolean 'true' is written to this attribute the memdev driver retrieves the poison list from the device. The list consists of addresses that are poisoned, or would result in poison if accessed, and the source of the poison. This attribute is only visible for devices supporting the capability. The retrieved errors are logged as kernel events when cxl_poison event tracing is enabled.

/sys/bus/cxl/devices/portX/decoders_committed

Defined on file *sysfs-bus-cxl*

(RO) A memory device is considered active when any of its decoders are in the ”committed” state (See CXL 3.0 8.2.4.19.7 CXL HDM Decoder n Control Register). Hotplug and destructive operations like ”sanitize” are blocked while device is actively decoding a Host Physical Address range. Note that this number may be elevated without any regionX objects active or even enumerated, as this may be due to decoders established by platform firwmare or a previous kernel (kexec).

/sys/bus/cxl/devices/portX/dportY

Defined on file *sysfs-bus-cxl*

(RO) CXL port objects are enumerated from either a platform firmware device (ACPI0017 and ACPI0016) or PCIe switch upstream port with CXL component registers. The 'dportY' symlink identifies one or more downstream ports that the upstream port may target in its decode of CXL memory resources. The 'Y' integer reflects the hardware port unique-id used in the hardware decoder target list.

/sys/bus/cxl/devices/portX/uport

Defined on file *sysfs-bus-cxl*

(RO) CXL port objects are enumerated from either a platform firmware device (ACPI0017 and ACPI0016) or PCIe switch upstream port with CXL component registers. The 'uport' symlink connects the CXL portX object to the device that published the CXL port capability.

/sys/bus/cxl/devices/regionZ/commit

Defined on file *sysfs-bus-cxl*

(RW) Write a boolean 'true' string value to this attribute to trigger the region to transition from the software programmed state to the actively decoding in hardware state. The commit operation in addition to validating that the region is in proper configured state, validates that the decoders are being committed in spec mandated order (last committed decoder id + 1), and checks that the hardware accepts the commit request. Reading this value indicates whether the region is committed or not.

/sys/bus/cxl/devices/regionZ/interleave_granularity

Defined on file *sysfs-bus-cxl*

(RW) Set the number of consecutive bytes each device in the interleave set will claim. The possible interleave granularity values are determined by the CXL spec and the participating devices.

/sys/bus/cxl/devices/regionZ/interleave_ways

Defined on file *sysfs-bus-cxl*

(RW) Configures the number of devices participating in the region is set by writing this value. Each device will provide 1/interleave_ways of storage for the region.

/sys/bus/cxl/devices/regionZ/mode

Defined on file *sysfs-bus-cxl*

(RO) The mode of a region is established at region creation time and dictates the mode of the endpoint decoder that comprise the region. For more details on the possible modes see /sys/bus/cxl/devices/decoderX.Y/mode

/sys/bus/cxl/devices/regionZ/resource

Defined on file *sysfs-bus-cxl*

(RO) A region is a contiguous partition of a CXL root decoder address space. Region capacity is allocated by writing to the size attribute, the resulting physical address space determined by the driver is reflected here. It is therefore not useful to read this before writing a value to the size attribute.

/sys/bus/cxl/devices/regionZ/size

Defined on file *sysfs-bus-cxl*

(RW) System physical address space to be consumed by the region. When written trigger the driver to allocate space out of the parent root decoder's address space. When read the size of the address space is reported and should match the span of the region's resource attribute. Size shall be set after the interleave configuration parameters. Once set it cannot be changed, only

freed by writing 0. The kernel makes no guarantees that data is maintained over an address space freeing event, and there is no guarantee that a free followed by an allocate results in the same address being allocated.

/sys/bus/cxl/devices/regionZ/target[0..N]

Defined on file *sysfs-bus-cxl*

(RW) Write an endpoint decoder object name to 'targetX' where X is the intended position of the endpoint device in the region interleave and N is the 'interleave_ways' setting for the region. ENXIO is returned if the write results in an impossible to map decode scenario, like the endpoint is unreachable at that position relative to the root decoder interleave. EBUSY is returned if the position in the region is already occupied, or if the region is not in a state to accept interleave configuration changes. EINVAL is returned if the object name is not an endpoint decoder. Once all positions have been successfully written a final validation for decode conflicts is performed before activating the region.

/sys/bus/cxl/devices/regionZ/uuid

Defined on file *sysfs-bus-cxl*

(RW) Write a unique identifier for the region. This field must be set for persistent regions and it must not conflict with the UUID of another region. For volatile ram regions this attribute is a read-only empty string.

/sys/bus/cxl/devices/{port,endpoint}X/parent_dport

Defined on file *sysfs-bus-cxl*

(RO) CXL port objects are instantiated for each upstream port in a CXL/PCIe switch, and for each endpoint to map the corresponding memory device into the CXL port hierarchy. When a descendant CXL port (switch or endpoint) is enumerated it is useful to know which 'dport' object in the parent CXL port routes to this descendant. The 'parent_dport' symlink points to the device representing the downstream port of a CXL switch that routes to {port,endpoint}X.

/sys/bus/cxl/flush

Defined on file *sysfs-bus-cxl*

(WO) If userspace manually unbinds a port the kernel schedules all descendant memdevs for unbind. Writing '1' to this attribute flushes that work.

/sys/bus/dfl/devices/dfl_dev.X/feature_id

Defined on file *sysfs-bus-dfl*

Read-only. It returns feature identifier local to its DFL FIU type.

Format: 0x%x

/sys/bus/dfl/devices/dfl_dev.X/fec_mode

Defined on file *sysfs-bus-dfl-devices-n3000-nios*

Read-only. Returns the FEC mode of the 25G links of the ethernet retimers configured by Nios firmware. "rs" for Reed Solomon FEC, "kr" for Fire Code FEC, "no" for NO FEC. "not supported" if the FEC mode setting is not supported, this happens when the Nios firmware version major < 3, or no link is configured to 25G. Format: string

/sys/bus/dfl/devices/dfl_dev.X/infX_cal_fail

Defined on file *sysfs-bus-dfl-devices-emif*

Read-only. It indicates if the calibration failed on this memory interface. "1" for calibration failure, "0" for OK. Format: %u

/sys/bus/dfl/devices/dfl_dev.X/infX_clear

Defined on file *sysfs-bus-dfl-devices-emif*

Write-only. Writing "1" to this file will zero out all memory data in this memory interface. Writing of other values is invalid. Format: %u

/sys/bus/dfl/devices/dfl_dev.X/infX_init_done

Defined on file *sysfs-bus-dfl-devices-emif*

Read-only. It indicates if the initialization completed on this memory interface. "1" for initialization complete, "0" for not yet. Format: %u

/sys/bus/dfl/devices/dfl_dev.X/nios_fw_version

Defined on file *sysfs-bus-dfl-devices-n3000-nios*

Read-only. Returns the version of the Nios firmware in the FPGA. Its format is "major.minor.patch". Format: %x.%x.%x

/sys/bus/dfl/devices/dfl_dev.X/retimer_A_mode

Defined on file *sysfs-bus-dfl-devices-n3000-nios*

Read-only. Returns the enumeration value of the working mode of the retimer A configured by the Nios firmware. The value is read out from shared registers filled by the Nios firmware. Now the values could be:

- "0": Reset
- "1": 4x10G
- "2": 4x25G
- "3": 2x25G
- "4": 2x25G+2x10G
- "5": 1x25G

If the Nios firmware is updated in future to support more retimer modes, more enumeration value is expected. Format: 0x%x

/sys/bus/dfl/devices/dfl_dev.X/retimer_B_mode

Defined on file *sysfs-bus-dfl-devices-n3000-nios*

Read-only. Returns the enumeration value of the working mode of the retimer B configured by the Nios firmware. The value format is the same as retimer_A_mode.

/sys/bus/dfl/devices/dfl_dev.X/type

Defined on file *sysfs-bus-dfl*

Read-only. It returns type of DFL FIU of the device. Now DFL supports 2 FIU types, 0 for FME, 1 for PORT.

Format: 0x%x

/sys/bus/drivers/corsair/<dev>/current_profile

Defined on file *sysfs-driver-hid-corsair*

Get/set the current selected profile. Values are from 1 to 3.

/sys/bus/drivers/corsair/<dev>/macro_mode

Defined on file *sysfs-driver-hid-corsair*

Get/set the current playback mode. "SW" for software mode where G-keys triggers their regular key codes. "HW" for hardware playback mode where the G-keys play their macro from the on-board memory.

/sys/bus/event_source/devices/<dev>/caps

Defined on file *sysfs-bus-event_source-devices-caps*

Attribute group to describe the capabilities exposed for a particular pmu. Each attribute of this group can expose information specific to a PMU, say pmu_name, so that userspace can understand some of the feature which the platform specific PMU supports.

One of the example available capability in supported platform like Intel is pmu_name, which exposes underlying CPU name known to the PMU driver.

Example output in powerpc: grep . /sys/bus/event_source/devices/cpu/caps/* /sys/bus/event_source/devices/cpu/caps/pmu_name:POWER9

The "branch_counter_nr" in the supported platform exposes the maximum number of counters which can be shown in the u64 counters of PERF_SAMPLE_BRANCH_COUNTERS, while the "branch_counter_width" exposes the width of each counter. Both of them can be used by the perf tool to parse the logged counters in each branch.

/sys/bus/event_source/devices/<dev>/format

Defined on file *sysfs-bus-event_source-devices-format*

Attribute group to describe the magic bits that go into perf_event_attr::config[012] for a particular pmu. Each attribute of this group defines the 'hardware' bitmask we want to export, so that userspace can deal with sane name/value pairs.

Userspace must be prepared for the possibility that attributes define overlapping bit ranges. For example:

```
attr1 = 'config:0-23'
attr2 = 'config:0-7'
attr3 = 'config:12-35'
```

Example: 'config1:1,6-10,44' Defines contents of attribute that occupies bits 1,6-10,44 of perf_event_attr::config1.

/sys/bus/event_source/devices/<pmu>/events/<event>

Defined on file *sysfs-bus-event_source-devices-events*

Per-pmu performance monitoring events specific to the running system

Each file (except for some of those with a '.' in them, '.unit' and '.scale') in the 'events' directory describes a single performance monitoring event supported by the <pmu>. The name of the file is the name of the event.

File contents:

> <term>[=<value>][,<term>[=<value>]]...

Where <term> is one of the terms listed under /sys/bus/event_source/devices/<pmu>/format/ and <value> is a number is base-16 format with a '0x' prefix (lowercase only). If a <term> is specified alone (without an assigned value), it is implied that 0x1 is assigned to that <term>.

Examples (each of these lines would be in a separate file):

> event=0x2abc event=0x423,inv,cmask=0x3 domain=0x1,offset=0x8,starting_index=0xffff domain=0x1,offset=0x8,core=?

Each of the assignments indicates a value to be assigned to a particular set of bits (as defined by the format file corresponding to the <term>) in the perf_event structure passed to the perf_open syscall.

In the case of the last example, a value replacing "?" would need to be provided by the user selecting the particular event. This is referred to as "event parameterization". Event parameters have the format 'param=?'.

/sys/bus/event_source/devices/<pmu>/events/<event>.scale

Defined on file *sysfs-bus-event_source-devices-events*

Perf event scaling factors

A string representing a floating point value expressed in scientific notation to be multiplied by the event count received from the kernel to match the unit specified in the <event>.unit file.

Example:

2.328306436538696289062 5e-10

This is provided to avoid performing floating point arithmetic in the kernel.

/sys/bus/event_source/devices/<pmu>/events/<event>.unit

Defined on file *sysfs-bus-event_source-devices-events*

Perf event units

A string specifying the English plural numerical unit that <event> (once multiplied by <event>.scale) represents.

Example:

Joules

/sys/bus/event_source/devices/dfl_fmeX/cpumask

Defined on file *sysfs-bus-event_source-devices-dfl_fme*

Read-only. This file always returns cpu which the PMU is bound for access to all fme pmu performance monitoring events.

/sys/bus/event_source/devices/dfl_fmeX/events

Defined on file *sysfs-bus-event_source-devices-dfl_fme*

Read-only. Attribute group to describe performance monitoring events specific to fme. Each attribute in this group describes a single performance monitoring event supported by this fme pmu. The name of the file is the name of the event. (See ABI/testing/sysfs-bus-event_source-devices-events).

All supported performance monitoring events are listed below.

Basic events (evtype=0x00):

```
clock = "event=0x00,evtype=0x00,portid=0xff"
```

Cache events (evtype=0x01):

```
cache_read_hit      = "event=0x00,evtype=0x01,portid=0xff"
cache_read_miss     = "event=0x01,evtype=0x01,portid=0xff"
cache_write_hit     = "event=0x02,evtype=0x01,portid=0xff"
cache_write_miss    = "event=0x03,evtype=0x01,portid=0xff"
cache_hold_request  = "event=0x05,evtype=0x01,portid=0xff"
cache_data_write_port_contention =
                      "event=0x06,evtype=0x01,portid=0xff"
cache_tag_write_port_contention =
                      "event=0x07,evtype=0x01,portid=0xff"
cache_tx_req_stall  = "event=0x08,evtype=0x01,portid=0xff"
cache_rx_req_stall  = "event=0x09,evtype=0x01,portid=0xff"
cache_eviction      = "event=0x0a,evtype=0x01,portid=0xff"
```

Fabric events (evtype=0x02):

```
fab_pcie0_read       = "event=0x00,evtype=0x02,portid=0xff"
fab_pcie0_write      = "event=0x01,evtype=0x02,portid=0xff"
fab_pcie1_read       = "event=0x02,evtype=0x02,portid=0xff"
fab_pcie1_write      = "event=0x03,evtype=0x02,portid=0xff"
fab_upi_read         = "event=0x04,evtype=0x02,portid=0xff"
fab_upi_write        = "event=0x05,evtype=0x02,portid=0xff"
fab_mmio_read        = "event=0x06,evtype=0x02,portid=0xff"
fab_mmio_write       = "event=0x07,evtype=0x02,portid=0xff"
fab_port_pcie0_read  = "event=0x00,evtype=0x02,portid=?"
fab_port_pcie0_write = "event=0x01,evtype=0x02,portid=?"
fab_port_pcie1_read  = "event=0x02,evtype=0x02,portid=?"
fab_port_pcie1_write = "event=0x03,evtype=0x02,portid=?"
fab_port_upi_read    = "event=0x04,evtype=0x02,portid=?"
fab_port_upi_write   = "event=0x05,evtype=0x02,portid=?"
fab_port_mmio_read   = "event=0x06,evtype=0x02,portid=?"
fab_port_mmio_write  = "event=0x07,evtype=0x02,portid=?"
```

VTD events (evtype=0x03):

```
vtd_port_read_transaction  = "event=0x00,evtype=0x03,portid=?"
vtd_port_write_transaction = "event=0x01,evtype=0x03,portid=?"
vtd_port_devtlb_read_hit   = "event=0x02,evtype=0x03,portid=?"
vtd_port_devtlb_write_hit  = "event=0x03,evtype=0x03,portid=?"
vtd_port_devtlb_4k_fill    = "event=0x04,evtype=0x03,portid=?"
vtd_port_devtlb_2m_fill    = "event=0x05,evtype=0x03,portid=?"
vtd_port_devtlb_1g_fill    = "event=0x06,evtype=0x03,portid=?"
```

VTD SIP events (evtype=0x04):

```
vtd_sip_iotlb_4k_hit  = "event=0x00,evtype=0x04,portid=0xff"
vtd_sip_iotlb_2m_hit  = "event=0x01,evtype=0x04,portid=0xff"
vtd_sip_iotlb_1g_hit  = "event=0x02,evtype=0x04,portid=0xff"
vtd_sip_slpwc_l3_hit  = "event=0x03,evtype=0x04,portid=0xff"
vtd_sip_slpwc_l4_hit  = "event=0x04,evtype=0x04,portid=0xff"
vtd_sip_rcc_hit       = "event=0x05,evtype=0x04,portid=0xff"
vtd_sip_iotlb_4k_miss = "event=0x06,evtype=0x04,portid=0xff"
vtd_sip_iotlb_2m_miss = "event=0x07,evtype=0x04,portid=0xff"
vtd_sip_iotlb_1g_miss = "event=0x08,evtype=0x04,portid=0xff"
vtd_sip_slpwc_l3_miss = "event=0x09,evtype=0x04,portid=0xff"
vtd_sip_slpwc_l4_miss = "event=0x0a,evtype=0x04,portid=0xff"
vtd_sip_rcc_miss      = "event=0x0b,evtype=0x04,portid=0xff"
```

/sys/bus/event_source/devices/dfl_fmeX/format

Defined on file *sysfs-bus-event_source-devices-dfl_fme*

Read-only. Attribute group to describe the magic bits that go into perf_event_attr.config for a particular pmu. (See ABI/testing/sysfs-bus-event_source-devices-format).

Each attribute under this group defines a bit range of the perf_event_attr.config. All supported attributes are listed below:

```
event  = "config:0-11"  - event ID
evtype = "config:12-15" - event type
portid = "config:16-23" - event source
```

For example:

```
fab_mmio_read = "event=0x06,evtype=0x02,portid=0xff"
```

It shows this fab_mmio_read is a fabric type (0x02) event with 0x06 local event id for overall monitoring (portid=0xff).

/sys/bus/event_source/devices/dmar*/cpumask

Defined on file *sysfs-bus-event_source-devices-iommu*

Read-only. This file always returns the CPU to which the IOMMU pmu is bound for access to all IOMMU pmu performance monitoring events.

/sys/bus/event_source/devices/dmar*/format

Defined on file *sysfs-bus-event_source-devices-iommu*

Read-only. Attribute group to describe the magic bits that go into perf_event_attr.config, perf_event_attr.config1 or perf_event_attr.config2 for the IOMMU pmu. (See also ABI/testing/sysfs-bus-event_source-devices-format).

Each attribute in this group defines a bit range in perf_event_attr.config, perf_event_attr.config1, or perf_event_attr.config2. All supported attributes are listed below (See the VT-d Spec 4.0 for possible attribute values):

```
event               = "config:0-27"   - event ID
event_group         = "config:28-31"  - event group ID

filter_requester_en = "config1:0"     - Enable Requester ID filter
filter_domain_en    = "config1:1"     - Enable Domain ID filter
filter_pasid_en     = "config1:2"     - Enable PASID filter
filter_ats_en       = "config1:3"     - Enable Address Type filter
filter_page_table_en= "config1:4"     - Enable Page Table Level filter
filter_requester_id = "config1:16-31" - Requester ID filter
filter_domain       = "config1:32-47" - Domain ID filter
filter_pasid        = "config2:0-21"  - PASID filter
filter_ats          = "config2:24-28" - Address Type filter
filter_page_table   = "config2:32-36" - Page Table Level filter
```

/sys/bus/event_source/devices/dsa*/cpumask

Defined on file *sysfs-bus-event_source-devices-dsa*

Read-only. This file always returns the cpu to which the IDXD DSA pmu is bound for access to all dsa pmu performance monitoring events.

/sys/bus/event_source/devices/dsa*/format

Defined on file *sysfs-bus-event_source-devices-dsa*

Read-only. Attribute group to describe the magic bits that go into perf_event_attr.config or perf_event_attr.config1 for the IDXD DSA pmu. (See also ABI/testing/sysfs-bus-event_source-devices-format).

Each attribute in this group defines a bit range in perf_event_attr.config or perf_event_attr.config1. All supported attributes are listed below (See the IDXD DSA Spec for possible attribute values):

```
event_category = "config:0-3"    - event category
event          = "config:4-31"   - event ID

filter_wq      = "config1:0-31"  - workqueue filter
filter_tc      = "config1:32-39" - traffic class filter
filter_pgsz    = "config1:40-43" - page size filter
filter_sz      = "config1:44-51" - transfer size filter
filter_eng     = "config1:52-59" - engine filter
```

/sys/bus/event_source/devices/hv_24x7/event_descs/<event-name>

Defined on file *sysfs-bus-event_source-devices-hv_24x7*

Provides the description of a particular event as provided by the firmware. If firmware does not provide a description, no file will be created.

Note that the event-name lacks the domain suffix appended for events in the events/ dir.

/sys/bus/event_source/devices/hv_24x7/event_long_descs/<event-name>

Defined on file *sysfs-bus-event_source-devices-hv_24x7*

Provides the "long" description of a particular event as provided by the firmware. If firmware does not provide a description, no file will be created.

Note that the event-name lacks the domain suffix appended for events in the events/ dir.

/sys/bus/event_source/devices/hv_24x7/format

Defined on file *sysfs-bus-event_source-devices-hv_24x7*

Read-only. Attribute group to describe the magic bits that go into perf_event_attr.config for a particular pmu. (See ABI/testing/sysfs-bus-event_source-devices-format).

Each attribute under this group defines a bit range of the perf_event_attr.config. All supported attributes are listed below:

```
chip = "config:16-31"
core  = "config:16-31"
domain = "config:0-3"
lpar = "config:0-15"
```

```
offset = "config:32-63"
vcpu = "config:16-31"
```

For example:

```
PM_PB_CYC =  "domain=1,offset=0x80,chip=?,lpar=0x0"
```

In this event, '?' after chip specifies that this value will be provided by user while running this event.

/sys/bus/event_source/devices/hv_24x7/interface/catalog

Defined on file *sysfs-bus-event_source-devices-hv_24x7*

Provides access to the binary "24x7 catalog" provided by the hypervisor on POWER7 and 8 systems. This catalog lists events available from the powerpc "hv_24x7" pmu. Its format is documented here: https://raw.githubusercontent.com/jmesmon/catalog-24x7/master/hv-24x7-catalog.h

/sys/bus/event_source/devices/hv_24x7/interface/catalog_length

Defined on file *sysfs-bus-event_source-devices-hv_24x7*

A number equal to the length in bytes of the catalog. This is also extractable from the provided binary "catalog" sysfs entry.

/sys/bus/event_source/devices/hv_24x7/interface/catalog_version

Defined on file *sysfs-bus-event_source-devices-hv_24x7*

Exposes the "version" field of the 24x7 catalog. This is also extractable from the provided binary "catalog" sysfs entry.

/sys/bus/event_source/devices/hv_gpci/format

Defined on file *sysfs-bus-event_source-devices-hv_gpci*

Read-only. Attribute group to describe the magic bits that go into perf_event_attr.config for a particular pmu. (See ABI/testing/sysfs-bus-event_source-devices-format).

Each attribute under this group defines a bit range of the perf_event_attr.config. All supported attributes are listed below:

```
counter_info_version  = "config:16-23"
length  = "config:24-31"
partition_id  = "config:32-63"
request = "config:0-31"
sibling_part_id = "config:32-63"
hw_chip_id = "config:32-63"
offset = "config:32-63"
phys_processor_idx = "config:32-63"
```

```
secondary_index = "config:0-15"
starting_index = "config:32-63"
```

For example:

```
processor_core_utilization_instructions_completed = "request=0x94,
                      phys_processor_idx=?,counter_info_version=0x8,
                      length=8,offset=0x18"
```

In this event, '?' after phys_processor_idx specifies this value this value will be provided by user while running this event.

/sys/bus/event_source/devices/hv_gpci/interface/collect_privileged

Defined on file *sysfs-bus-event_source-devices-hv_gpci*

'0' if the hypervisor is configured to forbid access to event counters being accumulated by other guests and to physical domain event counters.

'1' if that access is allowed.

/sys/bus/event_source/devices/hv_gpci/interface/expanded

Defined on file *sysfs-bus-event_source-devices-hv_gpci*

0 or 1. Indicates whether we have access to "EXPANDED" events (listed in arch/powerpc/perf/hv-gpci.h).

/sys/bus/event_source/devices/hv_gpci/interface/ga

Defined on file *sysfs-bus-event_source-devices-hv_gpci*

0 or 1. Indicates whether we have access to "GA" events (listed in arch/powerpc/perf/hv-gpci.h).

/sys/bus/event_source/devices/hv_gpci/interface/kernel_version

Defined on file *sysfs-bus-event_source-devices-hv_gpci*

A number indicating the latest version of the gpci interface that the kernel is aware of.

/sys/bus/event_source/devices/hv_gpci/interface/lab

Defined on file *sysfs-bus-event_source-devices-hv_gpci*

0 or 1. Indicates whether we have access to "LAB" events (listed in arch/powerpc/perf/hv-gpci.h).

/sys/bus/event_source/devices/hv_gpci/interface/version

Defined on file *sysfs-bus-event_source-devices-hv_gpci*

A number indicating the version of the gpci interface that the hypervisor reports supporting.

/sys/bus/event_source/devices/nmemX/cpumask

Defined on file *sysfs-bus-nvdimm*

(RO) This sysfs file exposes the cpumask which is designated to to retrieve nvdimm pmu event counter data.

/sys/bus/event_source/devices/nmemX/events

Defined on file *sysfs-bus-nvdimm*

(RO) Attribute group to describe performance monitoring events for the nvdimm memory device. Each attribute in this group describes a single performance monitoring event supported by this nvdimm pmu. The name of the file is the name of the event. (See ABI/testing/sysfs-bus-event_source-devices-events). A listing of the events supported by a given nvdimm provider type can be found in Documentation/driver-api/nvdimm/$provider.

/sys/bus/event_source/devices/nmemX/format

Defined on file *sysfs-bus-nvdimm*

(RO) Attribute group to describe the magic bits that go into perf_event_attr.config for a particular pmu. (See ABI/testing/sysfs-bus-event_source-devices-format).

Each attribute under this group defines a bit range of the perf_event_attr.config. Supported attribute is listed below:

```
event  = "config:0-4"  - event ID
```

For example:

```
ctl_res_cnt = "event=0x1"
```

/sys/bus/event_source/devices/uncore_*/alias

Defined on file *sysfs-bus-event_source-devices-uncore*

Read-only. An attribute to describe the alias name of the uncore PMU if an alias exists on some platforms. The 'perf(1)' tool should treat both names the same. They both can be used to access the uncore PMU.

Example:

$ cat /sys/devices/uncore_cha_2/alias uncore_type_0_2

/sys/bus/fcoe/

Defined on file *sysfs-bus-fcoe*

The FCoE bus. Attributes in this directory are control interfaces.

Attributes:

ctlr_create:
'FCoE Controller' instance creation interface. Writing an <ifname> to this file will allocate and populate sysfs with a fcoe_ctlr_device (ctlr_X). The user can then configure any per-port settings and finally write to the fcoe_ctlr_device's 'start' attribute to begin the kernel's discovery and login process.

ctlr_destroy:
'FCoE Controller' instance removal interface. Writing a fcoe_ctlr_device's sysfs name to this file will log the fcoe_ctlr_device out of the fabric or otherwise connected FCoE devices. It will also free all kernel memory allocated for this fcoe_ctlr_device and any structures associated with it, this includes the scsi_host.

/sys/bus/fcoe/devices/ctlr_X

Defined on file *sysfs-bus-fcoe*

'FCoE Controller' instances on the fcoe bus. The FCoE Controller now has a three stage creation process. 1) Write interface name to ctlr_create 2) Configure the FCoE Controller (ctlr_X) 3) Enable the FCoE Controller to begin discovery and login. The FCoE Controller is destroyed by writing its name, i.e. ctlr_X to the ctlr_delete file.

Attributes:

fcf_dev_loss_tmo:
Device loss timeout period (see below). Changing this value will change the dev_loss_tmo for all FCFs discovered by this controller.

mode:
Display or change the FCoE Controller's mode. Possible modes are 'Fabric' and 'VN2VN'. If a FCoE Controller is started in 'Fabric' mode then FIP FCF discovery is initiated and ultimately a fabric login is attempted. If a FCoE Controller is started in 'VN2VN' mode then FIP VN2VN discovery and login is performed. A FCoE Controller only supports one mode at a time.

enabled:
Whether an FCoE controller is enabled or disabled. 0 if disabled, 1 if enabled. Writing either 0 or 1 to this file will enable or disable the FCoE controller.

lesb/link_fail:
Link Error Status Block (LESB) link failure count.

lesb/vlink_fail:
Link Error Status Block (LESB) virtual link failure count.

lesb/miss_fka:
Link Error Status Block (LESB) missed FCoE Initialization Protocol (FIP) Keep-Alives (FKA).

lesb/symb_err:
Link Error Status Block (LESB) symbolic error count.

lesb/err_block:
Link Error Status Block (LESB) block error count.

lesb/fcs_error:
Link Error Status Block (LESB) Fibre Channel Services error count.

Notes: ctlr_X (global increment starting at 0)

/sys/bus/fcoe/devices/fcf_X

Defined on file *sysfs-bus-fcoe*

'FCoE FCF' instances on the fcoe bus. A FCF is a Fibre Channel Forwarder, which is a FCoE switch that can accept FCoE (Ethernet) packets, unpack them, and forward the embedded Fibre Channel frames into a FC fabric. It can also take outbound FC frames and pack them in Ethernet packets to be sent to their destination on the Ethernet segment.

Attributes:

fabric_name:
Identifies the fabric that the FCF services.

switch_name:
Identifies the FCF.

priority:
The switch's priority amongst other FCFs on the same fabric.

selected:
1 indicates that the switch has been selected for use; 0 indicates that the switch will not be used.

fc_map:
The Fibre Channel MAP

vfid:
The Virtual Fabric ID

mac:
The FCF's MAC address

fka_period:
The FIP Keep-Alive period

fabric_state: The internal kernel state

- ”Unknown” - Initialization value
- ”Disconnected” - No link to the FCF/fabric
- ”Connected” - Host is connected to the FCF
- ”Deleted” - FCF is being removed from the system

dev_loss_tmo: The device loss timeout period for this FCF.

Notes: A device loss infrastructure similar to the FC Transport's
is present in fcoe_sysfs. It is nice to have so that a link flapping adapter doesn't continually advance the count used to identify the discovered FCF. FCFs will exist in a ”Disconnected” state until either the timer expires and the FCF becomes ”Deleted” or the FCF is rediscovered and becomes ”Connected.”

Users: The first user of this interface will be the fcoeadm application, which is commonly packaged in the fcoe-utils package.

/sys/bus/fsi/devices/XX.XX.00:06/sbefifoX/timeout

Defined on file *sysfs-bus-fsi-devices-sbefifo*

Indicates whether or not this SBE device has experienced a timeout; i.e. the SBE did not respond within the time allotted by the driver. A value of 1 indicates that a timeout has occurred and no transfers have completed since the timeout. A value of 0 indicates that no timeout has occurred, or if one has, more recent transfers have completed successfully.

/sys/bus/fsl-mc/drivers/.../bind

Defined on file *sysfs-bus-fsl-mc*

Writing a device location to this file will cause the driver to attempt to bind to the device found at this location. The format for the location is Object.Id and is the same as found in /sys/bus/fsl-mc/devices/.

For example:

```
# echo dpni.2 > /sys/bus/fsl-mc/drivers/fsl_dpaa2_eth/bind
```

/sys/bus/fsl-mc/drivers/.../unbind

Defined on file *sysfs-bus-fsl-mc*

Writing a device location to this file will cause the driver to attempt to unbind from the device found at this location. The format for the location is Object.Id and is the same as found in /sys/bus/fsl-mc/devices/.

For example:

```
# echo dpni.2 > /sys/bus/fsl-mc/drivers/fsl_dpaa2_eth/unbind
```

/sys/bus/hid/devices/<bus>:<vid>:<pid>.<n>/speed

Defined on file *sysfs-driver-wacom*

The /sys/bus/hid/devices/<bus>:<vid>:<pid>.<n>/speed file controls reporting speed of Wacom bluetooth tablet. Reading from this file returns 1 if tablet reports in high speed mode or 0 otherwise. Writing to this file one of these values switches reporting speed.

/sys/bus/hid/devices/<bus>:<vid>:<pid>.<n>/wacom_led/button<n>_rawimg

Defined on file *sysfs-driver-wacom*

When writing a 1024 byte raw image in Wacom Intuos 4 interleaving format to the file, the image shows up on Button N of the device. The image is a 64x32 pixel 4-bit gray image. The 1024 byte binary is split up into 16x 64 byte chunks. Each 64 byte chunk encodes the image data for two consecutive lines on the display. The low nibble of each byte contains the first line, and the high nibble contains the second line. When the Wacom Intuos 4 is connected over Bluetooth, the image has to contain 256 bytes (64x32 px 1 bit colour). The format is also scrambled, like in the USB mode, and it can be summarized by converting:

```
76543210 into GECA6420.
HGFEDCBA      HFDB7531
```

/sys/bus/hid/devices/<bus>:<vid>:<pid>.<n>/wacom_led/buttons_luminance

Defined on file *sysfs-driver-wacom*

Writing to this file sets the overall luminance level (0..15) of all eight button OLED displays.

/sys/bus/hid/devices/<bus>:<vid>:<pid>.<n>/wacom_led/led

Defined on file *sysfs-driver-wacom*

Attribute group for control of the status LEDs and the OLEDs. This attribute group is only available for Intuos 4 M, L, and XL (with LEDs and OLEDs), Intuos 4 WL, Intuos 5 (LEDs only), Intuos Pro (LEDs only) and Cintiq 21UX2 and Cintiq 24HD (LEDs only). Therefore its presence implicitly signifies the presence of said LEDs and OLEDs on the tablet device.

/sys/bus/hid/devices/<bus>:<vid>:<pid>.<n>/wacom_led/status0_luminance

Defined on file *sysfs-driver-wacom*

<obsoleted by the LED class API now exported by the driver> Writing to this file sets the status LED luminance (1..127) when the stylus does not touch the tablet surface, and no button is pressed on the stylus. This luminance level is normally lower than the level when a button is pressed.

/sys/bus/hid/devices/<bus>:<vid>:<pid>.<n>/wacom_led/status1_luminance

Defined on file *sysfs-driver-wacom*

<obsoleted by the LED class API now exported by the driver> Writing to this file sets the status LED luminance (1..127) when the stylus touches the tablet surface, or any button is pressed on the stylus.

/sys/bus/hid/devices/<bus>:<vid>:<pid>.<n>/wacom_led/status_led0_select

Defined on file *sysfs-driver-wacom*

<obsoleted by the LED class API now exported by the driver> Writing to this file sets which one of the four (for Intuos 4 and Intuos 5) or of the right four (for Cintiq 21UX2 and Cintiq 24HD) status LEDs is active (0..3). The other three LEDs on the same side are always inactive.

/sys/bus/hid/devices/<bus>:<vid>:<pid>.<n>/wacom_led/status_led1_select

Defined on file *sysfs-driver-wacom*

<obsoleted by the LED class API now exported by the driver> Writing to this file sets which one of the left four (for Cintiq 21UX2 and Cintiq 24HD) status LEDs is active (0..3). The other three LEDs on the left are always inactive.

/sys/bus/hid/devices/<bus>:<vid>:<pid>.<n>/wacom_remote/<serial_number>/remote_mo

Defined on file *sysfs-driver-wacom*

<obsoleted by the LED class API now exported by the driver> Reading from this file reports the mode status of the remote as indicated by the LED lights on the device. If no reports have been received from the paired device, reading from this file will report '-1'. The mode is read-only and cannot be set through the driver.

/sys/bus/hid/devices/<bus>:<vid>:<pid>.<n>/wacom_remote/unpair_remote

Defined on file *sysfs-driver-wacom*

Writing the character sequence '*' followed by a newline to this file will delete all of the current pairings on the device. Other character sequences are reserved. This file is write only.

/sys/bus/hid/drivers/logitech-hidpp-device/<dev>/builtin_power_supply

Defined on file *sysfs-driver-hid-logitech-hidpp*

Presence of this file indicates that HID++ driver is capable of handling battery properties in the kernel. This way, upower can add a udev rule to decide whether or not it should use the internal unifying support or the generic kernel one.

/sys/bus/hid/drivers/logitech-hidpp-device/<dev>/range

Defined on file *sysfs-driver-hid-logitech-hidpp*

(RW) This attribute controls the amount of 'turn' permitted in Logitech G920 wheel. Reading from the file shows the current range of the steering wheel. Writing a value within the min and max boundary sets the range of the wheel.

/sys/bus/hid/drivers/logitech/<dev>/alternate_modes

Defined on file *sysfs-driver-hid-logitech-lg4ff*

Displays a set of alternate modes supported by a wheel. Each mode is listed as follows:

Tag: Mode Name

Currently active mode is marked with an asterisk. List also contains an abstract item ”native” which always denotes the native mode of the wheel. Echoing the mode tag switches the wheel into the corresponding mode. Depending on the exact model of the wheel not all listed modes might always be selectable. If a wheel cannot be switched into the desired mode, -EINVAL is returned accompanied with an explanatory message in the kernel log. This entry is not created for devices that have only one mode.

Currently supported mode switches:

Driving Force Pro:

```
DF-EX --> DFP
```

G25:

```
DF-EX --> DFP --> G25
```

G27:

```
DF-EX <*> DFP <-> G25 <-> G27
DF-EX <*--------> G25 <-> G27
DF-EX <*----------------> G27
```

G29:

```
DF-EX <*> DFP <-> G25 <-> G27 <-> G29
DF-EX <*--------> G25 <-> G27 <-> G29
DF-EX <*----------------> G27 <-> G29
DF-EX <*------------------------> G29
```

DFGT:

```
DF-EX <*> DFP <-> DFGT
DF-EX <*--------> DFGT
```

- hid_logitech module must be loaded with lg4ff_no_autoswitch=1 parameter set in order for the switch to DF-EX mode to work.

/sys/bus/hid/drivers/logitech/<dev>/combine_pedals

Defined on file *sysfs-driver-hid-logitech-lg4ff*

Controls whether a combined value of accelerator and brake is reported on the Y axis of the controller. Useful for older games which can do not work with separate accelerator/brake axis. Off ('0') by default, enabled by setting '1'.

/sys/bus/hid/drivers/logitech/<dev>/range

Defined on file *sysfs-driver-hid-logitech-lg4ff*

Display minimum, maximum and current range of the steering wheel. Writing a value within min and max boundaries sets the range of the wheel.

/sys/bus/hid/drivers/logitech/<dev>/real_id

Defined on file *sysfs-driver-hid-logitech-lg4ff*

Displays the real model of the wheel regardless of any alternate mode the wheel might be switched to. It is a read-only value. This entry is not created for devices that have only one mode.

/sys/bus/hid/drivers/ntrig/<dev>/activate_slack

Defined on file *sysfs-driver-hid-ntrig*

(RW) Number of contact frames ignored before acknowledging the start of activity (activating touch).

/sys/bus/hid/drivers/ntrig/<dev>/activation_width
/sys/bus/hid/drivers/ntrig/<dev>/activation_height

Defined on file *sysfs-driver-hid-ntrig*

Threholds to override activation slack.

activation_width	(RW) Width threshold to immediately start processing touch events.
activation_height	(RW) Height threshold to immediately start processing touch events.

/sys/bus/hid/drivers/ntrig/<dev>/decativate_slack

Defined on file *sysfs-driver-hid-ntrig*

(RW) Number of empty (no contact) frames ignored before acknowledging the end of activity (deactivating touch).

When the last finger is removed from the device, it sends a number of empty frames. By holding off on deactivation for a few frames false erroneous disconnects can be tolerated, where the sensor may mistakenly not detect a finger that is still present.

/sys/bus/hid/drivers/ntrig/<dev>/min_width
/sys/bus/hid/drivers/ntrig/<dev>/min_height

Defined on file *sysfs-driver-hid-ntrig*

Minimum size contact accepted.

min_width	(RW) Minimum touch contact width to decide activation and activity.
min_height	(RW) Minimum touch contact height to decide activation and activity.

/sys/bus/hid/drivers/ntrig/<dev>/sensor_logical_width
/sys/bus/hid/drivers/ntrig/<dev>/sensor_logical_height

Defined on file *sysfs-driver-hid-ntrig*

(RO) The range for positions reported during activity.

/sys/bus/hid/drivers/ntrig/<dev>/sensor_physical_width
/sys/bus/hid/drivers/ntrig/<dev>/sensor_physical_height

Defined on file *sysfs-driver-hid-ntrig*

(RO) These are internal ranges not used for normal events but useful for tuning.

/sys/bus/hid/drivers/prodikeys/.../channel

Defined on file *sysfs-driver-hid-prodikeys*

Allows control (via software) the midi channel to which that the pc-midi keyboard will output.midi data. Range: 0..15 Type: Read/write

/sys/bus/hid/drivers/prodikeys/.../octave

Defined on file *sysfs-driver-hid-prodikeys*

Controls the octave shift modifier in the pc-midi driver. The octave can be shifted via software up/down 2 octaves. 0 means the no ocatve shift. Range: -2..2 (minus 2 to plus 2) Type: Read/Write

/sys/bus/hid/drivers/prodikeys/.../sustain

Defined on file *sysfs-driver-hid-prodikeys*

Allows control (via software) the sustain duration of a note held by the pc-midi driver. 0 means sustain mode is disabled. Range: 0..5000 (milliseconds) Type: Read/write

/sys/bus/hid/drivers/wiimote/<dev>/bboard_calib

Defined on file *sysfs-driver-hid-wiimote*

This attribute is only provided if the device was detected as a balance board. It provides a single line with 3 calibration values for all 4 sensors. The values are separated by colons and are each 2 bytes long (encoded as 4 digit hexadecimal value). First, 0kg values for all 4 sensors are written, followed by the 17kg values for all 4 sensors and last the 34kg values for all 4 sensors.

Calibration data is already applied by the kernel to all input values but may be used by user-space to perform other transformations.

/sys/bus/hid/drivers/wiimote/<dev>/devtype

Defined on file *sysfs-driver-hid-wiimote*

While a device is initialized by the wiimote driver, we perform a device detection and signal a ”change” uevent after it is done. This file shows the detected device type. ”pending” means that the detection is still ongoing, ”unknown” means, that the device couldn't be detected or loaded. ”generic” means, that the device couldn't be detected but supports basic Wii Remote features and can be used. Other strings for each device-type are available and may be added if new device-specific detections are added. Currently supported are:

gen10:	First Wii Remote generation
gen20:	Second Wii Remote Plus generation (builtin MP)
balanceboard:	Wii Balance Board

/sys/bus/hid/drivers/wiimote/<dev>/extension

Defined on file *sysfs-driver-hid-wiimote*

This file contains the currently connected and initialized extensions. It can be one of: none, motionp, nunchuck, classic, motionp+nunchuck, motionp+classic motionp is the official Nintendo Motion+ extension, nunchuck is the official Nintendo Nunchuck extension and classic is the Nintendo Classic Controller extension. The motionp extension can be combined with the other two.

Starting with kernel-version 3.11 Motion Plus hotplugging is supported and if detected, it's no longer reported as static extension. You will get uevent notifications for the motion-plus device then.

/sys/bus/hid/drivers/wiimote/<dev>/led1
/sys/bus/hid/drivers/wiimote/<dev>/led2
/sys/bus/hid/drivers/wiimote/<dev>/led3
/sys/bus/hid/drivers/wiimote/<dev>/led4

Defined on file *sysfs-driver-hid-wiimote*

Make it possible to set/get current led state. Reading from it returns 0 if led is off and 1 if it is on. Writing 0 to it disables the led, writing 1 enables it.

/sys/bus/hid/drivers/wiimote/<dev>/pro_calib

Defined on file *sysfs-driver-hid-wiimote*

This attribute is only provided if the device was detected as a pro-controller. It provides a single line with 4 calibration values for all 4 analog sticks. Format is: "x1:y1 x2:y2". Data is prefixed with a +/-. Each value is a signed 16bit number. Data is encoded as decimal numbers and specifies the offsets of the analog sticks of the pro-controller.

Calibration data is already applied by the kernel to all input values but may be used by user-space to perform other transformations.

Calibration data is detected by the kernel during device setup. You can write "scann" into this file to re-trigger calibration. You can also write data directly in the form "x1:y1 x2:y2" to set the calibration values manually.

/sys/bus/hsi

Defined on file *sysfs-bus-hsi*

High Speed Synchronous Serial Interface (HSI) is a serial interface mainly used for connecting application engines (APE) with cellular modem engines (CMT) in cellular handsets. The bus will be populated with devices (hsi_clients) representing the protocols available in the system. Bus drivers implement those protocols.

/sys/bus/hsi/devices/.../modalias

Defined on file *sysfs-bus-hsi*

Stores the same MODALIAS value emitted by uevent Format: hsi:<hsi_client device name>

/sys/bus/i2c/.../idle_state

Defined on file *sysfs-bus-i2c-devices-pca954x*

Value that exists only for mux devices that can be written to control the behaviour of the multiplexer on idle. Possible values:

-2	disconnect on idle, i.e. deselect the last used channel, which is useful when there is a device with an address that conflicts with another device on another mux on the same parent bus.
-1	leave the mux as-is, which is the most optimal setting in terms of I2C operations and is the default mode.
0..<nchans>	set the mux to a predetermined channel, which is useful if there is one channel that is used almost always, and you want to reduce the latency for normal operations after rare transactions on other channels

/sys/bus/i2c/devices/.../bd9571mwv-regulator.*.auto/backup_mode

Defined on file *sysfs-driver-bd9571mwv-regulator*

Read/write the current state of DDR Backup Mode, which controls if DDR power rails will be kept powered during system suspend. ("on"/"1" = enabled, "off"/"0" = disabled). Two types of power switches (or control signals) can be used:

A. With a momentary power switch (or pulse signal), DDR Backup Mode is enabled by default when available, as the PMIC will be configured only during system suspend.

B. With a toggle power switch (or level signal), the following steps must be followed exactly:

   1. Configure PMIC for backup mode, to change the role of the accessory power switch from a power switch to a wake-up switch,
   2. Switch accessory power switch off, to prepare for system suspend, which is a manual step not controlled by software,
   3. Suspend system,
   4. Switch accessory power switch on, to resume the system.

   DDR Backup Mode must be explicitly enabled by the user, to invoke step 1.

See also Documentation/devicetree/bindings/mfd/rohm,bd9571mwv.yaml.

Users: User space applications for embedded boards equipped with a BD9571MWV PMIC.

/sys/bus/i2c/devices/.../calibration

Defined on file *sysfs-bus-i2c-devices-hm6352*

Sets the calibration on or off (1 = on, 0 = off). See the chip data sheet.

/sys/bus/i2c/devices/.../device

Defined on file *sysfs-bus-i2c-devices-fsa9480*

show what device is attached

NONE	no device
USB	USB device is attached
UART	UART is attached
CHARGER	Charger is attached
JIG	JIG is attached

/sys/bus/i2c/devices/.../heading0_input

Defined on file *sysfs-bus-i2c-devices-hm6352*

Reports the current heading from the compass as a floating point value in degrees.

/sys/bus/i2c/devices/.../output_hvled[n]

Defined on file *sysfs-bus-i2c-devices-lm3533*

Set the controlling backlight device for high-voltage current sink HVLED[n] (n = 1, 2) (0, 1).

/sys/bus/i2c/devices/.../output_lvled[n]

Defined on file *sysfs-bus-i2c-devices-lm3533*

Set the controlling led device for low-voltage current sink LVLED[n] (n = 1..5) (0..3).

/sys/bus/i2c/devices/.../power_state

Defined on file *sysfs-bus-i2c-devices-hm6352*

Sets the power state of the device. 0 sets the device into sleep mode, 1 wakes it up.

/sys/bus/i2c/devices/.../switch

Defined on file *sysfs-bus-i2c-devices-fsa9480*

show or set the state of manual switch

VAUDIO	switch to VAUDIO path
UART	switch to UART path
AUDIO	switch to AUDIO path
DHOST	switch to DHOST path
AUTO	switch automatically by device

/sys/bus/i2c/devices/.../trickle_charge_bypass

Defined on file *sysfs-bus-i2c-devices-bq32k*

Attribute for enable/disable the trickle charge bypass The trickle_charge_bypass attribute allows the userspace to enable/disable the Trickle charge FET bypass.

/sys/bus/i2c/devices/xxx/fw_version

Defined on file *sysfs-driver-input-exc3000*

Reports the firmware version provided by the touchscreen, for example "00_T6" on a EXC80H60

Access: Read

Valid values: Represented as string

/sys/bus/i2c/devices/xxx/model

Defined on file *sysfs-driver-input-exc3000*

Reports the model identification provided by the touchscreen, for example "Orion_1320" on a EXC80H60

Access: Read

Valid values: Represented as string

/sys/bus/i2c/devices/xxx/type

Defined on file *sysfs-driver-input-exc3000*

Reports the type identification provided by the touchscreen, for example "PCAP82H80 Series"

Access: Read

Valid values: Represented as string

/sys/bus/i2c/drivers/ucsi_ccg/.../do_flash

Defined on file *sysfs-driver-ucsi-ccg*

Tell the driver for Cypress CCGx Type-C controller to attempt firmware upgrade by writing [Yy1] to the file.

/sys/bus/i3c/devices/<bus-id>-<device-pid>

Defined on file *sysfs-bus-i3c*

These directories are just symbolic links to */sys/bus/i3c/devices/i3c-<bus-id>/<bus-id>-<device-pid>*.

/sys/bus/i3c/devices/i3c-<bus-id>

Defined on file *sysfs-bus-i3c*

An I3C bus. This directory will contain one sub-directory per I3C device present on the bus.

/sys/bus/i3c/devices/i3c-<bus-id>/<bus-id>-<device-pid>

Defined on file *sysfs-bus-i3c*

An I3C device present on I3C bus identified by <bus-id>. Note that all devices are represented including the master driving the bus.

/sys/bus/i3c/devices/i3c-<bus-id>/<bus-id>-<device-pid>/bcr

Defined on file *sysfs-bus-i3c*

BCR stands for Bus Characteristics Register and express the device capabilities in term of speed, maximum read/write length, etc. See the I3C specification for more details.

/sys/bus/i3c/devices/i3c-<bus-id>/<bus-id>-<device-pid>/dcr

Defined on file *sysfs-bus-i3c*

DCR stands for Device Characteristics Register and express the device capabilities in term of exposed features. See the I3C specification for more details.

/sys/bus/i3c/devices/i3c-<bus-id>/<bus-id>-<device-pid>/dynamic_address

Defined on file *sysfs-bus-i3c*

Dynamic address assigned to device <bus-id>-<device-pid>. This address may change if the bus is re-initialized.

/sys/bus/i3c/devices/i3c-<bus-id>/<bus-id>-<device-pid>/hdrcap

Defined on file *sysfs-bus-i3c*

Expose the HDR (High Data Rate) capabilities of a device. Returns a list of supported HDR mode, each element is separated by space. Modes can be ”hdr-ddr”, ”hdr-tsp” and ”hdr-tsl”.

See the I3C specification for more details about these HDR modes.

/sys/bus/i3c/devices/i3c-<bus-id>/<bus-id>-<device-pid>/pid

Defined on file *sysfs-bus-i3c*

PID stands for Provisioned ID and is used to uniquely identify a device on a bus. This PID contains information about the vendor, the part and an instance ID so that several devices of the same type can be connected on the same bus. See the I3C specification for more details.

/sys/bus/i3c/devices/i3c-<bus-id>/bcr

Defined on file *sysfs-bus-i3c*

BCR stands for Bus Characteristics Register and express the device capabilities in term of speed, maximum read/write length, etc. See the I3C specification for more details. This entry describes the BCR of the master controller driving the bus.

/sys/bus/i3c/devices/i3c-<bus-id>/current_master

Defined on file *sysfs-bus-i3c*

Expose the master that owns the bus (<bus-id>-<master-pid>) at the time this file is read. Note that bus ownership can change overtime, so there's no guarantee that when the read() call returns, the value returned is still valid.

/sys/bus/i3c/devices/i3c-<bus-id>/dcr

Defined on file *sysfs-bus-i3c*

DCR stands for Device Characteristics Register and express the device capabilities in term of exposed features. See the I3C specification for more details. This entry describes the DCR of the master controller driving the bus.

/sys/bus/i3c/devices/i3c-<bus-id>/dynamic_address

Defined on file *sysfs-bus-i3c*

Dynamic address assigned to the master controller. This address may change if the bus is re-initialized.

/sys/bus/i3c/devices/i3c-<bus-id>/hdrcap

Defined on file *sysfs-bus-i3c*

Expose the HDR (High Data Rate) capabilities of a device. Returns a list of supported HDR mode, each element is separated by space. Modes can be ”hdr-ddr”, ”hdr-tsp” and ”hdr-tsl”. See the I3C specification for more details about these HDR modes.

This entry describes the HDRCAP of the master controller driving the bus.

/sys/bus/i3c/devices/i3c-<bus-id>/hotjoin

Defined on file *sysfs-bus-i3c*

I3C’s Hot-Join mechanism allows an I3C Device to inform the Active Controller that a newly-joined Target is present on the I3C Bus and is ready to receive a Dynamic Address, in order to become fully functional on the Bus. Hot-Join is used when the Target is mounted on the same I3C bus and remains depowered until needed or until the Target is physically inserted into the I3C bus

This entry allows to enable or disable Hot-join of the Current Controller driving the bus.

/sys/bus/i3c/devices/i3c-<bus-id>/i2c_scl_frequency

Defined on file *sysfs-bus-i3c*

The frequency (expressed in Hz) of the SCL signal when operating in I2C mode.

/sys/bus/i3c/devices/i3c-<bus-id>/i3c_scl_frequency

Defined on file *sysfs-bus-i3c*

The frequency (expressed in Hz) of the SCL signal when operating in I3C SDR mode.

/sys/bus/i3c/devices/i3c-<bus-id>/mode

Defined on file *sysfs-bus-i3c*

I3C bus mode. Can be "pure", "mixed-fast" or "mixed-slow". See the I3C specification for a detailed description of what each of these modes implies.

/sys/bus/i3c/devices/i3c-<bus-id>/pid

Defined on file *sysfs-bus-i3c*

PID stands for Provisioned ID and is used to uniquely identify a device on a bus. This PID contains information about the vendor, the part and an instance ID so that several devices of the same type can be connected on the same bus. See the I3C specification for more details. This entry describes the PID of the master controller driving the bus.

/sys/bus/iio/devices/device[n]/in_illuminance0_calibrate

Defined on file *sysfs-bus-iio-light-tsl2772*

Causes an internal calibration of the als gain trim value which is later used in calculating illuminance in lux.

/sys/bus/iio/devices/device[n]/in_illuminance_calibrate

Defined on file *sysfs-bus-iio-light-tsl2583*

This property causes an internal calibration of the als gain trim value which is later used in calculating illuminance in lux.

/sys/bus/iio/devices/device[n]/in_illuminance_input_target

Defined on file *sysfs-bus-iio-light-tsl2583*

This property is the known externally illuminance (in lux). It is used in the process of calibrating the device accuracy.

/sys/bus/iio/devices/device[n]/in_illuminance_lux_table

Defined on file *sysfs-bus-iio-light-tsl2583*

This property gets/sets the table of coefficients used in calculating illuminance in lux.

/sys/bus/iio/devices/device[n]/in_proximity0_calibrate

Defined on file *sysfs-bus-iio-light-tsl2772*

Causes a recalculation and adjustment to the proximity_thresh_rising_value.

/sys/bus/iio/devices/iio:device*/buffer/hwfifo_timeout

Defined on file *sysfs-bus-iio*

A read/write property to provide capability to delay reporting of samples till a timeout is reached. This allows host processors to sleep, while the sensor is storing samples in its internal fifo. The maximum timeout in seconds can be specified by setting hwfifo_timeout.The current delay can be read by reading hwfifo_timeout. A value of 0 means that there is no timeout.

/sys/bus/iio/devices/iio:deviceX

Defined on file *sysfs-bus-iio*

Hardware chip or device accessed by one communication port. Corresponds to a grouping of sensor channels. X is the IIO index of the device.

/sys/bus/iio/devices/iio:deviceX/ac_excitation_en

Defined on file *sysfs-bus-iio-adc-ad7192*

This attribute, if available, is used to enable the AC excitation mode found on some converters. In ac excitation mode, the polarity of the excitation voltage is reversed on alternate cycles, to eliminate DC errors.

/sys/bus/iio/devices/iio:deviceX/auto_zeroing_mux_enable

Defined on file *sysfs-bus-iio-adc-mcp3564*

This attribute is used to enable the analog input multiplexer auto-zeroing algorithm (the input multiplexer and the ADC include an offset cancellation algorithm that cancels the offset contribution of the ADC). When the offset cancellation algorithm is enabled, ADC takes two conversions, one with the differential input as VIN+/VIN-, one with VIN+/VIN- inverted. In this case the conversion time is multiplied by two compared to the default case where the algorithm is disabled. This technique allows the cancellation of the ADC offset error and the achievement of ultra-low offset without any digital calibration. The resulting offset is the residue of the difference between the two conversions, which is on the order of magnitude of the noise floor. This offset is effectively canceled at every conversion, so the residual offset error temperature drift is extremely low. Write '1' to enable it, write '0' to disable it.

/sys/bus/iio/devices/iio:deviceX/auto_zeroing_ref_enable

Defined on file *sysfs-bus-iio-adc-mcp3564*

This attribute is used to enable the chopping algorithm for the internal voltage reference buffer. This setting has no effect when external voltage reference is selected. Internal voltage reference buffer injects a certain quantity of 1/f noise into the system that can be modulated with the incoming input signals and can limit the SNR performance at higher Oversampling Ratio values (over 256). To overcome this limitation, the buffer includes an auto-zeroing algorithm that greatly reduces (cancels out) the 1/f noise and cancels the offset value of the reference buffer. As a result, the SNR of the system is not affected by this 1/f noise component of the reference buffer, even at maximum oversampling ratio values. Write '1' to enable it, write '0' to disable it.

/sys/bus/iio/devices/iio:deviceX/battery_low

Defined on file *sysfs-bus-iio-meas-spec*

Reading returns either '1' or '0'. '1' means that the battery level supplied to sensor is below 2.25V. This ABI is available for tsys02d, htu21, ms8607

/sys/bus/iio/devices/iio:deviceX/boost_current_gain

Defined on file *sysfs-bus-iio-adc-mcp3564*

This attribute is used to set the gain of the biasing current circuit of the Delta-Sigma modulator. The different BOOST settings are applied to the entire modulator circuit, including the voltage reference buffers.

/sys/bus/iio/devices/iio:deviceX/boost_current_gain_available

Defined on file *sysfs-bus-iio-adc-mcp3564*

Reading returns a list with the possible gain values for the current biasing circuit of the Delta-Sigma modulator.

/sys/bus/iio/devices/iio:deviceX/bridge_switch_en

Defined on file *sysfs-bus-iio-adc-ad7192*

This attribute, if available, is used to close or open the bridge power down switch found on some converters. In bridge applications, such as strain gauges and load cells, the bridge itself consumes the majority of the current in the system. To minimize the current consumption of the system, the bridge can be disconnected (when it is not being used using the bridge_switch_en attribute.

/sys/bus/iio/devices/iio:deviceX/buffer

Defined on file *sysfs-bus-iio*

Directory of attributes relating to the buffer for the device.

/sys/bus/iio/devices/iio:deviceX/buffer/hwfifo_enabled

Defined on file *sysfs-bus-iio*

A read-only boolean value that indicates if the hardware fifo is currently enabled or disabled. If the device does not have a hardware fifo this entry is not present. The hardware fifo is enabled when the buffer is enabled if the current hardware fifo watermark level is set and other current device settings allows it (e.g. if a trigger is set that samples data differently that the hardware fifo does then hardware fifo will not enabled).

If the hardware fifo is enabled and the level of the hardware fifo reaches the hardware fifo watermark level the device will flush its hardware fifo to the device buffer. Doing a non blocking read on the device when no samples are present in the device buffer will also force a flush.

When the hardware fifo is enabled there is no need to use a trigger to use buffer mode since the watermark settings guarantees that the hardware fifo is flushed to the device buffer.

/sys/bus/iio/devices/iio:deviceX/buffer/hwfifo_watermark

Defined on file *sysfs-bus-iio*

Read-only entry that contains a single integer specifying the current watermark level for the hardware fifo. If the device does not have a hardware fifo this entry is not present. The watermark level for the hardware fifo is set by the driver based on the value set by the user in buffer/watermark but taking into account hardware limitations (e.g. most hardware buffers are limited to 32-64 samples, some hardware buffers watermarks are fixed or have minimum levels). A value of 0 means that the hardware watermark is unset.

/sys/bus/iio/devices/iio:deviceX/buffer/hwfifo_watermark_available

Defined on file *sysfs-bus-iio*

A list of positive integers specifying the available watermark levels for the hardware fifo. This entry is optional and if it is not present it means that all the values between hwfifo_watermark_min and hwfifo_watermark_max are supported.

If the user sets buffer/watermark to a value greater than hwfifo_watermak_min but not equal to any of the values in this list, the driver will chose an appropriate value for the hardware fifo watermark level.

/sys/bus/iio/devices/iio:deviceX/buffer/hwfifo_watermark_max

Defined on file *sysfs-bus-iio*

A single positive integer specifying the maximum watermark level for the hardware fifo of this device. If the device does not have a hardware fifo this entry is not present.

If the user sets buffer/watermark to a value greater than this one, then the hardware watermark will be capped at this value.

/sys/bus/iio/devices/iio:deviceX/buffer/hwfifo_watermark_min

Defined on file *sysfs-bus-iio*

A single positive integer specifying the minimum watermark level for the hardware fifo of this device. If the device does not have a hardware fifo this entry is not present.

If the user sets buffer/watermark to a value less than this one, then the hardware watermark will remain unset.

/sys/bus/iio/devices/iio:deviceX/buffer/length_align_bytes

Defined on file *sysfs-bus-iio-dma-buffer*

DMA buffers tend to have a alignment requirement for the buffers. If this alignment requirement is not met samples might be dropped from the buffer.

This property reports the alignment requirements in bytes. This means that the buffer size in bytes needs to be a integer multiple of the number reported by this file.

The alignment requirements in number of sample sets will depend on the enabled channels and the bytes per channel. This means that the alignment requirement in samples sets might change depending on which and how many channels are enabled. Whereas the alignment requirement reported in bytes by this property will remain static and does not depend on which channels are enabled.

/sys/bus/iio/devices/iio:deviceX/bufferY

Defined on file *sysfs-bus-iio*

Directory containing interfaces for elements that will be captured for a single triggered sample set in the buffer.

Since kernel 5.11 the scan_elements attributes are merged into the bufferY directory, to be configurable per buffer.

/sys/bus/iio/devices/iio:deviceX/bufferY/data_available

Defined on file *sysfs-bus-iio*

A read-only value indicating the bytes of data available in the buffer. In the case of an output buffer, this indicates the amount of empty space available to write data to. In the case of an input buffer, this indicates the amount of data available for reading.

/sys/bus/iio/devices/iio:deviceX/bufferY/enable

Defined on file *sysfs-bus-iio*

Actually start the buffer capture up. Will start trigger if first device and appropriate.

Note that it might be impossible to configure other attributes, (e.g.: events, scale, sampling rate) if they impact the currently active buffer capture session.

/sys/bus/iio/devices/iio:deviceX/bufferY/length

Defined on file *sysfs-bus-iio*

Number of scans contained by the buffer.

/sys/bus/iio/devices/iio:deviceX/bufferY/watermark

Defined on file *sysfs-bus-iio*

A single positive integer specifying the maximum number of scan elements to wait for.

Poll will block until the watermark is reached.

Blocking read will wait until the minimum between the requested read amount or the low water mark is available.

Non-blocking read will retrieve the available samples from the buffer even if there are less samples then watermark level. This allows the application to block on poll with a timeout and read the available samples after the timeout expires and thus have a maximum delay guarantee.

/sys/bus/iio/devices/iio:deviceX/calibrate

Defined on file *sysfs-bus-iio-cros-ec*

Writing '1' will perform a FOC (Fast Online Calibration). The corresponding calibration offsets can be read from *_*calibbias* entries.

/sys/bus/iio/devices/iio:deviceX/calibration_auto_enable

Defined on file *sysfs-bus-iio*

Some sensors have the ability to apply auto calibration at runtime. For example, it may be necessary to compensate for contaminant build-up in a measurement chamber or optical element deterioration that would otherwise lead to sensor drift.

Writing 1 or 0 to this attribute will respectively activate or deactivate this auto calibration function.

Upon reading, the current status is returned.

/sys/bus/iio/devices/iio:deviceX/calibration_data

Defined on file *sysfs-bus-iio-bno055*

Reports the binary calibration data blob for the IMU sensors.

/sys/bus/iio/devices/iio:deviceX/calibration_forced_value

Defined on file *sysfs-bus-iio*

Some sensors have the ability to apply a manual calibration using a known measurement value, perhaps obtained from an external reference device.

Writing a value to this function will force such a calibration change. For the scd30 the value should be from the range [400 1 2000].

Note for the scd30 that a valid value may only be obtained once it is has been written. Until then any read back of this value should be ignored. As for the scd4x an error will be returned immediately if the manual calibration has failed.

/sys/bus/iio/devices/iio:deviceX/calibration_forced_value_available

Defined on file *sysfs-bus-iio*

Available range for the forced calibration value, expressed as:

- a range specified as ”[min step max]”

/sys/bus/iio/devices/iio:deviceX/cleaning_period

Defined on file *sysfs-bus-iio-sps30*

Sensor is capable of triggering self cleaning periodically. Period can be changed by writing a new value here. Upon reading the current one is returned. Units are seconds.

Writing 0 disables periodical self cleaning entirely.

/sys/bus/iio/devices/iio:deviceX/cleaning_period_available

Defined on file *sysfs-bus-iio-sps30*

The range of available values in seconds represented as the minimum value, the step and the maximum value, all enclosed in square brackets.

/sys/bus/iio/devices/iio:deviceX/current_timestamp_clock

Defined on file *sysfs-bus-iio*

String identifying current posix clock used to timestamp buffered samples and events for device X.

/sys/bus/iio/devices/iio:deviceX/error_status

Defined on file *sysfs-bus-iio-chemical-sunrise-co2*

Reading returns the current chip error status.

/sys/bus/iio/devices/iio:deviceX/error_status_available

Defined on file *sysfs-bus-iio-chemical-sunrise-co2*

Reading returns the list of possible chip error status. Available options are: - 'error_fatal': Analog front-end initialization error - 'error_i2c': Read/write to non-existing register - 'error_algorithm': Corrupted parameters - 'error_calibration': Calibration has failed - 'error_self_diagnostic': Internal interface failure - 'error_out_of_range': Measured concentration out of scale - 'error_memory': Error during memory operations - 'error_no_measurement': Cleared at first measurement - 'error_low_voltage': Sensor regulated voltage too low - 'error_measurement_timeout': Unable to complete measurement

/sys/bus/iio/devices/iio:deviceX/events

Defined on file *sysfs-bus-iio*

Configuration of which hardware generated events are passed up to user-space.

/sys/bus/iio/devices/iio:deviceX/events/in_altvoltage0_mag_rising_reset_max

Defined on file *sysfs-bus-iio-resolver-ad2s1210*

Reading returns the current Degradation of Signal Reset Maximum Threshold value in millivolts. Writing sets the value.

/sys/bus/iio/devices/iio:deviceX/events/in_altvoltage0_mag_rising_reset_max_available

Defined on file *sysfs-bus-iio-resolver-ad2s1210*

Reading returns the allowable voltage range for in_altvoltage0_mag_rising_reset_max.

/sys/bus/iio/devices/iio:deviceX/events/in_altvoltage0_mag_rising_reset_min

Defined on file *sysfs-bus-iio-resolver-ad2s1210*

Reading returns the current Degradation of Signal Reset Minimum Threshold value in millivolts. Writing sets the value.

/sys/bus/iio/devices/iio:deviceX/events/in_altvoltage0_mag_rising_reset_min_available

Defined on file *sysfs-bus-iio-resolver-ad2s1210*

Reading returns the allowable voltage range for in_altvoltage0_mag_rising_reset_min.

/sys/bus/iio/devices/iio:deviceX/events/in_altvoltageY_mag_either_label
/sys/bus/iio/devices/iio:deviceX/events/in_altvoltageY_mag_rising_label
/sys/bus/iio/devices/iio:deviceX/events/in_altvoltageY_thresh_falling_label
/sys/bus/iio/devices/iio:deviceX/events/in_altvoltageY_thresh_rising_label
/sys/bus/iio/devices/iio:deviceX/events/in_anglvelY_mag_rising_label
/sys/bus/iio/devices/iio:deviceX/events/in_anglY_thresh_rising_label
/sys/bus/iio/devices/iio:deviceX/events/in_phaseY_mag_rising_label

Defined on file *sysfs-bus-iio*

Optional symbolic label to a device channel event. If a label is defined for this event add that to the event specific attributes. This is useful for userspace to be able to better identify an individual event.

/sys/bus/iio/devices/iio:deviceX/events/in_illuminance_period_available

Defined on file *sysfs-bus-iio*

List of valid periods (in seconds) for which the light intensity must be above the threshold level before interrupt is asserted.

/sys/bus/iio/devices/iio:deviceX/events/in_voltageY_thresh_falling_value

Defined on file *sysfs-bus-iio-adc-hi8435*

Channel Y low voltage threshold. If sensor input voltage goes lower then this value then the threshold falling event is pushed. Depending on in_voltageY_sensing_mode the low voltage threshold is separately set for "GND-Open" and "Supply-Open" modes. Channels 0..31 have common low threshold values, but could have different sensing_modes.

The low voltage threshold range is between 2..21V. Hysteresis between low and high thresholds can not be lower then 2 and can not be odd.

If falling threshold results hysteresis to odd value then rising threshold is automatically subtracted by one.

/sys/bus/iio/devices/iio:deviceX/events/in_voltageY_thresh_rising_value

Defined on file *sysfs-bus-iio-adc-hi8435*

Channel Y high voltage threshold. If sensor input voltage goes higher then this value then the threshold rising event is pushed. Depending on in_voltageY_sensing_mode the high voltage threshold is separately set for "GND-Open" and "Supply-Open" modes.

Channels 0..31 have common high threshold values, but could have different sensing_modes.

The high voltage threshold range is between 3..22V. Hysteresis between low and high thresholds can not be lower then 2 and can not be odd.

If rising threshold results hysteresis to odd value then falling threshold is automatically appended by one.

/sys/bus/iio/devices/iio:deviceX/fault_oc

Defined on file *sysfs-bus-iio-thermocouple*

Open-circuit fault. The detection of open-circuit faults, such as those caused by broken thermocouple wires. Reading returns '1' if fault, '0' otherwise.

/sys/bus/iio/devices/iio:deviceX/fault_ovuv

Defined on file *sysfs-bus-iio-thermocouple*

Overvoltage or Undervoltage Input Fault. The internal circuitry is protected from excessive voltages applied to the thermocouple cables. The device can also detect if such a condition occurs.

Reading returns '1' if input voltage is negative or greater than VDD, otherwise '0'.

/sys/bus/iio/devices/iio:deviceX/filter_mode

Defined on file *sysfs-bus-iio-filter-admv8818*

This attribute configures the filter mode. Reading returns the actual mode.

/sys/bus/iio/devices/iio:deviceX/filter_mode_available

Defined on file *sysfs-bus-iio-filter-admv8818*

Reading this returns the valid values that can be written to the on_altvoltage0_mode attribute:

- auto -> Adjust bandpass filter to track changes in input clock rate.
- manual -> disable/unregister the clock rate notifier / input clock tracking.
- **bypass -> bypass low pass filter, high pass filter and disable/unregister**
  the clock rate notifier

/sys/bus/iio/devices/iio:deviceX/fusion_enable

Defined on file *sysfs-bus-iio-bno055*

Can be 1 or 0. Enables/disables the "sensor fusion" (a.k.a. NDOF) HW function.

/sys/bus/iio/devices/iio:deviceX/heater_enable

Defined on file *sysfs-bus-iio*

'1' (enable) or '0' (disable) specifying the enable of heater function. Same reading values apply.

This ABI is especially applicable for humidity sensors to heatup the device and get rid of any condensation in some humidity environment

/sys/bus/iio/devices/iio:deviceX/id

Defined on file *sysfs-bus-iio-cros-ec*

This attribute is exposed by the CrOS EC sensors driver and represents the sensor ID as exposed by the EC. This ID is used by the Android sensor service hardware abstraction layer (sensor HAL) through the Android container on ChromeOS.

/sys/bus/iio/devices/iio:deviceX/in_X_mean_raw

Defined on file *sysfs-bus-iio*

Averaged raw measurement from channel X. The number of values used for averaging is device specific. The converting rules for normal raw values also applies to the averaged raw values.

/sys/bus/iio/devices/iio:deviceX/in_accel_calibbias_available
/sys/bus/iio/devices/iio:deviceX/in_anglvel_calibbias_available

Defined on file *sysfs-bus-iio*

Available values of calibbias. Maybe expressed as either of:

- a small discrete set of values like "0 2 4 6 8"
- a range specified as "[min step max]"

/sys/bus/iio/devices/iio:deviceX/in_accel_calibration_auto_status

Defined on file *sysfs-bus-iio-bno055*

Reports the autocalibration status for the accelerometer sensor. Can be 0 (calibration non even enabled) or 1 to 5 where the greater the number, the better the calibration status.

/sys/bus/iio/devices/iio:deviceX/in_accel_linear_x_raw
/sys/bus/iio/devices/iio:deviceX/in_accel_linear_y_raw
/sys/bus/iio/devices/iio:deviceX/in_accel_linear_z_raw

Defined on file *sysfs-bus-iio*

As per in_accel_X_raw attributes, but minus the acceleration due to gravity.

/sys/bus/iio/devices/iio:deviceX/in_accel_offset
/sys/bus/iio/devices/iio:deviceX/in_accel_x_offset
/sys/bus/iio/devices/iio:deviceX/in_accel_y_offset
/sys/bus/iio/devices/iio:deviceX/in_accel_z_offset
/sys/bus/iio/devices/iio:deviceX/in_voltageY_offset
/sys/bus/iio/devices/iio:deviceX/in_voltage_offset
/sys/bus/iio/devices/iio:deviceX/in_voltageY_i_offset
/sys/bus/iio/devices/iio:deviceX/in_voltageY_q_offset
/sys/bus/iio/devices/iio:deviceX/in_voltage_q_offset
/sys/bus/iio/devices/iio:deviceX/in_voltage_i_offset
/sys/bus/iio/devices/iio:deviceX/in_currentY_offset
/sys/bus/iio/devices/iio:deviceX/in_current_offset
/sys/bus/iio/devices/iio:deviceX/in_currentY_i_offset
/sys/bus/iio/devices/iio:deviceX/in_currentY_q_offset
/sys/bus/iio/devices/iio:deviceX/in_current_q_offset
/sys/bus/iio/devices/iio:deviceX/in_current_i_offset
/sys/bus/iio/devices/iio:deviceX/in_tempY_offset
/sys/bus/iio/devices/iio:deviceX/in_temp_offset
/sys/bus/iio/devices/iio:deviceX/in_pressureY_offset
/sys/bus/iio/devices/iio:deviceX/in_pressure_offset
/sys/bus/iio/devices/iio:deviceX/in_humidityrelative_offset
/sys/bus/iio/devices/iio:deviceX/in_magn_offset
/sys/bus/iio/devices/iio:deviceX/in_rot_offset
/sys/bus/iio/devices/iio:deviceX/in_angl_offset
/sys/bus/iio/devices/iio:deviceX/in_capacitanceX_offset

Defined on file *sysfs-bus-iio*

If known for a device, offset to be added to <type>[Y]_raw prior to scaling by <type>[Y]_scale in order to obtain value in the <type> units as specified in <type>[Y]_raw documentation. Not present if the offset is always 0 or unknown. If Y or axis <x|y|z> is not present, then the offset applies to all in channels of <type>. May be writable if a variable offset can be applied on the device. Note that this is different to calibbias which is for devices (or drivers) that apply offsets to compensate for variation between different instances of the part, typically adjusted by using some hardware supported calibration procedure. Calibbias is applied internally, offset is applied in userspace to the _raw output.

/sys/bus/iio/devices/iio:deviceX/in_accel_raw_range

Defined on file *sysfs-bus-iio-bno055*

Raw (unscaled) range for acceleration readings. Unit after application of scale is m/s^2. Note that this doesn't affects the scale (which should be used when changing the maximum and minimum readable value affects also the reading scaling factor).

/sys/bus/iio/devices/iio:deviceX/in_accel_raw_range_available

Defined on file *sysfs-bus-iio-bno055*

List of allowed values for in_accel_raw_range attribute

/sys/bus/iio/devices/iio:deviceX/in_accel_scale_available
/sys/.../iio:deviceX/in_anglvel_scale_available
/sys/.../iio:deviceX/in_magn_scale_available
/sys/.../iio:deviceX/in_illuminance_scale_available
/sys/.../iio:deviceX/in_intensity_scale_available
/sys/.../iio:deviceX/in_proximity_scale_available
/sys/.../iio:deviceX/in_voltageX_scale_available
/sys/.../iio:deviceX/in_voltage-voltage_scale_available
/sys/.../iio:deviceX/out_voltageX_scale_available
/sys/.../iio:deviceX/out_altvoltageX_scale_available
/sys/.../iio:deviceX/in_capacitance_scale_available
/sys/.../iio:deviceX/in_pressure_scale_available
/sys/.../iio:deviceX/in_pressureY_scale_available

Defined on file *sysfs-bus-iio*

If a discrete set of scale values is available, they are listed in this attribute. Unlike illumination, multiplying intensity by intensity_scale does not yield value with any standardized unit.

/sys/bus/iio/devices/iio:deviceX/in_accel_x_calibbias
/sys/bus/iio/devices/iio:deviceX/in_accel_y_calibbias
/sys/bus/iio/devices/iio:deviceX/in_accel_z_calibbias
/sys/bus/iio/devices/iio:deviceX/in_anglvel_x_calibbias
/sys/bus/iio/devices/iio:deviceX/in_anglvel_y_calibbias
/sys/bus/iio/devices/iio:deviceX/in_anglvel_z_calibbias
/sys/bus/iio/devices/iio:deviceX/in_illuminance0_calibbias
/sys/bus/iio/devices/iio:deviceX/in_proximity0_calibbias
/sys/bus/iio/devices/iio:deviceX/in_pressureY_calibbias
/sys/bus/iio/devices/iio:deviceX/in_pressure_calibbias

Defined on file *sysfs-bus-iio*

Hardware applied calibration offset (assumed to fix production inaccuracies). icm42600: For this device values are real physical offsets expressed in SI units (m/s^2 for accelerometers and rad/s for gyroscope)/

/sys/bus/iio/devices/iio:deviceX/in_accel_x_peak_raw
/sys/bus/iio/devices/iio:deviceX/in_accel_y_peak_raw
/sys/bus/iio/devices/iio:deviceX/in_accel_z_peak_raw
/sys/bus/iio/devices/iio:deviceX/in_humidityrelative_peak_raw
/sys/bus/iio/devices/iio:deviceX/in_temp_peak_raw

Defined on file *sysfs-bus-iio*

Highest value since some reset condition. These attributes allow access to this and are otherwise the direct equivalent of the <type>Y[_name]_raw attributes.

/sys/bus/iio/devices/iio:deviceX/in_accel_x_raw
/sys/bus/iio/devices/iio:deviceX/in_accel_y_raw
/sys/bus/iio/devices/iio:deviceX/in_accel_z_raw

Defined on file *sysfs-bus-iio*

Acceleration in direction x, y or z (may be arbitrarily assigned but should match other such assignments on device). Has all of the equivalent parameters as per voltageY. Units after application of scale and offset are m/s^2.

/sys/bus/iio/devices/iio:deviceX/in_accel_xyz_squared_peak_raw

Defined on file *sysfs-bus-iio*

A computed peak value based on the sum squared magnitude of the underlying value in the specified directions.

/sys/bus/iio/devices/iio:deviceX/in_activity_calibgender_available
/sys/bus/iio/devices/iio:deviceX/in_energy_calibgender_available
/sys/bus/iio/devices/iio:deviceX/in_distance_calibgender_available
/sys/bus/iio/devices/iio:deviceX/in_velocity_calibgender_available

Defined on file *sysfs-bus-iio*

Lists all available gender values (e.g.: male, female).

/sys/bus/iio/devices/iio:deviceX/in_activity_calibgender
/sys/bus/iio/devices/iio:deviceX/in_energy_calibgender
/sys/bus/iio/devices/iio:deviceX/in_distance_calibgender
/sys/bus/iio/devices/iio:deviceX/in_velocity_calibgender

Defined on file *sysfs-bus-iio*

Gender of the user (e.g.: male, female) used by some pedometers to compute the stride length, distance, speed and activity type.

/sys/bus/iio/devices/iio:deviceX/in_activity_calibheight
/sys/bus/iio/devices/iio:deviceX/in_energy_calibheight
/sys/bus/iio/devices/iio:deviceX/in_distance_calibheight
/sys/bus/iio/devices/iio:deviceX/in_velocity_calibheight

Defined on file *sysfs-bus-iio*

Height of the user (in meters) used by some pedometers to compute the stride length, distance, speed and activity type.

/sys/bus/iio/devices/iio:deviceX/in_allow_async_readout

Defined on file *sysfs-bus-iio-ina2xx-adc*

By default (value '0'), the capture thread checks for the Conversion Ready Flag to being set prior to committing a new value to the sample buffer. This synchronizes the in-chip conversion rate with the in-driver readout rate at the cost of an additional register read.

Writing '1' will remove the polling for the Conversion Ready Flags to save the additional i2c transaction, which will improve the bandwidth available for reading data. However, samples

can be occasionally skipped or repeated, depending on the beat between the capture and conversion rates.

/sys/bus/iio/devices/iio:deviceX/in_altvoltage0-1_i_calibphase

Defined on file *sysfs-bus-iio-frequency-admv1013*

Read/write unscaled value for the Local Oscillatior path quadrature I phase shift.

/sys/bus/iio/devices/iio:deviceX/in_altvoltage0-1_q_calibphase

Defined on file *sysfs-bus-iio-frequency-admv1013*

Read/write unscaled value for the Local Oscillatior path quadrature Q phase shift.

/sys/bus/iio/devices/iio:deviceX/in_altvoltage0_i_calibbias

Defined on file *sysfs-bus-iio-frequency-admv1013*

Read/write value for the Local Oscillatior Feedthrough Offset Calibration I Positive side.

/sys/bus/iio/devices/iio:deviceX/in_altvoltage0_i_calibscale_coarse

Defined on file *sysfs-bus-iio-frequency-admv1014*

Read/write value for the digital attenuator gain (IF_I) with coarse steps.

/sys/bus/iio/devices/iio:deviceX/in_altvoltage0_i_calibscale_fine

Defined on file *sysfs-bus-iio-frequency-admv1014*

Read/write value for the digital attenuator gain (IF_I) with fine steps.

/sys/bus/iio/devices/iio:deviceX/in_altvoltage0_q_calibbias

Defined on file *sysfs-bus-iio-frequency-admv1013*

Read/write value for the Local Oscillatior Feedthrough Offset Calibration Q Positive side.

/sys/bus/iio/devices/iio:deviceX/in_altvoltage0_q_calibscale_coarse

Defined on file *sysfs-bus-iio-frequency-admv1014*

Read/write value for the digital attenuator gain (IF_Q) with coarse steps.

/sys/bus/iio/devices/iio:deviceX/in_altvoltage0_q_calibscale_fine

Defined on file *sysfs-bus-iio-frequency-admv1014*

Read/write value for the digital attenuator gain (IF_Q) with fine steps.

/sys/bus/iio/devices/iio:deviceX/in_altvoltage1_i_calibbias

Defined on file *sysfs-bus-iio-frequency-admv1013*

Read/write raw value for the Local Oscillatior Feedthrough Offset Calibration I Negative side.

/sys/bus/iio/devices/iio:deviceX/in_altvoltage1_q_calibbias

Defined on file *sysfs-bus-iio-frequency-admv1013*

Read/write raw value for the Local Oscillatior Feedthrough Offset Calibration Q Negative side.

/sys/bus/iio/devices/iio:deviceX/in_altvoltageY_compare_interval

Defined on file *sysfs-bus-iio-adc-envelope-detector*

Number of milliseconds to wait for the comparator in each step of the binary search for the input peak level. Needs to relate to the frequency of the input signal.

/sys/bus/iio/devices/iio:deviceX/in_altvoltageY_invert

Defined on file *sysfs-bus-iio-adc-envelope-detector*

The DAC is used to find the peak level of an alternating voltage input signal by a binary search using the output of a comparator wired to an interrupt pin. Like so:

```
                      _
                     | \
input +------>-------|+ \
                     |   \
       .-------.     |    }---.
       |       |     |   /    |
       |    dac|-->--|- /     |
       |       |     |_/      |
       |       |              |
       |       |              |
       |    irq|------<-------'
       |       |
       '-------'
```

The boolean invert attribute (0/1) should be set when the input signal is centered around the maximum value of the dac instead of zero. The envelope detector will search from below in this case and will also invert the result.

The edge/level of the interrupt is also switched to its opposite value.

/sys/bus/iio/devices/iio:deviceX/in_anglY_label

Defined on file *sysfs-bus-iio*

Optional symbolic label for channel Y. For Intel hid hinge sensor, the label values are: hinge, keyboard, screen. It means the three channels each correspond respectively to hinge angle, keyboard angle, and screen angle.

/sys/bus/iio/devices/iio:deviceX/in_angl_raw
/sys/bus/iio/devices/iio:deviceX/in_anglY_raw

Defined on file *sysfs-bus-iio*

Angle of rotation. Units after application of scale and offset are radians.

/sys/bus/iio/devices/iio:deviceX/in_anglvel_raw_range

Defined on file *sysfs-bus-iio-bno055*

Range for angular velocity readings in radians per second. Note that this does not affects the scale (which should be used when changing the maximum and minimum readable value affects also the reading scaling factor).

/sys/bus/iio/devices/iio:deviceX/in_anglvel_raw_range_available

Defined on file *sysfs-bus-iio-bno055*

List of allowed values for in_anglvel_raw_range attribute

/sys/bus/iio/devices/iio:deviceX/in_anglvel_x_raw
/sys/bus/iio/devices/iio:deviceX/in_anglvel_y_raw
/sys/bus/iio/devices/iio:deviceX/in_anglvel_z_raw

Defined on file *sysfs-bus-iio*

Angular velocity about axis x, y or z (may be arbitrarily assigned). Has all the equivalent parameters as per voltageY. Units after application of scale and offset are radians per second.

/sys/bus/iio/devices/iio:deviceX/in_capacitanceY_raw

Defined on file *sysfs-bus-iio*

Raw capacitance measurement from channel Y. Units after application of scale and offset are nanofarads.

/sys/bus/iio/devices/iio:deviceX/in_chromaticity_x_raw
/sys/bus/iio/devices/iio:deviceX/in_chromaticity_y_raw

Defined on file *sysfs-bus-iio*

The x and y light color coordinate on the CIE 1931 chromaticity diagram.

/sys/bus/iio/devices/iio:deviceX/in_colortemp_raw

Defined on file *sysfs-bus-iio*

Represents light color temperature, which measures light color temperature in Kelvin.

/sys/bus/iio/devices/iio:deviceX/in_concentration_VOC_short_raw

Defined on file *sysfs-bus-iio-chemical-vz89x*

Get the raw calibration VOC value from the sensor. This value has little application outside of calibration.

/sys/bus/iio/devices/iio:deviceX/in_concentration_co2_calibration_background

Defined on file *sysfs-bus-iio-chemical-sunrise-co2*

Writing '1' triggers a 'Background' calibration cycle.

/sys/bus/iio/devices/iio:deviceX/in_concentration_co2_calibration_factory

Defined on file *sysfs-bus-iio-chemical-sunrise-co2*

Writing '1' triggers a 'Factory' calibration cycle.

/sys/bus/iio/devices/iio:deviceX/in_concentration_raw
/sys/bus/iio/devices/iio:deviceX/in_concentrationX_raw
/sys/bus/iio/devices/iio:deviceX/in_concentration_co2_raw
/sys/bus/iio/devices/iio:deviceX/in_concentrationX_co2_raw
/sys/bus/iio/devices/iio:deviceX/in_concentration_ethanol_raw
/sys/bus/iio/devices/iio:deviceX/in_concentrationX_ethanol_raw
/sys/bus/iio/devices/iio:deviceX/in_concentration_h2_raw
/sys/bus/iio/devices/iio:deviceX/in_concentrationX_h2_raw
/sys/bus/iio/devices/iio:deviceX/in_concentration_o2_raw
/sys/bus/iio/devices/iio:deviceX/in_concentrationX_o2_raw
/sys/bus/iio/devices/iio:deviceX/in_concentration_voc_raw
/sys/bus/iio/devices/iio:deviceX/in_concentrationX_voc_raw

Defined on file *sysfs-bus-iio*

Raw (unscaled no offset etc.) reading of a substance. Units after application of scale and offset are percents.

/sys/bus/iio/devices/iio:deviceX/in_conversion_mode

Defined on file *sysfs-bus-iio-vf610*

Specifies the hardware conversion mode used. The three available modes are ”normal”, ”high-speed” and ”low-power”, where the last is the default mode.

/sys/bus/iio/devices/iio:deviceX/in_count0_enable_mode

Defined on file *sysfs-bus-iio-timer-stm32*

Configure the device counter enable modes, in all case counting direction is set by in_count0_count_direction attribute and the counter is clocked by the internal clock.

always:
Counter is always ON.

gated:
Counting is enabled when connected trigger signal level is high else counting is disabled.

triggered:
Counting is enabled on rising edge of the connected trigger, and remains enabled for the duration of this selected mode.

/sys/bus/iio/devices/iio:deviceX/in_count0_preset

Defined on file *sysfs-bus-iio-timer-stm32*

Reading returns the current preset value. Writing sets the preset value. When counting up the counter starts from 0 and fires an event when reach preset value. When counting down the counter start from preset value and fire event when reach 0.

/sys/bus/iio/devices/iio:deviceX/in_count0_trigger_mode

Defined on file *sysfs-bus-iio-timer-stm32*

Configure the device counter trigger mode counting direction is set by in_count0_count_direction attribute and the counter is clocked by the connected trigger rising edges.

/sys/bus/iio/devices/iio:deviceX/in_countY_count_direction

Defined on file *sysfs-bus-iio*

This interface is deprecated; please use the Counter subsystem.

Raw counter device counters direction for channel Y.

/sys/bus/iio/devices/iio:deviceX/in_countY_raw

Defined on file *sysfs-bus-iio*

This interface is deprecated; please use the Counter subsystem.

Raw counter device counts from channel Y. For quadrature counters, multiplication by an available [Y]_scale results in the counts of a single quadrature signal phase from channel Y.

/sys/bus/iio/devices/iio:deviceX/in_count_count_direction_available

Defined on file *sysfs-bus-iio*

This interface is deprecated; please use the Counter subsystem.

A list of possible counting directions which are:

- ”up” : counter device is increasing.
- ”down”: counter device is decreasing.

/sys/bus/iio/devices/iio:deviceX/in_count_enable_mode_available

Defined on file *sysfs-bus-iio-timer-stm32*

Reading returns the list possible enable modes.

/sys/bus/iio/devices/iio:deviceX/in_count_trigger_mode_available

Defined on file *sysfs-bus-iio-timer-stm32*

Reading returns the list possible trigger modes.

/sys/bus/iio/devices/iio:deviceX/in_current5_raw

Defined on file *sysfs-bus-iio-adc-mt6360*

Indicated MT6360 IBUS ADC Calculating with scale and offset returns voltage in uA

/sys/bus/iio/devices/iio:deviceX/in_current6_raw

Defined on file *sysfs-bus-iio-adc-mt6360*

Indicated MT6360 IBAT ADC Calculating with scale and offset returns voltage in uA

/sys/bus/iio/devices/iio:deviceX/in_current7_raw

Defined on file *sysfs-bus-iio-adc-mt6360*

Indicated MT6360 CHG_VDDP ADC Calculating with scale and offset returns voltage in uV

/sys/bus/iio/devices/iio:deviceX/in_currentX_raw
/sys/bus/iio/devices/iio:deviceX/in_currentX_i_raw
/sys/bus/iio/devices/iio:deviceX/in_currentX_q_raw

Defined on file *sysfs-bus-iio*

Raw current measurement from channel X. Units are in milliamps after application of scale and offset. If no offset or scale is present, output should be considered as processed with the unit in milliamps.

Channels with 'i' and 'q' modifiers always exist in pairs and both channels refer to the same signal. The 'i' channel contains the in-phase component of the signal while the 'q' channel contains the quadrature component.

/sys/bus/iio/devices/iio:deviceX/in_currentY_raw
/sys/bus/iio/devices/iio:deviceX/in_currentY_supply_raw

Defined on file *sysfs-bus-iio*

Raw (unscaled no bias removal etc.) current measurement from channel Y. In special cases where the channel does not correspond to externally available input one of the named versions may be used. The number must always be specified and unique to allow association with event codes. Units after application of scale and offset are milliamps.

/sys/bus/iio/devices/iio:deviceX/in_current_shunt_resistor

Defined on file *sysfs-bus-iio-adc-max9611*

The value of the shunt resistor used to compute current flowing between RS+ and RS- voltage sense inputs. In Ohms.

These attributes describe a single physical component, exposed as two distinct attributes as it is used to calculate two different values: power load and current flowing between RS+ and RS- inputs.

/sys/bus/iio/devices/iio:deviceX/in_deltaangl_x_raw
/sys/bus/iio/devices/iio:deviceX/in_deltaangl_y_raw
/sys/bus/iio/devices/iio:deviceX/in_deltaangl_z_raw

Defined on file *sysfs-bus-iio*

Angular displacement between two consecutive samples on x, y or z (may be arbitrarily assigned but should match other such assignments on device). In order to compute the total angular displacement during a desired period of time, the application should sum-up the delta angle samples acquired during that time. Units after application of scale and offset are radians.

/sys/bus/iio/devices/iio:deviceX/in_deltavelocity_x_raw
/sys/bus/iio/devices/iio:deviceX/in_deltavelocity_y_raw
/sys/bus/iio/devices/iio:deviceX/in_deltavelocity_z_raw

Defined on file *sysfs-bus-iio*

The linear velocity change between two consecutive samples on x, y or z (may be arbitrarily assigned but should match other such assignments on device). In order to compute the total linear velocity change during a desired period of time, the application should sum-up the delta velocity samples acquired during that time. Units after application of scale and offset are meters per second.

/sys/bus/iio/devices/iio:deviceX/in_electricalconductivity_raw

Defined on file *sysfs-bus-iio*

Raw (unscaled no offset etc.) electric conductivity reading. Units after application of scale and offset are siemens per meter.

/sys/bus/iio/devices/iio:deviceX/in_energy_calibweight

Defined on file *sysfs-bus-iio*

Weight of the user (in kg). It is needed by some pedometers to compute the calories burnt by the user.

/sys/bus/iio/devices/iio:deviceX/in_filter_notch_center_frequency

Defined on file *sysfs-bus-iio*

Center frequency in Hz for a notch filter. Used i.e. for line noise suppression.

/sys/bus/iio/devices/iio:deviceX/in_gravity_x_raw
/sys/bus/iio/devices/iio:deviceX/in_gravity_y_raw
/sys/bus/iio/devices/iio:deviceX/in_gravity_z_raw

Defined on file *sysfs-bus-iio*

Gravity in direction x, y or z (may be arbitrarily assigned but should match other such assignments on device). Units after application of scale and offset are m/s^2.

/sys/bus/iio/devices/iio:deviceX/in_gyro_calibration_auto_status

Defined on file *sysfs-bus-iio-bno055*

Reports the autocalibration status for the gyroscope sensor. Can be 0 (calibration non even enabled) or 1 to 5 where the greater the number, the better the calibration status.

/sys/bus/iio/devices/iio:deviceX/in_gyro_matrix
/sys/bus/iio/devices/iio:deviceX/in_accel_matrix
/sys/bus/iio/devices/iio:deviceX/in_magn_matrix

Defined on file *sysfs-bus-iio-mpu6050*

This is mounting matrix for motion sensors. Mounting matrix is a 3x3 unitary matrix. A typical mounting matrix would look like [0, 1, 0; 1, 0, 0; 0, 0, -1]. Using this information, it would be easy to tell the relative positions among sensors as well as their positions relative to the board that holds these sensors. Identity matrix [1, 0, 0; 0, 1, 0; 0, 0, 1] means sensor chip and device are perfectly aligned with each other. All axes are exactly the same.

/sys/bus/iio/devices/iio:deviceX/in_humidityrelative_input

Defined on file *sysfs-bus-iio*

Scaled humidity measurement in milli percent.

/sys/bus/iio/devices/iio:deviceX/in_humidityrelative_raw

Defined on file *sysfs-bus-iio*

Raw humidity measurement of air. Units after application of scale and offset are milli percent.

/sys/bus/iio/devices/iio:deviceX/in_humidityrelative_trough_raw
/sys/bus/iio/devices/iio:deviceX/in_temp_trough_raw

Defined on file *sysfs-bus-iio*

Lowest value since some reset condition. These attributes allow access to this and are otherwise the direct equivalent of the <type>Y[_name]_raw attributes.

/sys/bus/iio/devices/iio:deviceX/in_illuminance0_zone

Defined on file *sysfs-bus-iio-light-lm3533-als*

Get the current light zone (0..4) as defined by the in_illuminance0_threshY_{falling,rising} thresholds.

/sys/bus/iio/devices/iio:deviceX/in_illuminance_hysteresis_relative
/sys/bus/iio/devices/iio:deviceX/in_intensity_hysteresis_relative

Defined on file *sysfs-bus-iio*

Specify the percent for light sensor relative to the channel absolute value that a data field should change before an event is generated. Units are a percentage of the prior reading.

/sys/bus/iio/devices/iio:deviceX/in_incli_x_raw
/sys/bus/iio/devices/iio:deviceX/in_incli_y_raw
/sys/bus/iio/devices/iio:deviceX/in_incli_z_raw

Defined on file *sysfs-bus-iio*

Inclination raw reading about axis x, y or z (may be arbitrarily assigned). Data converted by application of offset and scale to degrees.

/sys/bus/iio/devices/iio:deviceX/in_indexY_raw

Defined on file *sysfs-bus-iio*

This interface is deprecated; please use the Counter subsystem.

Raw counter device index value from channel Y. This attribute provides an absolute positional reference (e.g. a pulse once per revolution) which may be used to home positional systems as required.

/sys/bus/iio/devices/iio:deviceX/in_intensityY_offset

Defined on file *sysfs-bus-iio-health-afe440x*

Get and set the offset cancellation DAC setting for these stages. The values are expressed in 5-bit sign-magnitude.

/sys/bus/iio/devices/iio:deviceX/in_intensityY_raw

Defined on file *sysfs-bus-iio-health-afe440x*

Get measured values from the ADC for these stages. Y is the specific stage number corresponding to datasheet stage names as follows:

1	LED2
2	ALED2/LED3
3	LED1
4	ALED1/LED4

Note that channels 5 and 6 represent LED2-ALED2 and LED1-ALED1 respectively which simply helper channels containing the calculated difference in the value of stage 1 - 2 and 3 - 4. The

values are expressed in 24-bit twos complement. The LED current for the stage is controlled via out_currentY_raw.

/sys/bus/iio/devices/iio:deviceX/in_intensityY_resistance
/sys/bus/iio/devices/iio:deviceX/in_intensityY_capacitance

Defined on file *sysfs-bus-iio-health-afe440x*

Get and set the resistance and the capacitance settings for the Transimpedance Amplifier during the associated stage.

/sys/bus/iio/devices/iio:deviceX/in_intensity_hardwaregain_available

Defined on file *sysfs-bus-iio*

Lists all available hardware applied gain factors. Shared across all channels.

/sys/bus/iio/devices/iio:deviceX/in_intensity_ir_large_raw

Defined on file *sysfs-bus-iio-light-si1133*

Unit-less infrared intensity. The intensity is measured from 4 dark photodiodes. "large" indicate the surface area capturing infrared.

/sys/bus/iio/devices/iio:deviceX/in_intensity_ir_small_raw

Defined on file *sysfs-bus-iio-light-si1133*

Unit-less infrared intensity. The intensity is measured from 1 dark photodiode. "small" indicate the surface area capturing infrared.

/sys/bus/iio/devices/iio:deviceX/in_intensity_large_raw

Defined on file *sysfs-bus-iio-light-si1133*

Unit-less light intensity with more diodes.

/sys/bus/iio/devices/iio:deviceX/in_intensity_x_raw
/sys/bus/iio/devices/iio:deviceX/in_intensity_y_raw
/sys/bus/iio/devices/iio:deviceX/in_intensity_z_raw

Defined on file *sysfs-bus-iio*

Unscaled light intensity according to CIE 1931/DIN 5033 color space. Units after application of scale are nano nanowatts per square meter.

/sys/bus/iio/devices/iio:deviceX/in_magn_calibration_auto_status

Defined on file *sysfs-bus-iio-bno055*

Reports the autocalibration status for the magnetometer sensor. Can be 0 (calibration non even enabled) or 1 to 5 where the greater the number, the better the calibration status.

/sys/bus/iio/devices/iio:deviceX/in_magn_calibration_fast_enable

Defined on file *sysfs-bus-iio-bno055*

Can be 1 or 0. Enables/disables the "Fast Magnetometer Calibration" HW function.

/sys/bus/iio/devices/iio:deviceX/in_magn_x_oversampling_ratio
/sys/bus/iio/devices/iio:deviceX/in_magn_y_oversampling_ratio
/sys/bus/iio/devices/iio:deviceX/in_magn_z_oversampling_ratio

Defined on file *sysfs-bus-iio*

Hardware applied number of measurements for acquiring one data point. The HW will do <type>[_name]_oversampling_ratio measurements and return the average value as output data. Each value resulted from <type>[_name]_oversampling_ratio measurements is considered as one sample for <type>[_name]_sampling_frequency.

/sys/bus/iio/devices/iio:deviceX/in_magn_x_raw
/sys/bus/iio/devices/iio:deviceX/in_magn_y_raw
/sys/bus/iio/devices/iio:deviceX/in_magn_z_raw

Defined on file *sysfs-bus-iio*

Magnetic field along axis x, y or z (may be arbitrarily assigned). Data converted by application of offset then scale to Gauss.

/sys/bus/iio/devices/iio:deviceX/in_massconcentration_pm1_input
/sys/bus/iio/devices/iio:deviceX/in_massconcentrationY_pm1_input
/sys/bus/iio/devices/iio:deviceX/in_massconcentration_pm2p5_input
/sys/bus/iio/devices/iio:deviceX/in_massconcentrationY_pm2p5_input
/sys/bus/iio/devices/iio:deviceX/in_massconcentration_pm4_input
/sys/bus/iio/devices/iio:deviceX/in_massconcentrationY_pm4_input
/sys/bus/iio/devices/iio:deviceX/in_massconcentration_pm10_input
/sys/bus/iio/devices/iio:deviceX/in_massconcentrationY_pm10_input

Defined on file *sysfs-bus-iio*

Mass concentration reading of particulate matter in ug / m3. pmX consists of particles with aerodynamic diameter less or equal to X micrometers.

/sys/bus/iio/devices/iio:deviceX/in_ph_raw

Defined on file *sysfs-bus-iio*

Raw (unscaled no offset etc.) pH reading of a substance as a negative base-10 logarithm of hydrodium ions in a litre of water.

/sys/bus/iio/devices/iio:deviceX/in_phaseY_raw

Defined on file *sysfs-bus-iio*

Raw (unscaled) phase difference reading from channel Y. Units after application of scale and offset are radians.

/sys/bus/iio/devices/iio:deviceX/in_positionrelative_x_raw
/sys/bus/iio/devices/iio:deviceX/in_positionrelative_y_raw

Defined on file *sysfs-bus-iio*

Relative position in direction x or y on a pad (may be arbitrarily assigned but should match other such assignments on device). Units after application of scale and offset are milli percents from the pad's size in both directions. Should be calibrated by the consumer.

/sys/bus/iio/devices/iio:deviceX/in_powerY_raw

Defined on file *sysfs-bus-iio*

Raw (unscaled no bias removal etc.) power measurement from channel Y. The number must always be specified and unique to allow association with event codes. Units after application of scale and offset are milliwatts.

/sys/bus/iio/devices/iio:deviceX/in_power_shunt_resistor

Defined on file *sysfs-bus-iio-adc-max9611*

The value of the shunt resistor used to compute power drain on common input voltage pin (RS+). In Ohms.

/sys/bus/iio/devices/iio:deviceX/in_pressureY_input
/sys/bus/iio/devices/iio:deviceX/in_pressure_input

Defined on file *sysfs-bus-iio*

Scaled pressure measurement from channel Y, in kilopascal.

/sys/bus/iio/devices/iio:deviceX/in_pressureY_raw
/sys/bus/iio/devices/iio:deviceX/in_pressure_raw

Defined on file *sysfs-bus-iio*

Raw pressure measurement from channel Y. Units after application of scale and offset are kilopascal.

/sys/bus/iio/devices/iio:deviceX/in_proximity0_agc_gain
/sys/bus/iio/devices/iio:deviceX/in_proximity0_agc_gain_bias

Defined on file *sysfs-bus-iio-isl29501*

This sensor has an automatic gain control (agc) loop which sets the analog signal levels at an optimum level by controlling programmable gain amplifiers. The criteria for optimal gain is determined by the sensor.

Return the actual gain value as an integer in [0; 65536] range when read from.

The agc gain read when measuring crosstalk shall be written into in_proximity0_agc_gain_bias.

/sys/bus/iio/devices/iio:deviceX/in_proximity0_calib_phase_temp_a
/sys/bus/iio/devices/iio:deviceX/in_proximity0_calib_phase_temp_b
/sys/bus/iio/devices/iio:deviceX/in_proximity0_calib_phase_light_a
/sys/bus/iio/devices/iio:deviceX/in_proximity0_calib_phase_light_b

Defined on file *sysfs-bus-iio-isl29501*

The sensor is able to perform correction of distance measurements due to changing temperature and ambient light conditions. It can be programmed to correct for a second order error polynomial.

Phase data has to be collected when temperature and ambient light are modulated independently.

Then a least squares curve fit to a second order polynomial has to be generated from the data. The resultant curves have the form ax^2 + bx + c.

From those two curves, a and b coefficients shall be stored in in_proximity0_calib_phase_temp_a and in_proximity0_calib_phase_temp_b for temperature and in in_proximity0_calib_phase_light_a and in_proximity0_calib_phase_light_b for ambient light.

Those values must be integer in [0; 8355840] range.

Finally, the c constant is set by the sensor internally.

The value stored in sensor is displayed when read from.

/sys/bus/iio/devices/iio:deviceX/in_proximity3_comb_raw

Defined on file *sysfs-bus-iio-sx9310*

Proximity measurement indicating that some object is near the combined sensor. The combined sensor presents proximity measurements constructed by hardware by combining measurements taken from a given set of physical sensors.

/sys/bus/iio/devices/iio:deviceX/in_proximity<id>_setup

Defined on file *sysfs-bus-iio-sx9324*

SX9324 has 3 inputs, CS0, CS1 and CS2. Hardware layout defines if the input is

- not connected (HZ),
- grounded (GD),
- connected to an antenna where it can act as a base (DS - data shield), or measured input (MI).

The sensor rotates measurement across 4 phases (PH0, PH1, PH2, PH3), where the inputs are configured and then measured.

By default, during the first phase, [PH0], CS0 is measured, while CS1 and CS2 are used as shields. *cat in_proximity0_setup* returns "MI,DS,DS". [PH1], CS1 is measured, CS0 and CS2 are shield: *cat in_proximity1_setup* returns "DS,MI,DS". [PH2], CS2 is measured, CS0 and CS1

are shield: *cat in_proximity1_setup* returns "DS,DS,MI". [PH3], CS1 and CS2 are measured (combo mode): *cat in_proximity1_setup* returns "DS,MI,MI".

Note, these are the chip default. Hardware layout will most likely dictate different output. The entry is read-only.

/sys/bus/iio/devices/iio:deviceX/in_proximity_input

Defined on file *sysfs-bus-iio-proximity-as3935*

Get the current distance in meters of storm (1km steps) 1000-40000 = distance in meters

What /sys/bus/iio/devices/iio:deviceX/noise_level_tripped When 1 the noise level is over the trip level and not reporting valid data

/sys/bus/iio/devices/iio:deviceX/in_proximity_nearlevel

Defined on file *sysfs-bus-iio-proximity*

Near level for proximity sensors. This is a single integer value that tells user space when an object should be considered close to the device. If the value read from the sensor is above or equal to the value in this file an object should typically be considered near.

/sys/bus/iio/devices/iio:deviceX/in_resistance_calibbias

Defined on file *sysfs-bus-iio-chemical-sgp40*

Set the bias value for the resistance which is used for calculation of in_concentration_input as follows:

x = (in_resistance_raw - in_resistance_calibbias) * 0.65

in_concentration_input = 500 / (1 + e^x)

Default value: 30000

/sys/bus/iio/devices/iio:deviceX/in_resistance_raw
/sys/bus/iio/devices/iio:deviceX/in_resistanceX_raw
/sys/bus/iio/devices/iio:deviceX/out_resistance_raw
/sys/bus/iio/devices/iio:deviceX/out_resistanceX_raw

Defined on file *sysfs-bus-iio*

Raw (unscaled no offset etc.) resistance reading. Units after application of scale and offset are ohms.

/sys/bus/iio/devices/iio:deviceX/in_rot_from_north_magnetic_tilt_comp_raw
/sys/bus/iio/devices/iio:deviceX/in_rot_from_north_true_tilt_comp_raw
/sys/bus/iio/devices/iio:deviceX/in_rot_from_north_magnetic_raw
/sys/bus/iio/devices/iio:deviceX/in_rot_from_north_true_raw

Defined on file *sysfs-bus-iio*

Raw value of rotation from true/magnetic north measured with or without compensation from tilt sensors.

/sys/bus/iio/devices/iio:deviceX/in_rot_quaternion_raw

Defined on file *sysfs-bus-iio*

Raw value of quaternion components using a format x y z w. Here x, y, and z component represents the axis about which a rotation will occur and w component represents the amount of rotation.

/sys/bus/iio/devices/iio:deviceX/in_rot_yaw_raw
/sys/bus/iio/devices/iio:deviceX/in_rot_pitch_raw
/sys/bus/iio/devices/iio:deviceX/in_rot_roll_raw

Defined on file *sysfs-bus-iio*

Raw (unscaled) euler angles readings. Units after application of scale are deg.

/sys/bus/iio/devices/iio:deviceX/in_shunt_resistor

Defined on file *sysfs-bus-iio-ina2xx-adc*

The value of the shunt resistor may be known only at runtime fom an eeprom content read by a client application. This attribute allows to set its value in ohms.

/sys/bus/iio/devices/iio:deviceX/in_temp8_raw

Defined on file *sysfs-bus-iio-adc-mt6360*

Indicated MT6360 IC junction temperature Calculating with scale and offset returns temperature in degree

/sys/bus/iio/devices/iio:deviceX/in_tempX_input

Defined on file *sysfs-bus-iio*

Scaled temperature measurement in milli degrees Celsius.

/sys/bus/iio/devices/iio:deviceX/in_temp_calibemissivity
/sys/bus/iio/devices/iio:deviceX/in_tempX_calibemissivity
/sys/bus/iio/devices/iio:deviceX/in_temp_object_calibemissivity
/sys/bus/iio/devices/iio:deviceX/in_tempX_object_calibemissivity

Defined on file *sysfs-bus-iio*

The emissivity ratio of the surface in the field of view of the contactless temperature sensor. Emissivity varies from 0 to 1, with 1 being the emissivity of a black body.

/sys/bus/iio/devices/iio:deviceX/in_temp_object_calibambient
/sys/bus/iio/devices/iio:deviceX/in_tempX_object_calibambient

Defined on file *sysfs-bus-iio*

Calibrated ambient temperature for object temperature calculation in milli degrees Celsius.

/sys/bus/iio/devices/iio:deviceX/in_temp_raw
/sys/bus/iio/devices/iio:deviceX/in_tempX_raw
/sys/bus/iio/devices/iio:deviceX/in_temp_x_raw
/sys/bus/iio/devices/iio:deviceX/in_temp_y_raw
/sys/bus/iio/devices/iio:deviceX/in_temp_ambient_raw
/sys/bus/iio/devices/iio:deviceX/in_temp_object_raw

Defined on file *sysfs-bus-iio*

Raw (unscaled no bias removal etc.) temperature measurement. If an axis is specified it generally means that the temperature sensor is associated with one part of a compound device (e.g. a gyroscope axis). The ambient and object modifiers distinguish between ambient (reference) and distant temperature for contact- less measurements. Units after application of scale and offset are milli degrees Celsius.

/sys/bus/iio/devices/iio:deviceX/in_temp_thermocouple_type

Defined on file *sysfs-bus-iio*

One of the following thermocouple types: B, E, J, K, N, R, S, T.

/sys/bus/iio/devices/iio:deviceX/in_voltage-voltage_filter_mode_available

Defined on file *sysfs-bus-iio-adc-ad4130*

Reading returns a list with the possible filter modes.

- ”sinc4” - Sinc 4. Excellent noise performance. Long 1st conversion time. No natural 50/60Hz rejection.
- ”sinc4+sinc1” - Sinc4 + averaging by 8. Low 1st conversion time.
- ”sinc3” - Sinc3. Moderate 1st conversion time. Good noise performance.
- ”sinc3+rej60” - Sinc3 + 60Hz rejection. At a sampling frequency of 50Hz, achieves simultaneous 50Hz and 60Hz rejection.
- ”sinc3+sinc1” - Sinc3 + averaging by 8. Low 1st conversion time. Best used with a sampling frequency of at least 216.19Hz.
- ”sinc3+pf1” - Sinc3 + Post Filter 1. 53dB rejection @ 50Hz, 58dB rejection @ 60Hz.
- ”sinc3+pf2” - Sinc3 + Post Filter 2. 70dB rejection @ 50Hz, 70dB rejection @ 60Hz.
- ”sinc3+pf3” - Sinc3 + Post Filter 3. 99dB rejection @ 50Hz, 103dB rejection @ 60Hz.
- ”sinc3+pf4” - Sinc3 + Post Filter 4. 103dB rejection @ 50Hz, 109dB rejection @ 60Hz.

/sys/bus/iio/devices/iio:deviceX/in_voltage0_raw

Defined on file *sysfs-bus-iio-adc-mt6360*

Indicated MT6360 USBID ADC which connected to connector ID pin. Calculating with scale and offset returns voltage in uV

/sys/bus/iio/devices/iio:deviceX/in_voltage10_raw

Defined on file *sysfs-bus-iio-adc-mt6360*

Indicated MT6360 TS ADC Calculating with scale and offset returns voltage in uV

/sys/bus/iio/devices/iio:deviceX/in_voltage1_raw

Defined on file *sysfs-bus-iio-adc-mt6360*

Indicated MT6360 VBUS ADC with lower accuracy(+-75mA) higher measure range(1~22mV) Calculating with scale and offset returns voltage in uV

/sys/bus/iio/devices/iio:deviceX/in_voltage2-voltage2_shorted_raw

Defined on file *sysfs-bus-iio-adc-ad7192*

Measure voltage from AIN2 pin connected to AIN(+) and AIN(-) shorted.

/sys/bus/iio/devices/iio:deviceX/in_voltage2_raw

Defined on file *sysfs-bus-iio-adc-mt6360*

Indicated MT6360 VBUS ADC with higher accuracy(+-30mA) lower measure range(1~9.76V) Calculating with scale and offset returns voltage in uV

/sys/bus/iio/devices/iio:deviceX/in_voltage3_raw

Defined on file *sysfs-bus-iio-adc-mt6360*

Indicated MT6360 VSYS ADC Calculating with scale and offset returns voltage in uV

/sys/bus/iio/devices/iio:deviceX/in_voltage4_raw

Defined on file *sysfs-bus-iio-adc-mt6360*

Indicated MT6360 VBAT ADC Calculating with scale and offset returns voltage in uV

/sys/bus/iio/devices/iio:deviceX/in_voltage9_raw

Defined on file *sysfs-bus-iio-adc-mt6360*

Indicated MT6360 VREF_TS ADC Calculating with scale and offset returns voltage in uV

/sys/bus/iio/devices/iio:deviceX/in_voltageX_sampling_frequency
/sys/bus/iio/devices/iio:deviceX/in_powerY_sampling_frequency
/sys/bus/iio/devices/iio:deviceX/in_currentZ_sampling_frequency

Defined on file *sysfs-bus-iio*

Some devices have separate controls of sampling frequency for individual channels. If multiple channels are enabled in a scan, then the sampling_frequency of the scan may be computed from the per channel sampling frequencies.

/sys/bus/iio/devices/iio:deviceX/in_voltageY-voltageZ_balance_switch_en

Defined on file *sysfs-bus-iio-adc-ad7280a*

Used to enable an output for balancing cells for time controlled via in_voltage_Y-voltageZ_balance_switch_timer.

/sys/bus/iio/devices/iio:deviceX/in_voltageY-voltageZ_balance_switch_timer

Defined on file *sysfs-bus-iio-adc-ad7280a*

Time in seconds for which balance switch will be turned on. Multiple of 71.5 seconds.

/sys/bus/iio/devices/iio:deviceX/in_voltageY-voltageZ_filter_mode

Defined on file *sysfs-bus-iio-adc-ad4130*

Set the filter mode of the differential channel. When the filter mode changes, the in_voltageY-voltageZ_sampling_frequency and in_voltageY-voltageZ_sampling_frequency_available attributes might also change to accommodate the new filter mode. If the current sampling frequency is out of range for the new filter mode, the sampling frequency will be changed to the closest valid one.

/sys/bus/iio/devices/iio:deviceX/in_voltageY-voltageZ_raw

Defined on file *sysfs-bus-iio*

Raw (unscaled) differential voltage measurement equivalent to channel Y - channel Z where these channel numbers apply to the physically equivalent inputs when non differential readings are separately available. In differential only parts, then all that is required is a consistent labeling. Units after application of scale and offset are millivolts.

/sys/bus/iio/devices/iio:deviceX/in_voltageY_calibscale
/sys/bus/iio/devices/iio:deviceX/in_voltageY_supply_calibscale
/sys/bus/iio/devices/iio:deviceX/in_voltageY_i_calibscale
/sys/bus/iio/devices/iio:deviceX/in_voltageY_q_calibscale
/sys/bus/iio/devices/iio:deviceX/in_voltage_i_calibscale
/sys/bus/iio/devices/iio:deviceX/in_voltage_q_calibscale
/sys/bus/iio/devices/iio:deviceX/in_altvoltage_calibscale
/sys/bus/iio/devices/iio:deviceX/in_voltage_calibscale
/sys/bus/iio/devices/iio:deviceX/in_accel_x_calibscale
/sys/bus/iio/devices/iio:deviceX/in_accel_y_calibscale
/sys/bus/iio/devices/iio:deviceX/in_accel_z_calibscale
/sys/bus/iio/devices/iio:deviceX/in_anglvel_x_calibscale
/sys/bus/iio/devices/iio:deviceX/in_anglvel_y_calibscale
/sys/bus/iio/devices/iio:deviceX/in_anglvel_z_calibscale
/sys/bus/iio/devices/iio:deviceX/in_illuminance0_calibscale
/sys/bus/iio/devices/iio:deviceX/in_proximity0_calibscale
/sys/bus/iio/devices/iio:deviceX/in_pressureY_calibscale
/sys/bus/iio/devices/iio:deviceX/in_pressure_calibscale
/sys/bus/iio/devices/iio:deviceX/in_illuminance_calibscale

Defined on file *sysfs-bus-iio*

Hardware applied calibration scale factor (assumed to fix production inaccuracies). If shared across all channels, <type>_calibscale is used.

/sys/bus/iio/devices/iio:deviceX/in_voltageY_dither_enable

Defined on file *sysfs-bus-iio-dac-ad5766*

Dither enable. Write 1 to enable dither or 0 to disable it.

/sys/bus/iio/devices/iio:deviceX/in_voltageY_dither_invert

Defined on file *sysfs-bus-iio-dac-ad5766*

Inverts the dither applied to the selected DAC channel. Dither is not inverted by default. Write "1" to invert dither.

/sys/bus/iio/devices/iio:deviceX/in_voltageY_dither_scale

Defined on file *sysfs-bus-iio-dac-ad5766*

Scales the dither before it is applied to the selected channel.

/sys/bus/iio/devices/iio:deviceX/in_voltageY_dither_scale_available

Defined on file *sysfs-bus-iio-dac-ad5766*

Returns possible scalings available for the current channel.

/sys/bus/iio/devices/iio:deviceX/in_voltageY_dither_source

Defined on file *sysfs-bus-iio-dac-ad5766*

Selects dither source applied to the selected channel. Write "0" to select N0 source, write "1" to select N1 source.

/sys/bus/iio/devices/iio:deviceX/in_voltageY_label
/sys/bus/iio/devices/iio:deviceX/out_voltageY_label

Defined on file *sysfs-bus-iio*

Optional symbolic label to a device channel. If a label is defined for this channel add that to the channel specific attributes. This is useful for userspace to be able to better identify an individual channel.

/sys/bus/iio/devices/iio:deviceX/in_voltageY_raw
/sys/bus/iio/devices/iio:deviceX/in_voltageY_supply_raw
/sys/bus/iio/devices/iio:deviceX/in_voltageY_i_raw
/sys/bus/iio/devices/iio:deviceX/in_voltageY_q_raw

Defined on file *sysfs-bus-iio*

Raw (unscaled no bias removal etc.) voltage measurement from channel Y. In special cases where the channel does not correspond to externally available input one of the named versions may be used. The number must always be specified and unique to allow association with event codes. Units after application of scale and offset are millivolts.

Channels with 'i' and 'q' modifiers always exist in pairs and both channels refer to the same signal. The 'i' channel contains the in-phase component of the signal while the 'q' channel contains the quadrature component.

/sys/bus/iio/devices/iio:deviceX/in_intensity_z_scale
/sys/bus/iio/devices/iio:deviceX/in_concentration_co2_scale

Defined on file *sysfs-bus-iio*

If known for a device, scale to be applied to <type>Y[_name]_raw post addition of <type>[Y][_name]_offset in order to obtain the measured value in <type> units as specified in <type>[Y][_name]_raw documentation. If shared across all in channels then Y and <x|y|z> are not present and the value is called <type>[Y][_name]_scale. The peak modifier means this value is applied to <type>Y[_name]_peak_raw values.

/sys/bus/iio/devices/iio:deviceX/in_voltageY_sensing_mode

Defined on file *sysfs-bus-iio-adc-hi8435*

Program sensor type for threshold detector inputs. Could be either "GND-Open" or "Supply-Open" mode. Y is a threshold detector input channel. Channels 0..7, 8..15, 16..23 and 24..31 has common sensor types.

/sys/bus/iio/devices/iio:deviceX/in_voltage_filterY_notch_center

Defined on file *sysfs-bus-iio-adc-max11410*

Center frequency of the notch filter in Hz.

/sys/bus/iio/devices/iio:deviceX/in_voltage_filterY_notch_en

Defined on file *sysfs-bus-iio-adc-max11410*

Enable or disable a notch filter.

/sys/bus/iio/devices/iio:deviceX/in_voltage_spi_clk_freq

Defined on file *sysfs-bus-iio-dfsdm-adc-stm32*

For audio purpose only.

Used by audio driver to set/get the spi input frequency.

This is mandatory if DFSDM is slave on SPI bus, to provide information on the SPI clock frequency during runtime Notice that the SPI frequency should be a multiple of sample frequency to ensure the precision.

if DFSDM input is SPI master:

Reading SPI clkout frequency, error on writing

If DFSDM input is SPI Slave:

Reading returns value previously set. Writing value before starting conversions.

/sys/bus/iio/devices/iio:deviceX/in_voltagex_sys_calibration

Defined on file *sysfs-bus-iio-adc-ad7192*

Initiates the system calibration procedure. This is done on a single channel at a time. Write '1' to start the calibration.

/sys/bus/iio/devices/iio:deviceX/in_voltagex_sys_calibration_mode

Defined on file *sysfs-bus-iio-adc-ad7192*

Sets up the calibration mode used in the system calibration procedure. Reading returns the current calibration mode. Writing sets the system calibration mode.

/sys/bus/iio/devices/iio:deviceX/in_voltagex_sys_calibration_mode_available

Defined on file *sysfs-bus-iio-adc-ad7192*

Reading returns a list with the possible calibration modes. There are two available options: ”zero_scale” - calibrate to zero scale ”full_scale” - calibrate to full scale

/sys/bus/iio/devices/iio:deviceX/label

Defined on file *sysfs-bus-iio*

Optional symbolic label for a device. This is useful for userspace to be able to better identify an individual device.

The contents of the label are free-form, but there are some standardized uses:

For proximity sensors which give the proximity (of a person) to a certain wlan or wwan antenna the following standardized labels are used:

- ”proximity-wifi”

- ”proximity-lte”
- ”proximity-wifi-lte”
- ”proximity-wifi-left”
- ”proximity-wifi-right”

These are used to indicate to userspace that these proximity sensors may be used to tune transmit power to ensure that Specific Absorption Rate (SAR) limits are honored. The ”-left” and ”-right” labels are for devices with multiple antennas.

In some laptops/tablets the standardized proximity sensor labels instead indicate proximity to a specific part of the device:

- ”proximity-palmrest” indicates proximity to the keyboard's palmrest
- ”proximity-palmrest-left” indicates proximity to the left part of the palmrest
- ”proximity-palmrest-right” indicates proximity to the right part of the palmrest
- ”proximity-lap” indicates the device is being used on someone's lap

Note ”proximity-lap” is special in that its value may be calculated by firmware from other sensor readings, rather then being a raw sensor reading.

For accelerometers used in 2-in-1s with 360° (yoga-style) hinges, which have an accelerometer in both their base and their display, the following standardized labels are used:

- ”accel-base”
- ”accel-display”

For devices where an accelerometer is housed in the swivel camera subassembly (for AR application), the following standardized label is used:

- ”accel-camera”

/sys/bus/iio/devices/iio:deviceX/location

Defined on file *sysfs-bus-iio-cros-ec*

This attribute returns a string with the physical location where the motion sensor is placed. For example, in a laptop a motion sensor can be located on the base or on the lid. Current valid values are 'base' and 'lid'.

/sys/bus/iio/devices/iio:deviceX/meas_conf
/sys/bus/iio/devices/iio:deviceX/meas_conf_available

Defined on file *sysfs-bus-iio-magnetometer-hmc5843*

Current configuration and available configurations for the bias current.

normal	Normal measurement configurations (default)
positivebias	Positive bias configuration
negativebias	Negative bias configuration
disabled	Only available on HMC5983. Disables magnetic sensor and enables temperature sensor.

Note:
The effect of this configuration may vary according to the device. For exact documentation check the device's datasheet.

/sys/bus/iio/devices/iio:deviceX/mount_matrix
/sys/bus/iio/devices/iio:deviceX/in_mount_matrix
/sys/bus/iio/devices/iio:deviceX/out_mount_matrix
/sys/bus/iio/devices/iio:deviceX/in_anglvel_mount_matrix
/sys/bus/iio/devices/iio:deviceX/in_accel_mount_matrix

Defined on file *sysfs-bus-iio*

Mounting matrix for IIO sensors. This is a rotation matrix which informs userspace about sensor chip's placement relative to the main hardware it is mounted on.

Main hardware placement is defined according to the local reference frame related to the physical quantity the sensor measures.

Given that the rotation matrix is defined in a board specific way (platform data and / or device-tree), the main hardware reference frame definition is left to the implementor's choice (see below for a magnetometer example).

Applications should apply this rotation matrix to samples so that when main hardware reference frame is aligned onto local reference frame, then sensor chip reference frame is also perfectly aligned with it.

Matrix is a 3x3 unitary matrix and typically looks like [0, 1, 0; 1, 0, 0; 0, 0, -1]. Identity matrix [1, 0, 0; 0, 1, 0; 0, 0, 1] means sensor chip and main hardware are perfectly aligned with each other.

For example, a mounting matrix for a magnetometer sensor informs userspace about sensor chip's ORIENTATION relative to the main hardware.

More specifically, main hardware orientation is defined with respect to the LOCAL EARTH GEOMAGNETIC REFERENCE FRAME where :

- Y is in the ground plane and positive towards magnetic North ;
- X is in the ground plane, perpendicular to the North axis and positive towards the East ;
- Z is perpendicular to the ground plane and positive upwards.

An implementor might consider that for a hand-held device, a 'natural' orientation would be 'front facing camera at the top'. The main hardware reference frame could then be described as :

- Y is in the plane of the screen and is positive towards the top of the screen ;
- X is in the plane of the screen, perpendicular to Y axis, and positive towards the right hand side of the screen ;
- Z is perpendicular to the screen plane and positive out of the screen.

Another example for a quadrotor UAV might be :

- Y is in the plane of the propellers and positive towards the front-view camera;
- X is in the plane of the propellers, perpendicular to Y axis, and positive towards the starboard side of the UAV ;

- Z is perpendicular to propellers plane and positive upwards.

/sys/bus/iio/devices/iio:deviceX/name

Defined on file *sysfs-bus-iio*

Description of the physical chip / device for device X. Typically a part number.

/sys/bus/iio/devices/iio:deviceX/out_altvoltageY_frequency

Defined on file *sysfs-bus-iio*

Output frequency for channel Y in Hz. The number must always be specified and unique if the output corresponds to a single channel. Some drivers have additional constraints: ADF4371 has an integrated VCO with fundamendal output frequency ranging from 4000000000 Hz 8000000000 Hz.

out_altvoltage0_frequency:
A divide by 1, 2, 4, 8, 16, 32 or circuit generates frequencies from 62500000 Hz to 8000000000 Hz.

out_altvoltage1_frequency:
This channel duplicates the channel 0 frequency

out_altvoltage2_frequency:
A frequency doubler generates frequencies from 8000000000 Hz to 16000000000 Hz.

out_altvoltage3_frequency:
A frequency quadrupler generates frequencies from 16000000000 Hz to 32000000000 Hz.

Note: writes to one of the channels will affect the frequency of all the other channels, since it involves changing the VCO fundamental output frequency.

/sys/bus/iio/devices/iio:deviceX/out_altvoltageY_frequency_increment

Defined on file *sysfs-bus-iio-impedance-analyzer-ad5933*

Frequency increment in Hz (step size) between consecutive frequency points along the sweep.

/sys/bus/iio/devices/iio:deviceX/out_altvoltageY_frequency_points

Defined on file *sysfs-bus-iio-impedance-analyzer-ad5933*

Number of frequency points (steps) in the frequency sweep. This value, in conjunction with the out_altvoltageY_frequency_start and the out_altvoltageY_frequency_increment, determines the frequency sweep range for the sweep operation.

/sys/bus/iio/devices/iio:deviceX/out_altvoltageY_frequency_resolution

Defined on file *sysfs-bus-iio-frequency-adf4350*

Stores channel Y frequency resolution/channel spacing in Hz. The value given directly influences the MODULUS used by the fractional-N PLL. It is assumed that the algorithm that is

used to compute the various dividers, is able to generate proper values for multiples of channel spacing.

/sys/bus/iio/devices/iio:deviceX/out_altvoltageY_frequency_start

Defined on file *sysfs-bus-iio-impedance-analyzer-ad5933*

Frequency sweep start frequency in Hz.

/sys/bus/iio/devices/iio:deviceX/out_altvoltageY_name

Defined on file *sysfs-bus-iio-frequency-adf4371*

Reading returns the datasheet name for channel Y:

```
out_altvoltage0_name: RF8x
out_altvoltage1_name: RFAUX8x
out_altvoltage2_name: RF16x
out_altvoltage3_name: RF32x
```

/sys/bus/iio/devices/iio:deviceX/out_altvoltageY_phase

Defined on file *sysfs-bus-iio*

Phase in radians of one frequency/clock output Y (out_altvoltageY) relative to another frequency/clock output (out_altvoltageZ) of the device X. The number must always be specified and unique if the output corresponds to a single channel.

/sys/bus/iio/devices/iio:deviceX/out_altvoltageY_refin_frequency

Defined on file *sysfs-bus-iio-frequency-adf4350*

Sets channel Y REFin frequency in Hz. In some clock chained applications, the reference frequency used by the PLL may change during runtime. This attribute allows the user to adjust the reference frequency accordingly. The value written has no effect until out_altvoltageY_frequency is updated. Consider to use out_altvoltageY_powerdown to power down the PLL and its RFOut buffers during REFin changes.

/sys/bus/iio/devices/iio:deviceX/out_altvoltageY_settling_cycles

Defined on file *sysfs-bus-iio-impedance-analyzer-ad5933*

Number of output excitation cycles (settling time cycles) that are allowed to pass through the unknown impedance, after each frequency increment, and before the ADC is triggered to perform a conversion sequence of the response signal.

/sys/bus/iio/devices/iio:deviceX/out_conversion_mode

Defined on file *sysfs-bus-iio-vf610*

Specifies the hardware conversion mode used within DAC. The two available modes are ”high-power” and ”low-power”, where ”low-power” mode is the default mode.

/sys/bus/iio/devices/iio:deviceX/out_currentY_currentZ_raw

Defined on file *sysfs-bus-iio-light-lm3533-als*

Set the output current for channel out_currentY when in zone Z (0..255), where Y in 0..2 and Z in 0..4.

These values correspond to the ALS-mapper target registers for ALS-mapper Y + 1.

Note that out_currentY_raw provides the current for the current zone.

/sys/bus/iio/devices/iio:deviceX/out_currentY_raw

Defined on file *sysfs-bus-iio*

Set/get output current for channel Y. Units after application of scale and offset are milliamps. For some devices current channels are used to specify current supplied to elements used in taking a measurement of a different type. E.g. LED currents.

/sys/bus/iio/devices/iio:deviceX/out_current_heater_raw
/sys/bus/iio/devices/iio:deviceX/out_current_heater_raw_available

Defined on file *sysfs-bus-iio-humidity*

Controls the heater device within the humidity sensor to get rid of excess condensation.

In some devices, this is just a switch in which case 0 = OFF, and 1 = ON.

/sys/bus/iio/devices/iio:deviceX/out_humidityrelative_raw

Defined on file *sysfs-bus-iio-chemical-sgp40*

Set the relative humidity. This value is sent to the sensor for humidity compensation. Default value: 50000 (50 % relative humidity)

/sys/bus/iio/devices/iio:deviceX/out_resistance_raw_available

Defined on file *sysfs-bus-iio-potentiometer-mcp4531*

The range of available values represented as the minimum value, the step and the maximum value, all enclosed in square brackets. Example: [0 1 256]

/sys/bus/iio/devices/iio:deviceX/out_temp_raw

Defined on file *sysfs-bus-iio-chemical-sgp40*

Set the temperature. This value is sent to the sensor for temperature compensation. Default value: 25000 (25 °C)

/sys/bus/iio/devices/iio:deviceX/out_voltageY&Z_raw
/sys/bus/iio/devices/iio:deviceX/out_altvoltageY&Z_raw

Defined on file *sysfs-bus-iio*

Raw (unscaled, no bias etc.) output voltage for an aggregate of channel Y, channel Z, etc. This interface is available in cases where a single output sets the value for multiple channels simultaneously.

/sys/bus/iio/devices/iio:deviceX/out_voltageY_dither_en

Defined on file *sysfs-bus-iio-dac-ltc2688*

Dither enable. Write 1 to enable dither or 0 to disable it. This is useful for changing the dither parameters. They way it should be done is:

- disable dither operation;
- change dither parameters (eg: frequency, phase...);
- enabled dither operation

/sys/bus/iio/devices/iio:deviceX/out_voltageY_dither_frequency

Defined on file *sysfs-bus-iio-dac-ltc2688*

Sets the dither signal frequency. Units are in Hz.

/sys/bus/iio/devices/iio:deviceX/out_voltageY_dither_frequency_available

Defined on file *sysfs-bus-iio-dac-ltc2688*

Returns the available values for the dither frequency.

/sys/bus/iio/devices/iio:deviceX/out_voltageY_dither_offset

Defined on file *sysfs-bus-iio-dac-ltc2688*

Offset applied to out_voltageY_dither_raw. Read only attribute always set to 0.

/sys/bus/iio/devices/iio:deviceX/out_voltageY_dither_phase

Defined on file *sysfs-bus-iio-dac-ltc2688*

Sets the dither signal phase. Units are in Radians.

/sys/bus/iio/devices/iio:deviceX/out_voltageY_dither_phase_available

Defined on file *sysfs-bus-iio-dac-ltc2688*

Returns the available values for the dither phase.

/sys/bus/iio/devices/iio:deviceX/out_voltageY_dither_raw

Defined on file *sysfs-bus-iio-dac-ltc2688*

This raw, unscaled value refers to the dither signal amplitude. The same scale as in out_voltageY_raw applies. However, the offset might be different as it's always 0 for this attribute.

/sys/bus/iio/devices/iio:deviceX/out_voltageY_dither_raw_available

Defined on file *sysfs-bus-iio-dac-ltc2688*

Available range for dither raw amplitude values.

/sys/bus/iio/devices/iio:deviceX/out_voltageY_hardwaregain
/sys/bus/iio/devices/iio:deviceX/in_intensity_hardwaregain
/sys/bus/iio/devices/iio:deviceX/in_intensity_red_hardwaregain
/sys/bus/iio/devices/iio:deviceX/in_intensity_green_hardwaregain
/sys/bus/iio/devices/iio:deviceX/in_intensity_blue_hardwaregain
/sys/bus/iio/devices/iio:deviceX/in_intensity_clear_hardwaregain

Defined on file *sysfs-bus-iio*

Hardware applied gain factor. If shared across all channels, <type>_hardwaregain is used.

/sys/bus/iio/devices/iio:deviceX/out_voltageY_powerdown_mode
/sys/bus/iio/devices/iio:deviceX/out_voltage_powerdown_mode
/sys/bus/iio/devices/iio:deviceX/out_altvoltageY_powerdown_mode
/sys/bus/iio/devices/iio:deviceX/out_altvoltage_powerdown_mode

Defined on file *sysfs-bus-iio*

Specifies the output powerdown mode. DAC output stage is disconnected from the amplifier and 1kohm_to_gnd: connected to ground via an 1kOhm resistor, 2.5kohm_to_gnd: connected to ground via a 2.5kOhm resistor, 6kohm_to_gnd: connected to ground via a 6kOhm resistor, 20kohm_to_gnd: connected to ground via a 20kOhm resistor, 90kohm_to_gnd: connected to ground via a 90kOhm resistor, 100kohm_to_gnd: connected to ground via an 100kOhm resistor, 125kohm_to_gnd: connected to ground via an 125kOhm resistor, 500kohm_to_gnd: connected to ground via a 500kOhm resistor, 640kohm_to_gnd: connected to ground via a 640kOhm resistor, three_state: left floating. For a list of available output power down options read outX_powerdown_mode_available. If Y is not present the mode is shared across all outputs.

/sys/bus/iio/devices/iio:deviceX/out_voltageY_powerdown
/sys/bus/iio/devices/iio:deviceX/out_voltage_powerdown
/sys/bus/iio/devices/iio:deviceX/out_altvoltageY_powerdown
/sys/bus/iio/devices/iio:deviceX/out_altvoltage_powerdown

Defined on file *sysfs-bus-iio*

Writing 1 causes output Y to enter the power down mode specified by the corresponding outY_powerdown_mode. DAC output stage is disconnected from the amplifier. Clearing returns to normal operation. Y may be suppressed if all outputs are controlled together.

/sys/bus/iio/devices/iio:deviceX/out_voltageY_raw0
/sys/bus/iio/devices/iio:deviceX/out_voltageY_raw1

Defined on file *sysfs-bus-iio-dac-ltc2688*

It has the same meaning as out_voltageY_raw. This attribute is specific to toggle enabled channels and refers to the DAC output code in INPUT_A (_raw0) and INPUT_B (_raw1). The same scale and offset as in out_voltageY_raw applies.

/sys/bus/iio/devices/iio:deviceX/out_voltageY_raw_available

Defined on file *sysfs-bus-iio-dac-dpot-dac*

The range of available values represented as the minimum value, the step and the maximum value, all enclosed in square brackets. Example: [0 1 256]

/sys/bus/iio/devices/iio:deviceX/out_voltageY_raw
/sys/bus/iio/devices/iio:deviceX/out_altvoltageY_raw

Defined on file *sysfs-bus-iio*

Raw (unscaled, no bias etc.) output voltage for channel Y. The number must always be specified and unique if the output corresponds to a single channel. While DAC like devices typically use out_voltage, a continuous frequency generating device, such as a DDS or PLL should use out_altvoltage.

/sys/bus/iio/devices/iio:deviceX/out_voltageY_symbol

Defined on file *sysfs-bus-iio-dac-ltc2688*

Performs a SW toggle. This attribute is specific to toggle enabled channels and allows to toggle between out_voltageY_raw0 and out_voltageY_raw1 through software. Writing 0 will select out_voltageY_raw0 while 1 selects out_voltageY_raw1.

/sys/bus/iio/devices/iio:deviceX/out_voltageY_toggle_en

Defined on file *sysfs-bus-iio-dac-ltc2688*

Toggle enable. Write 1 to enable toggle or 0 to disable it. This is useful when one wants to change the DAC output codes. The way it should be done is:

- disable toggle operation;
- change out_voltageY_raw0 and out_voltageY_raw1;
- enable toggle operation.

/sys/bus/iio/devices/iio:deviceX/oversampling_ratio

Defined on file *sysfs-bus-iio*

Hardware dependent ADC oversampling. Controls the sampling ratio of the digital filter if available.

/sys/bus/iio/devices/iio:deviceX/oversampling_ratio_available

Defined on file *sysfs-bus-iio*

Hardware dependent values supported by the oversampling filter.

/sys/bus/iio/devices/iio:deviceX/pll2_feedback_clk_present
/sys/bus/iio/devices/iio:deviceX/pll2_reference_clk_present
/sys/bus/iio/devices/iio:deviceX/pll1_reference_clk_a_present
/sys/bus/iio/devices/iio:deviceX/pll1_reference_clk_b_present
/sys/bus/iio/devices/iio:deviceX/pll1_reference_clk_test_present
/sys/bus/iio/devices/iio:deviceX/vcxo_clk_present

Defined on file *sysfs-bus-iio-frequency-ad9523*

Reading returns either '1' or '0'.

'1' means that the clock in question is present.

'0' means that the clock is missing.

/sys/bus/iio/devices/iio:deviceX/pllY_locked

Defined on file *sysfs-bus-iio-frequency-ad9523*

Reading returns either '1' or '0'. '1' means that the pllY is locked.

/sys/bus/iio/devices/iio:deviceX/proximity_on_chip_ambient_infrared_suppression

Defined on file *sysfs-bus-iio-light-isl29018*

From ISL29018 Data Sheet (FN6619.4, Oct 8, 2012) regarding the infrared suppression:

Scheme 0, makes full n (4, 8, 12, 16) bits (unsigned) proximity detection. The range of Scheme 0 proximity count is from 0 to 2^n. Logic 1 of this bit, Scheme 1, makes n-1 (3, 7, 11, 15) bits (2's complementary) proximity_less_ambient detection. The range of Scheme 1 proximity count is from -2^(n-1) to 2^(n-1). The sign bit is extended for resolutions less than 16. While Scheme 0 has wider dynamic range, Scheme 1 proximity detection is less affected by the ambient IR noise variation.

0	Sensing IR from LED and ambient
1	Sensing IR from LED with ambient IR rejection

/sys/bus/iio/devices/iio:deviceX/sampling_frequency_available
/sys/bus/iio/devices/iio:deviceX/in_intensity_sampling_frequency_available
/sys/bus/iio/devices/iio:deviceX/in_proximity_sampling_frequency_available
/sys/.../iio:deviceX/buffer/sampling_frequency_available
/sys/bus/iio/devices/triggerX/sampling_frequency_available

Defined on file *sysfs-bus-iio*

When the internal sampling clock can only take a specific set of frequencies, we can specify the available values with:

- a small discrete set of values like "0 2 4 6 8"

- a range with minimum, step and maximum frequencies like "[min step max]"

/sys/bus/iio/devices/iio:deviceX/sampling_frequency
/sys/bus/iio/devices/iio:deviceX/in_intensity_sampling_frequency
/sys/bus/iio/devices/iio:deviceX/buffer/sampling_frequency
/sys/bus/iio/devices/triggerX/sampling_frequency

Defined on file *sysfs-bus-iio*

Some devices have internal clocks. This parameter sets the resulting sampling frequency. In many devices this parameter has an effect on input filters etc. rather than simply controlling when the input is sampled. As this affects data ready triggers, hardware buffers and the sysfs direct access interfaces, it may be found in any of the relevant directories. If it affects all of the above then it is to be found in the base device directory.

The stm32-timer-trigger has the additional characteristic that a sampling_frequency of 0 is defined to stop sampling.

/sys/bus/iio/devices/iio:deviceX/sensor_max_range

Defined on file *sysfs-bus-iio-distance-srf08*

Show or set the maximum range between the sensor and the first object echoed in meters. Default value is 6.020. This setting limits the time the driver is waiting for a echo.

Showing the range of available values is represented as the minimum value, the step and the maximum value, all enclosed in square brackets.

Example:

```
[0.043 0.043 11.008]
```

/sys/bus/iio/devices/iio:deviceX/sensor_sensitivity

Defined on file *sysfs-bus-iio-proximity*

Proximity sensors sometimes have a controllable amplifier on the signal from which time of flight measurements are taken. The appropriate values to take is dependent on both the sensor and its operating environment: * as3935 (0-31 range) 18 = indoors (default) 14 = outdoors

/sys/bus/iio/devices/iio:deviceX/serialnumber

Defined on file *sysfs-bus-iio*

An example format is 16-bytes, 2-digits-per-byte, HEX-string representing the sensor unique ID number.

/sys/bus/iio/devices/iio:deviceX/start_cleaning

Defined on file *sysfs-bus-iio-sps30*

Writing 1 starts sensor self cleaning. Internal fan accelerates to its maximum speed and keeps spinning for about 10 seconds in order to blow out accumulated dust.

/sys/bus/iio/devices/iio:deviceX/store_eeprom

Defined on file *sysfs-bus-iio*

Writing '1' stores the current device configuration into on-chip EEPROM. After power-up or chip reset the device will automatically load the saved configuration.

/sys/bus/iio/devices/iio:deviceX/sync_dividers

Defined on file *sysfs-bus-iio-frequency-ad9523*

Writing '1' triggers the clock distribution synchronization functionality. All dividers are reset and the channels start with their predefined phase offsets (out_altvoltageY_phase). Writing this file has the effect as driving the external /SYNC pin low.

/sys/bus/iio/devices/iio:deviceX/sys_calibration_auto_status

Defined on file *sysfs-bus-iio-bno055*

Reports the status for the IMU overall autocalibration. Can be 0 (calibration non even enabled) or 1 to 5 where the greater the number, the better the calibration status.

/sys/bus/iio/devices/iio:deviceX/trigger/current_trigger

Defined on file *sysfs-bus-iio*

The name of the trigger source being used, as per string given in /sys/class/iio/triggerY/name.

/sys/bus/iio/devices/iio_sysfs_trigger/add_trigger

Defined on file *sysfs-bus-iio-trigger-sysfs*

This attribute is provided by the iio-trig-sysfs stand-alone driver and it is used to activate the creation of a new trigger. In order to achieve this, one should write a positive integer into the associated file, which will serve as the id of the trigger. If the trigger with the specified id is already present in the system, an invalid argument message will be returned.

/sys/bus/iio/devices/iio_sysfs_trigger/remove_trigger

Defined on file *sysfs-bus-iio-trigger-sysfs*

This attribute is used to unregister and delete a previously created trigger from the list of available triggers. In order to achieve this, one should write a positive integer into the associated file, representing the id of the trigger that needs to be removed. If the trigger can't be found, an invalid argument message will be returned to the user.

/sys/bus/iio/devices/triggerX

Defined on file *sysfs-bus-iio*

An event driven driver of data capture to an in kernel buffer. May be provided by a device driver that also has an IIO device based on hardware generated events (e.g. data ready) or provided by a separate driver for other hardware (e.g. periodic timer, GPIO or high resolution timer).

Contains trigger type specific elements. These do not generalize well and hence are not documented in this file. X is the IIO index of the trigger.

/sys/bus/iio/devices/triggerX/master_mode

Defined on file *sysfs-bus-iio-timer-stm32*

Reading returns the current master modes. Writing set the master mode

/sys/bus/iio/devices/triggerX/master_mode_available

Defined on file *sysfs-bus-iio-timer-stm32*

Reading returns the list possible master modes which are:

- **"reset"**
  The UG bit from the TIMx_EGR register is used as trigger output (TRGO).
- **"enable"**
  The Counter Enable signal CNT_EN is used as trigger output.
- **"update"**
  The update event is selected as trigger output. For instance a master timer can then be used as a prescaler for a slave timer.
- **"compare_pulse"**
  The trigger output send a positive pulse when the CC1IF flag is to be set.
- **"OC1REF"**
  OC1REF signal is used as trigger output.
- **"OC2REF"**
  OC2REF signal is used as trigger output.
- **"OC3REF"**
  OC3REF signal is used as trigger output.
- **"OC4REF"**
  OC4REF signal is used as trigger output.

Additional modes (on TRGO2 only):

- **"OC5REF"**
  OC5REF signal is used as trigger output.
- **"OC6REF"**
  OC6REF signal is used as trigger output.
- **"compare_pulse_OC4REF":**
  OC4REF rising or falling edges generate pulses.
- **"compare_pulse_OC6REF":**
  OC6REF rising or falling edges generate pulses.

- **"compare_pulse_OC4REF_r_or_OC6REF_r":**
  OC4REF or OC6REF rising edges generate pulses.
- **"compare_pulse_OC4REF_r_or_OC6REF_f":**
  OC4REF rising or OC6REF falling edges generate pulses.
- **"compare_pulse_OC5REF_r_or_OC6REF_r":**
  OC5REF or OC6REF rising edges generate pulses.
- **"compare_pulse_OC5REF_r_or_OC6REF_f":**
  OC5REF rising or OC6REF falling edges generate pulses.

```
+-----------+   +-------------+            +---------+
| Prescaler +-> | Counter     |        +-> | Master  | TRGO(2)
+-----------+   +--+--------+-+        |-> | Control +-->
                   |        |          ||  +---------+
                +--v--------+-+ OCxREF ||  +---------+
                | Chx compare +----------> | Output  | ChX
                +-----------+-+         |  | Control +-->
                      .     |           |  +---------+
                      .     |           |    .
                +-----------v-+ OC6REF  |    .
                | Ch6 compare +---------+>
                +-------------+
```

Example with: "compare_pulse_OC4REF_r_or_OC6REF_r":

```
                X
              X   X
            X .   . X
          X   .   .   X
        X     .   .     X
count X .     .   .     . X
        .     .   .     .
        .     .   .     .
        +---------------+
OC4REF  |     .   .     |
      +-+     .   .     +-+
        .     +---+     .
OC6REF  .     |   |     .
      +-------+   +-------+
        +-+   +-+
TRGO2   | |   | |
      +-+ +---+ +---------+
```

/sys/bus/iio/devices/triggerX/name

Defined on file *sysfs-bus-iio-trigger-sysfs*

The name attribute holds a description string for the current trigger. In order to associate the trigger with an IIO device one should write this name string to /sys/bus/iio/devices/iio:deviceY/trigger/current_trigger.

/sys/bus/iio/devices/triggerX/name = "adxl372-devX-peak"

Defined on file *sysfs-bus-iio-accel-adxl372*

The adxl372 accelerometer kernel module provides an additional trigger, which sets the device in a mode in which it will record only the peak acceleration sensed over the set period of time in the events sysfs.

/sys/bus/iio/devices/triggerX/name = "bmc150_accel-any-motion-devX"

Defined on file *sysfs-bus-iio-accel-bmc150*

The BMC150 accelerometer kernel module provides an additional trigger, which sets driver in a mode, where data is pushed to the buffer only when there is any motion.

/sys/bus/iio/devices/triggerX/name = "bmg160-any-motion-devX"

Defined on file *sysfs-bus-iio-gyro-bmg160*

The BMG160 gyro kernel module provides an additional trigger, which sets driver in a mode, where data is pushed to the buffer only when there is any motion.

/sys/bus/iio/devices/triggerX/trigger_now

Defined on file *sysfs-bus-iio-trigger-sysfs*

This file is provided by the iio-trig-sysfs stand-alone trigger driver. Writing this file with any value triggers an event driven driver, associated with this trigger, to capture data into an in kernel buffer. This approach can be valuable during automated testing or in situations, where other trigger methods are not applicable. For example no RTC or spare GPIOs. X is the IIO index of the trigger.

/sys/bus/iio/devices/triggerX/trigger_polarity

Defined on file *sysfs-bus-iio-adc-stm32*

The STM32 ADC can be configured to use external trigger sources (e.g. timers, pwm or exti gpio). Then, it can be tuned to start conversions on external trigger by either:

- "rising-edge"
- "falling-edge"
- "both-edges".

Reading returns current trigger polarity.

Writing value before enabling conversions sets trigger polarity.

/sys/bus/iio/devices/triggerX/trigger_polarity_available

Defined on file *sysfs-bus-iio-adc-stm32*

List all available trigger_polarity settings.

/sys/bus/intel_th/devices/<intel_th_id>-<device><id>/active

Defined on file *sysfs-bus-intel_th-output-devices*

(RW) Writes of 1 or 0 enable or disable trace output to this output device. Reads return current status. Requires that the correstponding output port driver be loaded.

/sys/bus/intel_th/devices/<intel_th_id>-gth/masters/*

Defined on file *sysfs-bus-intel_th-devices-gth*

(RW) Configure output ports for STP masters. Writing -1 disables a master; any

/sys/bus/intel_th/devices/<intel_th_id>-gth/outputs/[0-7]_drop

Defined on file *sysfs-bus-intel_th-devices-gth*

(RW) Data retention policy setting: keep (0) or drop (1) incoming data while output port is in reset.

/sys/bus/intel_th/devices/<intel_th_id>-gth/outputs/[0-7]_flush

Defined on file *sysfs-bus-intel_th-devices-gth*

(RW) Force flush data from byte packing buffer for the output port.

/sys/bus/intel_th/devices/<intel_th_id>-gth/outputs/[0-7]_null

Defined on file *sysfs-bus-intel_th-devices-gth*

(RW) STP NULL packet generation: enabled (1) or disabled (0).

/sys/bus/intel_th/devices/<intel_th_id>-gth/outputs/[0-7]_port

Defined on file *sysfs-bus-intel_th-devices-gth*

(RO) Output port type:

0	not present,
1	MSU (Memory Storage Unit)
2	CTP (Common Trace Port)
4	PTI (MIPI PTI).

/sys/bus/intel_th/devices/<intel_th_id>-gth/outputs/[0-7]_reset

Defined on file *sysfs-bus-intel_th-devices-gth*

(RO) Output port is in reset (1).

/sys/bus/intel_th/devices/<intel_th_id>-gth/outputs/[0-7]_smcfreq

Defined on file *sysfs-bus-intel_th-devices-gth*

(RW) STP sync packet frequency for the port. Specifies the number of clocks between maintenance packets.

/sys/bus/intel_th/devices/<intel_th_id>-msc<msc-id>/mode

Defined on file *sysfs-bus-intel_th-devices-msc*

(RW) Configure MSC operating mode:

- "single", for contiguous buffer mode (high-order alloc);
- "multi", for multiblock mode;
- "ExI", for DCI handler mode;
- "debug", for debug mode;
- any of the currently loaded buffer sinks.

If operating mode changes, existing buffer is deallocated, provided there are no active users and tracing is not enabled, otherwise the write will fail.

/sys/bus/intel_th/devices/<intel_th_id>-msc<msc-id>/nr_pages

Defined on file *sysfs-bus-intel_th-devices-msc*

(RW) Configure MSC buffer size for "single" or "multi" modes.

In single mode, this is a single number of pages, has to be power of 2. In multiblock mode, this is a comma-separated list of numbers of pages for each window to be allocated. Number of windows is not limited.

Writing to this file deallocates existing buffer (provided there are no active users and tracing is not enabled) and then allocates a new one.

/sys/bus/intel_th/devices/<intel_th_id>-msc<msc-id>/port

Defined on file *sysfs-bus-intel_th-output-devices*

(RO) Port number, corresponding to this output device on the switch (GTH) or "unassigned" if the corresponding output port driver is not loaded.

/sys/bus/intel_th/devices/<intel_th_id>-msc<msc-id>/stop_on_full

Defined on file *sysfs-bus-intel_th-devices-msc*

(RW) Configure whether trace stops when the last available window becomes full (1/y/Y) or wraps around and continues until the next window becomes available again (0/n/N).

/sys/bus/intel_th/devices/<intel_th_id>-msc<msc-id>/win_switch

Defined on file *sysfs-bus-intel_th-devices-msc*

(RW) Trigger window switch for the MSC's buffer, in multi-window mode. In "multi" mode, accepts writes of "1", thereby triggering a window switch for the buffer. Returns an error in any other operating mode or attempts to write something other than "1".

/sys/bus/intel_th/devices/<intel_th_id>-msc<msc-id>/wrap

Defined on file *sysfs-bus-intel_th-devices-msc*

(RW) Configure MSC buffer wrapping. 1 == wrapping enabled.

/sys/bus/intel_th/devices/<intel_th_id>-pti/clock_divider

Defined on file *sysfs-bus-intel_th-devices-pti*

(RW) Configure PTI port clock divider:

- 0: Intel TH clock rate,
- 1: 1/2 Intel TH clock rate,
- 2: 1/4 Intel TH clock rate,
- 3: 1/8 Intel TH clock rate.

/sys/bus/intel_th/devices/<intel_th_id>-pti/freerunning_clock

Defined on file *sysfs-bus-intel_th-devices-pti*

(RW) 0: PTI trace clock acts as a strobe which only toggles when there is trace data to send. 1: PTI trace clock is a free-running clock.

/sys/bus/intel_th/devices/<intel_th_id>-pti/mode

Defined on file *sysfs-bus-intel_th-devices-pti*

(RW) Configure PTI output width. Currently supported values are 4, 8, 12, 16.

/sys/bus/mcb/devices/mcb:X

Defined on file *sysfs-bus-mcb*

Hardware chip or device hosting the MEN chameleon bus

/sys/bus/mcb/devices/mcb:X/minor

Defined on file *sysfs-bus-mcb*

The FPGA's minor number

/sys/bus/mcb/devices/mcb:X/model

Defined on file *sysfs-bus-mcb*

The FPGA's model number

/sys/bus/mcb/devices/mcb:X/name

Defined on file *sysfs-bus-mcb*

The FPGA's name

/sys/bus/mcb/devices/mcb:X/revision

Defined on file *sysfs-bus-mcb*

The FPGA's revision number

/sys/bus/mdio_bus/devices/.../statistics/errors_<addr>
/sys/class/mdio_bus/.../statistics/errors_<addr>

Defined on file *sysfs-bus-mdio*

Total number of transfer errors for this MDIO bus address.

/sys/bus/mdio_bus/devices/.../statistics/errors
/sys/class/mdio_bus/.../statistics/errors

Defined on file *sysfs-bus-mdio*

Total number of transfer errors for this MDIO bus.

/sys/bus/mdio_bus/devices/.../statistics/reads_<addr>
/sys/class/mdio_bus/.../statistics/reads_<addr>

Defined on file *sysfs-bus-mdio*

Total number of read transactions for this MDIO bus address.

/sys/bus/mdio_bus/devices/.../statistics/reads
/sys/class/mdio_bus/.../statistics/reads

Defined on file *sysfs-bus-mdio*

Total number of read transactions for this MDIO bus.

/sys/bus/mdio_bus/devices/.../statistics/transfers_<addr>
/sys/class/mdio_bus/.../statistics/transfers_<addr>

Defined on file *sysfs-bus-mdio*

Total number of transfers for this MDIO bus address.

/sys/bus/mdio_bus/devices/.../statistics/transfers
/sys/class/mdio_bus/.../transfers

Defined on file *sysfs-bus-mdio*

Total number of transfers for this MDIO bus.

/sys/bus/mdio_bus/devices/.../statistics/writes_<addr>
/sys/class/mdio_bus/.../statistics/writes_<addr>

Defined on file *sysfs-bus-mdio*

Total number of write transactions for this MDIO bus address.

/sys/bus/mdio_bus/devices/.../statistics/writes
/sys/class/mdio_bus/.../statistics/writes

Defined on file *sysfs-bus-mdio*

Total number of write transactions for this MDIO bus.

/sys/bus/mdio_bus/devices/.../statistics/
/sys/class/mdio_bus/.../statistics/

Defined on file *sysfs-bus-mdio*

This folder contains statistics about global and per MDIO bus address statistics.

/sys/bus/media/devices/.../model

Defined on file *sysfs-bus-media*

Contains the device model name in UTF-8. The device version is is not be appended to the model name.

/sys/bus/mei/devices/.../fixed

Defined on file *sysfs-bus-mei*

Stores mei client fixed address, if any Format: %d

/sys/bus/mei/devices/.../max_conn

Defined on file *sysfs-bus-mei*

Stores mei client maximum number of connections Format: %d

/sys/bus/mei/devices/.../max_len

Defined on file *sysfs-bus-mei*

Stores mei client maximum message length Format: %d

/sys/bus/mei/devices/.../modalias

Defined on file *sysfs-bus-mei*

Stores the same MODALIAS value emitted by uevent Format: mei:<mei device name>:<device uuid>:<protocol version>

/sys/bus/mei/devices/.../name

Defined on file *sysfs-bus-mei*

Stores mei client device name Format: string

/sys/bus/mei/devices/.../uuid

Defined on file *sysfs-bus-mei*

Stores mei client device uuid Format: xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxx

/sys/bus/mei/devices/.../version

Defined on file *sysfs-bus-mei*

Stores mei client protocol version Format: %d

/sys/bus/mei/devices/.../vtag

Defined on file *sysfs-bus-mei*

Stores mei client vtag support status Format: %d

/sys/bus/mmc/devices/.../rev

Defined on file *sysfs-bus-mmc*

Extended CSD revision number

/sys/bus/most/devices/<dev>/<channel>/

Defined on file *sysfs-bus-most*

For every channel of the device a directory is created, whose name is dictated by the HDM. This enables an application to collect information about the channel's capabilities and configure it.

/sys/bus/most/devices/<dev>/<channel>/available_datatypes

Defined on file *sysfs-bus-most*

Indicates the data types the channel can transport.

/sys/bus/most/devices/<dev>/<channel>/available_directions

Defined on file *sysfs-bus-most*

Indicates the directions the channel is capable of.

/sys/bus/most/devices/<dev>/<channel>/channel_starving

Defined on file *sysfs-bus-most*

Indicates whether channel ran out of buffers.

/sys/bus/most/devices/<dev>/<channel>/number_of_packet_buffers

Defined on file *sysfs-bus-most*

Indicates the number of packet buffers the channel can handle.

/sys/bus/most/devices/<dev>/<channel>/number_of_stream_buffers

Defined on file *sysfs-bus-most*

Indicates the number of streaming buffers the channel can handle.

/sys/bus/most/devices/<dev>/<channel>/set_buffer_size

Defined on file *sysfs-bus-most*

This is to read back the configured buffer size of the channel.

/sys/bus/most/devices/<dev>/<channel>/set_datatype

Defined on file *sysfs-bus-most*

This is to read back the configured data type of the channel. The following strings will be accepted:

```
'control',
'async',
'sync',
'isoc_avp'
```

/sys/bus/most/devices/<dev>/<channel>/set_direction

Defined on file *sysfs-bus-most*

This is to read back the configured direction of the channel. The following strings will be accepted:

```
'tx',
'rx'
```

/sys/bus/most/devices/<dev>/<channel>/set_number_of_buffers

Defined on file *sysfs-bus-most*

This is to read back the configured number of buffers of the channel.

/sys/bus/most/devices/<dev>/<channel>/set_packets_per_xact

Defined on file *sysfs-bus-most*

This is to read back the configured number of packets per transaction of the channel. This is only applicable when connected via USB.

/sys/bus/most/devices/<dev>/<channel>/set_subbuffer_size

Defined on file *sysfs-bus-most*

This is to read back the configured subbuffer size of the channel.

/sys/bus/most/devices/<dev>/<channel>/size_of_packet_buffer

Defined on file *sysfs-bus-most*

Indicates the size of a packet buffer the channel can handle.

/sys/bus/most/devices/<dev>/<channel>/size_of_stream_buffer

Defined on file *sysfs-bus-most*

Indicates the size of a streaming buffer the channel can handle.

/sys/bus/most/devices/<dev>/dci

Defined on file *sysfs-bus-most*

If the network interface controller is attached via USB, a dci directory is created that allows applications to read and write the controller's DCI registers.

/sys/bus/most/devices/<dev>/dci/arb_address

Defined on file *sysfs-bus-most*

This is used to set an arbitrary DCI register address an application wants to read from or write to.

/sys/bus/most/devices/<dev>/dci/arb_value

Defined on file *sysfs-bus-most*

This is used to read and write the DCI register whose address is stored in arb_address.

/sys/bus/most/devices/<dev>/dci/mep_eui48_hi

Defined on file *sysfs-bus-most*

This is used to check and configure the MAC address.

/sys/bus/most/devices/<dev>/dci/mep_eui48_lo

Defined on file *sysfs-bus-most*

This is used to check and configure the MAC address.

/sys/bus/most/devices/<dev>/dci/mep_eui48_mi

Defined on file *sysfs-bus-most*

This is used to check and configure the MAC address.

/sys/bus/most/devices/<dev>/dci/mep_filter

Defined on file *sysfs-bus-most*

This is used to check and configure the MEP filter address.

/sys/bus/most/devices/<dev>/dci/mep_hash0

Defined on file *sysfs-bus-most*

This is used to check and configure the MEP hash table.

/sys/bus/most/devices/<dev>/dci/mep_hash1

Defined on file *sysfs-bus-most*

This is used to check and configure the MEP hash table.

/sys/bus/most/devices/<dev>/dci/mep_hash2

Defined on file *sysfs-bus-most*

This is used to check and configure the MEP hash table.

/sys/bus/most/devices/<dev>/dci/mep_hash3

Defined on file *sysfs-bus-most*

This is used to check and configure the MEP hash table.

/sys/bus/most/devices/<dev>/dci/ni_state

Defined on file *sysfs-bus-most*

Indicates the current network interface state.

/sys/bus/most/devices/<dev>/dci/node_address

Defined on file *sysfs-bus-most*

Indicates the current node address.

/sys/bus/most/devices/<dev>/dci/node_position

Defined on file *sysfs-bus-most*

Indicates the current node position.

/sys/bus/most/devices/<dev>/dci/packet_bandwidth

Defined on file *sysfs-bus-most*

Indicates the configured packet bandwidth.

/sys/bus/most/devices/<dev>/dci/sync_ep

Defined on file *sysfs-bus-most*

Triggers the controller's synchronization process for a certain endpoint.

/sys/bus/most/devices/<dev>/description

Defined on file *sysfs-bus-most*

Provides information about the physical location of the device. Hardware attached via USB, for instance, might return <1-1.1:1.0>

/sys/bus/most/devices/<dev>/interface

Defined on file *sysfs-bus-most*

Indicates the type of peripheral interface the device uses.

/sys/bus/most/drivers/most_core/components

Defined on file *sysfs-bus-most*

This is used to retrieve a list of registered components.

/sys/bus/most/drivers/most_core/links

Defined on file *sysfs-bus-most*

This is used to retrieve a list of established links.

/sys/bus/moxtet/devices/moxtet-<name>.<addr>/module_description

Defined on file *sysfs-bus-moxtet-devices*

(Read) Moxtet module description. Format: string

/sys/bus/moxtet/devices/moxtet-<name>.<addr>/module_id

Defined on file *sysfs-bus-moxtet-devices*

(Read) Moxtet module ID. Format: %x

/sys/bus/moxtet/devices/moxtet-<name>.<addr>/module_name

Defined on file *sysfs-bus-moxtet-devices*

(Read) Moxtet module name. Format: string

/sys/bus/nd/devices/ndbusX/nfit/dsm_mask

Defined on file *sysfs-bus-nfit*

(RO) The bitmask indicates the supported bus specific control functions. See the section named 'NVDIMM Root Device _DSMs' in the ACPI specification.

/sys/bus/nd/devices/ndbusX/nfit/firmware_activate_noidle

Defined on file *sysfs-bus-nfit*

(RW) The Intel platform implementation of firmware activate support exposes an option let the platform force idle devices in the system over the activation event, or trust that the OS will do it. The safe default is to let the platform force idle devices since the kernel is already in a suspend state, and on the chance that a driver does not properly quiesce bus-mastering after a suspend callback the platform will handle it. However, the activation might abort if, for example, platform firmware determines that the activation time exceeds the max PCI-E completion timeout. Since the platform does not know whether the OS is running the activation from a suspend context it aborts, but if the system owner trusts driver suspend callback to be sufficient then 'firmware_activation_noidle' can be enabled to bypass the activation abort.

/sys/bus/nd/devices/ndbusX/nfit/hw_error_scrub

Defined on file *sysfs-bus-nfit*

(RW) Provides a way to toggle the behavior between just adding the address (cache line) where the MCE happened to the poison list and doing a full scrub. The former (selective insertion of the address) is done unconditionally.

This attribute can have the following values written to it:

'0': Switch to the default mode where an exception will only insert the address of the memory error into the poison and badblocks lists. '1': Enable a full scrub to happen if an exception for a memory error is received.

/sys/bus/nd/devices/ndbusX/nfit/revision

Defined on file *sysfs-bus-nfit*

(RO) ACPI NFIT table revision number.

/sys/bus/nd/devices/ndbusX/nfit/scrub

Defined on file *sysfs-bus-nfit*

(RW) This shows the number of full Address Range Scrubs (ARS) that have been completed since driver load time. Userspace can wait on this using select/poll etc. A '+' at the end indicates an ARS is in progress

Writing a value of 1 triggers an ARS scan.

/sys/bus/nd/devices/nmemX/cxl/id

Defined on file *sysfs-bus-nvdimm*

(RO) Show the id (serial) of the device. This is CXL specific.

/sys/bus/nd/devices/nmemX/cxl/provider

Defined on file *sysfs-bus-nvdimm*

(RO) Shows the CXL bridge device that ties to a CXL memory device to this NVDIMM device. I.e. the parent of the device returned is a /sys/bus/cxl/devices/memX instance.

/sys/bus/nd/devices/nmemX/nfit/device

Defined on file *sysfs-bus-nfit*

(RO) Device id for the NVDIMM, assigned by the module vendor.

/sys/bus/nd/devices/nmemX/nfit/dsm_mask

Defined on file *sysfs-bus-nfit*

(RO) The bitmask indicates the supported device specific control functions relative to the NVDIMM command family supported by the device

/sys/bus/nd/devices/nmemX/nfit/family

Defined on file *sysfs-bus-nfit*

(RO) Displays the NVDIMM family command sets. Values 0, 1, 2 and 3 correspond to NVDIMM_FAMILY_INTEL, NVDIMM_FAMILY_HPE1, NVDIMM_FAMILY_HPE2 and NVDIMM_FAMILY_MSFT respectively.

See the specifications for these command families here: http://pmem.io/documents/NVDIMM_DSM_Interface-V1.6.pdf https://github.com/HewlettPackard/hpe-nvm/blob/master/Documentation/ https://msdn.microsoft.com/library/windows/hardware/mt604741”

/sys/bus/nd/devices/nmemX/nfit/flags

Defined on file *sysfs-bus-nfit*

(RO) The flags in the NFIT memory device sub-structure indicate the state of the data on the nvdimm relative to its energy source or last ”flush to persistence”.

The attribute is a translation of the 'NVDIMM State Flags' field in section 5.2.25.3 'NVDIMM Region Mapping' Structure of the ACPI specification 6.2.

The health states are ”save_fail”, ”restore_fail”, ”flush_fail”, ”not_armed”, ”smart_event”, ”map_fail” and ”smart_notify”.

/sys/bus/nd/devices/nmemX/nfit/format
/sys/bus/nd/devices/nmemX/nfit/format1
/sys/bus/nd/devices/nmemX/nfit/formats

Defined on file *sysfs-bus-nfit*

(RO) The interface codes indicate support for persistent memory mapped directly into system physical address space and / or a block aperture access mechanism to the NVDIMM media. The 'formats' attribute displays the number of supported interfaces.

This layout is compatible with existing libndctl binaries that only expect one code per-dimm as they will ignore nmemX/nfit/formats and nmemX/nfit/formatN.

/sys/bus/nd/devices/nmemX/nfit/handle

Defined on file *sysfs-bus-nfit*

(RO) The address (given by the _ADR object) of the device on its parent bus of the NVDIMM device containing the NVDIMM region.

/sys/bus/nd/devices/nmemX/nfit/id

Defined on file *sysfs-bus-nfit*

(RO) ACPI specification 6.2 section 5.2.25.9, defines an identifier for an NVDIMM, which reflects the id attribute.

/sys/bus/nd/devices/nmemX/nfit/phys_id

Defined on file *sysfs-bus-nfit*

(RO) Handle (i.e., instance number) for the SMBIOS (system management BIOS) Memory Device structure describing the NVDIMM containing the NVDIMM region.

/sys/bus/nd/devices/nmemX/nfit/rev_id

Defined on file *sysfs-bus-nfit*

(RO) Revision of the NVDIMM, assigned by the module vendor.

/sys/bus/nd/devices/nmemX/nfit/serial

Defined on file *sysfs-bus-nfit*

(RO) Serial number of the NVDIMM (non-volatile dual in-line memory module), assigned by the module vendor.

/sys/bus/nd/devices/nmemX/nfit/subsystem_device

Defined on file *sysfs-bus-nfit*

(RO) Sub-system device id for the NVDIMM non-volatile memory subsystem controller, assigned by the non-volatile memory subsystem controller vendor.

/sys/bus/nd/devices/nmemX/nfit/subsystem_rev_id

Defined on file *sysfs-bus-nfit*

(RO) Sub-system revision id of the NVDIMM non-volatile memory subsystem controller, assigned by the non-volatile memory subsystem controller vendor.

/sys/bus/nd/devices/nmemX/nfit/subsystem_vendor

Defined on file *sysfs-bus-nfit*

(RO) Sub-system vendor id of the NVDIMM non-volatile memory subsystem controller.

/sys/bus/nd/devices/nmemX/nfit/vendor

Defined on file *sysfs-bus-nfit*

(RO) Vendor id of the NVDIMM.

/sys/bus/nd/devices/nmemX/papr/flags

Defined on file *sysfs-bus-papr-pmem*

(RO) Report flags indicating various states of a papr-pmem NVDIMM device. Each flag maps to a one or more bits set in the dimm-health-bitmap retrieved in response to H_SCM_HEALTH hcall. The details of the bit flags returned in response to this hcall is available at '/arch/powerpc/papr_hcalls' . Below are the flags reported in this sysfs file:

- **"not_armed"**
  Indicates that NVDIMM contents will not survive a power cycle.
- **"flush_fail"**
  Indicates that NVDIMM contents couldn't be flushed during last shut-down event.
- **"restore_fail"**
  Indicates that NVDIMM contents couldn't be restored during NVDIMM initialization.
- **"encrypted"**
  NVDIMM contents are encrypted.
- **"smart_notify"**
  There is health event for the NVDIMM.
- **"scrubbed"**
  Indicating that contents of the NVDIMM have been scrubbed.
- **"locked"**
  Indicating that NVDIMM contents can't be modified until next power cycle.

/sys/bus/nd/devices/nmemX/papr/health_bitmap_inject

Defined on file *sysfs-bus-papr-pmem*

(RO) Reports the health bitmap inject bitmap that is applied to bitmap received from PowerVM via the H_SCM_HEALTH. This is used to forcibly set specific bits returned from Hcall. These is then used to simulate various health or shutdown states for an nvdimm and are set by user-space tools like ndctl by issuing a PAPR DSM.

/sys/bus/nd/devices/nmemX/papr/perf_stats

Defined on file *sysfs-bus-papr-pmem*

(RO) Report various performance stats related to papr-scm NVDIMM device. This attribute is only available for NVDIMM devices that support reporting NVDIMM performance stats. Each stat is reported on a new line with each line composed of a stat-identifier followed by it value. Below are currently known dimm performance stats which are reported:

- ”CtlResCt” : Controller Reset Count
- ”CtlResTm” : Controller Reset Elapsed Time
- ”PonSecs ” : Power-on Seconds
- ”MemLife ” : Life Remaining
- ”CritRscU” : Critical Resource Utilization
- ”HostLCnt” : Host Load Count
- ”HostSCnt” : Host Store Count
- ”HostSDur” : Host Store Duration
- ”HostLDur” : Host Load Duration
- ”MedRCnt ” : Media Read Count
- ”MedWCnt ” : Media Write Count
- ”MedRDur ” : Media Read Duration
- ”MedWDur ” : Media Write Duration
- ”CchRHCnt” : Cache Read Hit Count
- ”CchWHCnt” : Cache Write Hit Count
- ”FastWCnt” : Fast Write Count

/sys/bus/nd/devices/regionX/nfit/range_index

Defined on file *sysfs-bus-nfit*

(RO) A unique number provided by the BIOS to identify an address range. Used by NVDIMM Region Mapping Structure to uniquely refer to this structure. Value of 0 is reserved and not used as an index.

/sys/bus/nvmem/devices/.../cells/<cell-name>

Defined on file *sysfs-nvmem-cells*

The "cells" folder contains one file per cell exposed by the NVMEM device. The name of the file is: "<name>@<byte>,<bit>", with <name> being the cell name and <where> its location in the NVMEM device, in hexadecimal bytes and bits (without the '0x' prefix, to mimic device tree node names). The length of the file is the size of the cell (when known). The content of the file is the binary content of the cell (may sometimes be ASCII, likely without trailing character). Note: This file is only present if CONFIG_NVMEM_SYSFS is enabled.

Example:

```
hexdump -C /sys/bus/nvmem/devices/1-00563/cells/product-name@d,0
00000000  54 4e 34 38 4d 2d 50 2d  44 4e         |TN48M-P-DN|
0000000a
```

/sys/bus/pci/devices/.../acpi_index

Defined on file *sysfs-bus-pci*

Reading this attribute will provide the firmware given instance (ACPI _DSM instance number) of the PCI device. The attribute will be created only if the firmware has given an instance number to the PCI device. ACPI _DSM instance number will be given priority if the system firmware provides SMBIOS type 41 device type instance also.

Users:

Userspace applications interested in knowing the firmware assigned instance number of the PCI device that can help in understanding the firmware intended order of the PCI device.

/sys/bus/pci/devices/.../d3cold_allowed

Defined on file *sysfs-bus-pci*

d3cold_allowed is bit to control whether the corresponding PCI device can be put into D3Cold state. If it is cleared, the device will never be put into D3Cold state. If it is set, the device may be put into D3Cold state if other requirements are satisfied too. Reading this attribute will show the current value of d3cold_allowed bit. Writing this attribute will set the value of d3cold_allowed bit.

/sys/bus/pci/devices/.../dep_link

Defined on file *sysfs-bus-pci*

This symbolic link appears when hardware supports the SR-IOV capability and the Physical Function driver has enabled it, and this device has vendor specific dependencies with others. The symbolic link points to the PCI device sysfs entry of Physical Function this device depends on.

/sys/bus/pci/devices/.../driver_override

Defined on file *sysfs-bus-pci*

This file allows the driver for a device to be specified which will override standard static and dynamic ID matching. When specified, only a driver with a name matching the value written to driver_override will have an opportunity to bind to the device. The override is specified by writing a string to the driver_override file (echo pci-stub > driver_override) and may be cleared with an empty string (echo > driver_override). This returns the device to standard matching rules binding. Writing to driver_override does not automatically unbind the device from its current driver or make any attempt to automatically load the specified driver. If no driver with a matching name is currently loaded in the kernel, the device will not bind to any driver. This also allows devices to opt-out of driver binding using a driver_override name such as "none". Only a single driver may be specified in the override, there is no support for parsing delimiters.

/sys/bus/pci/devices/.../index

Defined on file *sysfs-bus-pci*

Reading this attribute will provide the firmware given instance number of the PCI device. Depending on the platform this can be for example the SMBIOS type 41 device type instance or the user-defined ID (UID) on s390. The attribute will be created only if the firmware has given an instance number to the PCI device and that number is guaranteed to uniquely identify the device in the system.

Users:

Userspace applications interested in knowing the firmware assigned device type instance of the PCI device that can help in understanding the firmware intended order of the PCI device.

/sys/bus/pci/devices/.../irq

Defined on file *sysfs-bus-pci*

If a driver has enabled MSI (not MSI-X), "irq" contains the IRQ of the first MSI vector. Otherwise "irq" contains the IRQ of the legacy INTx interrupt.

"irq" being set to 0 indicates that the device isn't capable of generating legacy INTx interrupts.

/sys/bus/pci/devices/.../label

Defined on file *sysfs-bus-pci*

Reading this attribute will provide the firmware given name (SMBIOS type 41 string or ACPI _DSM string) of the PCI device. The attribute will be created only if the firmware has given a name to the PCI device. ACPI _DSM string name will be given priority if the system firmware provides SMBIOS type 41 string also.

Users:

Userspace applications interested in knowing the firmware assigned name of the PCI device.

/sys/bus/pci/devices/.../link/clkpm

Defined on file *sysfs-bus-pci*

If ASPM is supported for an endpoint, these files can be used to disable or enable the individual power management states. Write y/1/on to enable, n/0/off to disable.

/sys/bus/pci/devices/.../modalias

Defined on file *sysfs-bus-pci*

This attribute indicates the PCI ID of the device object.

That is in the format: pci:vXXXXXXXXdXXXXXXXXsvXXXXXXXXsdXXXXXXXXbcXXscXXiXX, where:

- vXXXXXXXX contains the vendor ID;
- dXXXXXXXX contains the device ID;
- svXXXXXXXX contains the sub-vendor ID;
- sdXXXXXXXX contains the subsystem device ID;
- bcXX contains the device class;
- scXX contains the device subclass;
- iXX contains the device class programming interface.

/sys/bus/pci/devices/.../msi_bus

Defined on file *sysfs-bus-pci*

Writing a zero value to this attribute disallows MSI and MSI-X for any future drivers of the device. If the device is a bridge, MSI and MSI-X will be disallowed for future drivers of all child devices under the bridge. Drivers must be reloaded for the new setting to take effect.

/sys/bus/pci/devices/.../msi_irqs/

Defined on file *sysfs-bus-pci*

The /sys/devices/.../msi_irqs directory contains a variable set of files, with each file being named after a corresponding msi irq vector allocated to that device.

/sys/bus/pci/devices/.../msi_irqs/<N>

Defined on file *sysfs-bus-pci*

This attribute indicates the mode that the irq vector named by the file is in (msi vs. msix)

/sys/bus/pci/devices/.../numa_node

Defined on file *sysfs-bus-pci*

This file contains the NUMA node to which the PCI device is attached, or -1 if the node is unknown. The initial value comes from an ACPI _PXM method or a similar firmware source. If that is missing or incorrect, this file can be written to override the node. In that case, please report a firmware bug to the system vendor. Writing to this file taints the kernel with TAINT_FIRMWARE_WORKAROUND, which reduces the supportability of your system.

/sys/bus/pci/devices/.../p2pmem/allocate

Defined on file *sysfs-bus-pci*

This file allows mapping p2pmem into userspace. For each mmap() call on this file, the kernel will allocate a chunk of Peer-to-Peer memory for use in Peer-to-Peer transactions. This memory can be used in O_DIRECT calls to NVMe backed files for Peer-to-Peer copies.

/sys/bus/pci/devices/.../p2pmem/available

Defined on file *sysfs-bus-pci*

If the device has any Peer-to-Peer memory registered, this file contains the amount of memory that has not been allocated (in decimal).

/sys/bus/pci/devices/.../p2pmem/published

Defined on file *sysfs-bus-pci*

If the device has any Peer-to-Peer memory registered, this file contains a '1' if the memory has been published for use outside the driver that owns the device.

/sys/bus/pci/devices/.../p2pmem/size

Defined on file *sysfs-bus-pci*

If the device has any Peer-to-Peer memory registered, this file contains the total amount of memory that the device provides (in decimal).

/sys/bus/pci/devices/.../pci_bus/.../rescan

Defined on file *sysfs-bus-pci*

Writing a non-zero value to this attribute will force a rescan of the bus and all child buses, and re-discover devices removed earlier from this part of the device tree.

/sys/bus/pci/devices/.../physfn

Defined on file *sysfs-bus-pci*

This symbolic link appears when a device is a Virtual Function. The symbolic link points to the PCI device sysfs entry of the Physical Function this device associates with.

/sys/bus/pci/devices/.../power_state

Defined on file *sysfs-bus-pci*

This file contains the current PCI power state of the device. The value comes from the PCI kernel device state and can be one of: ”unknown”, ”error”, ”D0”, D1”, ”D2”, ”D3hot”, ”D3cold”. The file is read only.

/sys/bus/pci/devices/.../remove

Defined on file *sysfs-bus-pci*

Writing a non-zero value to this attribute will hot-remove the PCI device and any of its children.

/sys/bus/pci/devices/.../rescan

Defined on file *sysfs-bus-pci*

Writing a non-zero value to this attribute will force a rescan of the device's parent bus and all child buses, and re-discover devices removed earlier from this part of the device tree.

/sys/bus/pci/devices/.../reset

Defined on file *sysfs-bus-pci*

Some devices allow an individual function to be reset without affecting other functions in the same device. For devices that have this support, a file named reset will be present in sysfs. Writing 1 to this file will perform reset.

/sys/bus/pci/devices/.../reset_method

Defined on file *sysfs-bus-pci*

Some devices allow an individual function to be reset without affecting other functions in the same slot.

For devices that have this support, a file named reset_method is present in sysfs. Reading this file gives names of the supported and enabled reset methods and their ordering. Writing a space-separated list of names of reset methods sets the reset methods and ordering to be used when resetting the device. Writing an empty string disables the ability to reset the device. Writing "default" enables all supported reset methods in the default ordering.

/sys/bus/pci/devices/.../resourceN_resize

Defined on file *sysfs-bus-pci*

These files provide an interface to PCIe Resizable BAR support. A file is created for each BAR resource (N) supported by the PCIe Resizable BAR extended capability of the device. Reading each file exposes the bitmap of available resource sizes:

cat resource1_resize 00000000000001c0

The bitmap represents supported resource sizes for the BAR, where bit0 = 1MB, bit1 = 2MB, bit2 = 4MB, etc. In the above example the device supports 64MB, 128MB, and 256MB BAR sizes.

When writing the file, the user provides the bit position of the desired resource size, for example:

echo 7 > resource1_resize

This indicates to set the size value corresponding to bit 7, 128MB. The resulting size is 2 ^ (bit# + 20). This definition matches the PCIe specification of this capability.

In order to make use of resource resizing, all PCI drivers must be unbound from the device and peer devices under the same parent bridge may need to be soft removed. In the case of VGA devices, writing a resize value will remove low level console drivers from the device. Raw users of pci-sysfs resourceN attributes must be terminated prior to resizing. Success of the resizing operation is not guaranteed.

/sys/bus/pci/devices/.../revision

Defined on file *sysfs-bus-pci*

This file contains the revision field of the PCI device. The value comes from device config space. The file is read only.

/sys/bus/pci/devices/.../sriov_drivers_autoprobe

Defined on file *sysfs-bus-pci*

This file is associated with the PF of a device that supports SR-IOV. It determines whether newly-enabled VFs are immediately bound to a driver. It initially contains 1, which means the kernel automatically binds VFs to a compatible driver immediately after they are enabled. If an application writes 0 to the file before enabling VFs, the kernel will not bind VFs to a driver.

A typical use case is to write 0 to this file, then enable VFs, then assign the newly-created VFs to virtual machines. Note that changing this file does not affect already- enabled VFs. In this scenario, the user must first disable the VFs, write 0 to sriov_drivers_autoprobe, then re-enable the VFs.

This is similar to /sys/bus/pci/drivers_autoprobe, but affects only the VFs associated with a specific PF.

/sys/bus/pci/devices/.../sriov_numvfs

Defined on file *sysfs-bus-pci*

This file appears when a physical PCIe device supports SR-IOV. Userspace applications can read and write to this file to determine and control the enablement or disablement of Virtual Functions (VFs) on the physical function (PF). A read of this file will return the number of VFs that are enabled on this PF. A number written to this file will enable the specified number of VFs. A userspace application would typically read the file and check that the value is zero, and then write the number of VFs that should be enabled on the PF; the value written should be less than or equal to the value in the sriov_totalvfs file. A userspace application wanting to disable the VFs would write a zero to this file. The core ensures that valid values are written to this file, and returns errors when values are not valid. For example, writing a 2 to this file when sriov_numvfs is not 0 and not 2 already will return an error. Writing a 10 when the value of sriov_totalvfs is 8 will return an error.

/sys/bus/pci/devices/.../sriov_totalvfs

Defined on file *sysfs-bus-pci*

This file appears when a physical PCIe device supports SR-IOV. Userspace applications can read this file to determine the maximum number of Virtual Functions (VFs) a PCIe physical function (PF) can support. Typically, this is the value reported in the PF's SR-IOV extended capability

structure's TotalVFs element. Drivers have the ability at probe time to reduce the value read from this file via the pci_sriov_set_totalvfs() function.

/sys/bus/pci/devices/.../sriov_vf_msix_count

Defined on file *sysfs-bus-pci*

This file is associated with a SR-IOV virtual function (VF). It allows configuration of the number of MSI-X vectors for the VF. This allows devices that have a global pool of MSI-X vectors to optimally divide them between VFs based on VF usage.

The values accepted are:

- **> 0 - this number will be reported as the Table Size in the** VF's MSI-X capability
- < 0 - not valid
- = 0 - will reset to the device default value

The file is writable if the PF is bound to a driver that implements ->sriov_set_msix_vec_count().

/sys/bus/pci/devices/.../sriov_vf_total_msix

Defined on file *sysfs-bus-pci*

This file is associated with a SR-IOV physical function (PF). It contains the total number of MSI-X vectors available for assignment to all virtual functions (VFs) associated with PF. The value will be zero if the device doesn't support this functionality. For supported devices, the value will be constant and won't be changed after MSI-X vectors assignment.

/sys/bus/pci/devices/.../virtfn<N>

Defined on file *sysfs-bus-pci*

This symbolic link appears when hardware supports the SR-IOV capability and the Physical Function driver has enabled it. The symbolic link points to the PCI device sysfs entry of the Virtual Function whose index is N (0...MaxVFs-1).

/sys/bus/pci/devices/.../vpd

Defined on file *sysfs-bus-pci*

A file named vpd in a device directory will be a binary file containing the Vital Product Data for the device. It should follow the VPD format defined in PCI Specification 2.1 or 2.2, but users should consider that some devices may have incorrectly formatted data. If the underlying VPD has a writable section then the corresponding section of this file will be writable.

/sys/bus/pci/devices/<BDF>/anti_rollback_status

Defined on file *sysfs-driver-ccp*

The */sys/bus/pci/devices/<BDF>/anti_rollback_status* file reports whether the PSP is enforcing rollback protection. Possible values: 0: Not enforcing 1: Enforcing

/sys/bus/pci/devices/<BDF>/bootloader_version

Defined on file *sysfs-driver-ccp*

The */sys/bus/pci/devices/<BDF>/bootloader_version* file reports the firmware version of the AMD AGESA bootloader.

/sys/bus/pci/devices/<BDF>/debug_lock_on

Defined on file *sysfs-driver-ccp*

The */sys/bus/pci/devices/<BDF>/debug_lock_on* reports whether the AMD CPU or APU has been unlocked for debugging. Possible values: 0: Not locked 1: Locked

/sys/bus/pci/devices/<BDF>/fused_part

Defined on file *sysfs-driver-ccp*

The */sys/bus/pci/devices/<BDF>/fused_part* file reports whether the CPU or APU has been fused to prevent tampering. 0: Not fused 1: Fused

/sys/bus/pci/devices/<BDF>/hsp_tpm_available

Defined on file *sysfs-driver-ccp*

The */sys/bus/pci/devices/<BDF>/hsp_tpm_available* file reports whether the HSP TPM has been activated. Possible values: 0: Not activated or present 1: Activated

/sys/bus/pci/devices/<BDF>/qat/cfg_services

Defined on file *sysfs-driver-qat*

(RW) Reports the current configuration of the QAT device. Write to the file to change the configured services.

The values are:

- sym;asym: the device is configured for running crypto services
- asym;sym: identical to sym;asym
- dc: the device is configured for running compression services
- dcc: identical to dc but enables the dc chaining feature, hash then compression. If this is not required chose dc
- sym: the device is configured for running symmetric crypto services
- asym: the device is configured for running asymmetric crypto services
- asym;dc: the device is configured for running asymmetric crypto services and compression services
- dc;asym: identical to asym;dc

- sym;dc: the device is configured for running symmetric crypto services and compression services
- dc;sym: identical to sym;dc

It is possible to set the configuration only if the device is in the *down* state (see */sys/bus/pci/devices/<BDF>/qat/state*)

The following example shows how to change the configuration of a device configured for running crypto services in order to run data compression:

```
# cat /sys/bus/pci/devices/<BDF>/qat/state
up
# cat /sys/bus/pci/devices/<BDF>/qat/cfg_services
sym;asym
# echo down > /sys/bus/pci/devices/<BDF>/qat/state
# echo dc > /sys/bus/pci/devices/<BDF>/qat/cfg_services
# echo up > /sys/bus/pci/devices/<BDF>/qat/state
# cat /sys/bus/pci/devices/<BDF>/qat/cfg_services
dc
```

This attribute is only available for qat_4xxx devices.

/sys/bus/pci/devices/<BDF>/qat/num_rps

Defined on file *sysfs-driver-qat*

(RO) Returns the number of ring pairs that a single device has.

Example usage:

```
# cat /sys/bus/pci/devices/<BDF>/qat/num_rps
64
```

This attribute is only available for qat_4xxx devices.

/sys/bus/pci/devices/<BDF>/qat/pm_idle_enabled

Defined on file *sysfs-driver-qat*

(RW) This configuration option provides a way to force the device into remaining in the MAX power state. If idle support is enabled the device will transition to the *MIN* power state when idle, otherwise will stay in the MAX power state. Write to the file to enable or disable idle support.

The values are:

- 0: idle support is disabled
- 1: idle support is enabled

Default value is 1.

It is possible to set the pm_idle_enabled value only if the device is in the *down* state (see */sys/bus/pci/devices/<BDF>/qat/state*)

The following example shows how to change the pm_idle_enabled of a device:

```
# cat /sys/bus/pci/devices/<BDF>/qat/state
up
# cat /sys/bus/pci/devices/<BDF>/qat/pm_idle_enabled
1
# echo down > /sys/bus/pci/devices/<BDF>/qat/state
# echo 0 > /sys/bus/pci/devices/<BDF>/qat/pm_idle_enabled
# echo up > /sys/bus/pci/devices/<BDF>/qat/state
# cat /sys/bus/pci/devices/<BDF>/qat/pm_idle_enabled
0
```

This attribute is only available for qat_4xxx devices.

/sys/bus/pci/devices/<BDF>/qat/rp2srv

Defined on file *sysfs-driver-qat*

(RW) This attribute provides a way for a user to query a specific ring pair for the type of service that it is currently configured for.

When written to, the value is cached and used to perform the read operation. Allowed values are in the range 0 to N-1, where N is the max number of ring pairs supported by a device. This can be queried using the attribute qat/num_rps.

A read returns the service associated to the ring pair queried.

The values are:

- dc: the ring pair is configured for running compression services
- sym: the ring pair is configured for running symmetric crypto services
- asym: the ring pair is configured for running asymmetric crypto services

Example usage:

```
# echo 1 > /sys/bus/pci/devices/<BDF>/qat/rp2srv
# cat /sys/bus/pci/devices/<BDF>/qat/rp2srv
sym
```

This attribute is only available for qat_4xxx devices.

/sys/bus/pci/devices/<BDF>/qat/state

Defined on file *sysfs-driver-qat*

(RW) Reports the current state of the QAT device. Write to the file to start or stop the device.

The values are:

- up: the device is up and running
- down: the device is down

It is possible to transition the device from up to down only if the device is up and vice versa.

This attribute is only available for qat_4xxx devices.

/sys/bus/pci/devices/<BDF>/qat_ras/errors_correctable

Defined on file *sysfs-driver-qat_ras*

(RO) Reports the number of correctable errors detected by the device.

This attribute is only available for qat_4xxx devices.

/sys/bus/pci/devices/<BDF>/qat_ras/errors_fatal

Defined on file *sysfs-driver-qat_ras*

(RO) Reports the number of fatal errors detected by the device.

This attribute is only available for qat_4xxx devices.

/sys/bus/pci/devices/<BDF>/qat_ras/errors_nonfatal

Defined on file *sysfs-driver-qat_ras*

(RO) Reports the number of non fatal errors detected by the device.

This attribute is only available for qat_4xxx devices.

/sys/bus/pci/devices/<BDF>/qat_ras/reset_error_counters

Defined on file *sysfs-driver-qat_ras*

(WO) Write to resets all error counters of a device.

The following example reports how to reset the counters:

```
# echo 1 > /sys/bus/pci/devices/<BDF>/qat_ras/reset_error_counters
# cat /sys/bus/pci/devices/<BDF>/qat_ras/errors_correctable
0
# cat /sys/bus/pci/devices/<BDF>/qat_ras/errors_nonfatal
0
# cat /sys/bus/pci/devices/<BDF>/qat_ras/errors_fatal
0
```

This attribute is only available for qat_4xxx devices.

/sys/bus/pci/devices/<BDF>/qat_rl/cap_rem

Defined on file *sysfs-driver-qat_rl*

(RW) This file will return the remaining capability for a particular service/sla. This is the remaining value that a new SLA can be set to or a current SLA can be increased with.

Example usage:

```
# echo "asym" > /sys/bus/pci/devices/<BDF>/qat_rl/cap_rem
# cat /sys/bus/pci/devices/<BDF>/qat_rl/cap_rem
250
```

```
# echo 250 > /sys/bus/pci/devices/<BDF>/qat_rl/cir
# echo "add" > /sys/bus/pci/devices/<BDF>/qat_rl/sla_op
# cat /sys/bus/pci/devices/<BDF>/qat_rl/cap_rem
0
```

This attribute is only available for qat_4xxx devices.

/sys/bus/pci/devices/<BDF>/qat_rl/cir

Defined on file *sysfs-driver-qat_rl*

(RW) Committed information rate (CIR). Rate guaranteed to be achieved by a particular SLA. The value is expressed in permille scale, i.e. 1000 refers to the maximum device throughput for a selected service.

After sending a "get" to sla_op, this will be populated with the CIR for that queried SLA. Write to this file before sending an "add/update" sla_op, to set the SLA to the specified value.

Applicability in sla_op:

- WRITE: add and update operations
- READ: get operation

Example usage:

```
## Write
# echo 500 > /sys/bus/pci/devices/<BDF>/qat_rl/cir
# echo "add" /sys/bus/pci/devices/<BDF>/qat_rl/sla_op

## Read
# echo 4 > /sys/bus/pci/devices/<BDF>/qat_rl/id
# echo "get" > /sys/bus/pci/devices/<BDF>/qat_rl/sla_op
# cat /sys/bus/pci/devices/<BDF>/qat_rl/cir
500
```

This attribute is only available for qat_4xxx devices.

/sys/bus/pci/devices/<BDF>/qat_rl/id

Defined on file *sysfs-driver-qat_rl*

(RW) If written to, the value is used to retrieve a particular SLA and operate on it. This is valid only for the following operations: update, rm, and get. A read of this attribute is only guaranteed to have correct data after creation of an SLA.

Applicability in sla_op:

- WRITE: rm and update operations
- READ: add and get operations

Example usage:

```
## Read
## Set attributes e.g. cir, pir, srv, etc
# echo "add" > /sys/bus/pci/devices/<BDF>/qat_rl/sla_op
# cat /sys/bus/pci/devices/<BDF>/qat_rl/id
4

## Write
# echo 7 > /sys/bus/pci/devices/<BDF>/qat_rl/id
# echo "get" > /sys/bus/pci/devices/<BDF>/qat_rl/sla_op
# cat /sys/bus/pci/devices/<BDF>/qat_rl/rp
0x5  ## ring pair ID 0 and ring pair ID 2
```

This attribute is only available for qat_4xxx devices.

/sys/bus/pci/devices/<BDF>/qat_rl/pir

Defined on file *sysfs-driver-qat_rl*

(RW) Peak information rate (PIR). The maximum rate that can be achieved by that particular SLA. An SLA can reach a value between CIR and PIR when the device is not fully utilized by requests from other users (assigned to different SLAs).

After sending a "get" to sla_op, this will be populated with the PIR for that queried SLA. Write to this file before sending an "add/update" sla_op, to set the SLA to the specified value.

Applicability in sla_op:

- WRITE: add and update operations
- READ: get operation

Example usage:

```
## Write
# echo 750 > /sys/bus/pci/devices/<BDF>/qat_rl/pir
# echo "add" > /sys/bus/pci/devices/<BDF>/qat_rl/sla_op

## Read
# echo 4 > /sys/bus/pci/devices/<BDF>/qat_rl/id
# echo "get" > /sys/bus/pci/devices/<BDF>/qat_rl/sla_op
# cat /sys/bus/pci/devices/<BDF>/qat_rl/pir
750
```

This attribute is only available for qat_4xxx devices.

/sys/bus/pci/devices/<BDF>/qat_rl/rp

Defined on file *sysfs-driver-qat_rl*

(RW) When read, reports the current assigned ring pairs for the queried SLA. When wrote to, configures the ring pairs associated to a new SLA.

The value is a 64-bit bit mask and is written/displayed in hex. Each bit of this mask represents a single ring pair i.e., bit 1 == ring pair id 0; bit 3 == ring pair id 2.

Selected ring pairs must to be assigned to a single service, i.e. the one provided with the srv attribute. The service assigned to a certain ring pair can be checked by querying the attribute qat/rp2srv.

The maximum number of ring pairs is 4 per SLA.

Applicability in sla_op:

- WRITE: add operation
- READ: get operation

Example usage:

```
## Read
# echo 4 > /sys/bus/pci/devices/<BDF>/qat_rl/id
# cat /sys/bus/pci/devices/<BDF>/qat_rl/rp
0x5

## Write
# echo 0x5 > /sys/bus/pci/devices/<BDF>/qat_rl/rp
```

This attribute is only available for qat_4xxx devices.

/sys/bus/pci/devices/<BDF>/qat_rl/sla_op

Defined on file *sysfs-driver-qat_rl*

(WO) This attribute is used to perform an operation on an SLA. The supported operations are: add, update, rm, rm_all, and get.

Input values must be filled through the associated attribute in this group before a write to this file. If the operation completes successfully, the associated attributes will be updated. The associated attributes are: cir, pir, srv, rp, and id.

Supported operations:

- **add: Creates a new SLA with the provided inputs from user.**
  - Inputs: cir, pir, srv, and rp
  - Output: id
- **get: Returns the configuration of the specified SLA in id attribute**
  - Inputs: id
  - Outputs: cir, pir, srv, and rp
- **update: Updates the SLA with new values set in the following attributes**
  - Inputs: id, cir, and pir
- **rm: Removes the specified SLA in the id attribute.**
  - Inputs: id
- **rm_all: Removes all the configured SLAs.**
  - Inputs: None

This attribute is only available for qat_4xxx devices.

/sys/bus/pci/devices/<BDF>/qat_rl/srv

Defined on file *sysfs-driver-qat_rl*

(RW) Service (SRV). Represents the service (sym, asym, dc) associated to an SLA. Can be written to or queried to set/show the SRV type for an SLA. The SRV attribute is used to specify the SRV type before adding an SLA. After an SLA is configured, reports the service associated to that SLA.

Applicability in sla_op:

- WRITE: add and update operations
- READ: get operation

Example usage:

```
## Write
# echo "dc" > /sys/bus/pci/devices/<BDF>/qat_rl/srv
# echo "add" > /sys/bus/pci/devices/<BDF>/qat_rl/sla_op
# cat /sys/bus/pci/devices/<BDF>/qat_rl/id
4

## Read
# echo 4 > /sys/bus/pci/devices/<BDF>/qat_rl/id
# echo "get" > /sys/bus/pci/devices/<BDF>/qat_rl/sla_op
# cat /sys/bus/pci/devices/<BDF>/qat_rl/srv
dc
```

This attribute is only available for qat_4xxx devices.

/sys/bus/pci/devices/<BDF>/rom_armor_enforced

Defined on file *sysfs-driver-ccp*

The */sys/bus/pci/devices/<BDF>/rom_armor_enforced* file reports whether RomArmor SPI protection is enforced. Possible values: 0: Not enforced 1: Enforced

/sys/bus/pci/devices/<BDF>/rpmc_production_enabled

Defined on file *sysfs-driver-ccp*

The */sys/bus/pci/devices/<BDF>/rpmc_production_enabled* file reports whether Replay Protected Monotonic Counter support has been enabled. Possible values: 0: Not enabled 1: Enabled

/sys/bus/pci/devices/<BDF>/rpmc_spirom_available

Defined on file *sysfs-driver-ccp*

The */sys/bus/pci/devices/<BDF>/rpmc_spirom_available* file reports whether an Replay Protected Monotonic Counter supported SPI is installed on the system. Possible values: 0: Not present 1: Present

/sys/bus/pci/devices/<BDF>/tee_version

Defined on file *sysfs-driver-ccp*

The */sys/bus/pci/devices/<BDF>/tee_version* file reports the firmware version of the AMD Trusted Execution Environment (TEE).

/sys/bus/pci/devices/<BDF>/tsme_status

Defined on file *sysfs-driver-ccp*

The */sys/bus/pci/devices/<BDF>/tsme_status* file reports the status of transparent secure memory encryption on AMD systems. Possible values: 0: Not active 1: Active

/sys/bus/pci/devices/<dev>/aer_dev_correctable

Defined on file *sysfs-bus-pci-devices-aer_stats*

List of correctable errors seen and reported by this PCI device using ERR_COR. Note that since multiple errors may be reported using a single ERR_COR message, thus TOTAL_ERR_COR at the end of the file may not match the actual total of all the errors in the file. Sample output:

```
localhost /sys/devices/pci0000:00/0000:00:1c.0 # cat aer_dev_correctable
Receiver Error 2
Bad TLP 0
Bad DLLP 0
RELAY_NUM Rollover 0
Replay Timer Timeout 0
Advisory Non-Fatal 0
Corrected Internal Error 0
Header Log Overflow 0
TOTAL_ERR_COR 2
```

/sys/bus/pci/devices/<dev>/aer_dev_fatal

Defined on file *sysfs-bus-pci-devices-aer_stats*

List of uncorrectable fatal errors seen and reported by this PCI device using ERR_FATAL. Note that since multiple errors may be reported using a single ERR_FATAL message, thus TOTAL_ERR_FATAL at the end of the file may not match the actual total of all the errors in the file. Sample output:

```
localhost /sys/devices/pci0000:00/0000:00:1c.0 # cat aer_dev_fatal
Undefined 0
Data Link Protocol 0
Surprise Down Error 0
Poisoned TLP 0
```

```
Flow Control Protocol 0
Completion Timeout 0
Completer Abort 0
Unexpected Completion 0
Receiver Overflow 0
Malformed TLP 0
ECRC 0
Unsupported Request 0
ACS Violation 0
Uncorrectable Internal Error 0
MC Blocked TLP 0
AtomicOp Egress Blocked 0
TLP Prefix Blocked Error 0
TOTAL_ERR_FATAL 0
```

/sys/bus/pci/devices/<dev>/aer_dev_nonfatal

Defined on file *sysfs-bus-pci-devices-aer_stats*

List of uncorrectable nonfatal errors seen and reported by this PCI device using ERR_NONFATAL. Note that since multiple errors may be reported using a single ERR_FATAL message, thus TOTAL_ERR_NONFATAL at the end of the file may not match the actual total of all the errors in the file. Sample output:

```
localhost /sys/devices/pci0000:00/0000:00:1c.0 # cat aer_dev_nonfatal
Undefined 0
Data Link Protocol 0
Surprise Down Error 0
Poisoned TLP 0
Flow Control Protocol 0
Completion Timeout 0
Completer Abort 0
Unexpected Completion 0
Receiver Overflow 0
Malformed TLP 0
ECRC 0
Unsupported Request 0
ACS Violation 0
Uncorrectable Internal Error 0
MC Blocked TLP 0
AtomicOp Egress Blocked 0
TLP Prefix Blocked Error 0
TOTAL_ERR_NONFATAL 0
```

PCIe Rootport AER statistics

These attributes show up under only the rootports (or root complex event collectors) that are AER capable. These indicate the number of error messages as ”reported to” the rootport. Please note that the rootports also transmit (internally) the ERR_* messages for errors seen by the internal rootport PCI device, so these counters include them and are thus cumulative of all the error messages on the PCI hierarchy originating at that root port.

/sys/bus/pci/devices/<dev>/aer_stats/aer_rootport_total_err_cor

Defined on file *sysfs-bus-pci-devices-aer_stats*

Total number of ERR_COR messages reported to rootport.

/sys/bus/pci/devices/<dev>/aer_stats/aer_rootport_total_err_fatal

Defined on file *sysfs-bus-pci-devices-aer_stats*

Total number of ERR_FATAL messages reported to rootport.

/sys/bus/pci/devices/<dev>/aer_stats/aer_rootport_total_err_nonfatal

Defined on file *sysfs-bus-pci-devices-aer_stats*

Total number of ERR_NONFATAL messages reported to rootport.

/sys/bus/pci/devices/<dev>/ccissX/cXdY/block:cciss!cXdY

Defined on file *sysfs-bus-pci-devices-cciss*

A symbolic link to /sys/block/cciss!cXdY

/sys/bus/pci/devices/<dev>/ccissX/cXdY/lunid

Defined on file *sysfs-bus-pci-devices-cciss*

Displays the 8-byte LUN ID used to address logical drive Y of controller X.

/sys/bus/pci/devices/<dev>/ccissX/cXdY/model

Defined on file *sysfs-bus-pci-devices-cciss*

Displays the SCSI INQUIRY page 0 model for logical drive Y of controller X.

/sys/bus/pci/devices/<dev>/ccissX/cXdY/raid_level

Defined on file *sysfs-bus-pci-devices-cciss*

Displays the RAID level of logical drive Y of controller X.

/sys/bus/pci/devices/<dev>/ccissX/cXdY/rev

Defined on file *sysfs-bus-pci-devices-cciss*

Displays the SCSI INQUIRY page 0 revision for logical drive Y of controller X.

/sys/bus/pci/devices/<dev>/ccissX/cXdY/unique_id

Defined on file *sysfs-bus-pci-devices-cciss*

Displays the SCSI INQUIRY page 83 serial number for logical drive Y of controller X.

/sys/bus/pci/devices/<dev>/ccissX/cXdY/usage_count

Defined on file *sysfs-bus-pci-devices-cciss*

Displays the usage count (number of opens) of logical drive Y of controller X.

/sys/bus/pci/devices/<dev>/ccissX/cXdY/vendor

Defined on file *sysfs-bus-pci-devices-cciss*

Displays the SCSI INQUIRY page 0 vendor for logical drive Y of controller X.

/sys/bus/pci/devices/<dev>/ccissX/rescan

Defined on file *sysfs-bus-pci-devices-cciss*

Kicks of a rescan of the controller to discover logical drive topology changes.

/sys/bus/pci/devices/<dev>/ccissX/resettable

Defined on file *sysfs-bus-pci-devices-cciss*

Value of 1 indicates the controller can honor the reset_devices kernel parameter. Value of 0 indicates reset_devices cannot be honored. This is to allow, for example, kexec tools to be able to warn the user if they designate an unresettable device as a dump device, as kdump requires resetting the device in order to work reliably.

/sys/bus/pci/devices/<dev>/ccissX/transport_mode

Defined on file *sysfs-bus-pci-devices-cciss*

Value of ”simple” indicates that the controller has been placed in ”simple mode”. Value of ”performant” indicates that the controller has been placed in ”performant mode”.

/sys/bus/pci/drivers/.../bind
/sys/devices/pciX/.../bind

Defined on file *sysfs-bus-pci*

Writing a device location to this file will cause the driver to attempt to bind to the device found at this location. This is useful for overriding default bindings. The format for the location is: DDDD:BB:DD.F. That is Domain:Bus:Device.Function and is the same as found in /sys/bus/pci/devices/. For example:

```
# echo 0000:00:19.0 > /sys/bus/pci/drivers/foo/bind
```

(Note: kernels before 2.6.28 may require echo -n).

/sys/bus/pci/drivers/.../new_id
/sys/devices/pciX/.../new_id

Defined on file *sysfs-bus-pci*

Writing a device ID to this file will attempt to dynamically add a new device ID to a PCI device driver. This may allow the driver to support more hardware than was included in the driver's static device ID support table at compile time. The format for the device ID is: VVVV DDDD SVVV SDDD CCCC MMMM PPPP. That is Vendor ID, Device ID, Subsystem Vendor ID, Subsystem Device ID, Class, Class Mask, and Private Driver Data. The Vendor ID and Device ID fields are required, the rest are optional. Upon successfully adding an ID, the driver will probe for the device and attempt to bind to it. For example:

```
# echo "8086 10f5" > /sys/bus/pci/drivers/foo/new_id
```

/sys/bus/pci/drivers/.../remove_id
/sys/devices/pciX/.../remove_id

Defined on file *sysfs-bus-pci*

Writing a device ID to this file will remove an ID that was dynamically added via the new_id sysfs entry. The format for the device ID is: VVVV DDDD SVVV SDDD CCCC MMMM. That is Vendor ID, Device ID, Subsystem Vendor ID, Subsystem Device ID, Class, and Class Mask. The Vendor ID and Device ID fields are required, the rest are optional. After successfully removing an ID, the driver will no longer support the device. This is useful to ensure auto probing won't match the driver to the device. For example:

```
# echo "8086 10f5" > /sys/bus/pci/drivers/foo/remove_id
```

/sys/bus/pci/drivers/.../unbind
/sys/devices/pciX/.../unbind

Defined on file *sysfs-bus-pci*

Writing a device location to this file will cause the driver to attempt to unbind from the device found at this location. This may be useful when overriding default bindings. The format for the location is: DDDD:BB:DD.F. That is Domain:Bus:Device.Function and is the same as found in /sys/bus/pci/devices/. For example:

```
# echo 0000:00:19.0 > /sys/bus/pci/drivers/foo/unbind
```

(Note: kernels before 2.6.28 may require echo -n).

/sys/bus/pci/drivers/altera-cvp/chkcfg

Defined on file *sysfs-driver-altera-cvp*

Contains either 1 or 0 and controls if configuration error checking in altera-cvp driver is turned on or off.

/sys/bus/pci/drivers/ehci_hcd/.../companion

Defined on file *sysfs-bus-pci-drivers-ehci_hcd*

PCI-based EHCI USB controllers (i.e., high-speed USB-2.0 controllers) are often implemented along with a set of ”companion” full/low-speed USB-1.1 controllers. When a high-speed device is plugged in, the connection is routed to the EHCI controller; when a full- or low-speed device is plugged in, the connection is routed to the companion controller.

Sometimes you want to force a high-speed device to connect at full speed, which can be accomplished by forcing the connection to be routed to the companion controller. That's what this file does. Writing a port number to the file causes connections on that port to be routed to the companion controller, and writing the negative of a port number returns the port to normal operation.

For example: To force the high-speed device attached to port 4 on bus 2 to run at full speed:

```
echo 4 >/sys/bus/usb/devices/usb2/../companion
```

To return the port to high-speed operation:

```
echo -4 >/sys/bus/usb/devices/usb2/../companion
```

Reading the file gives the list of ports currently forced to the companion controller.

Note: Some EHCI controllers do not have companions; they may contain an internal ”transaction translator” or they may be attached directly to a ”rate-matching hub”. This mechanism will not work with such controllers. Also, it cannot be used to force a port on a high-speed hub to connect at full speed.

Note: When this file was first added, it appeared in a different sysfs directory. The location given above is correct for 2.6.35 (and probably several earlier kernel versions as well).

/sys/bus/pci/drivers/i915/.../hwmon/hwmon<i>/curr1_crit

Defined on file *sysfs-driver-intel-i915-hwmon*

RW. Card reactive critical (I1) power limit in milliamperes.

Card reactive critical (I1) power limit in milliamperes is exposed for server products. The power controller will throttle the operating frequency if the power averaged over a window exceeds this limit.

Only supported for particular Intel i915 graphics platforms.

/sys/bus/pci/drivers/i915/.../hwmon/hwmon<i>/energy1_input

Defined on file *sysfs-driver-intel-i915-hwmon*

RO. Energy input of device or gt in microjoules.

For i915 device level hwmon devices (name ”i915”) this reflects energy input for the entire device. For gt level hwmon devices (name ”i915_gtN”) this reflects energy input for the gt.

Only supported for particular Intel i915 graphics platforms.

/sys/bus/pci/drivers/i915/.../hwmon/hwmon<i>/in0_input

Defined on file *sysfs-driver-intel-i915-hwmon*

RO. Current Voltage in millivolt.

Only supported for particular Intel i915 graphics platforms.

/sys/bus/pci/drivers/i915/.../hwmon/hwmon<i>/power1_crit

Defined on file *sysfs-driver-intel-i915-hwmon*

RW. Card reactive critical (I1) power limit in microwatts.

Card reactive critical (I1) power limit in microwatts is exposed for client products. The power controller will throttle the operating frequency if the power averaged over a window exceeds this limit.

Only supported for particular Intel i915 graphics platforms.

/sys/bus/pci/drivers/i915/.../hwmon/hwmon<i>/power1_max

Defined on file *sysfs-driver-intel-i915-hwmon*

RW. Card reactive sustained (PL1/Tau) power limit in microwatts.

The power controller will throttle the operating frequency if the power averaged over a window (typically seconds) exceeds this limit. A read value of 0 means that the PL1 power limit is disabled, writing 0 disables the limit. Writing values > 0 will enable the power limit.

Only supported for particular Intel i915 graphics platforms.

/sys/bus/pci/drivers/i915/.../hwmon/hwmon<i>/power1_max_interval

Defined on file *sysfs-driver-intel-i915-hwmon*

RW. Sustained power limit interval (Tau in PL1/Tau) in milliseconds over which sustained power is averaged.

Only supported for particular Intel i915 graphics platforms.

/sys/bus/pci/drivers/i915/.../hwmon/hwmon<i>/power1_rated_max

Defined on file *sysfs-driver-intel-i915-hwmon*

RO. Card default power limit (default TDP setting).

Only supported for particular Intel i915 graphics platforms.

/sys/bus/pci/drivers/janz-cmodio/.../modulbus_number

Defined on file *sysfs-bus-pci-drivers-janz-cmodio*

Value representing the HEX switch S2 of the janz carrier board CMOD-IO or CAN-PCI2

Read-only: value of the configuration switch (0..15)

/sys/bus/pci/drivers/pciback/allow_interrupt_control

Defined on file *sysfs-driver-pciback*

List of devices which can have interrupt control flag (INTx, MSI, MSI-X) set by a connected guest. It is meant to be set only when the guest is a stubdomain hosting device model (qemu) and the actual device is assigned to a HVM. It is not safe (similar to permissive attribute) to set for a devices assigned to a PV guest. The device is automatically removed from this list when the connected pcifront terminates.

/sys/bus/pci/drivers/pciback/quirks

Defined on file *sysfs-driver-pciback*

If the permissive attribute is set, then writing a string in the format of DDDD:BB:DD.F-REG:SIZE:MASK will allow the guest to write and read from the PCI device. That is Domain:Bus:Device.Function-Register:Size:Mask (Domain is optional). For example:

```
#echo 00:19.0-E0:2:FF > /sys/bus/pci/drivers/pciback/quirks
```

will allow the guest to read and write to the configuration register 0x0E.

/sys/bus/pci/drivers/xe/.../hwmon/hwmon<i>/curr1_crit

Defined on file *sysfs-driver-intel-xe-hwmon*

RW. Card reactive critical (I1) power limit in milliamperes.

Card reactive critical (I1) power limit in milliamperes is exposed for server products. The power controller will throttle the operating frequency if the power averaged over a window exceeds this limit.

/sys/bus/pci/drivers/xe/.../hwmon/hwmon<i>/energy1_input

Defined on file *sysfs-driver-intel-xe-hwmon*

RO. Energy input of device in microjoules.

Only supported for particular Intel xe graphics platforms.

/sys/bus/pci/drivers/xe/.../hwmon/hwmon<i>/in0_input

Defined on file *sysfs-driver-intel-xe-hwmon*

RO. Current Voltage in millivolt.

Only supported for particular Intel xe graphics platforms.

/sys/bus/pci/drivers/xe/.../hwmon/hwmon<i>/power1_crit

Defined on file *sysfs-driver-intel-xe-hwmon*

RW. Card reactive critical (I1) power limit in microwatts.

Card reactive critical (I1) power limit in microwatts is exposed for client products. The power controller will throttle the operating frequency if the power averaged over a window exceeds this limit.

Only supported for particular Intel xe graphics platforms.

/sys/bus/pci/drivers/xe/.../hwmon/hwmon<i>/power1_max

Defined on file *sysfs-driver-intel-xe-hwmon*

RW. Card reactive sustained (PL1) power limit in microwatts.

The power controller will throttle the operating frequency if the power averaged over a window (typically seconds) exceeds this limit. A read value of 0 means that the PL1 power limit is disabled, writing 0 disables the limit. Writing values > 0 and <= TDP will enable the power limit.

Only supported for particular Intel xe graphics platforms.

/sys/bus/pci/drivers/xe/.../hwmon/hwmon<i>/power1_max_interval

Defined on file *sysfs-driver-intel-xe-hwmon*

RW. Sustained power limit interval (Tau in PL1/Tau) in milliseconds over which sustained power is averaged.

Only supported for particular Intel xe graphics platforms.

/sys/bus/pci/drivers/xe/.../hwmon/hwmon<i>/power1_rated_max

Defined on file *sysfs-driver-intel-xe-hwmon*

RO. Card default power limit (default TDP setting).

Only supported for particular Intel xe graphics platforms.

/sys/bus/pci/drivers/xhci_hcd/.../dbc

Defined on file *sysfs-bus-pci-drivers-xhci_hcd*

xHCI compatible USB host controllers (i.e. super-speed USB3 controllers) are often implemented with the Debug Capability (DbC). It can present a debug device which is fully compliant with the USB framework and provides the equivalent of a very high performance full-duplex serial link for debug purpose.

The DbC debug device shares a root port with xHCI host. When the DbC is enabled, the root port will be assigned to the Debug Capability. Otherwise, it will be assigned to xHCI.

Writing "enable" to this attribute will enable the DbC functionality and the shared root port will be assigned to the DbC device. Writing "disable" to this attribute will disable the DbC functionality and the shared root port will roll back to the xHCI.

Reading this attribute gives the state of the DbC. It can be one of the following states: disabled, enabled, initialized, connected, configured and stalled.

/sys/bus/pci/drivers/xhci_hcd/.../dbc_bInterfaceProtocol

Defined on file *sysfs-bus-pci-drivers-xhci_hcd*

This attribute lets us change the bInterfaceProtocol field presented in the USB Interface descriptor by the xhci debug device. Value can only be changed while debug capability (DbC) is in disabled state to prevent USB descriptor change while connected to a USB host. The default value is 1 (GNU Remote Debug command). Other permissible value is 0 which is for vendor defined debug target.

/sys/bus/pci/drivers/xhci_hcd/.../dbc_bcdDevice

Defined on file *sysfs-bus-pci-drivers-xhci_hcd*

This dbc_bcdDevice attribute lets us change the bcdDevice field presented in the USB device descriptor by this xhci debug device. Value can only be changed while debug capability (DbC) is in disabled state to prevent USB device descriptor change while connected to a USB host. The default value is 0x0010. (device rev 0.10) It can be any 16-bit integer.

/sys/bus/pci/drivers/xhci_hcd/.../dbc_idProduct

Defined on file *sysfs-bus-pci-drivers-xhci_hcd*

This dbc_idProduct attribute lets us change the idProduct field presented in the USB device descriptor by this xhci debug device. Value can only be changed while debug capability (DbC) is in disabled state to prevent USB device descriptor change while connected to a USB host. The default value is 0x0010. It can be any 16-bit integer.

/sys/bus/pci/drivers/xhci_hcd/.../dbc_idVendor

Defined on file *sysfs-bus-pci-drivers-xhci_hcd*

This dbc_idVendor attribute lets us change the idVendor field presented in the USB device descriptor by this xhci debug device. Value can only be changed while debug capability (DbC) is in disabled state to prevent USB device descriptor change while connected to a USB host. The default value is 0x1d6b (Linux Foundation). It can be any 16-bit integer.

/sys/bus/pci/rescan

Defined on file *sysfs-bus-pci*

Writing a non-zero value to this attribute will force a rescan of all PCI buses in the system, and re-discover previously removed devices.

/sys/bus/pci/slots/.../module

Defined on file *sysfs-bus-pci*

This symbolic link points to the PCI hotplug controller driver module that manages the hotplug slot.

/sys/bus/peci/devices/<controller_id>-<device_addr>/remove

Defined on file *sysfs-bus-peci*

Writing a non-zero value to this attribute will remove the PECI device and any of its children.

/sys/bus/peci/rescan

Defined on file *sysfs-bus-peci*

Writing a non-zero value to this attribute will initiate scan for PECI devices on all PECI controllers in the system.

/sys/bus/platform/devices/*/frequency

Defined on file *sysfs-platform-brcmstb-memc*

DDR PHY frequency in Hz.

/sys/bus/platform/devices/*/srpd

Defined on file *sysfs-platform-brcmstb-memc*

Self Refresh Power Down (SRPD) inactivity timeout counted in internal DDR controller clock cycles. Possible values range from 0 (disable inactivity timeout) to 65535 (0xffff).

/sys/bus/platform/devices/*twl4030-usb/vbus

Defined on file *sysfs-platform-twl4030-usb*

Read-only status reporting if VBUS (approx 5V) is being supplied by the USB bus.

Possible values: ”on”, ”off”.

Changes are notified via select/poll.

/sys/bus/platform/devices/.../driver_override

Defined on file *sysfs-bus-platform*

This file allows the driver for a device to be specified which will override standard OF, ACPI, ID table, and name matching. When specified, only a driver with a name matching the value written to driver_override will have an opportunity to bind to the device. The override is specified by writing a string to the driver_override file (echo vfio-platform > driver_override) and may be cleared with an empty string (echo > driver_override). This returns the device to standard matching rules binding. Writing to driver_override does not automatically unbind the device from its current driver or make any attempt to automatically load the specified driver. If no driver with a matching name is currently loaded in the kernel, the device will not bind to any driver. This also allows devices to opt-out of driver binding using a driver_override name such as ”none”. Only a single driver may be specified in the override, there is no support for parsing delimiters.

/sys/bus/platform/devices/.../modalias

Defined on file *sysfs-bus-platform*

Same as MODALIAS in the uevent at device creation.

A platform device that it is exposed via devicetree uses:

- of:N`of node name`T`type`

Other platform devices use, instead:

- platform:*driver name*

/sys/bus/platform/devices/.../msi_irqs/

Defined on file *sysfs-bus-platform*

The /sys/devices/.../msi_irqs directory contains a variable set of files, with each file being named after a corresponding msi irq vector allocated to that device.

/sys/bus/platform/devices/.../msi_irqs/<N>

Defined on file *sysfs-bus-platform*

This attribute will show "msi" if <N> is a valid msi irq

/sys/bus/platform/devices/.../numa_node

Defined on file *sysfs-bus-platform*

This file contains the NUMA node to which the platform device is attached. It won't be visible if the node is unknown. The value comes from an ACPI _PXM method or a similar firmware source. Initial users for this file would be devices like arm smmu which are populated by arm64 acpi_iort.

/sys/bus/platform/devices/../cfam_reset

Defined on file *sysfs-bus-fsi*

Provides a means of resetting the cfam that is attached to the FSI device.

/sys/bus/platform/devices/../fsi-master/fsi0/break

Defined on file *sysfs-bus-fsi*

Sends an FSI BREAK command on a master's communication link to any connected slaves. A BREAK resets connected device's logic and preps it to receive further commands from the master.

/sys/bus/platform/devices/../fsi-master/fsi0/rescan

Defined on file *sysfs-bus-fsi*

Initiates a FSI master scan for all connected slave devices on its links.

/sys/bus/platform/devices/../fsi-master/fsi0/slave@00:00/raw

Defined on file *sysfs-bus-fsi*

Provides a means of reading/writing a 32 bit value from/to a specified FSI bus address.

/sys/bus/platform/devices/../fsi-master/fsi0/slave@00:00/term

Defined on file *sysfs-bus-fsi*

Sends an FSI terminate command from the master to its connected slave. A terminate resets the slave's state machines that control access to the internally connected engines. In addition the slave freezes its internal error register for debugging purposes. This command is also needed to abort any ongoing operation in case of an expired 'Master Time Out' timer.

/sys/bus/platform/devices/<dev>/always_powered_in_suspend

Defined on file *sysfs-bus-platform-onboard-usb-hub*

(RW) Controls whether the USB hub remains always powered during system suspend or not.

/sys/bus/platform/devices/ACPI000E:00/ac_alarm

Defined on file *sysfs-devices-platform-ACPI-TAD*

(RW) The AC alarm timer value.

Reads return the current AC alarm timer value in seconds or ”disabled”, if the AC alarm is not set to wake up the system.

Write a new AC alarm timer value in seconds or ”disabled” to it to set the AC alarm timer or to disable it, respectively.

If the AC alarm timer is set through this attribute and it expires, it will immediately wake up the system from the S3 sleep state (and from S4/S5 too if supported) until its status is explicitly cleared via the ac_status attribute.

/sys/bus/platform/devices/ACPI000E:00/ac_policy

Defined on file *sysfs-devices-platform-ACPI-TAD*

(RW) The AC alarm expired timer wake policy (see ACPI 6.2, Section 9.18 for details).

Reads return the current expired timer wake delay for the AC alarm timer or ”never”, if the policy is to discard AC timer wakeups if the system is on DC power.

Write a new expired timer wake delay for the AC alarm timer in seconds or ”never” to it to set the expired timer wake delay for the AC alarm timer or to set its expired wake policy to discard wakeups if the system is on DC power, respectively.

/sys/bus/platform/devices/ACPI000E:00/ac_status

Defined on file *sysfs-devices-platform-ACPI-TAD*

(RW) The AC alarm status.

Reads return a hexadecimal bitmask representing the AC alarm timer status with the following meaning of bits (see ACPI 6.2, Section 9.18.5):

Bit(0):	The timer has expired if set.
Bit(1):	The timer has woken up the system from a sleep state (S3 or S4/S5 if supported) if set.

The other bits are reserved.

Reads also cause the AC alarm timer status to be reset.

Another way to reset the status of the AC alarm timer is to write (the number) 0 to this file.

If the status return value indicates that the timer has expired, it will immediately wake up the system from the S3 sleep state (and from S4/S5 too if supported) until its status is explicitly cleared through this attribute.

/sys/bus/platform/devices/ACPI000E:00/caps

Defined on file *sysfs-devices-platform-ACPI-TAD*

(RO) Hexadecimal bitmask of the TAD attributes are reported by the platform firmware (see ACPI 6.2, section 9.18.2):

BIT(0):	AC wakeup implemented if set
BIT(1):	DC wakeup implemented if set
BIT(2):	Get/set real time features implemented if set
BIT(3):	Real time accuracy in milliseconds if set
BIT(4):	Correct status reported for wakeups from S4/S5 if set
BIT(5):	The AC timer wakes up from S4 if set
BIT(6):	The AC timer wakes up from S5 if set
BIT(7):	The DC timer wakes up from S4 if set
BIT(8):	The DC timer wakes up from S5 if set

The other bits are reserved.

/sys/bus/platform/devices/ACPI000E:00/dc_alarm

Defined on file *sysfs-devices-platform-ACPI-TAD*

(RW,optional) The DC alarm timer value.

This attribute is only present if the TAD supports a separate DC timer.

It is analogous to the ac_alarm attribute.

/sys/bus/platform/devices/ACPI000E:00/dc_policy

Defined on file *sysfs-devices-platform-ACPI-TAD*

(RW,optional) The DC alarm expired timer wake policy.

This attribute is only present if the TAD supports a separate DC timer.

It is analogous to the ac_policy attribute.

/sys/bus/platform/devices/ACPI000E:00/dc_status

Defined on file *sysfs-devices-platform-ACPI-TAD*

(RW,optional) The DC alarm status.

This attribute is only present if the TAD supports a separate DC timer.

It is analogous to the ac_status attribute.

/sys/bus/platform/devices/GGL0001:*/BINF.2

Defined on file *sysfs-driver-chromeos-acpi*

Returns active EC firmware of current boot (boolean).

0	Read only (recovery) firmware.
1	Rewritable firmware.

/sys/bus/platform/devices/GGL0001:*/BINF.3

Defined on file *sysfs-driver-chromeos-acpi*

Returns main firmware type for current boot (integer).

0	Recovery.
1	Normal.
2	Developer.
3	Netboot (factory installation only).

/sys/bus/platform/devices/GGL0001:*/CHSW

Defined on file *sysfs-driver-chromeos-acpi*

Returns switch position for Chrome OS specific hardware switches when the firmware is booted (integer).

0	No changes.
2	Recovery button was pressed.
4	Recovery button was pressed (EC firmware).
32	Developer switch was enabled.
512	Firmware write protection was disabled.

/sys/bus/platform/devices/GGL0001:*/FMAP

Defined on file *sysfs-driver-chromeos-acpi*

Returns physical memory address of the start of the main processor firmware flashmap.

/sys/bus/platform/devices/GGL0001:*/FRID

Defined on file *sysfs-driver-chromeos-acpi*

Returns firmware version for the read-only portion of the main processor firmware.

/sys/bus/platform/devices/GGL0001:*/FWID

Defined on file *sysfs-driver-chromeos-acpi*

Returns firmware version for the rewritable portion of the main processor firmware.

/sys/bus/platform/devices/GGL0001:*/GPIO.X/GPIO.0

Defined on file *sysfs-driver-chromeos-acpi*

Returns type of the GPIO signal for the Chrome OS specific GPIO assignments (integer).

1	Recovery button.
2	Developer mode switch.
3	Firmware write protection switch.
256 to 511	Debug header GPIO 0 to GPIO 255.

/sys/bus/platform/devices/GGL0001:*/GPIO.X/GPIO.1

Defined on file *sysfs-driver-chromeos-acpi*

Returns signal attributes of the GPIO signal (integer bitfield).

0	Signal is active low.
1	Signal is active high.

/sys/bus/platform/devices/GGL0001:*/GPIO.X/GPIO.2

Defined on file *sysfs-driver-chromeos-acpi*

Returns the GPIO number on the specified GPIO controller.

/sys/bus/platform/devices/GGL0001:*/GPIO.X/GPIO.3

Defined on file *sysfs-driver-chromeos-acpi*

Returns name of the GPIO controller.

/sys/bus/platform/devices/GGL0001:*/HWID

Defined on file *sysfs-driver-chromeos-acpi*

Returns hardware ID for the Chromebook.

/sys/bus/platform/devices/GGL0001:*/MECK

Defined on file *sysfs-driver-chromeos-acpi*

Returns the SHA-1 or SHA-256 hash that is read out of the Management Engine extended registers during boot. The hash is exported via ACPI so the OS can verify that the Management Engine firmware has not changed. If Management Engine is not present, or if the firmware was unable to read the extended registers, this buffer size can be zero.

/sys/bus/platform/devices/GGL0001:*/VBNV.0

Defined on file *sysfs-driver-chromeos-acpi*

Returns offset in CMOS bank 0 of the verified boot non-volatile storage block, counting from the first writable CMOS byte (that is, 'offset = 0' is the byte following the 14 bytes of clock data).

/sys/bus/platform/devices/GGL0001:*/VBNV.1

Defined on file *sysfs-driver-chromeos-acpi*

Return the size in bytes of the verified boot non-volatile storage block.

/sys/bus/platform/devices/GGL0001:*/VDAT

Defined on file *sysfs-driver-chromeos-acpi*

Returns the verified boot data block shared between the firmware verification step and the kernel verification step (hex dump).

/sys/bus/platform/devices/GOOG000C\:00/boot_on_ac

Defined on file *sysfs-platform-wilco-ec*

Boot on AC is a policy which makes the device boot from S5 when AC power is connected. This is useful for users who want to run their device headless or with a dock.

Input should be parseable by kstrtou8() to 0 or 1.

/sys/bus/platform/devices/GOOG000C\:00/build_date

Defined on file *sysfs-platform-wilco-ec*

Display Wilco Embedded Controller firmware build date. Output will a MM/DD/YY string.

/sys/bus/platform/devices/GOOG000C\:00/build_revision

Defined on file *sysfs-platform-wilco-ec*

Display Wilco Embedded Controller build revision. Output will a version string be similar to the example below: d2592cae0

/sys/bus/platform/devices/GOOG000C\:00/model_number

Defined on file *sysfs-platform-wilco-ec*

Display Wilco Embedded Controller model number. Output will a version string be similar to the example below: 08B6

/sys/bus/platform/devices/GOOG000C\:00/usb_charge

Defined on file *sysfs-platform-wilco-ec*

Control the USB PowerShare Policy. USB PowerShare is a policy which affects charging via the special USB PowerShare port (marked with a small lightning bolt or battery icon) when in low power states:

- In S0, the port will always provide power.
- In S0ix, if usb_charge is enabled, then power will be supplied to the port when on AC or if battery is > 50%. Else no power is supplied.
- In S5, if usb_charge is enabled, then power will be supplied to the port when on AC. Else no power is supplied.

Input should be either "0" or "1".

/sys/bus/platform/devices/GOOG000C\:00/version

Defined on file *sysfs-platform-wilco-ec*

Display Wilco Embedded Controller firmware version. The format of the string is x.y.z. Where x is major, y is minor and z is the build number. For example: 95.00.06

/sys/bus/platform/devices/INT3407:00/dptf_power/adapter_rating_mw

Defined on file *sysfs-platform-dptf*

(RO) Adapter rating in milliwatts (the maximum Adapter power). Must be 0 if no AC Adaptor is plugged in.

/sys/bus/platform/devices/INT3407:00/dptf_power/battery_steady_power

Defined on file *sysfs-platform-dptf*

(RO) The maximum sustained power for battery in milliwatts.

/sys/bus/platform/devices/INT3407:00/dptf_power/charger_type

Defined on file *sysfs-platform-dptf*

(RO) The charger type - Traditional, Hybrid or NVDC.

/sys/bus/platform/devices/INT3407:00/dptf_power/max_platform_power_mw

Defined on file *sysfs-platform-dptf*

(RO) Maximum platform power that can be supported by the battery in milliwatts.

/sys/bus/platform/devices/INT3407:00/dptf_power/platform_power_source

Defined on file *sysfs-platform-dptf*

(RO) Display the platform power source

bits[3:0]	Current power source - 0x00 = DC - 0x01 = AC - 0x02 = USB - 0x03 = Wireless Charger
bits[7:4]	Power source sequence number

/sys/bus/platform/devices/INT3407:00/dptf_power/prochot_confirm

Defined on file *sysfs-platform-dptf*

(WO) Confirm embedded controller about a prochot notification.

/sys/bus/platform/devices/INT3407:00/dptf_power/rest_of_platform_power_mw

Defined on file *sysfs-platform-dptf*

(RO) Shows the rest (outside of SoC) of worst-case platform power.

/sys/bus/platform/devices/INT3532:00/dptf_battery/current_discharge_capbility_ma

Defined on file *sysfs-platform-dptf*

(RO) The battery discharge current capability obtained from battery fuel gauge in milli Amps.

/sys/bus/platform/devices/INT3532:00/dptf_battery/high_freq_impedance_mohm

Defined on file *sysfs-platform-dptf*

(RO) The high frequency impedance value that can be obtained from battery fuel gauge in milli Ohms.

/sys/bus/platform/devices/INT3532:00/dptf_battery/max_platform_power_mw

Defined on file *sysfs-platform-dptf*

(RO) The maximum platform power that can be supported by the battery in milli watts.

/sys/bus/platform/devices/INT3532:00/dptf_battery/max_steady_state_power_mw

Defined on file *sysfs-platform-dptf*

(RO) The maximum sustained power for battery in milli watts.

/sys/bus/platform/devices/INT3532:00/dptf_battery/no_load_voltage_mv

Defined on file *sysfs-platform-dptf*

(RO) The no-load voltage that can be obtained from battery fuel gauge in milli volts.

/sys/bus/platform/devices/INTC1045:00/pch_fivr_switch_frequency/fivr_switching_fault_stat

Defined on file *sysfs-platform-dptf*

(RO) Read the FIVR switching frequency control fault status.

/sys/bus/platform/devices/INTC1045:00/pch_fivr_switch_frequency/fivr_switching_freq_mhz

Defined on file *sysfs-platform-dptf*

(RO) Get the FIVR switching control frequency in MHz.

/sys/bus/platform/devices/INTC1045:00/pch_fivr_switch_frequency/freq_mhz_high_clock

Defined on file *sysfs-platform-dptf*

(RW) The PCH FIVR (Fully Integrated Voltage Regulator) switching frequency in MHz, when FIVR clock is 38.4MHz.

/sys/bus/platform/devices/INTC1045:00/pch_fivr_switch_frequency/freq_mhz_low_clock

Defined on file *sysfs-platform-dptf*

(RW) The PCH FIVR (Fully Integrated Voltage Regulator) switching frequency in MHz, when FIVR clock is 19.2MHz or 24MHz.

/sys/bus/platform/devices/INTC1045:00/pch_fivr_switch_frequency/ssc_clock_info

Defined on file *sysfs-platform-dptf*

(RO) Presents SSC (spread spectrum clock) information for EMI (Electro magnetic interference) control. This is a bit mask.

Bits	Description
[7:0]	Sets clock spectrum spread percentage: 0x00=0.2% , 0x3F=10% 1 LSB = 0.1% increase in spread (for settings 0x01 thru 0x1C) 1 LSB = 0.2% increase in spread (for settings 0x1E thru 0x3F)
[8]	When set to 1, enables spread spectrum clock
[9]	0: Triangle mode. FFC frequency walks around the Fcenter in a linear fashion 1: Random walk mode. FFC frequency changes randomly within the SSC (Spread spectrum clock) range
[10]	0: No white noise. 1: Add white noise to spread waveform
[11]	When 1, future writes are ignored.

/sys/bus/platform/devices/INTC1092:00/intc_data

Defined on file *sysfs-driver-intc_sar*

This sysfs entry is used to retrieve Dynamic SAR information emitted/maintained by a BIOS that supports Dynamic SAR.

The retrieved information is in the order given below: - device_mode - bandtable_index - antennatable_index - sartable_index

The above information is sent as integer values separated by a single space. This information can then be pushed to a WWAN modem that uses this to control the transmit signal level using the Band/Antenna/SAR table index information. These parameters are derived/decided by aggregating device-mode like laptop/tablet/clamshell etc. and the proximity-sensor data available to the embedded controller on given host. The regulatory mode configured on Dynamic SAR driver also influences these values.

The userspace applications can poll for changes to this file using POLLPRI event on file-descriptor (fd) obtained by opening this sysfs entry. Application can then read this information from the sysfs node and consume the given information.

/sys/bus/platform/devices/INTC1092:00/intc_reg

Defined on file *sysfs-driver-intc_sar*

Specific Absorption Rate (SAR) regulatory mode is typically derived based on information like mcc (Mobile Country Code) and mnc (Mobile Network Code) that is available for the currently attached LTE network. A userspace application is required to set the current SAR regulatory mode on the Dynamic SAR driver using this sysfs node. Such an application can also read back using this sysfs node, the currently configured regulatory mode value from the Dynamic SAR driver.

Acceptable regulatory modes are:

0	FCC
1	CE
2	ISED

- The regulatory mode value has one of the above values.
- The default regulatory mode used in the driver is 0.

/sys/bus/platform/devices/MLNXBF04:00/bootfifo

Defined on file *sysfs-platform-mellanox-bootctl*

The file used to access the BlueField boot fifo.

/sys/bus/platform/devices/MLNXBF04:00/lifecycle_state

Defined on file *sysfs-platform-mellanox-bootctl*

The Life-cycle state of the SoC, which could be one of the following values.

Production	Production state and can be updated to secure
GA Secured	Secure chip and not able to change state
GA Non-Secured	Non-Secure chip and not able to change state
RMA	Return Merchandise Authorization

/sys/bus/platform/devices/MLNXBF04:00/mfg_lock

Defined on file *sysfs-platform-mellanox-bootctl*

The ”mfg_lock” sysfs attribute is write-only. A successful write to this attribute will latch the board-level attributes into EEPROM, making them read-only.

/sys/bus/platform/devices/MLNXBF04:00/modl

Defined on file *sysfs-platform-mellanox-bootctl*

The ”modl” sysfs attribute holds the board's model number. This value is provided on a board-level label.

/sys/bus/platform/devices/MLNXBF04:00/oob_mac

Defined on file *sysfs-platform-mellanox-bootctl*

The ”oob_mac” sysfs attribute holds the MAC address for the out-of-band 1Gbps Ethernet port. This MAC address is provided on a board-level label.

/sys/bus/platform/devices/MLNXBF04:00/opn

Defined on file *sysfs-platform-mellanox-bootctl*

The ”opn” sysfs attribute holds the board's part number. This value is provided on a board-level label.

/sys/bus/platform/devices/MLNXBF04:00/post_reset_wdog

Defined on file *sysfs-platform-mellanox-bootctl*

The watchdog setting in seconds for the next booting. It's used to reboot the chip and recover it to the old state if the new boot partition fails.

/sys/bus/platform/devices/MLNXBF04:00/reset_action

Defined on file *sysfs-platform-mellanox-bootctl*

The source of the boot stream for the next reset. It could be one of the following values:

external	boot from external source (USB or PCIe)
emmc	boot from the onchip eMMC
emmc_legacy	boot from the onchip eMMC in legacy (slow) mode

/sys/bus/platform/devices/MLNXBF04:00/rev

Defined on file *sysfs-platform-mellanox-bootctl*

The ”rev” sysfs attribute holds the board's revision. This value is provided on a board-level label.

/sys/bus/platform/devices/MLNXBF04:00/rsh_log

Defined on file *sysfs-platform-mellanox-bootctl*

The file used to write BlueField boot log with the format ”[INFO|WARN|ERR|ASSERT]<msg>”. Log level 'INFO' is used by default if not specified.

/sys/bus/platform/devices/MLNXBF04:00/second_reset_action

Defined on file *sysfs-platform-mellanox-bootctl*

Update the source of the boot stream after next reset. It could be one of the following values and will be applied after next reset.

external	boot from external source (USB or PCIe)
emmc	boot from the onchip eMMC
emmc_legacy	boot from the onchip eMMC in legacy (slow) mode
swap_emmc	swap the primary / secondary boot partition
none	cancel the action

/sys/bus/platform/devices/MLNXBF04:00/secure_boot_fuse_state

Defined on file *sysfs-platform-mellanox-bootctl*

The state of eFuse versions with the following values.

InUse	burnt, valid and currently in use
Used	burnt and valid
Free	not burnt and free to use
Skipped	not burnt but not free (skipped)
Wasted	burnt and invalid
Invalid	not burnt but marked as valid (error state).

/sys/bus/platform/devices/MLNXBF04:00/sku

Defined on file *sysfs-platform-mellanox-bootctl*

The ”sku” sysfs attribute holds the board's SKU number. This value is provided on a board-level label.

/sys/bus/platform/devices/MLNXBF04:00/sn

Defined on file *sysfs-platform-mellanox-bootctl*

The ”sn” sysfs attribute holds the board's serial number. This value is provided on a board-level label.

/sys/bus/platform/devices/MLNXBF04:00/uuid

Defined on file *sysfs-platform-mellanox-bootctl*

The ”uuid” sysfs attribute holds the board's UUID. This value is provided by the manufacturing team.

/sys/bus/platform/devices/VPC2004:*/camera_power

Defined on file *sysfs-platform-ideapad-laptop*

Control the power of camera module. 1 means on, 0 means off.

/sys/bus/platform/devices/VPC2004:*/conservation_mode

Defined on file *sysfs-platform-ideapad-laptop*

Controls whether the conservation mode is enabled or not. This feature limits the maximum battery charge percentage to around 50-60% in order to prolong the lifetime of the battery.

/sys/bus/platform/devices/VPC2004:*/fan_mode

Defined on file *sysfs-platform-ideapad-laptop*

Change fan mode There are four available modes:

- 0 -> Super Silent Mode
- 1 -> Standard Mode
- 2 -> Dust Cleaning
- 4 -> Efficient Thermal Dissipation Mode

/sys/bus/platform/devices/VPC2004:*/fn_lock

Defined on file *sysfs-platform-ideapad-laptop*

Control fn-lock mode.

- 1 -> Switched On
- 0 -> Switched Off

For example:

```
# echo "0" >  \
/sys/bus/pci/devices/0000:00:1f.0/PNP0C09:00/VPC2004:00/fn_lock
```

/sys/bus/platform/devices/VPC2004:*/touchpad

Defined on file *sysfs-platform-ideapad-laptop*

Control touchpad mode.

- 1 -> Switched On
- 0 -> Switched Off

/sys/bus/platform/devices/VPC2004:*/usb_charging

Defined on file *sysfs-platform-ideapad-laptop*

Controls whether the "always on USB charging" feature is enabled or not. This feature enables charging USB devices even if the computer is not turned on.

/sys/bus/platform/devices/[..]/fsi-master-gpio/external_mode

Defined on file *sysfs-driver-fsi-master-gpio*

Controls access arbitration for GPIO-based FSI master. A value of 0 (the default) sets normal mode, where the driver performs FSI bus transactions, 1 sets external mode, where the FSI bus is driven externally (for example, by a debug device).

/sys/bus/platform/devices/ci_hdrc.0/inputs/a_bus_drop

Defined on file *sysfs-platform-chipidea-usb-otg*

Can be set and read The a_bus_drop(A-device bus drop) input is 1 when the application running on the A-device wants to power down the bus, and is 0 otherwise, When a_bus_drop is 1, then the a_bus_req shall be 0.

Valid values are "1" and "0".

Reading: returns 1 if the bus is off(vbus is turned off) by
A-device, otherwise 0.

/sys/bus/platform/devices/ci_hdrc.0/inputs/a_bus_req

Defined on file *sysfs-platform-chipidea-usb-otg*

Can be set and read. Set a_bus_req(A-device bus request) input to be 1 if the application running on the A-device wants to use the bus, and to be 0 when the application no longer wants to use the bus(or wants to work as peripheral). a_bus_req can also be set to 1 by kernel in response to remote wakeup signaling from the B-device, the A-device should decide to resume the bus.

Valid values are "1" and "0".

Reading: returns 1 if the application running on the A-device is using the bus as host role, otherwise 0.

/sys/bus/platform/devices/ci_hdrc.0/inputs/a_clr_err

Defined on file *sysfs-platform-chipidea-usb-otg*

Only can be set. The a_clr_err(A-device Vbus error clear) input is used to clear vbus error, then A-device will power down the bus.

Valid value is "1"

/sys/bus/platform/devices/ci_hdrc.0/inputs/b_bus_req

Defined on file *sysfs-platform-chipidea-usb-otg*

Can be set and read. The b_bus_req(B-device bus request) input is 1 during the time that the application running on the B-device wants to use the bus as host, and is 0 when the application no longer wants to work as host and decides to switch back to be peripheral.

Valid values are "1" and "0".

Reading: returns if the application running on the B device is using the bus as host role, otherwise 0.

/sys/bus/platform/devices/ci_hdrc.0/role

Defined on file *sysfs-platform-chipidea-usb2*

When read, it returns string "gadget" or "host", indicating the current controller role.

It will do role switch when "gadget" or "host" is written to it. Only controller at dual-role configuration supports writing.

/sys/bus/platform/devices/dfl-fme.0/bitstream_id

Defined on file *sysfs-platform-dfl-fme*

Read-only. It returns Bitstream (static FPGA region) identifier number, which includes the detailed version and other information of this static FPGA region.

/sys/bus/platform/devices/dfl-fme.0/bitstream_metadata

Defined on file *sysfs-platform-dfl-fme*

Read-only. It returns Bitstream (static FPGA region) meta data, which includes the synthesis date, seed and other information of this static FPGA region.

/sys/bus/platform/devices/dfl-fme.0/cache_size

Defined on file *sysfs-platform-dfl-fme*

Read-only. It returns cache size of this FPGA device.

/sys/bus/platform/devices/dfl-fme.0/errors/catfatal_errors

Defined on file *sysfs-platform-dfl-fme*

Read-only. It returns catastrophic and fatal errors detected.

/sys/bus/platform/devices/dfl-fme.0/errors/first_error

Defined on file *sysfs-platform-dfl-fme*

Read-only. Read this file to get the first error detected by hardware.

/sys/bus/platform/devices/dfl-fme.0/errors/fme_errors

Defined on file *sysfs-platform-dfl-fme*

Read-Write. Read this file to get errors detected on FME. Write this file to clear errors logged in fme_errors. Write fails with -EINVAL if input parsing fails or input error code doesn't match.

/sys/bus/platform/devices/dfl-fme.0/errors/inject_errors

Defined on file *sysfs-platform-dfl-fme*

Read-Write. Read this file to check errors injected. Write this file to inject errors for testing purpose. Write fails with -EINVAL if input parsing fails or input inject error code isn't supported.

/sys/bus/platform/devices/dfl-fme.0/errors/next_error

Defined on file *sysfs-platform-dfl-fme*

Read-only. Read this file to get the second error detected by hardware.

/sys/bus/platform/devices/dfl-fme.0/errors/nonfatal_errors

Defined on file *sysfs-platform-dfl-fme*

Read-only. It returns non-fatal errors detected.

/sys/bus/platform/devices/dfl-fme.0/errors/pcie0_errors

Defined on file *sysfs-platform-dfl-fme*

Read-Write. Read this file for errors detected on pcie0 link. Write this file to clear errors logged in pcie0_errors. Write fails with -EINVAL if input parsing fails or input error code doesn't match.

/sys/bus/platform/devices/dfl-fme.0/errors/pcie1_errors

Defined on file *sysfs-platform-dfl-fme*

Read-Write. Read this file for errors detected on pcie1 link. Write this file to clear errors logged in pcie1_errors. Write fails with -EINVAL if input parsing fails or input error code doesn't match.

/sys/bus/platform/devices/dfl-fme.0/fabric_version

Defined on file *sysfs-platform-dfl-fme*

Read-only. It returns fabric version of this FPGA device. Userspace applications need this information to select best data channels per different fabric design.

/sys/bus/platform/devices/dfl-fme.0/hwmon/hwmonX/name

Defined on file *sysfs-platform-dfl-fme*

Read-Only. Read this file to get the name of hwmon device, it supports values:

'dfl_fme_thermal'	thermal hwmon device name
'dfl_fme_power'	power hwmon device name

/sys/bus/platform/devices/dfl-fme.0/hwmon/hwmonX/power1_crit

Defined on file *sysfs-platform-dfl-fme*

Read-Write. Read this file to get current hardware power threshold2 in uW. If power consumption rises at or above this threshold, hardware starts 90% throttling. Write this file to set current hardware power threshold2 in uW. As hardware only accepts values in Watts, so input value will be round down per Watts (< 1 watts part will be discarded) and clamped within the range from 0 to 127 Watts. Write fails with -EINVAL if input parsing fails.

/sys/bus/platform/devices/dfl-fme.0/hwmon/hwmonX/power1_crit_alarm

Defined on file *sysfs-platform-dfl-fme*

Read-only. It returns 1 if power consumption is currently at or above hardware threshold2 (see 'power1_crit'), otherwise 0.

/sys/bus/platform/devices/dfl-fme.0/hwmon/hwmonX/power1_fpga_limit

Defined on file *sysfs-platform-dfl-fme*

Read-Only. It returns power limit for FPGA in uW.

/sys/bus/platform/devices/dfl-fme.0/hwmon/hwmonX/power1_input

Defined on file *sysfs-platform-dfl-fme*

Read-Only. It returns current FPGA power consumption in uW.

/sys/bus/platform/devices/dfl-fme.0/hwmon/hwmonX/power1_ltr

Defined on file *sysfs-platform-dfl-fme*

Read-only. Read this file to get current Latency Tolerance Reporting (ltr) value. It returns 1 if all Accelerated Function Units (AFUs) can tolerate latency >= 40us for memory access or 0 if any AFU is latency sensitive (< 40us).

/sys/bus/platform/devices/dfl-fme.0/hwmon/hwmonX/power1_max

Defined on file *sysfs-platform-dfl-fme*

Read-Write. Read this file to get current hardware power threshold1 in uW. If power consumption rises at or above this threshold, hardware starts 50% throttling. Write this file to set current hardware power threshold1 in uW. As hardware only accepts values in Watts, so input value will be round down per Watts (< 1 watts part will be discarded) and clamped within the range from 0 to 127 Watts. Write fails with -EINVAL if input parsing fails.

/sys/bus/platform/devices/dfl-fme.0/hwmon/hwmonX/power1_max_alarm

Defined on file *sysfs-platform-dfl-fme*

Read-only. It returns 1 if power consumption is currently at or above hardware threshold1 (see 'power1_max'), otherwise 0.

/sys/bus/platform/devices/dfl-fme.0/hwmon/hwmonX/power1_xeon_limit

Defined on file *sysfs-platform-dfl-fme*

Read-Only. It returns power limit for XEON in uW.

/sys/bus/platform/devices/dfl-fme.0/hwmon/hwmonX/temp1_crit

Defined on file *sysfs-platform-dfl-fme*

Read-Only. It returns hardware threshold2 temperature in millidegrees Celsius. If temperature rises at or above this threshold, hardware starts 100% throttling.

/sys/bus/platform/devices/dfl-fme.0/hwmon/hwmonX/temp1_crit_alarm

Defined on file *sysfs-platform-dfl-fme*

Read-only. It returns 1 if temperature is currently at or above hardware threshold2 (see 'temp1_crit'), otherwise 0.

/sys/bus/platform/devices/dfl-fme.0/hwmon/hwmonX/temp1_emergency

Defined on file *sysfs-platform-dfl-fme*

Read-Only. It returns hardware trip threshold temperature in millidegrees Celsius. If temperature rises at or above this threshold, a fatal event will be triggered to board management controller (BMC) to shutdown FPGA.

/sys/bus/platform/devices/dfl-fme.0/hwmon/hwmonX/temp1_input

Defined on file *sysfs-platform-dfl-fme*

Read-Only. It returns FPGA device temperature in millidegrees Celsius.

/sys/bus/platform/devices/dfl-fme.0/hwmon/hwmonX/temp1_max

Defined on file *sysfs-platform-dfl-fme*

Read-Only. It returns hardware threshold1 temperature in millidegrees Celsius. If temperature rises at or above this threshold, hardware starts 50% or 90% throttling (see 'temp1_max_policy').

/sys/bus/platform/devices/dfl-fme.0/hwmon/hwmonX/temp1_max_alarm

Defined on file *sysfs-platform-dfl-fme*

Read-only. It returns 1 if temperature is currently at or above hardware threshold1 (see 'temp1_max'), otherwise 0.

/sys/bus/platform/devices/dfl-fme.0/hwmon/hwmonX/temp1_max_policy

Defined on file *sysfs-platform-dfl-fme*

Read-Only. Read this file to get the policy of hardware threshold1 (see 'temp1_max'). It only supports two values (policies):

0	AP2 state (90% throttling)
1	AP1 state (50% throttling)

/sys/bus/platform/devices/dfl-fme.0/ports_num

Defined on file *sysfs-platform-dfl-fme*

Read-only. One DFL FPGA device may have more than 1 port/Accelerator Function Unit (AFU). It returns the number of ports on the FPGA device when read it.

/sys/bus/platform/devices/dfl-fme.0/socket_id

Defined on file *sysfs-platform-dfl-fme*

Read-only. It returns socket_id to indicate which socket this FPGA belongs to, only valid for integrated solution. User only needs this information, in case standard numa node can't provide correct information.

/sys/bus/platform/devices/dfl-port.0/afu_id

Defined on file *sysfs-platform-dfl-port*

Read-only. User can program different PR bitstreams to FPGA Accelerator Function Unit (AFU) for different functions. It returns uuid which could be used to identify which PR bitstream is programmed in this AFU.

/sys/bus/platform/devices/dfl-port.0/ap1_event

Defined on file *sysfs-platform-dfl-port*

Read-write. Read this file for AP1 (AFU Power State 1) event. It's used to indicate transient AP1 state. Write 1 to this file to clear AP1 event.

/sys/bus/platform/devices/dfl-port.0/ap2_event

Defined on file *sysfs-platform-dfl-port*

Read-write. Read this file for AP2 (AFU Power State 2) event. It's used to indicate transient AP2 state. Write 1 to this file to clear AP2 event.

/sys/bus/platform/devices/dfl-port.0/errors/errors

Defined on file *sysfs-platform-dfl-port*

Read-Write. Read this file to get errors detected on port and Accelerated Function Unit (AFU). Write error code to this file to clear errors. Write fails with -EINVAL if input parsing fails or input error code doesn't match. Write fails with -EBUSY or -ETIMEDOUT if error can't be cleared as hardware in low power state (-EBUSY) or not respoding (-ETIMEDOUT).

/sys/bus/platform/devices/dfl-port.0/errors/first_error

Defined on file *sysfs-platform-dfl-port*

Read-only. Read this file to get the first error detected by hardware.

/sys/bus/platform/devices/dfl-port.0/errors/first_malformed_req

Defined on file *sysfs-platform-dfl-port*

Read-only. Read this file to get the first malformed request captured by hardware.

/sys/bus/platform/devices/dfl-port.0/id

Defined on file *sysfs-platform-dfl-port*

Read-only. It returns id of this port. One DFL FPGA device may have more than one port. Userspace could use this id to distinguish different ports under same FPGA device.

/sys/bus/platform/devices/dfl-port.0/ltr

Defined on file *sysfs-platform-dfl-port*

Read-write. Read or set AFU latency tolerance reporting value. Set ltr to 1 if the AFU can tolerate latency >= 40us or set it to 0 if it is latency sensitive.

/sys/bus/platform/devices/dfl-port.0/power_state

Defined on file *sysfs-platform-dfl-port*

Read-only. It reports the APx (AFU Power) state, different APx means different throttling level. When reading this file, it returns ”0” - Normal / ”1” - AP1 / ”2” - AP2 / ”6” - AP6.

/sys/bus/platform/devices/dfl-port.0/userclk_freqcmd

Defined on file *sysfs-platform-dfl-port*

Write-only. User writes command to this interface to set userclock to AFU.

/sys/bus/platform/devices/dfl-port.0/userclk_freqcntrcmd

Defined on file *sysfs-platform-dfl-port*

Write-only. User writes command to this interface to set userclock counter.

/sys/bus/platform/devices/dfl-port.0/userclk_freqcntrsts

Defined on file *sysfs-platform-dfl-port*

Read-only. Read this file to get the status of issued command to userclck_freqcntrcmd.

/sys/bus/platform/devices/dfl-port.0/userclk_freqsts

Defined on file *sysfs-platform-dfl-port*

Read-only. Read this file to get the status of issued command to userclck_freqcmd.

/sys/bus/platform/devices/occ-hwmon.X/ffdc

Defined on file *sysfs-bus-platform-devices-occ-hwmon*

Contains the First Failure Data Capture from the SBEFIFO hardware, if there is any from a previous transfer. Otherwise, the file is empty. The data is cleared when it's been completely read by a user. As the name suggests, only the data from the first error is saved, until it's cleared upon read. The OCC hwmon driver, running on a Baseboard Management Controller (BMC), communicates with POWER9 and up processors over the Self-Boot Engine (SBE) FIFO. In many error conditions, the SBEFIFO will return error data indicating the type of error and system state, etc.

/sys/bus/platform/devices/smpro-errmon.*/[error|warn]_[smpro|pmpro]

Defined on file *sysfs-bus-platform-devices-ampere-smpro*

(RO) Contains the internal firmware error/warning printed as hex format.

The detail of each sysfs entries is as below:

Error	Sysfs entry	Description
SMpro error	/sys/bus/platform/devices/smpro-errmon.*/error_smpro	system has SMpro error
SMpro warning	/sys/bus/platform/devices/smpro-errmon.*/warn_smpro	system has SMpro warning
PMpro error	/sys/bus/platform/devices/smpro-errmon.*/error_pmpro	system has PMpro error
PMpro warning	/sys/bus/platform/devices/smpro-errmon.*/warn_pmpro	system has PMpro warning

For details, see section *5.10 RAS Internal Error Register Definitions, Altra Family Soc BMC Interface Specification*.

/sys/bus/platform/devices/smpro-errmon.*/error_[core|mem|pcie|other]_[ce|ue]

Defined on file *sysfs-bus-platform-devices-ampere-smpro*

(RO) Contains the 48-byte Ampere (Vendor-Specific) Error Record printed in hex format according to the table below:

Offset	Field	Size (byte)	Description
00	Error Type	1	See *the table below* for details
01	Subtype	1	See *the table below* for details
02	Instance	2	See *the table below* for details
04	Error status	4	See ARM RAS specification for details
08	Error Address	8	See ARM RAS specification for details
16	Error Misc 0	8	See ARM RAS specification for details
24	Error Misc 1	8	See ARM RAS specification for details
32	Error Misc 2	8	See ARM RAS specification for details
40	Error Misc 3	8	See ARM RAS specification for details

The table below defines the value of error types, their subtype, subcomponent and instance:

Error Group	Error Type	Sub type	Sub component	Instance
CPM (core)	0	0	Snoop-Logic	CPM #
CPM (core)	0	2	Armv8 Core 1	CPM #
MCU (mem)	1	1	ERR1	MCU # | SLOT << 11
MCU (mem)	1	2	ERR2	MCU # | SLOT << 11
MCU (mem)	1	3	ERR3	MCU #
MCU (mem)	1	4	ERR4	MCU #
MCU (mem)	1	5	ERR5	MCU #
MCU (mem)	1	6	ERR6	MCU #
MCU (mem)	1	7	Link Error	MCU #
Mesh (other)	2	0	Cross Point	X | (Y << 5) | NS <<11
Mesh (other)	2	1	Home Node(IO)	X | (Y << 5) | NS <<11
Mesh (other)	2	2	Home Node(Mem)	X | (Y << 5) | NS <<11 | device<<
Mesh (other)	2	4	CCIX Node	X | (Y << 5) | NS <<11
2P Link (other)	3	0	N/A	Altra 2P Link #
GIC (other)	5	0	ERR0	0
GIC (other)	5	1	ERR1	0
GIC (other)	5	2	ERR2	0
GIC (other)	5	3	ERR3	0
GIC (other)	5	4	ERR4	0
GIC (other)	5	5	ERR5	0
GIC (other)	5	6	ERR6	0
GIC (other)	5	7	ERR7	0
GIC (other)	5	8	ERR8	0
GIC (other)	5	9	ERR9	0

PCIe AER (pcie)	7	Device	1	RC #
PCIe RC (pcie)	8	RCA HB	0	RC #
PCIe RC (pcie)	8	RCB HB	1	RC #
PCIe RC (pcie)	8	RASDP	8	RC #
OCM (other)	9	ERR0	0	0
OCM (other)	9	ERR1	1	0
OCM (other)	9	ERR2	2	0
SMpro (other)	10	ERR0	0	0
SMpro (other)	10	ERR1	1	0
SMpro (other)	10	MPA_ERR	2	0
PMpro (other)	11	ERR0	0	0
PMpro (other)	11	ERR1	1	0
PMpro (other)	11	MPA_ERR	2	0

Example:

```
# cat error_other_ue
880807001e0040104010401015000000010040104010401 00c0000000000000000000000000000000000
```

The detail of each sysfs entries is as below:

Error	Sysfs entry	Description (when triggered)
Core's CE	/sys/bus/platform/devices/smpro-errmon.*/error_core_ce	Core has CE error
Core's UE	/sys/bus/platform/devices/smpro-errmon.*/error_core_ue	Core has UE error
Memory's CE	/sys/bus/platform/devices/smpro-errmon.*/error_mem_ce	Memory has CE error
Memory's UE	/sys/bus/platform/devices/smpro-errmon.*/error_mem_ue	Memory has UE error
PCIe's CE	/sys/bus/platform/devices/smpro-errmon.*/error_pcie_ce	any PCIe controller has CE error
PCIe's UE	/sys/bus/platform/devices/smpro-errmon.*/error_pcie_ue	any PCIe controller has UE error
Other's CE	/sys/bus/platform/devices/smpro-errmon.*/error_other_ce	any other CE error
Other's UE	/sys/bus/platform/devices/smpro-errmon.*/error_other_ue	any other UE error

UE: Uncorrect-able Error CE: Correct-able Error

For details, see section *3.3 Ampere (Vendor-Specific) Error Record Formats, Altra Family RAS Supplement*.

/sys/bus/platform/devices/smpro-errmon.*/event_[vrd_warn_fault|vrd_hot|dimm_hot|dimm_

Defined on file *sysfs-bus-platform-devices-ampere-smpro*

(RO) Contains the detail information in case of VRD/DIMM warning/hot events in hex format as below:

```
AAAA
```

where:

- `AAAA`: The event detail information data

The detail of each sysfs entries is as below:

Event	Sysfs entry	Description
VRD HOT	/sys/bus/platform/devices/smpro-errmon.*/event_vrd_hot	VRD Hot
VR Warn/Fault	/sys/bus/platform/devices/smpro-errmon.*/event_vrd_warn_fault	VR Warning or Fault
DIMM HOT	/sys/bus/platform/devices/smpro-errmon.*/event_dimm_hot	DIMM Hot
DIMM 2X REFRESH RATE	/sys/bus/platform/devices/smpro-errmon.*/event_dimm_2x_refresh	DIMM 2x refresh rate event in high temp

For more details, see section *5.7 GPI Status Registers and 5.9 Memory Error Register Definitions, Altra Family Soc BMC Interface Specification*.

/sys/bus/platform/devices/smpro-errmon.*/event_dimm[0-15]_syndrome

Defined on file *sysfs-bus-platform-devices-ampere-smpro*

(RO) The sysfs returns the 2-byte DIMM failure syndrome data for slot 0-15 if it failed to initialize.

For more details, see section *5.11 Boot Stage Register Definitions, Altra Family Soc BMC Interface Specification*.

/sys/bus/platform/devices/smpro-errmon.*/overflow_[core|mem|pcie|other]_[ce|ue]

Defined on file *sysfs-bus-platform-devices-ampere-smpro*

(RO) Return the overflow status of each type HW error reported:

- 0 : No overflow
- 1 : There is an overflow and the oldest HW errors are dropped

The detail of each sysfs entries is as below:

Overflow	Sysfs entry	Description
Core's CE	/sys/bus/platform/devices/smpro-errmon.*/overflow_core_ce	Core CE error overflow
Core's UE	/sys/bus/platform/devices/smpro-errmon.*/overflow_core_ue	Core UE error overflow
Memory's CE	/sys/bus/platform/devices/smpro-errmon.*/overflow_mem_ce	Memory CE error overflow
Memory's UE	/sys/bus/platform/devices/smpro-errmon.*/overflow_mem_ue	Memory UE error overflow
PCIe's CE	/sys/bus/platform/devices/smpro-errmon.*/overflow_pcie_ce	any PCIe controller CE error overflow
PCIe's UE	/sys/bus/platform/devices/smpro-errmon.*/overflow_pcie_ue	any PCIe controller UE error overflow
Other's CE	/sys/bus/platform/devices/smpro-errmon.*/overflow_other_ce	any other CE error overflow
Other's UE	/sys/bus/platform/devices/smpro-errmon.*/overflow_other_ue	other UE error overflow

where:

- UE: Uncorrect-able Error
- CE: Correct-able Error

/sys/bus/platform/devices/smpro-misc*/soc_power_limit

Defined on file *sysfs-bus-platform-devices-ampere-smpro*

(RW) Contains the desired SoC power limit in Watt. Writes to this sysfs set the desired SoC power limit (W). Reads from this register return the current SoC power limit (W). The value ranges:

- Minimum: 120 W
- Maximum: Socket TDP power

/sys/bus/platform/devices/smpro-misc.*/boot_progress

Defined on file *sysfs-bus-platform-devices-ampere-smpro*

(RO) Contains the boot stages information in hex as format below:

```
AABBCCCCCCCC
```

where:

- `AA` : The boot stages
  - 00: SMpro firmware booting
  - 01: PMpro firmware booting
  - 02: ATF BL1 firmware booting
  - 03: DDR initialization
  - 04: DDR training report status
  - 05: ATF BL2 firmware booting
  - 06: ATF BL31 firmware booting
  - 07: ATF BL32 firmware booting
  - 08: UEFI firmware booting
  - 09: OS booting
- `BB` : Boot status
  - 00: Not started
  - 01: Started
  - 02: Completed without error
  - 03: Failed.
- `CCCCCCCC`: Boot status information defined for each boot stages

For details, see section *5.11 Boot Stage Register Definitions* and section *6. Processor Boot Progress Codes, Altra Family Soc BMC Interface Specification*.

/sys/bus/platform/devices/tahvo-usb/otg_mode

Defined on file *sysfs-platform-tahvo-usb*

Set or read the current OTG mode. Valid values are ”host” and ”peripheral”.

Reading: returns the current mode.

/sys/bus/platform/devices/tahvo-usb/vbus

Defined on file *sysfs-platform-tahvo-usb*

Read the current VBUS state.

Reading: returns "on" or "off".

/sys/bus/platform/drivers/amd_pmc/*/smu_fw_version

Defined on file *sysfs-amd-pmc*

Reading this file reports the version of the firmware loaded to System Management Unit (SMU) contained in AMD CPUs and APUs.

/sys/bus/platform/drivers/amd_pmc/*/smu_program

Defined on file *sysfs-amd-pmc*

Reading this file reports the program corresponding to the SMU firmware version. The program field is used to disambiguate two APU/CPU models that can share the same firmware binary.

/sys/bus/platform/drivers/aspeed-uart-routing/*/io*

Defined on file *sysfs-driver-aspeed-uart-routing*

Selects the RX source of IOx serial port. The current selection will be marked by brackets "[]".

Users: OpenBMC. Proposed changes should be mailed to openbmc@lists.ozlabs.org

/sys/bus/platform/drivers/aspeed-uart-routing/*/uart*

Defined on file *sysfs-driver-aspeed-uart-routing*

Selects the RX source of the UARTx device.

When read, each file shows the list of available options with currently selected option marked by brackets "[]". The list of available options depends on the selected file.

e.g. cat /sys/bus/platform/drivers/aspeed-uart-routing/*.uart_routing/uart1 [io1] io2 io3 io4 uart2 uart3 uart4 io6

In this case, UART1 gets its input from IO1 (physical serial port 1).

Users: OpenBMC. Proposed changes should be mailed to openbmc@lists.ozlabs.org

/sys/bus/platform/drivers/intel-m10bmc-sec-update/.../security/bmc_canceled_csks

Defined on file *sysfs-driver-intel-m10-bmc-sec-update*

Read only. Returns a list of indices for canceled code signing keys for the BMC. The standard bitmap list format is used (e.g. "1,2-6,9").

/sys/bus/platform/drivers/intel-m10bmc-sec-update/.../security/bmc_root_entry_hash

Defined on file *sysfs-driver-intel-m10-bmc-sec-update*

Read only. Returns the root entry hash for the BMC image if one is programmed, else it returns the string: "hash not programmed". This file is only visible if the underlying device supports it. Format: string.

/sys/bus/platform/drivers/intel-m10bmc-sec-update/.../security/flash_count

Defined on file *sysfs-driver-intel-m10-bmc-sec-update*

Read only. Returns number of times the secure update staging area has been flashed. Format: "%u".

/sys/bus/platform/drivers/intel-m10bmc-sec-update/.../security/pr_canceled_csks

Defined on file *sysfs-driver-intel-m10-bmc-sec-update*

Read only. Returns a list of indices for canceled code signing keys for the partial reconfiguration region. The standard bitmap list format is used (e.g. "1,2-6,9").

/sys/bus/platform/drivers/intel-m10bmc-sec-update/.../security/pr_root_entry_hash

Defined on file *sysfs-driver-intel-m10-bmc-sec-update*

Read only. Returns the root entry hash for the partial reconfiguration region if one is programmed, else it returns the string: "hash not programmed". This file is only visible if the underlying device supports it. Format: string.

/sys/bus/platform/drivers/intel-m10bmc-sec-update/.../security/sr_canceled_csks

Defined on file *sysfs-driver-intel-m10-bmc-sec-update*

Read only. Returns a list of indices for canceled code signing keys for the static region. The standard bitmap list format is used (e.g. "1,2-6,9").

/sys/bus/platform/drivers/intel-m10bmc-sec-update/.../security/sr_root_entry_hash

Defined on file *sysfs-driver-intel-m10-bmc-sec-update*

Read only. Returns the root entry hash for the static region if one is programmed, else it returns the string: "hash not programmed". This file is only visible if the underlying device supports it. Format: string.

/sys/bus/platform/drivers/qcom_eud/.../enable

Defined on file *sysfs-driver-eud*

The Enable/Disable sysfs interface for Embedded USB Debugger(EUD). This enables and disables the EUD based on a 1 or a 0 value. By enabling EUD, the user is able to activate the mini-usb hub of EUD for debug and trace capabilities.

/sys/bus/platform/drivers/ufshcd/*/attributes/active_icc_level
/sys/bus/platform/devices/*.ufs/attributes/active_icc_level

Defined on file *sysfs-driver-ufs*

This file provides the active icc level UFS device attribute. The full information about the attribute could be found at UFS specifications 2.1.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/attributes/bkops_status
/sys/bus/platform/devices/*.ufs/attributes/bkops_status

Defined on file *sysfs-driver-ufs*

This file provides the background operations status UFS device attribute. The full information about the attribute could be found at UFS specifications 2.1.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/attributes/boot_lun_enabled
/sys/bus/platform/devices/*.ufs/attributes/boot_lun_enabled

Defined on file *sysfs-driver-ufs*

This file provides the boot lun enabled UFS device attribute. The full information about the attribute could be found at UFS specifications 2.1.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/attributes/configuration_descriptor_lock
/sys/bus/platform/devices/*.ufs/attributes/configuration_descriptor_lock

Defined on file *sysfs-driver-ufs*

This file shows whether the configuration descriptor is locked. The full information about the attribute could be found at UFS specifications 2.1. The file is read only.

/sys/bus/platform/drivers/ufshcd/*/attributes/current_power_mode
/sys/bus/platform/devices/*.ufs/attributes/current_power_mode

Defined on file *sysfs-driver-ufs*

This file provides the current power mode UFS device attribute. The full information about the attribute could be found at UFS specifications 2.1.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/attributes/exception_event_control
/sys/bus/platform/devices/*.ufs/attributes/exception_event_control

Defined on file *sysfs-driver-ufs*

This file provides the exception event control UFS device attribute. The full information about the attribute could be found at UFS specifications 2.1.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/attributes/exception_event_status
/sys/bus/platform/devices/*.ufs/attributes/exception_event_status

Defined on file *sysfs-driver-ufs*

This file provides the exception event status UFS device attribute. The full information about the attribute could be found at UFS specifications 2.1.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/attributes/ffu_status
/sys/bus/platform/devices/*.ufs/attributes/ffu_status

Defined on file *sysfs-driver-ufs*

This file provides the ffu status UFS device attribute. The full information about the attribute could be found at UFS specifications 2.1.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/attributes/max_data_in_size
/sys/bus/platform/devices/*.ufs/attributes/max_data_in_size

Defined on file *sysfs-driver-ufs*

This file shows the maximum data size in a DATA IN UPIU. The full information about the attribute could be found at UFS specifications 2.1.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/attributes/max_data_out_size
/sys/bus/platform/devices/*.ufs/attributes/max_data_out_size

Defined on file *sysfs-driver-ufs*

This file shows the maximum number of bytes that can be requested with a READY TO TRANSFER UPIU. The full information about the attribute could be found at UFS specifications 2.1.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/attributes/max_number_of_rtt
/sys/bus/platform/devices/*.ufs/attributes/max_number_of_rtt

Defined on file *sysfs-driver-ufs*

This file provides the maximum current number of outstanding RTTs in device that is allowed. The full information about the attribute could be found at UFS specifications 2.1.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/attributes/ooo_data_enabled
/sys/bus/platform/devices/*.ufs/attributes/ooo_data_enabled

Defined on file *sysfs-driver-ufs*

This file provides the out of order data transfer enabled UFS device attribute. The full information about the attribute could be found at UFS specifications 2.1.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/attributes/psa_data_size
/sys/bus/platform/devices/*.ufs/attributes/psa_data_size

Defined on file *sysfs-driver-ufs*

This file shows the amount of data that the host plans to load to all logical units in pre-soldering state. The full information about the attribute could be found at UFS specifications 2.1.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/attributes/psa_state
/sys/bus/platform/devices/*.ufs/attributes/psa_state

Defined on file *sysfs-driver-ufs*

This file show the PSA feature status. The full information about the attribute could be found at UFS specifications 2.1.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/attributes/purge_status
/sys/bus/platform/devices/*.ufs/attributes/purge_status

Defined on file *sysfs-driver-ufs*

This file provides the purge operation status UFS device attribute. The full information about the attribute could be found at UFS specifications 2.1.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/attributes/reference_clock_frequency
/sys/bus/platform/devices/*.ufs/attributes/reference_clock_frequency

Defined on file *sysfs-driver-ufs*

This file provides the reference clock frequency UFS device attribute. The full information about the attribute could be found at UFS specifications 2.1.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/attributes/wb_avail_buf
/sys/bus/platform/devices/*.ufs/attributes/wb_avail_buf

Defined on file *sysfs-driver-ufs*

This entry shows the amount of unused WriteBooster buffer available.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/attributes/wb_cur_buf
/sys/bus/platform/devices/*.ufs/attributes/wb_cur_buf

Defined on file *sysfs-driver-ufs*

This entry shows the amount of unused current buffer.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/attributes/wb_flush_status
/sys/bus/platform/devices/*.ufs/attributes/wb_flush_status

Defined on file *sysfs-driver-ufs*

This entry shows the flush operation status.

00h	idle
01h	Flush operation in progress
02h	Flush operation stopped prematurely.
03h	Flush operation completed successfully
04h	Flush operation general failure

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/attributes/wb_life_time_est
/sys/bus/platform/devices/*.ufs/attributes/wb_life_time_est

Defined on file *sysfs-driver-ufs*

This entry shows an indication of the WriteBooster Buffer lifetime based on the amount of performed program/erase cycles

01h	0% - 10% WriteBooster Buffer life time used
...	
0Ah	90% - 100% WriteBooster Buffer life time used

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/capabilities/clock_scaling
/sys/bus/platform/devices/*.ufs/capabilities/clock_scaling

Defined on file *sysfs-driver-ufs*

Indicates status of clock scaling.

0	Clock scaling is not supported.
1	Clock scaling is supported.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/capabilities/write_booster
/sys/bus/platform/devices/*.ufs/capabilities/write_booster

Defined on file *sysfs-driver-ufs*

Indicates status of Write Booster.

0	Write Booster can not be enabled.
1	Write Booster can be enabled.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/capabilities/
/sys/bus/platform/devices/*.ufs/capabilities/

Defined on file *sysfs-driver-ufs*

The group represents the effective capabilities of the host-device pair. i.e. the capabilities which are enabled in the driver for the specific host controller, supported by the host controller and are supported and/or have compatible configuration on the device side.

/sys/bus/platform/drivers/ufshcd/*/device_descriptor/bkops_termination_latency
/sys/bus/platform/devices/*.ufs/device_descriptor/bkops_termination_latency

Defined on file *sysfs-driver-ufs*

This file shows the background operations termination latency. This is one of the UFS device descriptor parameters. The full information about the descriptor could be found at UFS specifications 2.1.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/device_descriptor/boot_enable
/sys/bus/platform/devices/*.ufs/device_descriptor/boot_enable

Defined on file *sysfs-driver-ufs*

This file shows value that indicates whether the device is enabled for boot. This is one of the UFS device descriptor parameters. The full information about the descriptor could be found at UFS specifications 2.1.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/device_descriptor/descriptor_access_enable
/sys/bus/platform/devices/*.ufs/device_descriptor/descriptor_access_enable

Defined on file *sysfs-driver-ufs*

This file shows value that indicates whether the device descriptor could be read after partial initialization phase of the boot sequence. This is one of the UFS device descriptor parameters. The full information about the descriptor could be found at UFS specifications 2.1.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/device_descriptor/device_class
/sys/bus/platform/devices/*.ufs/device_descriptor/device_class

Defined on file *sysfs-driver-ufs*

This file shows the device class. This is one of the UFS device descriptor parameters. The full information about the descriptor could be found at UFS specifications 2.1.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/device_descriptor/device_sub_class
/sys/bus/platform/devices/*.ufs/device_descriptor/device_sub_class

Defined on file *sysfs-driver-ufs*

This file shows the UFS storage subclass. This is one of the UFS device descriptor parameters. The full information about the descriptor could be found at UFS specifications 2.1.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/device_descriptor/device_type
/sys/bus/platform/devices/*.ufs/device_descriptor/device_type

Defined on file *sysfs-driver-ufs*

This file shows the device type. This is one of the UFS device descriptor parameters. The full information about the descriptor could be found at UFS specifications 2.1.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/device_descriptor/device_version
/sys/bus/platform/devices/*.ufs/device_descriptor/device_version

Defined on file *sysfs-driver-ufs*

This file shows the device version. This is one of the UFS device descriptor parameters. The full information about the descriptor could be found at UFS specifications 2.1.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/device_descriptor/ffu_timeout
/sys/bus/platform/devices/*.ufs/device_descriptor/ffu_timeout

Defined on file *sysfs-driver-ufs*

This file shows the FFU timeout. This is one of the UFS device descriptor parameters. The full information about the descriptor could be found at UFS specifications 2.1.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/device_descriptor/high_priority_lun
/sys/bus/platform/devices/*.ufs/device_descriptor/high_priority_lun

Defined on file *sysfs-driver-ufs*

This file shows the high priority lun. This is one of the UFS device descriptor parameters. The full information about the descriptor could be found at UFS specifications 2.1.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/device_descriptor/initial_active_icc_level
/sys/bus/platform/devices/*.ufs/device_descriptor/initial_active_icc_level

Defined on file *sysfs-driver-ufs*

This file shows the initial active ICC level. This is one of the UFS device descriptor parameters. The full information about the descriptor could be found at UFS specifications 2.1.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/device_descriptor/initial_power_mode
/sys/bus/platform/devices/*.ufs/device_descriptor/initial_power_mode

Defined on file *sysfs-driver-ufs*

This file shows value that defines the power mode after device initialization or hardware reset. This is one of the UFS device descriptor parameters. The full information about the descriptor could be found at UFS specifications 2.1.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/device_descriptor/manufacturer_id
/sys/bus/platform/devices/*.ufs/device_descriptor/manufacturer_id

Defined on file *sysfs-driver-ufs*

This file shows the manufacturer ID. This is one of the UFS device descriptor parameters. The full information about the descriptor could be found at UFS specifications 2.1.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/device_descriptor/manufacturing_date
/sys/bus/platform/devices/*.ufs/device_descriptor/manufacturing_date

Defined on file *sysfs-driver-ufs*

This file shows the manufacturing date in BCD format. This is one of the UFS device descriptor parameters. The full information about the descriptor could be found at UFS specifications 2.1.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/device_descriptor/number_of_luns
/sys/bus/platform/devices/*.ufs/device_descriptor/number_of_luns

Defined on file *sysfs-driver-ufs*

This file shows number of logical units. This is one of the UFS device descriptor parameters. The full information about the descriptor could be found at UFS specifications 2.1.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/device_descriptor/number_of_secure_wpa
/sys/bus/platform/devices/*.ufs/device_descriptor/number_of_secure_wpa

Defined on file *sysfs-driver-ufs*

This file shows number of secure write protect areas supported by the device. This is one of the UFS device descriptor parameters. The full information about the descriptor could be found at UFS specifications 2.1.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/device_descriptor/number_of_wluns
/sys/bus/platform/devices/*.ufs/device_descriptor/number_of_wluns

Defined on file *sysfs-driver-ufs*

This file shows number of well known logical units. This is one of the UFS device descriptor parameters. The full information about the descriptor could be found at UFS specifications 2.1.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/device_descriptor/protocol
/sys/bus/platform/devices/*.ufs/device_descriptor/protocol

Defined on file *sysfs-driver-ufs*

This file shows the protocol supported by an UFS device. This is one of the UFS device descriptor parameters. The full information about the descriptor could be found at UFS specifications 2.1.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/device_descriptor/psa_max_data_size
/sys/bus/platform/devices/*.ufs/device_descriptor/psa_max_data_size

Defined on file *sysfs-driver-ufs*

This file shows the maximum amount of data that may be written during the pre-soldering phase of the PSA flow. This is one of the UFS device descriptor parameters. The full information about the descriptor could be found at UFS specifications 2.1.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/device_descriptor/psa_state_timeout
/sys/bus/platform/devices/*.ufs/device_descriptor/psa_state_timeout

Defined on file *sysfs-driver-ufs*

This file shows the command maximum timeout for a change in PSA state. This is one of the UFS device descriptor parameters. The full information about the descriptor could be found at UFS specifications 2.1.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/device_descriptor/queue_depth
/sys/bus/platform/devices/*.ufs/device_descriptor/queue_depth

Defined on file *sysfs-driver-ufs*

This file shows the device queue depth. This is one of the UFS device descriptor parameters. The full information about the descriptor could be found at UFS specifications 2.1.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/device_descriptor/rtc_update
/sys/bus/platform/devices/*.ufs/device_descriptor/rtc_update

Defined on file *sysfs-driver-ufs*

This file shows the frequency and method of the realtime clock update. This is one of the UFS device descriptor parameters. The full information about the descriptor could be found at UFS specifications 2.1.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/device_descriptor/rtt_capability
/sys/bus/platform/devices/*.ufs/device_descriptor/rtt_capability

Defined on file *sysfs-driver-ufs*

This file shows the maximum number of outstanding RTTs supported by the device. This is one of the UFS device descriptor parameters. The full information about the descriptor could be found at UFS specifications 2.1.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/device_descriptor/secure_removal_type
/sys/bus/platform/devices/*.ufs/device_descriptor/secure_removal_type

Defined on file *sysfs-driver-ufs*

This file shows the secure removal type. This is one of the UFS device descriptor parameters. The full information about the descriptor could be found at UFS specifications 2.1.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/device_descriptor/specification_version
/sys/bus/platform/devices/*.ufs/device_descriptor/specification_version

Defined on file *sysfs-driver-ufs*

This file shows the specification version. This is one of the UFS device descriptor parameters. The full information about the descriptor could be found at UFS specifications 2.1.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/device_descriptor/support_security_lun
/sys/bus/platform/devices/*.ufs/device_descriptor/support_security_lun

Defined on file *sysfs-driver-ufs*

This file shows whether the security lun is supported. This is one of the UFS device descriptor parameters. The full information about the descriptor could be found at UFS specifications 2.1.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/device_descriptor/ufs_features
/sys/bus/platform/devices/*.ufs/device_descriptor/ufs_features

Defined on file *sysfs-driver-ufs*

This file shows which features are supported by the device. This is one of the UFS device descriptor parameters. The full information about the descriptor could be found at UFS specifications 2.1.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/device_descriptor/wb_presv_us_en
/sys/bus/platform/devices/*.ufs/device_descriptor/wb_presv_us_en

Defined on file *sysfs-driver-ufs*

This entry shows if preserve user-space was configured

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/device_descriptor/wb_shared_alloc_units
/sys/bus/platform/devices/*.ufs/device_descriptor/wb_shared_alloc_units

Defined on file *sysfs-driver-ufs*

This entry shows the shared allocated units of WB buffer

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/device_descriptor/wb_type
/sys/bus/platform/devices/*.ufs/device_descriptor/wb_type

Defined on file *sysfs-driver-ufs*

This entry shows the configured WB type. 0x1 for shared buffer mode. 0x0 for dedicated buffer mode.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/enable_wb_buf_flush
/sys/bus/platform/devices/*.ufs/enable_wb_buf_flush

Defined on file *sysfs-driver-ufs*

This entry shows the status of WriteBooster buffer flushing and it can be used to enable or disable the flushing. If flushing is enabled, the device executes the flush operation when the command queue is empty.

/sys/bus/platform/drivers/ufshcd/*/flags/bkops_enable
/sys/bus/platform/devices/*.ufs/flags/bkops_enable

Defined on file *sysfs-driver-ufs*

This file shows whether the device background operations are enabled. The full information about the flag could be found at UFS specifications 2.1.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/flags/busy_rtc
/sys/bus/platform/devices/*.ufs/flags/busy_rtc

Defined on file *sysfs-driver-ufs*

This file shows whether the device is executing internal operation related to real time clock. The full information about the flag could be found at UFS specifications 2.1.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/flags/device_init
/sys/bus/platform/devices/*.ufs/flags/device_init

Defined on file *sysfs-driver-ufs*

This file shows the device init status. The full information about the flag could be found at UFS specifications 2.1.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/flags/disable_fw_update
/sys/bus/platform/devices/*.ufs/flags/disable_fw_update

Defined on file *sysfs-driver-ufs*

This file shows whether the device FW update is permanently disabled. The full information about the flag could be found at UFS specifications 2.1.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/flags/life_span_mode_enable
/sys/bus/platform/devices/*.ufs/flags/life_span_mode_enable

Defined on file *sysfs-driver-ufs*

This file shows whether the device life span mode is enabled. The full information about the flag could be found at UFS specifications 2.1.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/flags/permanent_wpe
/sys/bus/platform/devices/*.ufs/flags/permanent_wpe

Defined on file *sysfs-driver-ufs*

This file shows whether permanent write protection is enabled. The full information about the flag could be found at UFS specifications 2.1.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/flags/phy_resource_removal
/sys/bus/platform/devices/*.ufs/flags/phy_resource_removal

Defined on file *sysfs-driver-ufs*

This file shows whether physical resource removal is enable. The full information about the flag could be found at UFS specifications 2.1.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/flags/power_on_wpe
/sys/bus/platform/devices/*.ufs/flags/power_on_wpe

Defined on file *sysfs-driver-ufs*

This file shows whether write protection is enabled on all logical units configured as power on write protected. The full information about the flag could be found at UFS specifications 2.1.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/flags/wb_enable
/sys/bus/platform/devices/*.ufs/flags/wb_enable

Defined on file *sysfs-driver-ufs*

This entry shows the status of WriteBooster.

0	WriteBooster is not enabled.
1	WriteBooster is enabled

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/flags/wb_flush_during_h8
/sys/bus/platform/devices/*.ufs/flags/wb_flush_during_h8

Defined on file *sysfs-driver-ufs*

Flush WriteBooster Buffer during hibernate state.

0	Device is not allowed to flush the WriteBooster Buffer during link hibernate state.
1	Device is allowed to flush the WriteBooster Buffer during link hibernate state.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/flags/wb_flush_en
/sys/bus/platform/devices/*.ufs/flags/wb_flush_en

Defined on file *sysfs-driver-ufs*

This entry shows if flush is enabled.

0	Flush operation is not performed.
1	Flush operation is performed.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/geometry_descriptor/*_memory_capacity_adjustment_fac
/sys/bus/platform/devices/*.ufs/geometry_descriptor/*_memory_capacity_adjustment_factor

Defined on file *sysfs-driver-ufs*

This file shows the memory capacity adjustment factor for different memory types (system code, non persistent, enhanced type 1-4). This is one of the UFS geometry descriptor parameters. The full information about the descriptor could be found at UFS specifications 2.1.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/geometry_descriptor/*_memory_max_alloc_units
/sys/bus/platform/devices/*.ufs/geometry_descriptor/*_memory_max_alloc_units

Defined on file *sysfs-driver-ufs*

This file shows the maximum number of allocation units for different memory types (system code, non persistent, enhanced type 1-4). This is one of the UFS geometry descriptor parameters. The full information about the descriptor could be found at UFS specifications 2.1.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/geometry_descriptor/allocation_unit_size
/sys/bus/platform/devices/*.ufs/geometry_descriptor/allocation_unit_size

Defined on file *sysfs-driver-ufs*

This file shows the allocation unit size. This is one of the UFS geometry descriptor parameters. The full information about the descriptor could be found at UFS specifications 2.1.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/geometry_descriptor/data_ordering
/sys/bus/platform/devices/*.ufs/geometry_descriptor/data_ordering

Defined on file *sysfs-driver-ufs*

This file shows support for out-of-order data transfer. This is one of the UFS geometry descriptor parameters. The full information about the descriptor could be found at UFS specifications 2.1.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/geometry_descriptor/dyn_capacity_resource_policy
/sys/bus/platform/devices/*.ufs/geometry_descriptor/dyn_capacity_resource_policy

Defined on file *sysfs-driver-ufs*

This file shows the dynamic capacity resource policy. This is one of the UFS geometry descriptor parameters. The full information about the descriptor could be found at UFS specifications 2.1.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/geometry_descriptor/max_in_buffer_size
/sys/bus/platform/devices/*.ufs/geometry_descriptor/max_in_buffer_size

Defined on file *sysfs-driver-ufs*

This file shows the maximum data-in buffer size. This is one of the UFS geometry descriptor parameters. The full information about the descriptor could be found at UFS specifications 2.1.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/geometry_descriptor/max_number_of_contexts
/sys/bus/platform/devices/*.ufs/geometry_descriptor/max_number_of_contexts

Defined on file *sysfs-driver-ufs*

This file shows maximum available number of contexts which are supported by the device. This is one of the UFS geometry descriptor parameters. The full information about the descriptor could be found at UFS specifications 2.1.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/geometry_descriptor/max_number_of_luns
/sys/bus/platform/devices/*.ufs/geometry_descriptor/max_number_of_luns

Defined on file *sysfs-driver-ufs*

This file shows the maximum number of logical units supported by the UFS device. This is one of the UFS geometry descriptor parameters. The full information about the descriptor could be found at UFS specifications 2.1.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/geometry_descriptor/max_out_buffer_size
/sys/bus/platform/devices/*.ufs/geometry_descriptor/max_out_buffer_size

Defined on file *sysfs-driver-ufs*

This file shows the maximum data-out buffer size. This is one of the UFS geometry descriptor parameters. The full information about the descriptor could be found at UFS specifications 2.1.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/geometry_descriptor/memory_types
/sys/bus/platform/devices/*.ufs/geometry_descriptor/memory_types

Defined on file *sysfs-driver-ufs*

This file shows supported memory types. This is one of the UFS geometry descriptor parameters. The full information about the descriptor could be found at UFS specifications 2.1.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/geometry_descriptor/min_addressable_block_size
/sys/bus/platform/devices/*.ufs/geometry_descriptor/min_addressable_block_size

Defined on file *sysfs-driver-ufs*

This file shows the minimum addressable block size. This is one of the UFS geometry descriptor parameters. The full information about the descriptor could be found at UFS specifications 2.1.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/geometry_descriptor/optimal_read_block_size
/sys/bus/platform/devices/*.ufs/geometry_descriptor/optimal_read_block_size

Defined on file *sysfs-driver-ufs*

This file shows the optimal read block size. This is one of the UFS geometry descriptor parameters. The full information about the descriptor could be found at UFS specifications 2.1.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/geometry_descriptor/optimal_write_block_size
/sys/bus/platform/devices/*.ufs/geometry_descriptor/optimal_write_block_size

Defined on file *sysfs-driver-ufs*

This file shows the optimal write block size. This is one of the UFS geometry descriptor parameters. The full information about the descriptor could be found at UFS specifications 2.1.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/geometry_descriptor/raw_device_capacity
/sys/bus/platform/devices/*.ufs/geometry_descriptor/raw_device_capacity

Defined on file *sysfs-driver-ufs*

This file shows the total memory quantity available to the user to configure the device logical units. This is one of the UFS geometry descriptor parameters. The full information about the descriptor could be found at UFS specifications 2.1.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/geometry_descriptor/rpmb_rw_size
/sys/bus/platform/devices/*.ufs/geometry_descriptor/rpmb_rw_size

Defined on file *sysfs-driver-ufs*

This file shows the maximum number of RPMB frames allowed in Security Protocol In/Out. This is one of the UFS geometry descriptor parameters. The full information about the descriptor could be found at UFS specifications 2.1.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/geometry_descriptor/secure_removal_types
/sys/bus/platform/devices/*.ufs/geometry_descriptor/secure_removal_types

Defined on file *sysfs-driver-ufs*

This file shows supported secure removal types. This is one of the UFS geometry descriptor parameters. The full information about the descriptor could be found at UFS specifications 2.1.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/geometry_descriptor/segment_size
/sys/bus/platform/devices/*.ufs/geometry_descriptor/segment_size

Defined on file *sysfs-driver-ufs*

This file shows the segment size. This is one of the UFS geometry descriptor parameters. The full information about the descriptor could be found at UFS specifications 2.1.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/geometry_descriptor/sys_data_tag_resource_size
/sys/bus/platform/devices/*.ufs/geometry_descriptor/sys_data_tag_resource_size

Defined on file *sysfs-driver-ufs*

This file shows maximum storage area size allocated by the device to handle system data by the tagging mechanism. This is one of the UFS geometry descriptor parameters. The full information about the descriptor could be found at UFS specifications 2.1.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/geometry_descriptor/sys_data_tag_unit_size
/sys/bus/platform/devices/*.ufs/geometry_descriptor/sys_data_tag_unit_size

Defined on file *sysfs-driver-ufs*

This file shows system data tag unit size. This is one of the UFS geometry descriptor parameters. The full information about the descriptor could be found at UFS specifications 2.1.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/geometry_descriptor/wb_buff_cap_adj
/sys/bus/platform/devices/*.ufs/geometry_descriptor/wb_buff_cap_adj

Defined on file *sysfs-driver-ufs*

This entry shows the total user-space decrease in shared buffer mode. The value of this parameter is 3 for TLC NAND when SLC mode is used as WriteBooster Buffer. 2 for MLC NAND.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/geometry_descriptor/wb_max_alloc_units
/sys/bus/platform/devices/*.ufs/geometry_descriptor/wb_max_alloc_units

Defined on file *sysfs-driver-ufs*

This entry shows the Maximum total WriteBooster Buffer size which is supported by the entire device.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/geometry_descriptor/wb_max_wb_luns
/sys/bus/platform/devices/*.ufs/geometry_descriptor/wb_max_wb_luns

Defined on file *sysfs-driver-ufs*

This entry shows the maximum number of luns that can support WriteBooster.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/geometry_descriptor/wb_sup_red_type
/sys/bus/platform/devices/*.ufs/geometry_descriptor/wb_sup_red_type

Defined on file *sysfs-driver-ufs*

The supportability of user space reduction mode and preserve user space mode. 00h: WriteBooster Buffer can be configured only in user space reduction type. 01h: WriteBooster Buffer can be configured only in preserve user space type. 02h: Device can be configured in either user space reduction type or preserve user space type.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/geometry_descriptor/wb_sup_wb_type
/sys/bus/platform/devices/*.ufs/geometry_descriptor/wb_sup_wb_type

Defined on file *sysfs-driver-ufs*

The supportability of WriteBooster Buffer type.

00h	LU based WriteBooster Buffer configuration
01h	Single shared WriteBooster Buffer configuration
02h	Supporting both LU based WriteBooster. Buffer and Single shared WriteBooster Buffer configuration

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/health_descriptor/eol_info
/sys/bus/platform/devices/*.ufs/health_descriptor/eol_info

Defined on file *sysfs-driver-ufs*

This file shows preend of life information. This is one of the UFS health descriptor parameters. The full information about the descriptor could be found at UFS specifications 2.1.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/health_descriptor/life_time_estimation_a
/sys/bus/platform/devices/*.ufs/health_descriptor/life_time_estimation_a

Defined on file *sysfs-driver-ufs*

This file shows indication of the device life time (method a). This is one of the UFS health descriptor parameters. The full information about the descriptor could be found at UFS specifications 2.1.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/health_descriptor/life_time_estimation_b
/sys/bus/platform/devices/*.ufs/health_descriptor/life_time_estimation_b

Defined on file *sysfs-driver-ufs*

This file shows indication of the device life time (method b). This is one of the UFS health descriptor parameters. The full information about the descriptor could be found at UFS specifications 2.1.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/interconnect_descriptor/mphy_version
/sys/bus/platform/devices/*.ufs/interconnect_descriptor/mphy_version

Defined on file *sysfs-driver-ufs*

This file shows the MIPI M-PHY version number in BCD format. This is one of the UFS interconnect descriptor parameters. The full information about the descriptor could be found at UFS specifications 2.1.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/interconnect_descriptor/unipro_version
/sys/bus/platform/devices/*.ufs/interconnect_descriptor/unipro_version

Defined on file *sysfs-driver-ufs*

This file shows the MIPI UniPro version number in BCD format. This is one of the UFS interconnect descriptor parameters. The full information about the descriptor could be found at UFS specifications 2.1.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/monitor/monitor_chunk_size
/sys/bus/platform/devices/*.ufs/monitor/monitor_chunk_size

Defined on file *sysfs-driver-ufs*

This file tells the monitor to focus on requests transferring data of specific chunk size (in Bytes). 0 means any chunk size. It can only be changed when monitor is disabled.

/sys/bus/platform/drivers/ufshcd/*/monitor/monitor_enable
/sys/bus/platform/devices/*.ufs/monitor/monitor_enable

Defined on file *sysfs-driver-ufs*

This file shows the status of performance monitor enablement and it can be used to start/stop the monitor. When the monitor is stopped, the performance data collected is also cleared.

/sys/bus/platform/drivers/ufshcd/*/monitor/read_nr_requests
/sys/bus/platform/devices/*.ufs/monitor/read_nr_requests

Defined on file *sysfs-driver-ufs*

This file shows how many read requests have been sent after monitor gets started.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/monitor/read_req_latency_avg
/sys/bus/platform/devices/*.ufs/monitor/read_req_latency_avg

Defined on file *sysfs-driver-ufs*

This file shows the average latency (in micro seconds) of read requests after monitor gets started.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/monitor/read_req_latency_max
/sys/bus/platform/devices/*.ufs/monitor/read_req_latency_max

Defined on file *sysfs-driver-ufs*

This file shows the maximum latency (in micro seconds) of read requests after monitor gets started.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/monitor/read_req_latency_min
/sys/bus/platform/devices/*.ufs/monitor/read_req_latency_min

Defined on file *sysfs-driver-ufs*

This file shows the minimum latency (in micro seconds) of read requests after monitor gets started.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/monitor/read_req_latency_sum
/sys/bus/platform/devices/*.ufs/monitor/read_req_latency_sum

Defined on file *sysfs-driver-ufs*

This file shows the total latency (in micro seconds) of read requests sent after monitor gets started.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/monitor/read_total_busy
/sys/bus/platform/devices/*.ufs/monitor/read_total_busy

Defined on file *sysfs-driver-ufs*

This file shows how long (in micro seconds) has been spent sending data from device to host after monitor gets started.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/monitor/read_total_sectors
/sys/bus/platform/devices/*.ufs/monitor/read_total_sectors

Defined on file *sysfs-driver-ufs*

This file shows how many sectors (in 512 Bytes) have been sent from device to host after monitor gets started.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/monitor/write_nr_requests
/sys/bus/platform/devices/*.ufs/monitor/write_nr_requests

Defined on file *sysfs-driver-ufs*

This file shows how many write requests have been sent after monitor gets started.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/monitor/write_req_latency_avg
/sys/bus/platform/devices/*.ufs/monitor/write_req_latency_avg

Defined on file *sysfs-driver-ufs*

This file shows the average latency (in micro seconds) of write requests after monitor gets started.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/monitor/write_req_latency_max
/sys/bus/platform/devices/*.ufs/monitor/write_req_latency_max

Defined on file *sysfs-driver-ufs*

This file shows the maximum latency (in micro seconds) of write requests after monitor gets started.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/monitor/write_req_latency_min
/sys/bus/platform/devices/*.ufs/monitor/write_req_latency_min

Defined on file *sysfs-driver-ufs*

This file shows the minimum latency (in micro seconds) of write requests after monitor gets started.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/monitor/write_req_latency_sum
/sys/bus/platform/devices/*.ufs/monitor/write_req_latency_sum

Defined on file *sysfs-driver-ufs*

This file shows the total latency (in micro seconds) of write requests after monitor gets started.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/monitor/write_total_busy
/sys/bus/platform/devices/*.ufs/monitor/write_total_busy

Defined on file *sysfs-driver-ufs*

This file shows how long (in micro seconds) has been spent sending data from host to device after monitor gets started.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/monitor/write_total_sectors
/sys/bus/platform/devices/*.ufs/monitor/write_total_sectors

Defined on file *sysfs-driver-ufs*

This file shows how many sectors (in 512 Bytes) have been sent from host to device after monitor gets started.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/power_descriptor/active_icc_levels_vcc*
/sys/bus/platform/devices/*.ufs/power_descriptor/active_icc_levels_vcc*

Defined on file *sysfs-driver-ufs*

This file shows maximum VCC, VCCQ and VCCQ2 value for active ICC levels from 0 to 15. This is one of the UFS power descriptor parameters. The full information about the descriptor could be found at UFS specifications 2.1.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/power_info/dev_pm
/sys/bus/platform/devices/*.ufs/power_info/dev_pm

Defined on file *sysfs-driver-ufs*

This file shows the UFS device power mode.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/power_info/gear
/sys/bus/platform/devices/*.ufs/power_info/gear

Defined on file *sysfs-driver-ufs*

This file shows the gear of UFS link.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/power_info/lane
/sys/bus/platform/devices/*.ufs/power_info/lane

Defined on file *sysfs-driver-ufs*

This file shows how many lanes are enabled on the UFS link, i.e., an output 2 means UFS link is operating with 2 lanes.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/power_info/link_state
/sys/bus/platform/devices/*.ufs/power_info/link_state

Defined on file *sysfs-driver-ufs*

This file shows the state of UFS link.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/power_info/mode
/sys/bus/platform/devices/*.ufs/power_info/mode

Defined on file *sysfs-driver-ufs*

This file shows the PA power mode of UFS.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/power_info/rate
/sys/bus/platform/devices/*.ufs/power_info/rate

Defined on file *sysfs-driver-ufs*

This file shows the speed rate of UFS link.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/rpm_lvl
/sys/bus/platform/devices/*.ufs/rpm_lvl

Defined on file *sysfs-driver-ufs*

This entry could be used to set or show the UFS device runtime power management level. The current driver implementation supports 7 levels with next target states:

0	UFS device will stay active, UIC link will stay active
1	UFS device will stay active, UIC link will hibernate
2	UFS device will be moved to sleep, UIC link will stay active
3	UFS device will be moved to sleep, UIC link will hibernate
4	UFS device will be powered off, UIC link will hibernate
5	UFS device will be powered off, UIC link will be powered off
6	UFS device will be moved to deep sleep, UIC link will be powered off. Note, deep sleep might not be supported in which case this value will not be accepted

/sys/bus/platform/drivers/ufshcd/*/rpm_target_dev_state
/sys/bus/platform/devices/*.ufs/rpm_target_dev_state

Defined on file *sysfs-driver-ufs*

This entry shows the target power mode of an UFS device for the chosen runtime power management level.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/rpm_target_link_state
/sys/bus/platform/devices/*.ufs/rpm_target_link_state

Defined on file *sysfs-driver-ufs*

This entry shows the target state of an UFS UIC link for the chosen runtime power management level.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/rtc_update_ms
/sys/bus/platform/devices/*.ufs/rtc_update_ms

Defined on file *sysfs-driver-ufs*

rtc_update_ms indicates how often the host should synchronize or update the UFS RTC. If set to 0, this will disable UFS RTC periodic update.

/sys/bus/platform/drivers/ufshcd/*/spm_lvl
/sys/bus/platform/devices/*.ufs/spm_lvl

Defined on file *sysfs-driver-ufs*

This entry could be used to set or show the UFS device system power management level. The current driver implementation supports 7 levels with next target states:

0	UFS device will stay active, UIC link will stay active
1	UFS device will stay active, UIC link will hibernate
2	UFS device will be moved to sleep, UIC link will stay active
3	UFS device will be moved to sleep, UIC link will hibernate
4	UFS device will be powered off, UIC link will hibernate
5	UFS device will be powered off, UIC link will be powered off
6	UFS device will be moved to deep sleep, UIC link will be powered off. Note, deep sleep might not be supported in which case this value will not be accepted

/sys/bus/platform/drivers/ufshcd/*/spm_target_dev_state
/sys/bus/platform/devices/*.ufs/spm_target_dev_state

Defined on file *sysfs-driver-ufs*

This entry shows the target power mode of an UFS device for the chosen system power management level.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/spm_target_link_state
/sys/bus/platform/devices/*.ufs/spm_target_link_state

Defined on file *sysfs-driver-ufs*

This entry shows the target state of an UFS UIC link for the chosen system power management level.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/string_descriptors/manufacturer_name
/sys/bus/platform/devices/*.ufs/string_descriptors/manufacturer_name

Defined on file *sysfs-driver-ufs*

This file contains a device manufacturer name string. The full information about the descriptor could be found at UFS specifications 2.1.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/string_descriptors/oem_id
/sys/bus/platform/devices/*.ufs/string_descriptors/oem_id

Defined on file *sysfs-driver-ufs*

This file contains a OEM ID string. The full information about the descriptor could be found at UFS specifications 2.1.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/string_descriptors/product_name
/sys/bus/platform/devices/*.ufs/string_descriptors/product_name

Defined on file *sysfs-driver-ufs*

This file contains a product name string. The full information about the descriptor could be found at UFS specifications 2.1.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/string_descriptors/product_revision
/sys/bus/platform/devices/*.ufs/string_descriptors/product_revision

Defined on file *sysfs-driver-ufs*

This file contains a product revision string. The full information about the descriptor could be found at UFS specifications 2.1.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/string_descriptors/serial_number
/sys/bus/platform/devices/*.ufs/string_descriptors/serial_number

Defined on file *sysfs-driver-ufs*

This file contains a device serial number string. The full information about the descriptor could be found at UFS specifications 2.1.

The file is read only.

/sys/bus/platform/drivers/ufshcd/*/wb_flush_threshold
/sys/bus/platform/devices/*.ufs/wb_flush_threshold

Defined on file *sysfs-driver-ufs*

wb_flush_threshold represents the threshold for flushing WriteBooster buffer, whose value expressed in unit of 10% granularity, such as '1' representing 10%, '2' representing 20%, and so on. If avail_wb_buff < wb_flush_threshold, it indicates that WriteBooster buffer needs to be flushed, otherwise it is not necessary.

/sys/bus/platform/drivers/ufshcd/*/wb_on
/sys/bus/platform/devices/*.ufs/wb_on

Defined on file *sysfs-driver-ufs*

This node is used to set or display whether UFS WriteBooster is enabled. Echo 0 to this file to disable UFS WriteBooster or 1 to enable it. The WriteBooster is enabled after power-on/reset, however, it will be disabled/enable while CLK scaling down/up (if the platform supports UFSHCD_CAP_CLK_SCALING). For a platform that doesn't support UFSHCD_CAP_CLK_SCALING, we can disable/enable WriteBooster through this sysfs node.

/sys/bus/platform/drivers/zynqmp_fpga_manager/firmware:zynqmp-firmware:pcap/status

Defined on file *sysfs-driver-zynqmp-fpga*

(RO) Read fpga status. Read returns a hexadecimal value that tells the current status of the FPGA device. Each bit position in the status value is described Below(see ug570 chapter 9). https://docs.xilinx.com/v/u/en-US/ug570-ultrascale-configuration

BIT(0)	0: No CRC error 1: CRC error
BIT(1)	0: Decryptor security not set 1: Decryptor security set
BIT(2)	0: MMCMs/PLLs are not locked 1: MMCMs/PLLs are locked
BIT(3)	0: DCI not matched 1: DCI matched
BIT(4)	0: Start-up sequence has not finished 1: Start-up sequence has finished
BIT(5)	0: All I/Os are placed in High-Z state 1: All I/Os behave as configured
BIT(6)	0: Flip-flops and block RAM are write disabled 1: Flip-flops and block RAM are write enabled
BIT(7)	0: GHIGH_B_STATUS asserted 1: GHIGH_B_STATUS deasserted
BIT(8) to BIT(10)	Status of the mode pins
BIT(11)	0: Initialization has not finished 1: Initialization finished
BIT(12)	Value on INIT_B_PIN pin
BIT(13)	0: Signal not released 1: Signal released
BIT(14)	Value on DONE_PIN pin.
BIT(15)	0: No IDCODE_ERROR 1: IDCODE_ERROR
BIT(16)	0: No SECURITY_ERROR 1: SECURITY_ERROR
BIT(17)	System Monitor over-temperature if set
BIT(18) to BIT(20)	Start-up state machine (0 to 7) Phase 0 = 000 Phase 1 = 001 Phase 2 = 011 Phase 3 = 010 Phase 4 = 110 Phase 5 = 111 Phase 6 = 101 Phase 7 = 100
BIT(25) to BIT(26)	Indicates the detected bus width 00 = x1 01 = x8 10 = x16 11 = x32

The other bits are reserved.

/sys/bus/rapidio/devices/<nn>:<d>:<iiii>

Defined on file *sysfs-bus-rapidio*

For each RapidIO device, the RapidIO subsystem creates files in an individual subdirectory with the following name format of device_name "nn:d:iiii", where:

nn	two-digit hexadecimal ID of RapidIO network where the device resides
d	device type: 'e' - for endpoint or 's' - for switch
iiii	four-digit device destID for endpoints, or switchID for switches

For example, below is a list of device directories that represents a typical RapidIO network with one switch, one host, and two agent endpoints, as it is seen by the enumerating host (with destID = 1):

```
/sys/bus/rapidio/devices/00:e:0000
/sys/bus/rapidio/devices/00:e:0002
/sys/bus/rapidio/devices/00:s:0001
```

NOTE:

An enumerating or discovering endpoint does not create a sysfs entry for itself, this is why an endpoint with destID=1 is not shown in the list.

Attributes Common for All RapidIO Devices

/sys/bus/rapidio/devices/<nn>:<d>:<iiii>/asm_did

Defined on file *sysfs-bus-rapidio*

(RO) returns identifier for the assembly containing the device

/sys/bus/rapidio/devices/<nn>:<d>:<iiii>/asm_rev

Defined on file *sysfs-bus-rapidio*

(RO) returns revision level of the assembly containing the device

/sys/bus/rapidio/devices/<nn>:<d>:<iiii>/asm_vid

Defined on file *sysfs-bus-rapidio*

(RO) returns vendor identifier of the assembly containing the device

/sys/bus/rapidio/devices/<nn>:<d>:<iiii>/config

Defined on file *sysfs-bus-rapidio*

(RW) Binary attribute to read from and write to the device configuration registers using the RapidIO maintenance transactions. This attribute is similar in behaviour to the ”config” attribute of PCI devices and provides an access to the RapidIO device registers using standard file read and write operations.

RapidIO Switch Device Attributes

RapidIO switches have additional attributes in sysfs. RapidIO subsystem supports common and device-specific sysfs attributes for switches. Because switches are integrated into the RapidIO subsystem, it offers a method to create device-specific sysfs attributes by specifying a callback function that may be set by the switch initialization routine during enumeration or discovery process.

/sys/bus/rapidio/devices/<nn>:<d>:<iiii>/destid

Defined on file *sysfs-bus-rapidio*

(RO) returns device destination ID assigned by the enumeration routine

/sys/bus/rapidio/devices/<nn>:<d>:<iiii>/device_rev

Defined on file *sysfs-bus-rapidio*

(RO) returns the device revision level

/sys/bus/rapidio/devices/<nn>:<d>:<iiii>/did

Defined on file *sysfs-bus-rapidio*

(RO) returns the device identifier

/sys/bus/rapidio/devices/<nn>:<d>:<iiii>/lprev

Defined on file *sysfs-bus-rapidio*

(RO) returns name of previous device (switch) on the path to the device that that owns this attribute

/sys/bus/rapidio/devices/<nn>:<d>:<iiii>/modalias

Defined on file *sysfs-bus-rapidio*

(RO) returns the device modalias

/sys/bus/rapidio/devices/<nn>:<d>:<iiii>/vid

Defined on file *sysfs-bus-rapidio*

(RO) returns the device vendor identifier

/sys/bus/rapidio/devices/<nn>:<s>:<iiii>/destid

Defined on file *sysfs-bus-rapidio*

(RO) device destination ID of the associated device that defines a route to the switch

/sys/bus/rapidio/devices/<nn>:<s>:<iiii>/errlog

Defined on file *sysfs-bus-rapidio*

(RO) reads contents of device error log until it is empty.

RapidIO Bus Attributes

/sys/bus/rapidio/devices/<nn>:<s>:<iiii>/hopcount

Defined on file *sysfs-bus-rapidio*

(RO) number of hops on the path to the switch

/sys/bus/rapidio/devices/<nn>:<s>:<iiii>/lnext

Defined on file *sysfs-bus-rapidio*

(RO) returns names of devices linked to the switch except one of a device linked to the ingress port (reported as ”lprev”). This is an array names with number of lines equal to number of ports in switch. If a switch port has no attached device, returns ”null” instead of a device name.

Device-specific Switch Attributes

IDT_GEN2-

/sys/bus/rapidio/devices/<nn>:<s>:<iiii>/routes

Defined on file *sysfs-bus-rapidio*

(RO) reports switch routing information in "destID port" format. This attribute reports only valid routing table entries, one line for each entry.

/sys/bus/rapidio/scan

Defined on file *sysfs-bus-rapidio*

(WO) Allows to trigger enumeration discovery process from user space. To initiate an enumeration or discovery process on specific mport device, a user needs to write mport_ID (not RapidIO destination ID) into this file. The mport_ID is a sequential number (0 ... RIO_MAX_MPORTS) assigned to the mport device. For example, for a machine with a single RapidIO controller, mport_ID for that controller always will be 0. To initiate RapidIO enumeration/discovery on all available mports a user must write '-1' (or RIO_MPORT_ANY) into this attribute file.

/sys/bus/rbd/add

Defined on file *sysfs-bus-rbd*

(WO) Add rbd block device.

Usage: <mon ip addr> <options> <pool name> <rbd image name> [<snap name>]

Example:

```
$ echo "192.168.0.1 name=admin rbd foo" > /sys/bus/rbd/add
```

The snapshot name can be "-" or omitted to map the image read/write. A <dev-id> will be assigned for any registered block device. If snapshot is used, it will be mapped read-only.

/sys/bus/rbd/add_single_major

Defined on file *sysfs-bus-rbd*

(WO) Available only if rbd module is inserted with single_major parameter set to true.

Usage is the same as for */sys/bus/rbd/add*. If present, this should be used instead of the latter: any attempts to use */sys/bus/rbd/add* if */sys/bus/rbd/add_single_major* is available will fail for backwards compatibility reasons.

/sys/bus/rbd/devices/<dev-id>/image_id
/sys/bus/rbd/devices/<dev-id>/features

Defined on file *sysfs-bus-rbd*

image_id	(RO) The unique id for the rbd image. (For rbd image format 1 this is empty.)
features	(RO) A hexadecimal encoding of the feature bits for this image.

/sys/bus/rbd/devices/<dev-id>/minor

Defined on file *sysfs-bus-rbd*

(RO) The block device minor number.

/sys/bus/rbd/devices/<dev-id>/parent

Defined on file *sysfs-bus-rbd*

(RO) Information identifying the chain of parent images in a layered rbd image. Entries are separated by empty lines.

/sys/bus/rbd/devices/<dev-id>/pool_id

Defined on file *sysfs-bus-rbd*

(RO) The unique identifier for the rbd image's pool. This is a permanent attribute of the pool. A pool's id will never change.

/sys/bus/rbd/devices/<dev-id>/size
/sys/bus/rbd/devices/<dev-id>/major
/sys/bus/rbd/devices/<dev-id>/client_id
/sys/bus/rbd/devices/<dev-id>/pool
/sys/bus/rbd/devices/<dev-id>/name
/sys/bus/rbd/devices/<dev-id>/refresh
/sys/bus/rbd/devices/<dev-id>/current_snap

Defined on file *sysfs-bus-rbd*

size	(RO) The size (in bytes) of the mapped block device.
major	(RO) The block device major number.
client_id	(RO) The ceph unique client id that was assigned for this specific session.
pool	(RO) The name of the storage pool where this rbd image resides. An rbd image name is unique within its pool.
name	(RO) The name of the rbd image.
refresh	(WO) Writing to this file will reread the image header data and set all relevant data structures accordingly.
current_snap	(RO) The current snapshot for which the device is mapped.

/sys/bus/rbd/devices/<dev-id>/snap_id
/sys/bus/rbd/devices/<dev-id>/config_info
/sys/bus/rbd/devices/<dev-id>/cluster_fsid
/sys/bus/rbd/devices/<dev-id>/client_addr

Defined on file *sysfs-bus-rbd*

snap_id	(RO) The current snapshot's id.
config_info	(RO) The string written into /sys/bus/rbd/add{,_single_major}.
cluster_fsid	(RO) The ceph cluster UUID.
client_addr	(RO) The ceph unique client entity_addr_t (address + nonce). The format is <address>:<port>/<nonce>: '1.2.3.4:1234/5678' or '[1:2:3:4:5:6:7:8]:1234/5678'.

/sys/bus/rbd/remove

Defined on file *sysfs-bus-rbd*

(WO) Remove rbd block device.

Usage: <dev-id> [force]

Example:

```
$ echo 2 > /sys/bus/rbd/remove
```

Optional "force" argument which when passed will wait for running requests and then unmap the image. Requests sent to the driver after initiating the removal will be failed. (August 2016, since 4.9.)

/sys/bus/rbd/remove_single_major

Defined on file *sysfs-bus-rbd*

(WO) Available only if rbd module is inserted with single_major parameter set to true.

Usage is the same as for */sys/bus/rbd/remove*. If present, this should be used instead of the latter: any attempts to use */sys/bus/rbd/remove* if */sys/bus/rbd/remove_single_major* is available will fail for backwards compatibility reasons.

/sys/bus/rbd/supported_features

Defined on file *sysfs-bus-rbd*

(RO) Displays the features supported by the rbd module so that userspace can generate meaningful error messages and spell out unsupported features that need to be disabled.

/sys/bus/rpmsg/devices/.../announce

Defined on file *sysfs-bus-rpmsg*

Every rpmsg device is a communication channel with a remote processor. Channels are identified by a textual name (see /sys/bus/rpmsg/devices/.../name above) and have a local ("source") rpmsg address, and remote ("destination") rpmsg address.

A channel is first created when an entity, whether local or remote, starts listening on it for messages (and is thus called an rpmsg server).

When that happens, a ”name service” announcement is sent to the other processor, in order to let it know about the creation of the channel (this way remote clients know they can start sending messages).

This sysfs entry tells us whether the channel is a local server channel that is announced (values are either true or false).

/sys/bus/rpmsg/devices/.../driver_override

Defined on file *sysfs-bus-rpmsg*

Every rpmsg device is a communication channel with a remote processor. Channels are identified by a textual name (see /sys/bus/rpmsg/devices/.../name above) and have a local (”source”) rpmsg address, and remote (”destination”) rpmsg address.

The listening entity (or client) which communicates with a remote processor is referred as rpmsg driver. The rpmsg device and rpmsg driver are matched based on rpmsg device name and rpmsg driver ID table.

This sysfs entry allows the rpmsg driver for a rpmsg device to be specified which will override standard OF, ID table and name matching.

/sys/bus/rpmsg/devices/.../dst

Defined on file *sysfs-bus-rpmsg*

Every rpmsg device is a communication channel with a remote processor. Channels have a local (”source”) rpmsg address, and remote (”destination”) rpmsg address. When an entity starts listening on one end of a channel, it assigns it with a unique rpmsg address (a 32 bits integer). This way when inbound messages arrive to this address, the rpmsg core dispatches them to the listening entity.

This sysfs entry contains the dst (remote) rpmsg address of this channel. If it contains 0xffffffff, then an address wasn't assigned (can happen if the kernel driver that is attached to this channel is exposing a service to the remote processor. This make it a local rpmsg server, and it is listening for inbound messages that may be sent from any remote rpmsg client; it is not bound to a single remote entity).

/sys/bus/rpmsg/devices/.../name

Defined on file *sysfs-bus-rpmsg*

Every rpmsg device is a communication channel with a remote processor. Channels are identified with a (textual) name, which is maximum 32 bytes long (defined as RPMSG_NAME_SIZE in rpmsg.h).

This sysfs entry contains the name of this channel.

/sys/bus/rpmsg/devices/.../src

Defined on file *sysfs-bus-rpmsg*

Every rpmsg device is a communication channel with a remote processor. Channels have a local (”source”) rpmsg address, and remote (”destination”) rpmsg address. When an entity

starts listening on one end of a channel, it assigns it with a unique rpmsg address (a 32 bits integer). This way when inbound messages arrive to this address, the rpmsg core dispatches them to the listening entity (a kernel driver).

This sysfs entry contains the src (local) rpmsg address of this channel. If it contains 0xffffffff, then an address wasn't assigned (can happen if no driver exists for this channel).

/sys/bus/scsi/drivers/st/debug_flag

Defined on file *sysfs-driver-st*

This file allows you to turn debug output from the st driver off if you write a '0' to the file or on if you write a '1'. Note that debug output requires that the module be compiled with the #define DEBUG set to a non-zero value (this is the default). If DEBUG is set to 0 then this file will not appear in sysfs as its presence is conditional upon debug output support being compiled into the module.

/sys/bus/siox/devices/siox-X-Y/connected

Defined on file *sysfs-bus-siox*

Read-only value. ”0” means the Yth device on siox bus X isn't ”connected” i.e. communication with it is not ensured. ”1” signals a working connection.

/sys/bus/siox/devices/siox-X-Y/inbytes

Defined on file *sysfs-bus-siox*

Read-only value reporting the inbytes value provided to siox-X/device_add

/sys/bus/siox/devices/siox-X-Y/outbytes

Defined on file *sysfs-bus-siox*

Read-only value reporting the outbytes value provided to siox-X/device_add.

/sys/bus/siox/devices/siox-X-Y/status_errors

Defined on file *sysfs-bus-siox*

Counts the number of time intervals when the read status byte doesn't yield the expected value.

/sys/bus/siox/devices/siox-X-Y/type

Defined on file *sysfs-bus-siox*

Read-only value reporting the type value provided to siox-X/device_add.

/sys/bus/siox/devices/siox-X-Y/watchdog

Defined on file *sysfs-bus-siox*

Read-only value reporting if the watchdog of the siox device is active. ”0” means the watchdog is not active and the device is expected to be operational. ”1” means the watchdog keeps the device in reset.

/sys/bus/siox/devices/siox-X-Y/watchdog_errors

Defined on file *sysfs-bus-siox*

Read-only value reporting the number to time intervals when the watchdog was active.

/sys/bus/siox/devices/siox-X/active

Defined on file *sysfs-bus-siox*

On reading represents the current state of the bus. If it contains a ”0” the bus is stopped and connected devices are expected to not do anything because their watchdog triggered. When the file contains a ”1” the bus is operated and periodically does a push-pull cycle to write and read data from the connected devices.

When writing a ”0” or ”1” the bus moves to the described state.

/sys/bus/siox/devices/siox-X/device_add

Defined on file *sysfs-bus-siox*

Write-only file. Write

<type> <inbytes> <outbytes> <statustype>

to add a new device dynamically. <type> is the name that is used to match to a driver (similar to the platform bus). <inbytes> and <outbytes> define the length of the input and output shift register in bytes respectively.

<statustype> defines the 4 bit device type that is check to identify connection problems.

The new device is added to the end of the existing chain.

/sys/bus/siox/devices/siox-X/device_remove

Defined on file *sysfs-bus-siox*

Write-only file. A single write removes the last device in the siox chain.

/sys/bus/siox/devices/siox-X/poll_interval_ns

Defined on file *sysfs-bus-siox*

Defines the interval between two poll cycles in nano seconds. Note this is rounded to jiffies on writing. On reading the current value is returned.

/sys/bus/soc

Defined on file *sysfs-devices-soc*

The /sys/bus/soc/ directory contains the usual sub-folders expected under most buses. /sys/bus/soc/devices is of particular interest, as it contains a symlink for each SoC device found on the system. Each symlink points back into the aforementioned */sys/devices/socX* devices.

/sys/bus/soundwire/devices/sdw-master-<N>/revision

Defined on file *sysfs-bus-soundwire-master*

SoundWire Master-N DisCo properties. These properties are defined by MIPI DisCo Specification for SoundWire. They define various properties of the Master and are used by the bus to configure the Master. clk_stop_modes is a bitmask for simplifications and combines the clock-stop-mode0 and clock-stop-mode1 properties.

/sys/bus/soundwire/devices/sdw:.../dev-properties/mipi_revision

Defined on file *sysfs-bus-soundwire-slave*

SoundWire Slave DisCo properties. These properties are defined by MIPI DisCo Specification for SoundWire. They define various properties of the SoundWire Slave and are used by the bus to configure the Slave

/sys/bus/soundwire/devices/sdw:.../dp0/max_word

Defined on file *sysfs-bus-soundwire-slave*

SoundWire Slave Data Port-0 DisCo properties. These properties are defined by MIPI DisCo Specification for the SoundWire. They define various properties of the Data port 0 are used by the bus to configure the Data Port 0.

/sys/bus/soundwire/devices/sdw:.../dp<N>_src/max_word

Defined on file *sysfs-bus-soundwire-slave*

SoundWire Slave Data Source/Sink Port-N DisCo properties. These properties are defined by MIPI DisCo Specification for SoundWire. They define various properties of the Source/Sink Data port N and are used by the bus to configure the Data Port N.

/sys/bus/soundwire/devices/sdw:.../status

Defined on file *sysfs-bus-soundwire-slave*

SoundWire Slave status

These properties report the Slave status, e.g. if it is UNATTACHED or not, and in the latter case show the device_number. This status information is useful to detect devices exposed by platform firmware but not physically present on the bus, and conversely devices not exposed in platform firmware but enumerated.

/sys/bus/spi/<dev>/reset

Defined on file *sysfs-driver-ge-achc*

This file represents the microcontroller's reset line. 1 means the reset line is asserted, 0 means it's not asserted. The file is read and writable.

/sys/bus/spi/<dev>/update_firmware

Defined on file *sysfs-driver-ge-achc*

Write 1 to this file to update the ACHC microcontroller firmware via the EzPort interface. For this the kernel will load "achc.bin" via the firmware API (so usually from /lib/firmware). The write will block until the FW has either been flashed successfully or an error occurred.

/sys/bus/spi/devices/.../spi-nor/jedec_id

Defined on file *sysfs-bus-spi-devices-spi-nor*

(RO) The JEDEC ID of the SPI NOR flash as reported by the flash device.

The attribute is not present if the flash doesn't support the "Read JEDEC ID" command (9Fh). This is the case for non-JEDEC compliant flashes.

/sys/bus/spi/devices/.../spi-nor/manufacturer

Defined on file *sysfs-bus-spi-devices-spi-nor*

(RO) Manufacturer of the SPI NOR flash.

The attribute is not present if the flash device isn't known to the kernel and is only probed by its SFDP tables.

/sys/bus/spi/devices/.../spi-nor/partname

Defined on file *sysfs-bus-spi-devices-spi-nor*

(RO) Part name of the SPI NOR flash.

The attribute is optional. User space should not rely on it to be present or even correct. Instead, user space should read the jedec_id attribute.

/sys/bus/spi/devices/.../spi-nor/sfdp

Defined on file *sysfs-bus-spi-devices-spi-nor*

(RO) This attribute is only present if the SPI NOR flash device supports the "Read SFDP" command (5Ah).

If present, it contains the complete SFDP (serial flash discoverable parameters) binary data of the flash.

/sys/bus/surface_aggregator/devices/01:0e:01:00:01/state

Defined on file *sysfs-bus-surface_aggregator-tabletsw*

This attribute returns a string with the current type-cover or device posture, as indicated by the embedded controller. Currently returned posture states are:

- ”disconnected”: The type-cover has been disconnected.
- ”closed”: The type-cover has been folded closed and lies on top of the display.
- ”laptop”: The type-cover is open and in laptop-mode, i.e., ready for normal use.
- ”folded-canvas”: The type-cover has been folded back part-ways, but does not lie flush with the back side of the device. In general, this means that the kick-stand is used and extended atop of the cover.
- ”folded-back”: The type cover has been fully folded back and lies flush with the back side of the device.
- ”<unknown>”: The current state is unknown to the driver, for example due to newer as-of-yet unsupported hardware.

New states may be introduced with new hardware. Users therefore must not rely on this list of states being exhaustive and gracefully handle unknown states.

/sys/bus/surface_aggregator/devices/01:26:01:00:01/state

Defined on file *sysfs-bus-surface_aggregator-tabletsw*

This attribute returns a string with the current device posture, as indicated by the embedded controller. Currently returned posture states are:

- ”closed”: The lid of the device is closed.
- ”laptop”: The lid of the device is opened and the device operates as a normal laptop.
- ”slate”: The screen covers the keyboard or has been flipped back and the device operates mainly based on touch input.
- ”tablet”: The device operates as tablet and exclusively relies on touch input (or external peripherals).
- ”<unknown>”: The current state is unknown to the driver, for example due to newer as-of-yet unsupported hardware.

New states may be introduced with new hardware. Users therefore must not rely on this list of states being exhaustive and gracefully handle unknown states.

/sys/bus/tee/devices/optee-ta-<uuid>/

Defined on file *sysfs-bus-optee-devices*

OP-TEE bus provides reference to registered drivers under this directory. The <uuid> matches Trusted Application (TA) driver and corresponding TA in secure OS. Drivers are free to create needed API under optee-ta-<uuid> directory.

/sys/bus/tee/devices/optee-ta-<uuid>/need_supplicant

Defined on file *sysfs-bus-optee-devices*

Allows to distinguish whether an OP-TEE based TA/device requires user-space tee-supplicant to function properly or not. This attribute will be present for devices which depend on tee-supplicant to be running.

/sys/bus/thunderbolt/devices/.../authorized

Defined on file *sysfs-bus-thunderbolt*

This attribute is used to authorize Thunderbolt devices after they have been connected. If the device is not authorized, no PCIe devices are available to the system.

Contents of this attribute will be 0 when the device is not yet authorized.

Possible values are supported:

0	The device will be de-authorized (only supported if deauthorization attribute under domain contains 1)
1	The device will be authorized and connected

When key attribute contains 32 byte hex string the possible values are:

0	The device will be de-authorized (only supported if deauthorization attribute under domain contains 1)
1	The 32 byte hex string is added to the device NVM and the device is authorized.
2	Send a challenge based on the 32 byte hex string. If the challenge response from device is valid, the device is authorized. In case of failure errno will be ENOKEY if the device did not contain a key at all, and EKEYREJECTED if the challenge response did not match.

/sys/bus/thunderbolt/devices/.../boot

Defined on file *sysfs-bus-thunderbolt*

This attribute contains 1 if Thunderbolt device was already authorized on boot and 0 otherwise.

/sys/bus/thunderbolt/devices/.../device

Defined on file *sysfs-bus-thunderbolt*

This attribute contains id of this device extracted from the device DROM.

/sys/bus/thunderbolt/devices/.../device_name

Defined on file *sysfs-bus-thunderbolt*

This attribute contains name of this device extracted from the device DROM.

/sys/bus/thunderbolt/devices/.../domainX/boot_acl

Defined on file *sysfs-bus-thunderbolt*

Holds a comma separated list of device unique_ids that are allowed to be connected automatically during system startup (e.g boot devices). The list always contains maximum supported number of unique_ids where unused entries are empty. This allows the userspace software to determine how many entries the controller supports. If there are multiple controllers, each controller has its own ACL list and size may be different between the controllers.

System BIOS may have an option "Preboot ACL" or similar that needs to be selected before this list is taken into consideration.

Software always updates a full list in each write.

If a device is authorized automatically during boot its boot attribute is set to 1.

/sys/bus/thunderbolt/devices/.../domainX/deauthorization

Defined on file *sysfs-bus-thunderbolt*

This attribute tells whether the system supports de-authorization of devices. Value of 1 means user can de-authorize PCIe tunnel by writing 0 to authorized attribute under each device.

/sys/bus/thunderbolt/devices/.../domainX/iommu_dma_protection

Defined on file *sysfs-bus-thunderbolt*

This attribute tells whether the system uses IOMMU for DMA protection. Value of 1 means IOMMU is used 0 means it is not (DMA protection is solely based on Thunderbolt security levels).

/sys/bus/thunderbolt/devices/.../domainX/security

Defined on file *sysfs-bus-thunderbolt*

This attribute holds current Thunderbolt security level set by the system BIOS. Possible values are:

none	All devices are automatically authorized
user	Devices are only authorized based on writing appropriate value to the authorized attribute
secure	Require devices that support secure connect at minimum. User needs to authorize each device.
dponly	Automatically tunnel Display port (and USB). No PCIe tunnels are created.
usbonly	Automatically tunnel USB controller of the connected Thunderbolt dock (and Display Port). All PCIe links downstream of the dock are removed.
nopcie	USB4 system where PCIe tunneling is disabled from the BIOS.

/sys/bus/thunderbolt/devices/.../generation

Defined on file *sysfs-bus-thunderbolt*

This attribute contains the generation of the Thunderbolt controller associated with the device. It will contain 4 for USB4.

/sys/bus/thunderbolt/devices/.../key

Defined on file *sysfs-bus-thunderbolt*

When a devices supports Thunderbolt secure connect it will have this attribute. Writing 32 byte hex string changes authorization to use the secure connection method instead. Writing an empty string clears the key and regular connection method can be used again.

/sys/bus/thunderbolt/devices/.../maxhopid

Defined on file *sysfs-bus-thunderbolt*

Only set for XDomains. The maximum HopID the other host supports as its input HopID.

/sys/bus/thunderbolt/devices/.../nvm_authenticate

Defined on file *sysfs-bus-thunderbolt*

When new NVM image is written to the non-active NVM area (through non_activeX NVMem device), the authentication procedure is started by writing to this file. If everything goes well, the device is restarted with the new NVM firmware. If the image verification fails an error code is returned instead.

This file will accept writing values "1", "2" or "3".

- Writing "1" will flush the image to the storage area and authenticate the image in one action.
- Writing "2" will run some basic validation on the image and flush it to the storage area.
- Writing "3" will authenticate the image that is currently written in the storage area. This is only supported with USB4 devices and retimers.

When read holds status of the last authentication operation if an error occurred during the process. This is directly the status value from the DMA configuration based mailbox before the device is power cycled. Writing 0 here clears the status.

/sys/bus/thunderbolt/devices/.../nvm_authenticate_on_disconnect

Defined on file *sysfs-bus-thunderbolt*

For supported devices, automatically authenticate the new Thunderbolt image when the device is disconnected from the host system.

This file will accept writing values "1" or "2"

- Writing "1" will flush the image to the storage area and prepare the device for authentication on disconnect.
- Writing "2" will run some basic validation on the image and flush it to the storage area.

/sys/bus/thunderbolt/devices/.../nvm_version

Defined on file *sysfs-bus-thunderbolt*

If the device has upgradeable firmware the version number is available here. Format: %x.%x, major.minor. If the device is in safe mode reading the file returns -ENODATA instead as the NVM version is not available.

/sys/bus/thunderbolt/devices/.../rx_lanes

Defined on file *sysfs-bus-thunderbolt*

This attribute reports number of RX lanes the device is using simultaneously through its upstream port.

/sys/bus/thunderbolt/devices/.../rx_speed

Defined on file *sysfs-bus-thunderbolt*

This attribute reports the device RX speed per lane. All RX lanes run at the same speed.

/sys/bus/thunderbolt/devices/.../tx_lanes

Defined on file *sysfs-bus-thunderbolt*

This attribute reports number of TX lanes the device is using simultaneously through its upstream port.

/sys/bus/thunderbolt/devices/.../tx_speed

Defined on file *sysfs-bus-thunderbolt*

This attribute reports the TX speed per lane. All TX lanes run at the same speed.

/sys/bus/thunderbolt/devices/.../unique_id

Defined on file *sysfs-bus-thunderbolt*

This attribute contains unique_id string of this device. This is either read from hardware registers (UUID on newer hardware) or based on UID from the device DROM. Can be used to uniquely identify particular device.

/sys/bus/thunderbolt/devices/.../vendor

Defined on file *sysfs-bus-thunderbolt*

This attribute contains vendor id of this device extracted from the device DROM.

/sys/bus/thunderbolt/devices/.../vendor_name

Defined on file *sysfs-bus-thunderbolt*

This attribute contains vendor name of this device extracted from the device DROM.

/sys/bus/thunderbolt/devices/<device>:<port>.<index>/device

Defined on file *sysfs-bus-thunderbolt*

Retimer device identifier read from the hardware.

/sys/bus/thunderbolt/devices/<device>:<port>.<index>/nvm_authenticate

Defined on file *sysfs-bus-thunderbolt*

When new NVM image is written to the non-active NVM area (through non_activeX NVMem device), the authentication procedure is started by writing 1 to this file. If everything goes well, the device is restarted with the new NVM firmware. If the image verification fails an error code is returned instead.

When read holds status of the last authentication operation if an error occurred during the process. Format: %x.

/sys/bus/thunderbolt/devices/<device>:<port>.<index>/nvm_version

Defined on file *sysfs-bus-thunderbolt*

Holds retimer NVM version number. Format: %x.%x, major.minor.

/sys/bus/thunderbolt/devices/<device>:<port>.<index>/vendor

Defined on file *sysfs-bus-thunderbolt*

Retimer vendor identifier read from the hardware.

/sys/bus/thunderbolt/devices/<xdomain>.<service>/key

Defined on file *sysfs-bus-thunderbolt*

This contains name of the property directory the XDomain service exposes. This entry describes the protocol in question. Following directories are already reserved by the Apple XDomain specification:

network	IP/ethernet over Thunderbolt
targetdm	Target disk mode protocol over Thunderbolt
extdisp	External display mode protocol over Thunderbolt

/sys/bus/thunderbolt/devices/<xdomain>.<service>/modalias

Defined on file *sysfs-bus-thunderbolt*

Stores the same MODALIAS value emitted by uevent for the XDomain service. Format: tbtsvc:kSpNvNrN

/sys/bus/thunderbolt/devices/<xdomain>.<service>/prtcid

Defined on file *sysfs-bus-thunderbolt*

This contains XDomain protocol identifier the XDomain service supports.

/sys/bus/thunderbolt/devices/<xdomain>.<service>/prtcrevs

Defined on file *sysfs-bus-thunderbolt*

This contains XDomain software version the XDomain service supports.

/sys/bus/thunderbolt/devices/<xdomain>.<service>/prtcstns

Defined on file *sysfs-bus-thunderbolt*

This contains XDomain service specific settings as bitmask. Format: %x

/sys/bus/thunderbolt/devices/<xdomain>.<service>/prtcvers

Defined on file *sysfs-bus-thunderbolt*

This contains XDomain protocol version the XDomain service supports.

/sys/bus/thunderbolt/devices/usb4_portX/connector

Defined on file *sysfs-bus-thunderbolt*

Symlink to the USB Type-C connector. This link is only created when USB Type-C Connector Class is enabled, and only if the system firmware is capable of describing the connection between a port and its connector.

/sys/bus/thunderbolt/devices/usb4_portX/link

Defined on file *sysfs-bus-thunderbolt*

Returns the current link mode. Possible values are ”usb4”, ”tbt” and ”none”.

/sys/bus/thunderbolt/devices/usb4_portX/offline

Defined on file *sysfs-bus-thunderbolt*

Writing 1 to this attribute puts the USB4 port into offline mode. Only allowed when there is nothing connected to the port (link attribute returns ”none”). Once the port is in offline mode it does not receive any hotplug events. This is used to update NVM firmware of on-board retimers. Writing 0 puts the port back to online mode.

This attribute is only visible if the platform supports powering on retimers when there is no cable connected.

/sys/bus/thunderbolt/devices/usb4_portX/rescan

Defined on file *sysfs-bus-thunderbolt*

When the USB4 port is in offline mode writing 1 to this attribute forces rescan of the sideband for on-board retimers. Each retimer appear under the USB4 port as if the USB4 link was up. These retimers act in the same way as if the cable was connected so upgrading their NVM firmware can be done the usual way.

/sys/bus/typec/devices/.../active

Defined on file *sysfs-bus-typec*

Shows if the mode is active or not. The attribute can be used for entering/exiting the mode. Entering/exiting modes is supported as synchronous operation so write(2) to the attribute does not return until the enter/exit mode operation has finished. The attribute is notified when the mode is entered/exited so poll(2) on the attribute wakes up. Entering/exiting a mode will also generate uevent KOBJ_CHANGE.

Valid values are boolean.

/sys/bus/typec/devices/.../description

Defined on file *sysfs-bus-typec*

Shows description of the mode. The description is optional for the drivers, just like with the Billboard Devices.

/sys/bus/typec/devices/.../displayport/configuration

Defined on file *sysfs-driver-typec-displayport*

Shows the current DisplayPort configuration for the connector. Valid values are USB, source and sink. Source means DisplayPort source, and sink means DisplayPort sink.

All supported configurations are listed as space separated list with the active one wrapped in square brackets.

Source example:

USB [source] sink

The configuration can be changed by writing to the file

Note. USB configuration does not equal to Exit Mode. It is separate configuration defined in VESA DisplayPort Alt Mode on USB Type-C Standard. Functionally it equals to the situation where the mode has been exited (to exit the mode, see *testing/sysfs-bus-typec*, and use file /sys/bus/typec/devices/.../active).

/sys/bus/typec/devices/.../displayport/hpd

Defined on file *sysfs-driver-typec-displayport*

VESA DisplayPort Alt Mode on USB Type-C Standard defines how HotPlugDetect(HPD) shall be supported on the USB-C connector when operating in DisplayPort Alt Mode. This is a read only node which reflects the current state of HPD.

Valid values:

- **1: when HPD's logical state is high (HPD_High) as defined** by VESA DisplayPort Alt Mode on USB Type-C Standard.
- **0 when HPD's logical state is low (HPD_Low) as defined by** VESA DisplayPort Alt Mode on USB Type-C Standard.

/sys/bus/typec/devices/.../displayport/pin_assignment

Defined on file *sysfs-driver-typec-displayport*

VESA DisplayPort Alt Mode on USB Type-C Standard defines six different pin assignments for USB Type-C connector that are labeled A, B, C, D, E, and F. The supported pin assignments are listed as space separated list with the active one wrapped in square brackets.

Example:

C [D]

Pin assignment can be changed by writing to the file. It is possible to set pin assignment before configuration has been set, but the assignment will not be active before the connector is actually configured.

Note. As of VESA DisplayPort Alt Mode on USB Type-C Standard version 1.0b, pin assignments A, B, and F are deprecated. Only pin assignment D can now carry simultaneously one channel of USB SuperSpeed protocol. From user perspective pin assignments C and E are equal, where all channels on the connector are used for carrying DisplayPort protocol (allowing higher resolutions).

/sys/bus/typec/devices/.../mode

Defined on file *sysfs-bus-typec*

The index number of the mode returned by Discover Modes USB Power Delivery command. Depending on the alternate mode, the mode index may be significant.

With some alternate modes (SVIDs), the mode index is assigned for specific functionality in the specification for that alternate mode.

With other alternate modes, the mode index values are not assigned, and can not be therefore used for identification. When the mode index is not assigned, identifying the alternate mode must be done with either mode VDO or the description.

/sys/bus/typec/devices/.../svid

Defined on file *sysfs-bus-typec*

The Standard or Vendor ID (SVID) assigned by USB-IF for this alternate mode.

/sys/bus/typec/devices/.../vdo

Defined on file *sysfs-bus-typec*

Shows the VDO in hexadecimal returned by Discover Modes command for this mode.

/sys/bus/usb-serial/drivers/.../new_id

Defined on file *sysfs-bus-usb*

For serial USB drivers, this attribute appears under the extra bus folder ”usb-serial” in sysfs; apart from that difference, all descriptions from the entry ”/sys/bus/usb/drivers/.../new_id” apply.

/sys/bus/usb/.../decimals

Defined on file *sysfs-bus-usb-devices-usbsevseg*

Controls the decimal places on the device. To set the nth decimal place, give this field the value of `10 ** n`. Assume this field has the value k and has 1 or more decimal places set, to set the mth place (where m is not already set), change this fields value to `k + 10 ** m`.

/sys/bus/usb/.../mode_msb
/sys/bus/usb/.../mode_lsb

Defined on file *sysfs-bus-usb-devices-usbsevseg*

Controls the devices display mode. For a 6 character display the values are

MSB 0x06; LSB 0x3F, and

for an 8 character display the values are

MSB 0x08; LSB 0xFF.

/sys/bus/usb/.../powered

Defined on file *sysfs-bus-usb-devices-usbsevseg*

Controls whether the device's display will powered. A value of 0 is off and a non-zero value is on.

/sys/bus/usb/.../text

Defined on file *sysfs-bus-usb-devices-usbsevseg*

The text (or data) for the device to display

/sys/bus/usb/.../textmode

Defined on file *sysfs-bus-usb-devices-usbsevseg*

Controls the way the device interprets its text buffer. raw: each character controls its segment manually hex: each character is between 0-15 ascii: each character is between '0'-'9' and 'A'-'F'.

/sys/bus/usb/device/.../authorized

Defined on file *sysfs-bus-usb*

Authorized devices are available for use by device drivers, non-authorized one are not. By default, wired USB devices are authorized.

/sys/bus/usb/devices/.../<hub_interface>/port<X>

Defined on file *sysfs-bus-usb*

The /sys/bus/usb/devices/.../<hub_interface>/port<X> is usb port device's sysfs directory.

/sys/bus/usb/devices/.../<hub_interface>/port<X>/connect_type

Defined on file *sysfs-bus-usb*

Some platforms provide usb port connect types through ACPI. This attribute is to expose these information to user space. The file will read ”hotplug”, ”hardwired” and ”not used” if the information is available, and ”unknown” otherwise.

/sys/bus/usb/devices/.../<hub_interface>/port<X>/connector

Defined on file *sysfs-bus-usb*

Link to the USB Type-C connector when available. This link is only created when USB Type-C Connector Class is enabled, and only if the system firmware is capable of describing the connection between a port and its connector.

/sys/bus/usb/devices/.../<hub_interface>/port<X>/disable

Defined on file *sysfs-bus-usb*

This file controls the state of a USB port, including Vbus power output (but only on hubs that support power switching -- most hubs don't support it). If a port is disabled, the port is unusable: Devices attached to the port will not be detected, initialized, or enumerated.

/sys/bus/usb/devices/.../<hub_interface>/port<X>/early_stop

Defined on file *sysfs-bus-usb*

Some USB hosts have some watchdog mechanisms so that the device may enter ramdump if it takes a long time during port initialization. This attribute allows each port just has two attempts so that the port initialization will be failed quickly. In addition, if a port which is marked with early_stop has failed to initialize, it will ignore all future connections until this attribute is clear.

/sys/bus/usb/devices/.../<hub_interface>/port<X>/location

Defined on file *sysfs-bus-usb*

Some platforms provide usb port physical location through firmware. This is used by the kernel to pair up logical ports mapping to the same physical connector. The attribute exposes the raw location value as a hex integer.

/sys/bus/usb/devices/.../<hub_interface>/port<X>/over_current_count

Defined on file *sysfs-bus-usb*

Most hubs are able to detect over-current situations on their ports and report them to the kernel. This attribute is to expose the number of over-current situation occurred on a specific port to user space. This file will contain an unsigned 32 bit value which wraps to 0 after its maximum is reached. This file supports poll() for monitoring changes to this value in user space.

Any time this value changes the corresponding hub device will send a udev event with the following attributes:

```
OVER_CURRENT_PORT=/sys/bus/usb/devices/.../<hub_interface>/port<X>
OVER_CURRENT_COUNT=[current value of this sysfs attribute]
```

/sys/bus/usb/devices/.../<hub_interface>/port<X>/quirks

Defined on file *sysfs-bus-usb*

In some cases, we care about time-to-active for devices connected on a specific port (e.g. non-standard USB port like pogo pins), where the device to be connected is known in advance, and behaves well according to the specification. This attribute is a bit-field that controls the behavior of a specific port:

- Bit 0 of this field selects the "old" enumeration scheme, as it is considerably faster (it only causes one USB reset instead of 2).

  The old enumeration scheme can also be selected globally using /sys/module/usbcore/parameters/old_scheme_first, but it is often not desirable as the new scheme was introduced to increase compatibility with more devices.

- Bit 1 reduces TRSTRCY to the 10 ms that are required by the USB 2.0 specification, instead of the 50 ms that are normally used to help make enumeration work better on some high speed devices.

/sys/bus/usb/devices/.../<hub_interface>/port<X>/state

Defined on file *sysfs-bus-usb*

Indicates current state of the USB device attached to the port. Valid states are: 'not-attached', 'attached', 'powered', 'reconnecting', 'unauthenticated', 'default', 'addressed', 'configured', and 'suspended'. This file supports poll() to monitor the state change from user space.

/sys/bus/usb/devices/.../<hub_interface>/port<X>/usb3_lpm_permit

Defined on file *sysfs-bus-usb*

Some USB3.0 devices are not friendly to USB3 LPM. usb3_lpm_permit attribute allows enabling/disabling usb3 lpm of a port. It takes effect both before and after a usb device is enumerated. Supported values are "0" if both u1 and u2 are NOT permitted, "u1" if only u1 is permitted, "u2" if only u2 is permitted, "u1_u2" if both u1 and u2 are permitted.

/sys/bus/usb/devices/.../enable_compliance

Defined on file *sysfs-bus-usb-lvstest*

Write to this node to set the port to compliance mode to test with Link Layer Validation device. It is needed for TD.7.34.

/sys/bus/usb/devices/.../get_dev_desc

Defined on file *sysfs-bus-usb-lvstest*

Write to this node to issue "Get Device Descriptor" for Link Layer Validation device. It is needed for TD.7.06.

/sys/bus/usb/devices/.../hot_reset

Defined on file *sysfs-bus-usb-lvstest*

Write to this node to issue "Reset" for Link Layer Validation device. It is needed for TD.7.29, TD.7.31, TD.7.34 and TD.7.35.

/sys/bus/usb/devices/.../ltm_capable

Defined on file *sysfs-bus-usb*

USB 3.0 devices may optionally support Latency Tolerance Messaging (LTM). They indicate their support by setting a bit in the bmAttributes field of their SuperSpeed BOS descriptors. If that bit is set for the device, ltm_capable will read "yes". If the device doesn't support LTM, the file will read "no". The file will be present for all speeds of USB devices, and will always read "no" for USB 1.1 and USB 2.0 devices.

/sys/bus/usb/devices/.../power/usb2_hardware_lpm

Defined on file *sysfs-bus-usb*

If CONFIG_PM is set and a USB 2.0 lpm-capable device is plugged in to a xHCI host which support link PM, it will perform a LPM test; if the test is passed and host supports USB2 hardware LPM (xHCI 1.0 feature), USB2 hardware LPM will be enabled for the device and the USB device directory will contain a file named power/usb2_hardware_lpm. The file holds a string value (enable or disable) indicating whether or not USB2 hardware LPM is enabled for the device. Developer can write y/Y/1 or n/N/0 to the file to enable/disable the feature.

/sys/bus/usb/devices/.../power/usb2_lpm_besl

Defined on file *sysfs-bus-usb*

USB 2.0 devices that support hardware link power management (LPM) L1 sleep state now use a best effort service latency value (BESL) to indicate the best effort to resumption of service to the device after the initiation of the resume event. If the device does not have a preferred besl value then the host can select one instead. This usb2_lpm_besl attribute allows to tune the host selected besl value in order to tune power saving and service latency.

Supported values are 0 - 15. More information on how besl values map to microseconds can be found in USB 2.0 ECN Errata for Link Power Management, section 4.10)

/sys/bus/usb/devices/.../power/usb2_lpm_l1_timeout

Defined on file *sysfs-bus-usb*

USB 2.0 devices may support hardware link power management (LPM) L1 sleep state. The usb2_lpm_l1_timeout attribute allows tuning the timeout for L1 inactivity timer (LPM timer), e.g. needed inactivity time before host requests the device to go to L1 sleep. Useful for power management tuning. Supported values are 0 - 65535 microseconds.

/sys/bus/usb/devices/.../power/usb3_hardware_lpm_u1

Defined on file *sysfs-bus-usb*

If CONFIG_PM is set and a USB 3.0 lpm-capable device is plugged in to a xHCI host which supports link PM, it will check if U1 and U2 exit latencies have been set in the BOS descriptor; if the check is passed and the host supports USB3 hardware LPM, USB3 hardware LPM will be enabled for the device and the USB device directory will contain two files named power/usb3_hardware_lpm_u1 and power/usb3_hardware_lpm_u2. These files hold a string value (enable or disable) indicating whether or not USB3 hardware LPM U1 or U2 is enabled for the device.

/sys/bus/usb/devices/.../rx_lanes

Defined on file *sysfs-bus-usb*

Number of rx lanes the device is using. USB 3.2 adds Dual-lane support, 2 rx and 2 tx lanes over Type-C. Inter-Chip SSIC devices support asymmetric lanes up to 4 lanes per direction. Devices before USB 3.2 are single lane (rx_lanes = 1)

/sys/bus/usb/devices/.../tx_lanes

Defined on file *sysfs-bus-usb*

Number of tx lanes the device is using. USB 3.2 adds Dual-lane support, 2 rx and 2 tx -lanes over Type-C. Inter-Chip SSIC devices support asymmetric lanes up to 4 lanes per direction. Devices before USB 3.2 are single lane (tx_lanes = 1)

/sys/bus/usb/devices/.../typec

Defined on file *sysfs-bus-usb*

Symlink to the USB Type-C partner device. USB Type-C partner represents the component that communicates over the Configuration Channel (CC signal on USB Type-C connectors and cables) with the local port.

/sys/bus/usb/devices/.../u1_timeout

Defined on file *sysfs-bus-usb-lvstest*

Set "U1 timeout" for the downstream port where Link Layer Validation device is connected. Timeout value must be between 0 and 127. It is needed for TD.7.18, TD.7.19, TD.7.20 and TD.7.21.

/sys/bus/usb/devices/.../u2_timeout

Defined on file *sysfs-bus-usb-lvstest*

Set "U2 timeout" for the downstream port where Link Layer Validation device is connected. Timeout value must be between 0 and 127. It is needed for TD.7.18, TD.7.19, TD.7.20 and TD.7.21.

/sys/bus/usb/devices/.../u3_entry

Defined on file *sysfs-bus-usb-lvstest*

Write to this node to issue "U3 entry" for Link Layer Validation device. It is needed for TD.7.35 and TD.7.36.

/sys/bus/usb/devices/.../u3_exit

Defined on file *sysfs-bus-usb-lvstest*

Write to this node to issue "U3 exit" for Link Layer Validation device. It is needed for TD.7.36.

/sys/bus/usb/devices/.../warm_reset

Defined on file *sysfs-bus-usb-lvstest*

Write to this node to issue "Warm Reset" for Link Layer Validation device. It may be needed to properly reset an xHCI 1.1 host port if compliance mode needed to be explicitly enabled.

/sys/bus/usb/devices/<INTERFACE>/authorized

Defined on file *sysfs-bus-usb*

This allows to authorize (1) or deauthorize (0) individual interfaces instead a whole device in contrast to the device authorization. If a deauthorized interface will be authorized so the driver probing must be triggered manually by writing INTERFACE to /sys/bus/usb/drivers_probe This allows to avoid side-effects with drivers that need multiple interfaces.

A deauthorized interface cannot be probed or claimed.

/sys/bus/usb/devices/<INTERFACE>/wireless_status

Defined on file *sysfs-bus-usb*

Some USB devices use a USB receiver dongle to communicate wirelessly with their device using proprietary protocols. This attribute allows user-space to know whether the device is connected to its receiver dongle, and, for example, consider the device to be absent when choosing whether to show the device's battery, show a headset in a list of outputs, or show an on-screen keyboard if the only wireless keyboard is turned off. This attribute is not to be used to replace protocol specific statuses available in WWAN, WLAN/Wi-Fi, Bluetooth, etc. If the device does not use a receiver dongle with a wireless device, then this attribute will not exist.

/sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/country
/sys/class/bluetooth/hci<addr>/<hid-bus>:<vendor-id>:<product-id>.<num>/country
/sys/class/hidraw/hidraw<num>/device/country

Defined on file *sysfs-driver-hid*

When read, this file returns the hex integer value in ASCII of the device's HID country code (e.g. 21 for US). This file cannot be written.

/sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/dragging

Defined on file *sysfs-driver-hid-lenovo*

If this setting is enabled, it is possible to do dragging by pressing the trackpoint. This requires press_to_select to be enabled.

Values are 0 or 1.

Applies to Thinkpad USB Keyboard with TrackPoint.

/sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/fb_update_rate

Defined on file *sysfs-driver-hid-picolcd*

Make it possible to adjust defio refresh rate.

Reading: returns list of available refresh rates (expressed in Hz), the active refresh rate being enclosed in brackets ('[' and ']')

Writing: accepts new refresh rate expressed in integer Hz within permitted rates.

Note: As device can barely do 2 complete refreshes a second it only makes sense to adjust this value if only one or two tiles get changed and it's not appropriate to expect the application to flush its tiny changes explicitly at higher than default rate.

/sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/fn_lock

Defined on file *sysfs-driver-hid-lenovo*

This setting controls whether Fn Lock is enabled on the keyboard (i.e. if F1 is Mute or F1)

Values are 0 or 1

Applies to ThinkPad Compact (USB|Bluetooth) Keyboard with TrackPoint.

/sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/kone/roccatkone<minor>/actual_dpi

Defined on file *sysfs-driver-hid-roccat-kone*

It is possible to switch the dpi setting of the mouse with the press of a button.

When read, this file returns the raw number of the actual dpi setting reported by the mouse. This number has to be further processed to receive the real dpi value:

VALUE	DPI
1	800
2	1200
3	1600
4	2000
5	2400
6	3200

This file is readonly.

Users: http://roccat.sourceforge.net

/sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/kone/roccatkone<minor>/actual_profile

Defined on file *sysfs-driver-hid-roccat-kone*

When read, this file returns the number of the actual profile.

This file is readonly.

Users: http://roccat.sourceforge.net

/sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/kone/roccatkone<minor>/firmware_version

Defined on file *sysfs-driver-hid-roccat-kone*

When read, this file returns the raw integer version number of the firmware reported by the mouse. Using the integer value eases further usage in other programs. To receive the real version number the decimal point has to be shifted 2 positions to the left. E.g. a returned value of 138 means 1.38

This file is readonly.

Users: http://roccat.sourceforge.net

/sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/kone/roccatkone<minor>/profile[1-5]

Defined on file *sysfs-driver-hid-roccat-kone*

The mouse can store 5 profiles which can be switched by the press of a button. A profile holds information like button mappings, sensitivity, the colors of the 5 leds and light effects.

When read, these files return the respective profile. The returned data is 975 bytes in size.

When written, this file lets one write the respective profile data back to the mouse. The data has to be 975 bytes long.

The mouse will reject invalid data, whereas the profile number stored in the profile doesn't need to fit the number of the store.

Users: http://roccat.sourceforge.net

/sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/kone/roccatkone<minor>/settings

Defined on file *sysfs-driver-hid-roccat-kone*

When read, this file returns the settings stored in the mouse. The size of the data is 36 bytes and holds information like the startup_profile, tcu state and calibration_data.

When written, this file lets write settings back to the mouse. The data has to be 36 bytes long. The mouse will reject invalid data.

Users: http://roccat.sourceforge.net

/sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/kone/roccatkone<minor>/startup_profile

Defined on file *sysfs-driver-hid-roccat-kone*

The integer value of this attribute ranges from 1 to 5.

When read, this attribute returns the number of the profile that's active when the mouse is powered on.

When written, this file sets the number of the startup profile and the mouse activates this profile immediately.

Users: http://roccat.sourceforge.net

/sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/kone/roccatkone<minor>/tcu

Defined on file *sysfs-driver-hid-roccat-kone*

The mouse has a ”Tracking Control Unit” which lets the user calibrate the laser power to fit the mousepad surface. When read, this file returns the current state of the TCU, where 0 means off and 1 means on.

Writing 0 in this file will switch the TCU off.

Writing 1 in this file will start the calibration which takes around 6 seconds to complete and activates the TCU.

Users: http://roccat.sourceforge.net

/sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/kone/roccatkone<minor>/weight

Defined on file *sysfs-driver-hid-roccat-kone*

The mouse can be equipped with one of four supplied weights ranging from 5 to 20 grams which are recognized by the mouse and its value can be read out. When read, this file returns the raw value returned by the mouse which eases further processing in other software.

The values map to the weights as follows:

VALUE	WEIGHT
0	none
1	5g
2	10g
3	15g
4	20g

This file is readonly.

Users: http://roccat.sourceforge.net

/sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/operation_mode

Defined on file *sysfs-driver-hid-picolcd*

Make it possible to switch the PicoLCD device between LCD (firmware) and bootloader (flasher) operation modes.

Reading: returns list of available modes, the active mode being enclosed in brackets ('[' and ']')

Writing: causes operation mode switch. Permitted values are the non-active mode names listed when read.

Note: when switching mode the current PicoLCD HID device gets disconnected and reconnects after above delay (see attribute operation_mode_delay for its value).

/sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/operation_mode_delay

Defined on file *sysfs-driver-hid-picolcd*

Delay PicoLCD waits before restarting in new mode when operation_mode has changed.

Reading/Writing: It is expressed in ms and permitted range is 0..30000ms.

/sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/press_speed

Defined on file *sysfs-driver-hid-lenovo*

This setting controls how fast the trackpoint needs to be pressed to generate a mouse click if press_to_select is enabled.

Values are decimal integers from 1 (slowest) to 255 (fastest).

Applies to Thinkpad USB Keyboard with TrackPoint.

/sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/press_to_select

Defined on file *sysfs-driver-hid-lenovo*

This controls if mouse clicks should be generated if the trackpoint is quickly pressed. How fast this press has to be is being controlled by press_speed.

Values are 0 or 1.

Applies to Thinkpad USB Keyboard with TrackPoint.

/sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/quirks

Defined on file *sysfs-driver-hid-multitouch*

The integer value of this attribute corresponds to the quirks actually in place to handle the device's protocol. When read, this attribute returns the current settings (see MT_QUIRKS_* in hid-multitouch.c). When written this attribute change on the fly the quirks, then the protocol to handle the device.

/sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/release_to_select

Defined on file *sysfs-driver-hid-lenovo*

For details regarding this setting please refer to http://www.pc.ibm.com/ww/healthycomputing/trkpntb.html Values are 0 or 1. Applies to Thinkpad USB Keyboard with TrackPoint.

/sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/report_descriptor
/sys/class/bluetooth/hci<addr>/<hid-bus>:<vendor-id>:<product-id>.<num>/report_descriptor
/sys/class/hidraw/hidraw<num>/device/report_descriptor

Defined on file *sysfs-driver-hid*

When read, this file returns the device's raw binary HID report descriptor. This file cannot be written.

Users: HIDAPI library (http://www.signal11.us/oss/hidapi)

/sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/select_right

Defined on file *sysfs-driver-hid-lenovo*

This setting controls if the mouse click events generated by pressing the trackpoint (if press_to_select is enabled) generate a left or right mouse button click.

Values are 0 or 1.

Applies to Thinkpad USB Keyboard with TrackPoint.

/sys/bus/usb/devices/<busnum>-<devnum>:<config num>.<interface num>/<hid-bus>:<vendor-id>:<product-id>.<num>/sensitivity

Defined on file *sysfs-driver-hid-lenovo*

This file contains the trackpoint sensitivity. Values are decimal integers from 1 (lowest sensitivity) to 255 (highest sensitivity). Applies to Thinkpad USB Keyboard with TrackPoint.

/sys/bus/usb/devices/usbX/avoid_reset_quirk

Defined on file *sysfs-bus-usb*

Most devices have this set to zero.

If the value is 1, enable a USB quirk that prevents this device to use reset.

(read/write)

/sys/bus/usb/devices/usbX/bAlternateSetting

Defined on file *sysfs-bus-usb*

The current interface alternate setting number, in decimal.

See USB specs for its meaning.

/sys/bus/usb/devices/usbX/bConfigurationValue

Defined on file *sysfs-bus-usb*

While a USB device typically have just one configuration setting, some devices support multiple configurations.

This value shows the current configuration, in decimal.

Changing its value will change the device's configuration to another setting.

The number of configurations supported by a device is at:

/sys/bus/usb/devices/usbX/bNumConfigurations

See USB specs for its meaning.

/sys/bus/usb/devices/usbX/bDeviceClass

Defined on file *sysfs-bus-usb*

Class code of the device, in hexadecimal.

See USB specs for its meaning.

/sys/bus/usb/devices/usbX/bDeviceProtocol

Defined on file *sysfs-bus-usb*

Protocol code of the device, in hexadecimal.

See USB specs for its meaning.

/sys/bus/usb/devices/usbX/bDeviceSubClass

Defined on file *sysfs-bus-usb*

Subclass code of the device, in hexadecimal.

See USB specs for its meaning.

/sys/bus/usb/devices/usbX/bInterfaceClass

Defined on file *sysfs-bus-usb*

Class code of the interface, in hexadecimal.

See USB specs for its meaning.

/sys/bus/usb/devices/usbX/bInterfaceNumber

Defined on file *sysfs-bus-usb*

Interface number, in hexadecimal.

See USB specs for its meaning.

/sys/bus/usb/devices/usbX/bInterfaceProtocol

Defined on file *sysfs-bus-usb*

Protocol code of the interface, in hexadecimal.

See USB specs for its meaning.

/sys/bus/usb/devices/usbX/bInterfaceSubClass

Defined on file *sysfs-bus-usb*

Subclass code of the interface, in hexadecimal.

See USB specs for its meaning.

/sys/bus/usb/devices/usbX/bMaxPacketSize0

Defined on file *sysfs-bus-usb*

Maximum endpoint 0 packet size, in decimal.

See USB specs for its meaning.

/sys/bus/usb/devices/usbX/bMaxPower

Defined on file *sysfs-bus-usb*

Maximum power consumption of the active configuration of the device, in miliamperes.

/sys/bus/usb/devices/usbX/bNumConfigurations

Defined on file *sysfs-bus-usb*

Number of the possible configurations of the device, in decimal. The current configuration is controlled via:

/sys/bus/usb/devices/usbX/bConfigurationValue

See USB specs for its meaning.

/sys/bus/usb/devices/usbX/bNumEndpoints

Defined on file *sysfs-bus-usb*

Number of endpoints used on this interface, in hexadecimal.

See USB specs for its meaning.

/sys/bus/usb/devices/usbX/bNumInterfaces

Defined on file *sysfs-bus-usb*

Number of interfaces on this device, in decimal.

/sys/bus/usb/devices/usbX/bcdDevice

Defined on file *sysfs-bus-usb*

The device's release number, in hexadecimal.

See USB specs for its meaning.

/sys/bus/usb/devices/usbX/bmAttributes

Defined on file *sysfs-bus-usb*

Attributes of the current configuration, in hexadecimal.

See USB specs for its meaning.

/sys/bus/usb/devices/usbX/busnum

Defined on file *sysfs-bus-usb*

Number of the bus.

/sys/bus/usb/devices/usbX/configuration

Defined on file *sysfs-bus-usb*

Contents of the string descriptor associated with the current configuration. It may include the firmware version of a device and/or its serial number.

/sys/bus/usb/devices/usbX/descriptors

Defined on file *sysfs-bus-usb*

Contains the interface descriptors, in binary.

/sys/bus/usb/devices/usbX/devnum

Defined on file *sysfs-bus-usb*

USB interface device number, in decimal.

/sys/bus/usb/devices/usbX/devpath

Defined on file *sysfs-bus-usb*

String containing the USB interface device path.

/sys/bus/usb/devices/usbX/devspec

Defined on file *sysfs-bus-usb*

Displays the Device Tree Open Firmware node of the interface.

/sys/bus/usb/devices/usbX/ep_<N>/bEndpointAddress

Defined on file *sysfs-bus-usb*

The address of the endpoint described by this descriptor, in hexadecimal. The endpoint direction on this bitmapped field is also shown at:

/sys/bus/usb/devices/usbX/ep_<N>/direction

See USB specs for its meaning.

/sys/bus/usb/devices/usbX/ep_<N>/bInterval

Defined on file *sysfs-bus-usb*

The interval of the endpoint as described on its descriptor, in hexadecimal. The actual interval depends on the version of the USB. Also shown in time units at */sys/bus/usb/devices/usbX/ep_<N>/interval*.

/sys/bus/usb/devices/usbX/ep_<N>/bLength

Defined on file *sysfs-bus-usb*

Number of bytes of the endpoint descriptor, in hexadecimal.

/sys/bus/usb/devices/usbX/ep_<N>/bmAttributes

Defined on file *sysfs-bus-usb*

Attributes which apply to the endpoint as described on its descriptor, in hexadecimal. The endpoint type on this bitmapped field is also shown at:

/sys/bus/usb/devices/usbX/ep_<N>/type

See USB specs for its meaning.

/sys/bus/usb/devices/usbX/ep_<N>/direction

Defined on file *sysfs-bus-usb*

Direction of the endpoint. Can be:

- both (on control endpoints)
- in
- out

/sys/bus/usb/devices/usbX/ep_<N>/interval

Defined on file *sysfs-bus-usb*

Interval for polling endpoint for data transfers, in milisseconds or microseconds.

/sys/bus/usb/devices/usbX/ep_<N>/type

Defined on file *sysfs-bus-usb*

Descriptor type. Can be:

- Control
- Isoc
- Bulk
- Interrupt
- unknown

/sys/bus/usb/devices/usbX/ep_<N>/wMaxPacketSize

Defined on file *sysfs-bus-usb*

Maximum packet size this endpoint is capable of sending or receiving, in hexadecimal.

/sys/bus/usb/devices/usbX/idProduct

Defined on file *sysfs-bus-usb*

Product ID, in hexadecimal.

/sys/bus/usb/devices/usbX/idVendor

Defined on file *sysfs-bus-usb*

Vendor ID, in hexadecimal.

/sys/bus/usb/devices/usbX/interface_authorized_default

Defined on file *sysfs-bus-usb*

This is used as value that determines if interfaces would be authorized by default. The value can be 1 or 0. It's by default 1.

/sys/bus/usb/devices/usbX/manufacturer

Defined on file *sysfs-bus-usb*

Vendor specific string containing the name of the manufacturer of the device.

/sys/bus/usb/devices/usbX/maxchild

Defined on file *sysfs-bus-usb*

Number of ports of an USB hub

/sys/bus/usb/devices/usbX/persist

Defined on file *sysfs-bus-usb*

Keeps the device even if it gets disconnected.

/sys/bus/usb/devices/usbX/power/active_duration

Defined on file *sysfs-bus-usb*

The total time the device has not been suspended.

/sys/bus/usb/devices/usbX/power/autosuspend

Defined on file *sysfs-bus-usb*

Time in milliseconds for the device to autosuspend. If the value is negative, then autosuspend is prevented.

(read/write)

/sys/bus/usb/devices/usbX/power/connected_duration

Defined on file *sysfs-bus-usb*

The total time (in msec) that the device has been connected.

/sys/bus/usb/devices/usbX/power/level

Defined on file *sysfs-bus-usb*

DESCRIPTION MISSING for /sys/bus/usb/devices/usbX/power/level

/sys/bus/usb/devices/usbX/product

Defined on file *sysfs-bus-usb*

Vendor specific string containing the name of the device's product.

/sys/bus/usb/devices/usbX/speed

Defined on file *sysfs-bus-usb*

Shows the device's max speed, according to the USB version, in Mbps. Can be:

Unknown	speed unknown
1.5	Low speed
15	Full speed
480	High Speed
5000	Super Speed
10000	Super Speed+
20000	Super Speed+ Gen 2x2

/sys/bus/usb/devices/usbX/supports_autosuspend

Defined on file *sysfs-bus-usb*

Returns 1 if the device doesn't support autosuspend. Otherwise, returns 0.

/sys/bus/usb/devices/usbX/urbnum

Defined on file *sysfs-bus-usb*

Number of URBs submitted for the whole device.

/sys/bus/usb/devices/usbX/version

Defined on file *sysfs-bus-usb*

String containing the USB device version, as encoded at the BCD descriptor.

/sys/bus/usb/drivers/.../new_id

Defined on file *sysfs-bus-usb*

Writing a device ID to this file will attempt to dynamically add a new device ID to a USB device driver. This may allow the driver to support more hardware than was included in the driver's static device ID support table at compile time. The format for the device ID is: idVendor idProduct bInterfaceClass RefIdVendor RefIdProduct The vendor ID and device ID fields are required, the rest is optional. The *Ref** tuple can be used to tell the driver to use the same driver_data for the new device as it is used for the reference device. Upon successfully adding an ID, the driver will probe for the device and attempt to bind to it. For example:

```
# echo "8086 10f5" > /sys/bus/usb/drivers/foo/new_id
```

Here add a new device (0458:7045) using driver_data from an already supported device (0458:704c):

```
# echo "0458 7045 0 0458 704c" > /sys/bus/usb/drivers/foo/new_id
```

Reading from this file will list all dynamically added device IDs in the same format, with one entry per line. For example:

```
# cat /sys/bus/usb/drivers/foo/new_id
8086 10f5
dead beef 06
f00d cafe
```

The list will be truncated at PAGE_SIZE bytes due to sysfs restrictions.

/sys/bus/usb/drivers/.../remove_id

Defined on file *sysfs-bus-usb*

Writing a device ID to this file will remove an ID that was dynamically added via the new_id sysfs entry. The format for the device ID is: idVendor idProduct. After successfully removing an ID, the driver will no longer support the device. This is useful to ensure auto probing won't match the driver to the device. For example: # echo "046d c315" > /sys/bus/usb/drivers/foo/remove_id

Reading from this file will list the dynamically added device IDs, exactly like reading from the entry "/sys/bus/usb/drivers/.../new_id"

/sys/bus/vdpa/devices/.../driver_override

Defined on file *sysfs-bus-vdpa*

This file allows the driver for a device to be specified. When specified, only a driver with a name matching the value written to driver_override will have an opportunity to bind to the device. The override is specified by writing a string to the driver_override file (echo vhost-vdpa > driver_override) and may be cleared with an empty string (echo > driver_override). This returns the device to standard matching rules binding. Writing to driver_override does not automatically unbind the device from its current driver or make any attempt to automatically load the specified driver. If no driver with a matching name is currently loaded in the kernel, the device will not bind to any driver. This also allows devices to opt-out of driver binding using a driver_override name such as "none". Only a single driver may be specified in the override, there is no support for parsing delimiters.

/sys/bus/vdpa/driver_probe

Defined on file *sysfs-bus-vdpa*

Writing a device name to this file will cause the kernel binds devices to a compatible driver.

This can be useful when */sys/bus/vdpa/drivers_autoprobe* is disabled.

/sys/bus/vdpa/drivers/.../bind

Defined on file *sysfs-bus-vdpa*

Writing a device name to this file will cause the driver to attempt to bind to the device. This is useful for overriding default bindings.

/sys/bus/vdpa/drivers/.../unbind

Defined on file *sysfs-bus-vdpa*

Writing a device name to this file will cause the driver to attempt to unbind from the device. This may be useful when overriding default bindings.

/sys/bus/vdpa/drivers_autoprobe

Defined on file *sysfs-bus-vdpa*

This file determines whether new devices are immediately bound to a driver after the creation. It initially contains 1, which means the kernel automatically binds devices to a compatible driver immediately after they are created.

Writing "0" to this file disable this feature, any other string enable it.

/sys/bus/vmbus/devices/.../driver_override

Defined on file *sysfs-bus-vmbus*

This file allows the driver for a device to be specified which will override standard static and dynamic ID matching. When specified, only a driver with a name matching the value written to driver_override will have an opportunity to bind to the device. The override is specified by writing a string to the driver_override file (echo uio_hv_generic > driver_override) and may be cleared with an empty string (echo > driver_override). This returns the device to standard matching rules binding. Writing to driver_override does not automatically unbind the device from its current driver or make any attempt to automatically load the specified driver. If no driver with a matching name is currently loaded in the kernel, the device will not bind to any driver. This also allows devices to opt-out of driver binding using a driver_override name such as "none". Only a single driver may be specified in the override, there is no support for parsing delimiters.

/sys/bus/w1/devices/.../alarms

Defined on file *sysfs-driver-w1_therm*

(RW) read or write TH and TL (Temperature High an Low) alarms. Values shall be space separated and in the device range (typical -55 degC to 125 degC), if not values will be trimmed to device min/max capabilities. Values are integer as they are stored in a 8bit register in the device. Lowest value is automatically put to TL. Once set, alarms could be search at master level, refer to /w1/w1-generic for detailed information

Users: any user space application which wants to communicate with w1_term device

/sys/bus/w1/devices/.../conv_time

Defined on file *sysfs-driver-w1_therm*

(RW) Get, set, or measure a temperature conversion time. The setting remains active until a resolution change. Then it is reset to default (datasheet) conversion time for a new resolution.

***read*:**
Actual conversion time in milliseconds.

***write*:**

- **'0':**
  Set the default conversion time from the datasheet.
- **'1':**
  Measure and set the conversion time. Make a single temperature conversion, measure an actual value. Increase it by 20% for temperature range. A new conversion time can be obtained by reading this same attribute.
- **other positive value:**
  Set the conversion time in milliseconds.

Users: An application using the w1_term device

/sys/bus/w1/devices/.../eeprom_cmd

Defined on file *sysfs-driver-w1_therm*

(WO) writing that file will either trigger a save of the device data to its embedded EEPROM, either restore data embedded in device EEPROM. Be aware that devices support limited EEPROM writing cycles (typical 50k)

- 'save': save device RAM to EEPROM
- 'restore': restore EEPROM data in device RAM

Users: any user space application which wants to communicate with w1_term device

/sys/bus/w1/devices/.../ext_power

Defined on file *sysfs-driver-w1_therm*

(RO) return the power status by asking the device

- '0': device parasite powered
- '1': device externally powered
- '-xx': xx is kernel error when reading power status

Users: any user space application which wants to communicate with w1_term device

/sys/bus/w1/devices/.../features

Defined on file *sysfs-driver-w1_therm*

(RW) Control optional driver settings. Bit masks to read/write (bitwise OR):

1	Enable check for conversion success. If byte 6 of scratchpad memory is 0xC after conversion, and temperature reads 85.00 (powerup value) or 127.94 (insufficient power) - return a conversion error.
2	Enable poll for conversion completion. Generate read cycles after the conversion start and wait for 1's. In parasite power mode this feature is not available.

***read*:**
Currently selected features.

***write*:**
Select features.

Users: An application using the w1_term device

/sys/bus/w1/devices/.../resolution

Defined on file *sysfs-driver-w1_therm*

(RW) get or set the device resolution (on supported devices, if not, this entry is not present). Note that the resolution will be changed only in device RAM, so it will be cleared when power is lost. Trigger a 'save' to EEPROM command to keep values after power-on. Read or write are :

- '9..14': device resolution in bit or resolution to set in bit
- '-xx': xx is kernel error when reading the resolution
- Anything else: do nothing

Some DS18B20 clones are fixed in 12-bit resolution, so the actual resolution is read back from the chip and verified. Error is reported if the results differ.

Users: any user space application which wants to communicate with w1_term device

/sys/bus/w1/devices/.../temperature

Defined on file *sysfs-driver-w1_therm*

(RO) return the temperature in 1/1000 degC.

- If a bulk read has been triggered, it will directly return the temperature computed when the bulk read occurred, if available. If not yet available, nothing is returned (a debug kernel message is sent), you should retry later on.
- If no bulk read has been triggered, it will trigger a conversion and send the result. Note that the conversion duration depend on the resolution (if device support this feature). It takes 94ms in 9bits resolution, 750ms for 12bits.

Users: any user space application which wants to communicate with w1_term device

/sys/bus/w1/devices/.../w1_slave

Defined on file *sysfs-driver-w1_therm*

(RW) return the temperature in 1/1000 degC. *read*: return 2 lines with the hexa output data sent on the bus, return the CRC check and temperature in 1/1000 degC *write*:

- '0' : save the 2 or 3 bytes to the device EEPROM (i.e. TH, TL and config register)
- '9..14' : set the device resolution in RAM (if supported)
- Anything else: do nothing

refer to /w1/slaves/w1_therm for detailed information.

Users: any user space application which wants to communicate with w1_term device

/sys/bus/w1/devices/19-<id>/speed

Defined on file *sysfs-driver-w1_ds28e17*

When written, this file sets the I2C speed on the connected DS28E17 chip. When read, it reads the current setting from the DS28E17 chip.

Valid values: 100, 400, 900 [kBaud].

Default 100, can be set by w1_ds28e17.speed= module parameter.

Users: w1_ds28e17 driver

/sys/bus/w1/devices/19-<id>/stretch

Defined on file *sysfs-driver-w1_ds28e17*

When written, this file sets the multiplier used to calculate the busy timeout for I2C operations on the connected DS28E17 chip. When read, returns the current setting. Valid values: 1 to 9.

Default 1, can be set by w1_ds28e17.stretch= module parameter.

Users: w1_ds28e17 driver

/sys/bus/w1/devices/w1_bus_masterXX/therm_bulk_read

Defined on file *sysfs-driver-w1_therm*

(RW) trigger a bulk read conversion. read the status

***read*:**

- **'-1':**
  conversion in progress on at least 1 sensor
- **'1' :**
  conversion complete but at least one sensor value has not been read yet
- **'0' :**
  no bulk operation. Reading temperature will trigger a conversion on each device

***write*:**
'trigger': trigger a bulk read on all supporting devices on the bus

Note that if a bulk read is sent but one sensor is not read immediately, the next access to temperature on this device will return the temperature measured at the time of issue of the bulk read command (not the current temperature).

Users: any user space application which wants to communicate with w1_term device

/sys/bus/wmi/devices/44FADEB1-B204-40F2-8581-394BBDC1B651/firmware_update_reque

Defined on file *sysfs-platform-intel-wmi-sbl-fw-update*

Allow user space entities to trigger update of Slim Bootloader (SBL). This attribute normally has a value of 0 and userspace can signal SBL to update firmware, on next reboot, by writing a value of 1. There are two available states:

- 0 -> Skip firmware update while rebooting
- 1 -> Attempt firmware update on next reboot

/sys/bus/wmi/devices/6932965F-1671-4CEB-B988-D3AB0A901919/dell_privacy_current_sta

Defined on file *sysfs-platform-dell-privacy-wmi*

Allow user space to check current dell privacy device state. Describes the Device State class exposed by BIOS which can be consumed by various applications interested in knowing the Privacy feature capabilities

Attributes:

Microphone:
Identifies the local microphone can be muted by hardware, no applications is available to capture system mic sound

Camera Shutter:
Identifies camera shutter controlled by hardware, which is a micromechanical shutter assembly that is built onto the camera module to block capturing images from outside the laptop

Values:

muted:
Identifies the privacy device is turned off and cannot send stream to OS applications

unmuted:
Identifies the privacy device is turned on, audio or camera driver can get stream from mic and camera module to OS applications

For example to check all supported current privacy device states:

```
# cat /sys/bus/wmi/drivers/dell-privacy/6932965F-1671-4CEB-B988-D3AB0A901919/
↪dell_privacy_current_state
[Microphone] [unmuted]
[Camera Shutter] [unmuted]
```

/sys/bus/wmi/devices/6932965F-1671-4CEB-B988-D3AB0A901919/dell_privacy_supported_t

Defined on file *sysfs-platform-dell-privacy-wmi*

Display which dell hardware level privacy devices are supported "Dell Privacy" is a set of HW, FW, and SW features to enhance Dell's commitment to platform privacy for MIC, Camera, and ePrivacy screens. The supported hardware privacy devices are:

Attributes:

Microphone Mute:
Identifies the local microphone can be muted by hardware, no applications is available to capture system mic sound

Camera Shutter:
Identifies camera shutter controlled by hardware, which is a micromechanical shutter assembly that is built onto the camera module to block capturing images from outside the laptop

Values:

supported:
The privacy device is supported by this system

unsupported:
The privacy device is not supported on this system

For example to check which privacy devices are supported:

```
# cat /sys/bus/wmi/drivers/dell-privacy/6932965F-1671-4CEB-B988-D3AB0A901919/
↪dell_privacy_supported_type
[Microphone Mute] [supported]
```

```
[Camera Shutter] [supported]
[ePrivacy Screen] [unsupported]
```

5.2.32 Symbols under /sys/class

/sys/class/

Defined on file *sysfs-class*

The /sys/class directory will consist of a group of subdirectories describing individual classes of devices in the kernel. The individual directories will consist of either subdirectories, or symlinks to other directories.

All programs that use this directory tree must be able to handle both subdirectories or symlinks in order to work properly.

Users:

udev <linux-hotplug-devel@lists.sourceforge.net>

/sys/class/accel/accel<n>/device/armcp_kernel_ver

Defined on file *sysfs-driver-habanalabs*

Version of the Linux kernel running on the device's CPU. Will be DEPRECATED in Linux kernel version 5.10, and be replaced with cpucp_kernel_ver

/sys/class/accel/accel<n>/device/armcp_ver

Defined on file *sysfs-driver-habanalabs*

Version of the application running on the device's CPU Will be DEPRECATED in Linux kernel version 5.10, and be replaced with cpucp_ver

/sys/class/accel/accel<n>/device/clk_cur_freq_mhz

Defined on file *sysfs-driver-habanalabs*

Displays the current frequency, in MHz, of the device clock. This property is valid only for the Gaudi ASIC family

/sys/class/accel/accel<n>/device/clk_max_freq_mhz

Defined on file *sysfs-driver-habanalabs*

Allows the user to set the maximum clock frequency, in MHz. The device clock might be set to lower value than the maximum. The user should read the clk_cur_freq_mhz to see the actual frequency value of the device clock. This property is valid only for the Gaudi ASIC family

/sys/class/accel/accel<n>/device/cpld_ver

Defined on file *sysfs-driver-habanalabs*

Version of the Device's CPLD F/W

/sys/class/accel/accel<n>/device/cpucp_kernel_ver

Defined on file *sysfs-driver-habanalabs*

Version of the Linux kernel running on the device's CPU

/sys/class/accel/accel<n>/device/cpucp_ver

Defined on file *sysfs-driver-habanalabs*

Version of the application running on the device's CPU

/sys/class/accel/accel<n>/device/device_type

Defined on file *sysfs-driver-habanalabs*

Displays the code name of the device according to its type. The supported values are: "GOYA"

/sys/class/accel/accel<n>/device/eeprom

Defined on file *sysfs-driver-habanalabs*

A binary file attribute that contains the contents of the on-board EEPROM

/sys/class/accel/accel<n>/device/fuse_ver

Defined on file *sysfs-driver-habanalabs*

Displays the device's version from the eFuse

/sys/class/accel/accel<n>/device/fw_os_ver

Defined on file *sysfs-driver-habanalabs*

Version of the firmware OS running on the device's CPU

/sys/class/accel/accel<n>/device/hard_reset

Defined on file *sysfs-driver-habanalabs*

Interface to trigger a hard-reset operation for the device. Hard-reset will reset ALL internal components of the device except for the PCI interface and the internal PLLs

/sys/class/accel/accel<n>/device/hard_reset_cnt

Defined on file *sysfs-driver-habanalabs*

Displays how many times the device have undergone a hard-reset operation since the driver was loaded

/sys/class/accel/accel<n>/device/high_pll

Defined on file *sysfs-driver-habanalabs*

Allows the user to set the maximum clock frequency for MME, TPC and IC when the power management profile is set to "automatic". This property is valid only for the Goya ASIC family

/sys/class/accel/accel<n>/device/ic_clk

Defined on file *sysfs-driver-habanalabs*

Allows the user to set the maximum clock frequency, in Hz, of the Interconnect fabric. Writes to this parameter affect the device only when the power management profile is set to "manual" mode. The device IC clock might be set to lower value than the maximum. The user should read the ic_clk_curr to see the actual frequency value of the IC. This property is valid only for the Goya ASIC family

/sys/class/accel/accel<n>/device/ic_clk_curr

Defined on file *sysfs-driver-habanalabs*

Displays the current clock frequency, in Hz, of the Interconnect fabric. This property is valid only for the Goya ASIC family

/sys/class/accel/accel<n>/device/infineon_ver

Defined on file *sysfs-driver-habanalabs*

Version of the Device's power supply F/W code. Relevant only to GOYA and GAUDI

/sys/class/accel/accel<n>/device/max_power

Defined on file *sysfs-driver-habanalabs*

Allows the user to set the maximum power consumption of the device in milliwatts.

/sys/class/accel/accel<n>/device/mme_clk

Defined on file *sysfs-driver-habanalabs*

Allows the user to set the maximum clock frequency, in Hz, of the MME compute engine. Writes to this parameter affect the device only when the power management profile is set to "manual" mode. The device MME clock might be set to lower value than the maximum. The user should read the mme_clk_curr to see the actual frequency value of the MME. This property is valid only for the Goya ASIC family

/sys/class/accel/accel<n>/device/mme_clk_curr

Defined on file *sysfs-driver-habanalabs*

Displays the current clock frequency, in Hz, of the MME compute engine. This property is valid only for the Goya ASIC family

/sys/class/accel/accel<n>/device/module_id

Defined on file *sysfs-driver-habanalabs*

Displays the device's module id

/sys/class/accel/accel<n>/device/parent_device

Defined on file *sysfs-driver-habanalabs*

Displays the name of the parent device of the accel device

/sys/class/accel/accel<n>/device/pci_addr

Defined on file *sysfs-driver-habanalabs*

Displays the PCI address of the device. This is needed so the user would be able to open a device based on its PCI address

/sys/class/accel/accel<n>/device/pm_mng_profile

Defined on file *sysfs-driver-habanalabs*

Power management profile. Values are "auto", "manual". In "auto" mode, the driver will set the maximum clock frequency to a high value when a user-space process opens the device's file (unless it was already opened by another process). The driver will set the max clock frequency to a low value when there are no user processes that are opened on the device's file. In "manual" mode, the user sets the maximum clock frequency by writing to ic_clk, mme_clk and tpc_clk. This property is valid only for the Goya ASIC family

/sys/class/accel/accel<n>/device/preboot_btl_ver

Defined on file *sysfs-driver-habanalabs*

Version of the device's preboot F/W code

/sys/class/accel/accel<n>/device/security_enabled

Defined on file *sysfs-driver-habanalabs*

Displays the device's security status

/sys/class/accel/accel<n>/device/soft_reset

Defined on file *sysfs-driver-habanalabs*

Interface to trigger a soft-reset operation for the device. Soft-reset will reset only the compute and DMA engines of the device

/sys/class/accel/accel<n>/device/soft_reset_cnt

Defined on file *sysfs-driver-habanalabs*

Displays how many times the device have undergone a soft-reset operation since the driver was loaded

/sys/class/accel/accel<n>/device/status

Defined on file *sysfs-driver-habanalabs*

Status of the card:

- ”operational” - Device is available for work.
- ”in reset” - Device is going through reset, will be available shortly.
- ”disabled” - Device is not usable.
- ”needs reset” - Device is not usable until a hard reset is initiated.
- ”in device creation” - Device is not available yet, as it is still initializing.
- ”in reset after device release” - Device is going through a compute-reset which is executed after a device release (relevant for Gaudi2 only).

/sys/class/accel/accel<n>/device/thermal_ver

Defined on file *sysfs-driver-habanalabs*

Version of the Device's thermal daemon

/sys/class/accel/accel<n>/device/tpc_clk

Defined on file *sysfs-driver-habanalabs*

Allows the user to set the maximum clock frequency, in Hz, of the TPC compute engines. Writes to this parameter affect the device only when the power management profile is set to ”manual” mode. The device TPC clock might be set to lower value than the maximum. The user should read the tpc_clk_curr to see the actual frequency value of the TPC. This property is valid only for Goya ASIC family

/sys/class/accel/accel<n>/device/tpc_clk_curr

Defined on file *sysfs-driver-habanalabs*

Displays the current clock frequency, in Hz, of the TPC compute engines. This property is valid only for the Goya ASIC family

/sys/class/accel/accel<n>/device/uboot_ver

Defined on file *sysfs-driver-habanalabs*

Version of the u-boot running on the device's CPU

/sys/class/accel/accel<n>/device/vrm_ver

Defined on file *sysfs-driver-habanalabs*

Version of the Device's Voltage Regulator Monitor F/W code. N/A to GOYA and GAUDI

/sys/class/ata_*

Defined on file *sysfs-ata*

Provide a place in sysfs for storing the ATA topology of the system. This allows retrieving various information about ATA objects.

Files under /sys/class/ata_port

For each port, a directory ataX is created where X is the ata_port_id of the port. The device parent is the ata host device.

/sys/class/ata_device/devX[.Y].Z/spdn_cnt
/sys/class/ata_device/devX[.Y].Z/gscr
/sys/class/ata_device/devX[.Y].Z/ering
/sys/class/ata_device/devX[.Y].Z/id
/sys/class/ata_device/devX[.Y].Z/pio_mode
/sys/class/ata_device/devX[.Y].Z/xfer_mode
/sys/class/ata_device/devX[.Y].Z/dma_mode
/sys/class/ata_device/devX[.Y].Z/class

Defined on file *sysfs-ata*

spdn_cnt: (RO) Number of times libata decided to lower the
speed of link due to errors.

gscr: (RO) Cached result of the dump of PM GSCR
register. Valid registers are:

0: SATA_PMP_GSCR_PROD_ID, 1: SATA_PMP_GSCR_REV, 2: SATA_PMP_GSCR_PORT_INFO, 32: SATA_PMP_GSCR_ERROR, 33: SATA_PMP_GSCR_ERROR_EN, 64: SATA_PMP_GSCR_FEAT, 96: SATA_PMP_GSCR_FEAT_EN, 130: SATA_PMP_GSCR_SII_GPIO

Only valid if the device is a PM.

ering: (RO) Formatted output of the error ring of the
device.

id: (RO) Cached result of IDENTIFY command, as
described in ATA8 7.16 and 7.17. Only valid if the device is not a PM.

pio_mode: (RO) PIO transfer mode used by the device.
Mostly used by PATA devices.

xfer_mode: (RO) Current transfer mode. Mostly used by
PATA devices.

dma_mode: (RO) DMA transfer mode used by the device.
Mostly used by PATA devices.

class: (RO) Device class. Can be "ata" for disk,
"atapi" for packet device, "pmp" for PM, or "none" if no device was found behind the link.

/sys/class/ata_device/devX[.Y].Z/trim

Defined on file *sysfs-ata*

(RO) Shows the DSM TRIM mode currently used by the device. Valid values are:

unsupported: Drive does not support DSM TRIM

unqueued: Drive supports unqueued DSM TRIM only

queued: Drive supports queued DSM TRIM

forced_unqueued: Drive's queued DSM support is known to
be buggy and only unqueued TRIM commands are sent

/sys/class/ata_link/linkX[.Y]/hw_sata_spd_limit
/sys/class/ata_link/linkX[.Y]/sata_spd_limit
/sys/class/ata_link/linkX[.Y]/sata_spd

Defined on file *sysfs-ata*

hw_sata_spd_limit: (RO) Maximum speed supported by the
connected SATA device.

sata_spd_limit: (RO) Maximum speed imposed by libata.

sata_spd: (RO) Current speed of the link
eg. 1.5, 3 Gbps etc.

Files under /sys/class/ata_device

Behind each link, up to two ata devices are created. The name of the directory is devX[.Y].Z where: - X is ata_port_id of the port where the device is connected, - Y the port of the PM if any, and - Z the device id: for PATA, there is usually 2 devices [0,1], only 1 for SATA.

/sys/class/ata_port/ataX/nr_pmp_links
/sys/class/ata_port/ataX/idle_irq

Defined on file *sysfs-ata*

nr_pmp_links: (RO) If a SATA Port Multiplier (PM) is
connected, the number of links behind it.

idle_irq: (RO) Number of IRQ received by the port while
idle [some ata HBA only].

/sys/class/ata_port/ataX/port_no

Defined on file *sysfs-ata*

(RO) Host local port number. While registering host controller, port numbers are tracked based upon number of ports available on the controller. This attribute is needed by udev for composing persistent links in /dev/disk/by-path.

Files under /sys/class/ata_link

Behind each port, there is a ata_link. If there is a SATA PM in the topology, 15 ata_link objects are created.

If a link is behind a port, the directory name is linkX, where X is ata_port_id of the port. If a link is behind a PM, its name is linkX.Y where X is ata_port_id of the parent port and Y the PM port.

/sys/class/backlight/<backlight>/<ambient light zone>_dim

Defined on file *sysfs-class-backlight*

Control the dim brightness for <ambient light zone> on this <backlight>. Values are between 0 and 127, typically set to 0. Full off when the backlight is disabled. This file will also show the dim brightness level stored for this <ambient light zone>.

The <ambient light zone> is device-driver specific:

For ADP5520 and ADP5501, <ambient light zone> can be:

Ambient light zone	sysfs entry
daylight	/sys/class/backlight/<backlight>/daylight_dim
office	/sys/class/backlight/<backlight>/office_dim
dark	/sys/class/backlight/<backlight>/dark_dim

For ADP8860, <ambient light zone> can be:

Ambient light zone	sysfs entry
l1_daylight	/sys/class/backlight/<backlight>/l1_daylight_dim
l2_office	/sys/class/backlight/<backlight>/l2_office_dim
l3_dark	/sys/class/backlight/<backlight>/l3_dark_dim

For ADP8870, <ambient light zone> can be:

Ambient light zone	sysfs entry
l1_daylight	/sys/class/backlight/<backlight>/l1_daylight_dim
l2_bright	/sys/class/backlight/<backlight>/l2_bright_dim
l3_office	/sys/class/backlight/<backlight>/l3_office_dim
l4_indoor	/sys/class/backlight/<backlight>/l4_indoor_dim
l5_dark	/sys/class/backlight/<backlight>/l5_dark_dim

See also: */sys/class/backlight/<backlight>/ambient_light_zone*.

/sys/class/backlight/<backlight>/<ambient light zone>_max

Defined on file *sysfs-class-backlight*

Control the maximum brightness for <ambient light zone> on this <backlight>. Values are between 0 and 127. This file will also show the brightness level stored for this <ambient light zone>.

The <ambient light zone> is device-driver specific:

For ADP5520 and ADP5501, <ambient light zone> can be:

Ambient light zone	sysfs entry
daylight	/sys/class/backlight/<backlight>/daylight_max
office	/sys/class/backlight/<backlight>/office_max
dark	/sys/class/backlight/<backlight>/dark_max

For ADP8860, <ambient light zone> can be:

Ambient light zone	sysfs entry
l1_daylight	/sys/class/backlight/<backlight>/l1_daylight_max
l2_office	/sys/class/backlight/<backlight>/l2_office_max
l3_dark	/sys/class/backlight/<backlight>/l3_dark_max

For ADP8870, <ambient light zone> can be:

Ambient light zone	sysfs entry
l1_daylight	/sys/class/backlight/<backlight>/l1_daylight_max
l2_bright	/sys/class/backlight/<backlight>/l2_bright_max
l3_office	/sys/class/backlight/<backlight>/l3_office_max
l4_indoor	/sys/class/backlight/<backlight>/l4_indoor_max
l5_dark	/sys/class/backlight/<backlight>/l5_dark_max

See also: */sys/class/backlight/<backlight>/ambient_light_zone*.

/sys/class/backlight/<backlight>/als_channel

Defined on file *sysfs-class-backlight-driver-lm3533*

Get the ALS output channel used as input in ALS-current-control mode (0, 1), where:

0	out_current0 (backlight 0)
1	out_current1 (backlight 1)

/sys/class/backlight/<backlight>/als_en

Defined on file *sysfs-class-backlight-driver-lm3533*

Enable ALS-current-control mode (0, 1).

/sys/class/backlight/<backlight>/ambient_light_level

Defined on file *sysfs-class-backlight*

(RO) Get conversion value of the light sensor.

The value is automatically updated every 80 ms when the light sensor is enabled.

The value range is device-driver specific:

For ADP8870:

It returns integer between 0 (dark) and 8000 (max ambient brightness).

For ADP8860:

It returns a 13-bits integer.

/sys/class/backlight/<backlight>/ambient_light_zone

Defined on file *sysfs-class-backlight*

(RW) Read or write the specific brightness level at which the backlight operates.

The value meaning is device-driver specific:

For ADP8860:

0	Off: Backlight set to 0 mA
1	Level 1: daylight
2	Level 2: bright
3	Level 3: dark

For ADP8870:

0	Off: Backlight set to 0 mA
1	Level 1: daylight
2	Level 2: bright
3	Level 3: office
4	Level 4: indoor
5	Level 5: dark

Writing 0 returns to normal/automatic ambient light level operation.

It can be enabled by writing the value stored in /sys/class/backlight/<backlight>/max_brightness to /sys/class/backlight/<backlight>/brightness.

/sys/class/backlight/<backlight>/bled_mode

Defined on file *sysfs-class-backlight-lm3639*

(WO) Write to the backlight mapping mode. The backlight current can be mapped for either exponential (value "0") or linear mapping modes (default).

/sys/class/backlight/<backlight>/id

Defined on file *sysfs-class-backlight-driver-lm3533*

Get the id of this backlight (0, 1).

/sys/class/backlight/<backlight>/linear

Defined on file *sysfs-class-backlight-driver-lm3533*

Set the brightness-mapping mode (0, 1), where:

0	exponential mode
1	linear mode

/sys/class/backlight/<backlight>/pwm

Defined on file *sysfs-class-backlight-driver-lm3533*

Set the PWM-input control mask (5 bits), where:

bit 5	PWM-input enabled in Zone 4
bit 4	PWM-input enabled in Zone 3
bit 3	PWM-input enabled in Zone 2
bit 2	PWM-input enabled in Zone 1
bit 1	PWM-input enabled in Zone 0
bit 0	PWM-input enabled

/sys/class/backlight/<backlight>/scale

Defined on file *sysfs-class-backlight*

Description of the scale of the brightness curve.

The human eye senses brightness approximately logarithmically, hence linear changes in brightness are perceived as being non-linear. To achieve a linear perception of brightness changes controls like sliders need to apply a logarithmic mapping for backlights with a linear brightness curve.

Possible values of the attribute are:

unknown
: The scale of the brightness curve is unknown.

linear
: The brightness changes linearly with each step. Brightness controls should apply a logarithmic mapping for a linear perception.

non-linear
The brightness changes non-linearly with each step. Brightness controls should use a linear mapping for a linear perception.

/sys/class/bdi/<bdi>/

Defined on file *sysfs-class-bdi*

Provide a place in sysfs for the backing_dev_info object. This allows setting and retrieving various BDI specific variables.

The <bdi> identifier can be either of the following:

MAJOR:MINOR

Device number for block devices, or value of st_dev on non-block filesystems which provide their own BDI, such as NFS and FUSE.

MAJOR:MINOR-fuseblk

Value of st_dev on fuseblk filesystems.

default

The default backing dev, used for non-block device backed filesystems which do not provide their own BDI.

/sys/class/bdi/<bdi>/max_bytes

Defined on file *sysfs-class-bdi*

Allows limiting a particular device to use not more than the given 'max_bytes' of the write-back cache. This is useful in situations where we want to avoid one device taking all or most of the write-back cache. For example in case of an NFS mount that is prone to get stuck, a FUSE mount which cannot be trusted to play fair, or a nbd device.

(read-write)

/sys/class/bdi/<bdi>/max_ratio

Defined on file *sysfs-class-bdi*

Allows limiting a particular device to use not more than the given percentage of the write-back cache. This is useful in situations where we want to avoid one device taking all or most of the write-back cache. For example in case of an NFS mount that is prone to get stuck, or a FUSE mount which cannot be trusted to play fair.

(read-write)

/sys/class/bdi/<bdi>/max_ratio_fine

Defined on file *sysfs-class-bdi*

Allows limiting a particular device to use not more than the given value of the write-back cache. The value is given as part of 1 million. This is useful in situations where we want to avoid one

device taking all or most of the write-back cache. For example in case of an NFS mount that is prone to get stuck, or a FUSE mount which cannot be trusted to play fair.

(read-write)

/sys/class/bdi/<bdi>/min_bytes

Defined on file *sysfs-class-bdi*

Under normal circumstances each device is given a part of the total write-back cache that relates to its current average writeout speed in relation to the other devices.

The 'min_bytes' parameter allows assigning a minimum percentage of the write-back cache to a particular device expressed in bytes. For example, this is useful for providing a minimum QoS.

(read-write)

/sys/class/bdi/<bdi>/min_ratio

Defined on file *sysfs-class-bdi*

Under normal circumstances each device is given a part of the total write-back cache that relates to its current average writeout speed in relation to the other devices.

The 'min_ratio' parameter allows assigning a minimum percentage of the write-back cache to a particular device. For example, this is useful for providing a minimum QoS.

(read-write)

/sys/class/bdi/<bdi>/min_ratio_fine

Defined on file *sysfs-class-bdi*

Under normal circumstances each device is given a part of the total write-back cache that relates to its current average writeout speed in relation to the other devices.

The 'min_ratio_fine' parameter allows assigning a minimum reserve of the write-back cache to a particular device. The value is expressed as part of 1 million. For example, this is useful for providing a minimum QoS.

(read-write)

/sys/class/bdi/<bdi>/read_ahead_kb

Defined on file *sysfs-class-bdi*

Size of the read-ahead window in kilobytes

(read-write)

/sys/class/bdi/<bdi>/stable_pages_required

Defined on file *sysfs-class-bdi*

If set, the backing device requires that all pages comprising a write request must not be changed until writeout is complete.

(read-only)

/sys/class/bdi/<bdi>/strict_limit

Defined on file *sysfs-class-bdi*

Forces per-BDI checks for the share of given device in the write-back cache even before the global background dirty limit is reached. This is useful in situations where the global limit is much higher than affordable for given relatively slow (or untrusted) device. Turning strictlimit on has no visible effect if max_ratio is equal to 100%.

(read-write)

/sys/class/bsr/bsr*/bsr_length

Defined on file *sysfs-class-bsr*

(RO) The length of memory region that can be mapped in bytes.

/sys/class/bsr/bsr*/bsr_size

Defined on file *sysfs-class-bsr*

(RO) Size of the barrier-synchronization register (BSR) register in bytes.

/sys/class/bsr/bsr*/bsr_stride

Defined on file *sysfs-class-bsr*

(RO) The stride or the interval at which the allocated BSR bytes repeat within the mapping.

/sys/class/c2port/

Defined on file *sysfs-c2port*

The */sys/class/c2port/* directory will contain files and directories that will provide a unified interface to the C2 port interface.

/sys/class/c2port/c2portX

Defined on file *sysfs-c2port*

The /sys/class/c2port/c2portX/ directory is related to X-th C2 port into the system. Each directory will contain files to manage and control its C2 port.

/sys/class/c2port/c2portX/access

Defined on file *sysfs-c2port*

The */sys/class/c2port/c2portX/access* file enable the access to the C2 port from the system. No commands can be sent till this entry is set to 0.

/sys/class/c2port/c2portX/dev_id

Defined on file *sysfs-c2port*

The */sys/class/c2port/c2portX/dev_id* file show the device ID of the connected micro.

/sys/class/c2port/c2portX/flash_access

Defined on file *sysfs-c2port*

The */sys/class/c2port/c2portX/flash_access* file enable the access to the on-board flash of the connected micro. No commands can be sent till this entry is set to 0.

/sys/class/c2port/c2portX/flash_block_size

Defined on file *sysfs-c2port*

The */sys/class/c2port/c2portX/flash_block_size* file show the on-board flash block size of the connected micro.

/sys/class/c2port/c2portX/flash_blocks_num

Defined on file *sysfs-c2port*

The */sys/class/c2port/c2portX/flash_blocks_num* file show the on-board flash blocks number of the connected micro.

/sys/class/c2port/c2portX/flash_data

Defined on file *sysfs-c2port*

The */sys/class/c2port/c2portX/flash_data* file export the content of the on-board flash of the connected micro.

/sys/class/c2port/c2portX/flash_erase

Defined on file *sysfs-c2port*

The */sys/class/c2port/c2portX/flash_erase* file execute the ”erase” command on the on-board flash of the connected micro.

/sys/class/c2port/c2portX/reset

Defined on file *sysfs-c2port*

The */sys/class/c2port/c2portX/reset* file execute a ”reset” command on the connected micro.

/sys/class/c2port/c2portX/rev_id

Defined on file *sysfs-c2port*

The */sys/class/c2port/c2portX/rev_id* file show the revision ID of the connected micro.

/sys/class/chromeos/<ec-device-name>/flashinfo

Defined on file *sysfs-class-chromeos*

Show the EC flash information.

/sys/class/chromeos/<ec-device-name>/kb_wake_angle

Defined on file *sysfs-class-chromeos*

Control the keyboard wake lid angle. Values are between 0 and 360. This file will also show the keyboard wake lid angle by querying the hardware.

/sys/class/chromeos/<ec-device-name>/lightbar/brightness

Defined on file *sysfs-class-chromeos-driver-cros-ec-lightbar*

Writing to this file adjusts the overall brightness of the lightbar, separate from any color intensity. The valid range is 0 (off) to 255 (maximum brightness).

/sys/class/chromeos/<ec-device-name>/lightbar/interval_msec

Defined on file *sysfs-class-chromeos-driver-cros-ec-lightbar*

The lightbar is controlled by an embedded controller (EC), which also manages the keyboard, battery charging, fans, and other system hardware. To prevent unprivileged users from interfering with the other EC functions, the rate at which the lightbar control files can be read or written is limited.

Reading this file will return the number of milliseconds that must elapse between accessing any of the lightbar functions through this interface. Going faster will simply block until the necessary interval has lapsed. The interval applies uniformly to all accesses of any kind by any user.

/sys/class/chromeos/<ec-device-name>/lightbar/led_rgb

Defined on file *sysfs-class-chromeos-driver-cros-ec-lightbar*

This allows you to control each LED segment. If the lightbar is already running one of the automatic sequences, you probably won't see anything change because your color setting will be almost immediately replaced. To get useful results, you should stop the lightbar sequence first.

The values written to this file are sets of four integers, indicating LED, RED, GREEN, BLUE. The LED number is 0 to 3 to select a single segment, or 4 to set all four segments to the same value at once. The RED, GREEN, and BLUE numbers should be in the range 0 (off) to 255 (maximum). You can update more than one segment at a time by writing more than one set of four integers.

/sys/class/chromeos/<ec-device-name>/lightbar/program

Defined on file *sysfs-class-chromeos-driver-cros-ec-lightbar*

This allows you to upload and run custom lightbar sequences.

/sys/class/chromeos/<ec-device-name>/lightbar/sequence

Defined on file *sysfs-class-chromeos-driver-cros-ec-lightbar*

The Pixel lightbar has a number of built-in sequences that it displays under various conditions, such as at power on, shut down, or while running. Reading from this file displays the current sequence that the lightbar is displaying. Writing to this file allows you to change the sequence.

/sys/class/chromeos/<ec-device-name>/lightbar/userspace_control

Defined on file *sysfs-class-chromeos-driver-cros-ec-lightbar*

This allows you to take the control of the lightbar. This prevents the kernel from going through its normal sequences.

/sys/class/chromeos/<ec-device-name>/lightbar/version

Defined on file *sysfs-class-chromeos-driver-cros-ec-lightbar*

Show the information about the lightbar version.

/sys/class/chromeos/<ec-device-name>/reboot

Defined on file *sysfs-class-chromeos*

Tell the EC to reboot in various ways. Options are:

- ”cancel”: Cancel a pending reboot.
- ”ro”: Jump to RO without rebooting.
- ”rw”: Jump to RW without rebooting.
- ”cold”: Cold reboot.
- ”disable-jump”: Disable jump until next reboot.
- ”hibernate”: Hibernate the EC.
- ”at-shutdown”: Reboot after an AP shutdown.

/sys/class/chromeos/<ec-device-name>/vbc/vboot_context

Defined on file *sysfs-class-chromeos-driver-cros-ec-vbc*

Read/write the verified boot context data included on a small nvram space on some EC implementations.

/sys/class/chromeos/<ec-device-name>/version

Defined on file *sysfs-class-chromeos*

Show the information about the EC software and hardware.

/sys/class/cxl/<afu>/afu_err_buf

Defined on file *sysfs-class-cxl*

read only AFU Error Buffer contents. The contents of this file are application specific and depends on the AFU being used. Applications interacting with the AFU can use this attribute to know about the current error condition and take appropriate action like logging the event etc.

/sys/class/cxl/<afu>/api_version

Defined on file *sysfs-class-cxl*

read only Decimal value of the current version of the kernel/user API.

Users: https://github.com/ibm-capi/libcxl

/sys/class/cxl/<afu>/api_version_compatible

Defined on file *sysfs-class-cxl*

read only Decimal value of the lowest version of the userspace API this kernel supports.

Users: https://github.com/ibm-capi/libcxl AFU configuration records (eg. /sys/class/cxl/afu0.0/cr0): An AFU may optionally export one or more PCIe like configuration records, known as AFU configuration records, which will show up here (if present).

/sys/class/cxl/<afu>/cr<config num>/class

Defined on file *sysfs-class-cxl*

read only Hexadecimal value of the class code found in this AFU configuration record.

Users: https://github.com/ibm-capi/libcxl

/sys/class/cxl/<afu>/cr<config num>/config

Defined on file *sysfs-class-cxl*

read only This binary file provides raw access to the AFU configuration record. The format is expected to match the either the standard or extended configuration space defined by the PCIe specification.

Users: https://github.com/ibm-capi/libcxl Master contexts (eg. /sys/class/cxl/afu0.0m)

/sys/class/cxl/<afu>/cr<config num>/device

Defined on file *sysfs-class-cxl*

read only Hexadecimal value of the device ID found in this AFU configuration record.

Users: https://github.com/ibm-capi/libcxl

/sys/class/cxl/<afu>/cr<config num>/vendor

Defined on file *sysfs-class-cxl*

read only Hexadecimal value of the vendor ID found in this AFU configuration record.

Users: https://github.com/ibm-capi/libcxl

/sys/class/cxl/<afu>/irqs_max

Defined on file *sysfs-class-cxl*

read/write Decimal value of maximum number of interrupts that can be requested by userspace. The default on probe is the maximum that hardware can support (eg. 2037). Write values will limit userspace applications to that many userspace interrupts. Must be >= irqs_min.

Users: https://github.com/ibm-capi/libcxl

/sys/class/cxl/<afu>/irqs_min

Defined on file *sysfs-class-cxl*

read only Decimal value of the minimum number of interrupts that userspace must request on a CXL_START_WORK ioctl. Userspace may omit the num_interrupts field in the START_WORK IOCTL to get this minimum automatically.

Users: https://github.com/ibm-capi/libcxl

/sys/class/cxl/<afu>/mmio_size

Defined on file *sysfs-class-cxl*

read only Decimal value of the size of the MMIO space that may be mmapped by userspace.

Users: https://github.com/ibm-capi/libcxl

/sys/class/cxl/<afu>/mode

Defined on file *sysfs-class-cxl*

read/write The current mode the AFU is using. Will be one of the modes given in modes_supported. Writing will change the mode provided that no user contexts are attached.

Users: https://github.com/ibm-capi/libcxl

/sys/class/cxl/<afu>/modes_supported

Defined on file *sysfs-class-cxl*

read only List of the modes this AFU supports. One per line. Valid entries are: "dedicated_process" and "afu_directed"

Users: https://github.com/ibm-capi/libcxl

/sys/class/cxl/<afu>/prefault_mode

Defined on file *sysfs-class-cxl*

read/write Set the mode for prefaulting in segments into the segment table when performing the START_WORK ioctl. Only applicable when running under hashed page table mmu. Possible values:

none	No prefaulting (default)
work_element_descriptor	Treat the work element descriptor as an effective address and prefault what it points to.
all	all segments process calling START_WORK maps.

Users: https://github.com/ibm-capi/libcxl

/sys/class/cxl/<afu>/reset

Defined on file *sysfs-class-cxl*

write only Writing 1 here will reset the AFU provided there are not contexts active on the AFU.

Users: https://github.com/ibm-capi/libcxl

/sys/class/cxl/<afu>m/mmio_size

Defined on file *sysfs-class-cxl*

read only Decimal value of the size of the MMIO space that may be mmapped by userspace. This includes all slave contexts space also.

Users: https://github.com/ibm-capi/libcxl

/sys/class/cxl/<afu>m/pp_mmio_len

Defined on file *sysfs-class-cxl*

read only Decimal value of the Per Process MMIO space length.

Users: https://github.com/ibm-capi/libcxl

/sys/class/cxl/<afu>m/pp_mmio_off

Defined on file *sysfs-class-cxl*

read only (not in a guest) Decimal value of the Per Process MMIO space offset.

Users: https://github.com/ibm-capi/libcxl Card info (eg. /sys/class/cxl/card0)

/sys/class/cxl/<card>/base_image

Defined on file *sysfs-class-cxl*

read only (not in a guest) Identifies the revision level of the base image for devices that support loadable PSLs. For FPGAs this field identifies the image contained in the on-adapter flash which is loaded during the initial program load.

Users: https://github.com/ibm-capi/libcxl

/sys/class/cxl/<card>/caia_version

Defined on file *sysfs-class-cxl*

read only Identifies the CAIA Version the card implements.

Users: https://github.com/ibm-capi/libcxl

/sys/class/cxl/<card>/image_loaded

Defined on file *sysfs-class-cxl*

read only (not in a guest) Will return "user" or "factory" depending on the image loaded onto the card.

Users: https://github.com/ibm-capi/libcxl

/sys/class/cxl/<card>/load_image_on_perst

Defined on file *sysfs-class-cxl*

read/write (not in a guest) Valid entries are "none", "user", and "factory". "none" means PERST will not cause image to be loaded to the card. A power cycle is required to load the image. "none" could be useful for debugging because the trace arrays are preserved.

"user" and "factory" means PERST will cause either the user or user or factory image to be loaded. Default is to reload on PERST whichever image the card has loaded.

Users: https://github.com/ibm-capi/libcxl

/sys/class/cxl/<card>/perst_reloads_same_image

Defined on file *sysfs-class-cxl*

read/write (not in a guest) Trust that when an image is reloaded via PERST, it will not have changed.

0	don't trust, the image may be different (default)
1	trust that the image will not change.

Users: https://github.com/ibm-capi/libcxl

/sys/class/cxl/<card>/psl_revision

Defined on file *sysfs-class-cxl*

read only Identifies the revision level of the PSL.

Users: https://github.com/ibm-capi/libcxl

/sys/class/cxl/<card>/psl_timebase_synced

Defined on file *sysfs-class-cxl*

read only Returns 1 if the psl timebase register is synchronized with the core timebase register, 0 otherwise.

Users: https://github.com/ibm-capi/libcxl

/sys/class/cxl/<card>/reset

Defined on file *sysfs-class-cxl*

write only Writing 1 will issue a PERST to card provided there are no contexts active on any one of the card AFUs. This may cause the card to reload the FPGA depending on load_image_on_perst. Writing -1 will do a force PERST irrespective of any active contexts on the card AFUs.

Users: https://github.com/ibm-capi/libcxl

/sys/class/cxl/<card>/tunneled_ops_supported

Defined on file *sysfs-class-cxl*

read only Returns 1 if tunneled operations are supported in capi mode, 0 otherwise.

Users: https://github.com/ibm-capi/libcxl

/sys/class/devfreq-event/event<x>/

Defined on file *sysfs-class-devfreq-event*

Provide a place in sysfs for the devfreq-event objects. This allows accessing various devfreq-event specific variables. The name of devfreq-event object denoted as 'event<x>' which includes the unique number of 'x' for each devfreq-event object.

/sys/class/devfreq-event/event<x>/enable_count

Defined on file *sysfs-class-devfreq-event*

The */sys/class/devfreq-event/event<x>/enable_count* attribute contains the reference count to enable the devfreq-event object. If the device is enabled, the value of attribute is greater than zero.

/sys/class/devfreq-event/event<x>/name

Defined on file *sysfs-class-devfreq-event*

The */sys/class/devfreq-event/event<x>/name* attribute contains the name of the devfreq-event object. This attribute is read-only.

/sys/class/devfreq/.../

Defined on file *sysfs-class-devfreq*

Provide a place in sysfs for the devfreq objects. This allows accessing various devfreq specific variables. The name of devfreq object denoted as ... is same as the name of device using devfreq.

/sys/class/devfreq/.../available_frequencies

Defined on file *sysfs-class-devfreq*

The /sys/class/devfreq/.../available_frequencies shows the available frequencies of the corresponding devfreq object. This is a snapshot of available frequencies and not limited by the min/max frequency restrictions.

/sys/class/devfreq/.../available_governors

Defined on file *sysfs-class-devfreq*

The /sys/class/devfreq/.../available_governors shows currently available governors in the system.

/sys/class/devfreq/.../cur_freq

Defined on file *sysfs-class-devfreq*

The /sys/class/devfreq/.../cur_freq shows the current frequency of the corresponding devfreq object. Same as target_freq when get_cur_freq() is not implemented by devfreq driver.

/sys/class/devfreq/.../governor

Defined on file *sysfs-class-devfreq*

The /sys/class/devfreq/.../governor show or set the name of the governor used by the corresponding devfreq object.

/sys/class/devfreq/.../max_freq

Defined on file *sysfs-class-devfreq*

The /sys/class/devfreq/.../max_freq shows and stores the maximum frequency requested by users. It is 0 if the user does not care. max_freq overrides the frequency requested by governors and min_freq. The max_freq overrides min_freq because max_freq may be used to throttle devices to avoid overheating.

/sys/class/devfreq/.../min_freq

Defined on file *sysfs-class-devfreq*

The /sys/class/devfreq/.../min_freq shows and stores the minimum frequency requested by users. It is 0 if the user does not care. min_freq overrides the frequency requested by governors.

/sys/class/devfreq/.../name

Defined on file *sysfs-class-devfreq*

The /sys/class/devfreq/.../name shows the name of device of the corresponding devfreq object.

/sys/class/devfreq/.../polling_interval

Defined on file *sysfs-class-devfreq*

The /sys/class/devfreq/.../polling_interval shows and sets the requested polling interval of the corresponding devfreq object. The values are represented in ms. If the value is less than 1 jiffy, it is considered to be 0, which means no polling. This value is meaningless if the governor is not polling.

A list of governors that support the node: - simple_ondmenad - tegra_actmon

/sys/class/devfreq/.../target_freq

Defined on file *sysfs-class-devfreq*

The /sys/class/devfreq/.../target_freq shows the next governor predicted target frequency of the corresponding devfreq object.

/sys/class/devfreq/.../timer

Defined on file *sysfs-class-devfreq*

This ABI shows and stores the kind of work timer by users. This work timer is used by devfreq workqueue in order to monitor the device status such as utilization. The user can change the work timer on runtime according to their demand as following:

```
echo deferrable > /sys/class/devfreq/.../timer
echo delayed > /sys/class/devfreq/.../timer
```

A list of governors that support the node: - simple_ondemand

/sys/class/devfreq/.../trans_stat

Defined on file *sysfs-class-devfreq*

This ABI shows or clears the statistics of devfreq behavior on a specific device. It shows the time spent in each state and the number of transitions between states. In order to activate this ABI, the devfreq target device driver should provide the list of available frequencies with its profile. If need to reset the statistics of devfreq behavior on a specific device, enter 0(zero) to 'trans_stat' as following:

```
echo 0 > /sys/class/devfreq/.../trans_stat
```

If the transition table is bigger than PAGE_SIZE, reading this will return an -EFBIG error.

/sys/class/devfreq/.../userspace/set_freq

Defined on file *sysfs-class-devfreq*

The /sys/class/devfreq/.../userspace/set_freq shows and sets the requested frequency for the devfreq object if userspace governor is in effect.

A list of governors that support the node: - userspace

/sys/class/devlink/.../

Defined on file *sysfs-class-devlink*

Provide a place in sysfs for the device link objects in the kernel at any given time. The name of a device link directory, denoted as ... above, is of the form <supplier>--<consumer> where <supplier> is the supplier bus:device name and <consumer> is the consumer bus:device name.

/sys/class/devlink/.../auto_remove_on

Defined on file *sysfs-class-devlink*

This file indicates if the device link will ever be automatically removed by the driver core when the consumer and supplier devices themselves are still present.

This will be one of the following strings:

- 'consumer unbind'
- 'supplier unbind'
- 'never'

'consumer unbind' means the device link will be removed when the consumer's driver is unbound from the consumer device.

'supplier unbind' means the device link will be removed when the supplier's driver is unbound from the supplier device.

'never' means the device link will not be automatically removed when as long as the supplier and consumer devices themselves are still present.

/sys/class/devlink/.../consumer

Defined on file *sysfs-class-devlink*

This file is a symlink to the consumer device's sysfs directory.

/sys/class/devlink/.../runtime_pm

Defined on file *sysfs-class-devlink*

This file indicates if the device link has any impact on the runtime power management behavior of the consumer and supplier devices. For example: Making sure the supplier doesn't enter runtime suspend while the consumer is active.

This will be one of the following strings:

'0'	Does not affect runtime power management
'1'	Affects runtime power management

/sys/class/devlink/.../status

Defined on file *sysfs-class-devlink*

This file indicates the status of the device link. The status of a device link is affected by whether the supplier and consumer devices have been bound to their corresponding drivers. The status of a device link also affects the binding and unbinding of the supplier and consumer devices with their drivers and also affects whether the software state of the supplier device is synced with the hardware state of the supplier device after boot up. See also: sysfs-devices-state_synced.

This will be one of the following strings:

- 'not tracked'
- 'dormant'
- 'available'
- 'consumer probing'
- 'active'
- 'supplier unbinding'
- 'unknown'

'not tracked' means this device link does not track the status and has no impact on the binding, unbinding and syncing the hardware and software device state.

'dormant' means the supplier and the consumer devices have not bound to their driver.

'available' means the supplier has bound to its driver and is available to supply resources to the consumer device.

'consumer probing' means the consumer device is currently trying to bind to its driver.

'active' means the supplier and consumer devices have both bound successfully to their drivers.

'supplier unbinding' means the supplier devices is currently in the process of unbinding from its driver.

'unknown' means the state of the device link is not any of the above. If this is ever the value, there's a bug in the kernel.

/sys/class/devlink/.../supplier

Defined on file *sysfs-class-devlink*

This file is a symlink to the supplier device's sysfs directory.

/sys/class/devlink/.../sync_state_only

Defined on file *sysfs-class-devlink*

This file indicates if the device link is limited to only affecting the syncing of the hardware and software state of the supplier device.

This will be one of the following strings:

'0'	
'1'	Affects runtime power management

'0' means the device link can affect other device behaviors like binding/unbinding, suspend/resume, runtime power management, etc.

'1' means the device link will only affect the syncing of hardware and software state of the supplier device after boot up and doesn't not affect other behaviors of the devices.

/sys/class/extcon/.../

Defined on file *sysfs-class-extcon*

Provide a place in sysfs for the extcon objects. This allows accessing extcon specific variables. The name of extcon object denoted as ... is the name given with extcon_dev_register.

One extcon device denotes a single external connector port. An external connector may have multiple cables attached simultaneously. Many of docks, cradles, and accessory cables have such capability. For example, the 30-pin port of Nuri board (/arch/arm/mach-exynos) may have both HDMI and Charger attached, or analog audio, video, and USB cables attached simultaneously.

If there are cables mutually exclusive with each other, such binary relations may be expressed with extcon_dev's mutually_exclusive array.

/sys/class/extcon/.../cable.X/name

Defined on file *sysfs-class-extcon*

The /sys/class/extcon/.../cable.X/name shows the name of cable "X" (integer between 0 and 31) of an extcon device.

/sys/class/extcon/.../cable.X/state

Defined on file *sysfs-class-extcon*

The /sys/class/extcon/.../cable.X/state shows and stores the state of cable "X" (integer between 0 and 31) of an extcon device. The state value is either 0 (detached) or 1 (attached).

/sys/class/extcon/.../mutually_exclusive/..

Defined on file *sysfs-class-extcon*

Shows the relations of mutually exclusiveness. For example, if the mutually_exclusive array of extcon device is {0x3, 0x5, 0xC, 0x0}, then the output is:

```
# ls mutually_exclusive/
0x3
0x5
0xc
#
```

Note that mutually_exclusive is a sub-directory of the extcon device and the file names under the mutually_exclusive directory show the mutually-exclusive sets, not the contents of the files.

/sys/class/extcon/.../name

Defined on file *sysfs-class-extcon*

The /sys/class/extcon/.../name shows the name of the extcon object. If the extcon object has an optional callback "show_name" defined, the callback will provide the name with this sysfs node.

/sys/class/extcon/.../state

Defined on file *sysfs-class-extcon*

The /sys/class/extcon/.../state shows and stores the cable attach/detach information of the corresponding extcon object. If the extcon object has an optional callback "show_state" defined, the showing function is overridden with the optional callback.

If the default callback for showing function is used, the format is like this:

```
# cat state
USB_OTG=1
HDMI=0
TA=1
EAR_JACK=0
#
```

In this example, the extcon device has USB_OTG and TA cables attached and HDMI and EAR_JACK cables detached.

In order to update the state of an extcon device, enter a hex state number starting with 0x:

```
# echo 0xHEX > state
```

This updates the whole state of the extcon device. Inputs of all the methods are required to meet the mutually_exclusive conditions if they exist.

It is recommended to use this "global" state interface if you need to set the value atomically. The later state interface associated with each cable cannot update multiple cable states of an extcon device simultaneously.

/sys/class/fc/fc_udev_device/appid_store

Defined on file *sysfs-class-fc*

This interface allows an admin to set an FC application identifier in the blkcg associated with a cgroup id. The identifier is typically a UUID that is associated with an application or logical entity such as a virtual machine or container group. The application or logical entity utilizes a block device via the cgroup id. FC adapter drivers may query the identifier and tag FC traffic based on the identifier. FC host and FC fabric entities can utilize the application id and FC traffic tag to identify traffic sources.

The interface expects a string "<cgroupid>:<appid>" where: <cgroupid> is inode of the cgroup in hexadecimal <appid> is user provided string upto 128 characters in length.

If an appid_store is done for a cgroup id that already has an appid set, the new value will override the previous value.

If an admin wants to remove an FC application identifier from a cgroup, an appid_store should be done with the following string: "<cgroupid>:"

/sys/class/fc_host/hostX/statistics/fpin_cn_yyy

Defined on file *sysfs-class-fc_host*

These files contain the number of congestion notification events recorded by the F_Port, reported using fabric performance impact notification (FPIN) event.

/sys/class/fc_host/hostX/statistics/fpin_dn_yyy

Defined on file *sysfs-class-fc_host*

These files contain the number of delivery related errors recorded by the F_Port/Nx_Port, reported using fabric performance impact notification (FPIN) event.

/sys/class/fc_host/hostX/statistics/fpin_li_yyy

Defined on file *sysfs-class-fc_host*

These files contain the number of link integrity error events recorded by the F_Port/Nx_Port, reported using fabric performance impact notification (FPIN) event.

/sys/class/fc_remote_ports/rport-X:Y-Z/statistics/fpin_cn_yyy

Defined on file *sysfs-class-fc_remote_ports*

These files contain the number of congestion notification events recorded by the F_Port/Nx_Port, reported using fabric performance impact notification (FPIN) event.

/sys/class/fc_remote_ports/rport-X:Y-Z/statistics/fpin_dn_yyy

Defined on file *sysfs-class-fc_remote_ports*

These files contain the number of delivery related errors recorded by the F_Port/Nx_Port, reported using fabric performance impact notification (FPIN) event.

/sys/class/fc_remote_ports/rport-X:Y-Z/statistics/fpin_li_yyy

Defined on file *sysfs-class-fc_remote_ports*

These files contain the number of link integrity error events recorded by the F_Port/Nx_Port, reported using fabric performance impact notification (FPIN) event.

/sys/class/firmware-attributes/*/attributes/*/

Defined on file *sysfs-class-firmware-attributes*

A sysfs interface for systems management software to enable configuration capability on supported systems. This directory exposes interfaces for interacting with configuration options.

Unless otherwise specified in an attribute description all attributes are optional and will accept UTF-8 input.

type:
A file that can be read to obtain the type of attribute. This attribute is mandatory.

The following are known types:

- enumeration: a set of pre-defined valid values
- integer: a range of numerical values
- string

HP specific types

- ordered-list - a set of ordered list valid values

All attribute types support the following values:

current_value:
A file that can be read to obtain the current value of the <attr>.

This file can also be written to in order to update the value of a <attr>

This attribute is mandatory.

default_value:
A file that can be read to obtain the default value of the <attr>

display_name:
A file that can be read to obtain a user friendly description of the at <attr>

display_name_language_code:
A file that can be read to obtain the IETF language tag corresponding to the "display_name" of the <attr>

"enumeration"-type specific properties:

possible_values:
A file that can be read to obtain the possible values of the <attr>. Values are separated using semi-colon (;).

"integer"-type specific properties:

min_value:
A file that can be read to obtain the lower bound value of the <attr>

max_value:
A file that can be read to obtain the upper bound value of the <attr>

scalar_increment:
A file that can be read to obtain the scalar value used for increments of current_value this attribute accepts.

”string”-type specific properties:

max_length:
A file that can be read to obtain the maximum length value of the <attr>

min_length:
A file that can be read to obtain the minimum length value of the <attr>

Dell specific class extensions

On Dell systems the following additional attributes are available:

dell_modifier:
A file that can be read to obtain attribute-level dependency rule. It says an attribute X will become read-only or suppressed, if/if-not attribute Y is configured.

modifier rules can be in following format:

```
[ReadOnlyIf:<attribute>=<value>]
[ReadOnlyIfNot:<attribute>=<value>]
[SuppressIf:<attribute>=<value>]
[SuppressIfNot:<attribute>=<value>]
```

For example:

```
AutoOnFri/dell_modifier has value,
        [SuppressIfNot:AutoOn=SelectDays]
```

This means AutoOnFri will be suppressed in BIOS setup if AutoOn attribute is not ”SelectDays” and its value will not be effective through sysfs until this rule is met.

Enumeration attributes also support the following:

dell_value_modifier:
A file that can be read to obtain value-level dependency. This file is similar to dell_modifier but here, an attribute's current value will be forcefully changed based dependent attributes value.

dell_value_modifier rules can be in following format:

```
<value>[ForceIf:<attribute>=<value>]
<value>[ForceIfNot:<attribute>=<value>]
```

For example:

```
LegacyOrom/dell_value_modifier has value:
        Disabled[ForceIf:SecureBoot=Enabled]
```

This means LegacyOrom's current value will be forced to ”Disabled” in BIOS setup if SecureBoot is Enabled and its value will not be effective through sysfs until this rule is met.

HP specific class extensions

On HP systems the following additional attributes are available:

”ordered-list”-type specific properties:

elements:
A file that can be read to obtain the possible list of values of the <attr>. Values are separated using semi-colon (;) and listed according to their priority. An element listed first has the highest priority. Writing the list in a different order to current_value alters the priority order for the particular attribute.

/sys/class/firmware-attributes/*/attributes/Sure_Start/audit_log_entries

Defined on file *sysfs-class-firmware-attributes*

'audit_log_entries' is a read-only file that returns the events in the log.

Audit log entry format

Byte 0-15: Requested Audit Log entry (Each Audit log is 16 bytes) Byte 16-127: Unused

/sys/class/firmware-attributes/*/attributes/Sure_Start/audit_log_entry_count

Defined on file *sysfs-class-firmware-attributes*

'audit_log_entry_count' is a read-only file that returns the number of existing audit log events available to be read. Values are separated using comma. (,)

[No of entries],[log entry size],[Max number of entries supported]

log entry size identifies audit log size for the current BIOS version. The current size is 16 bytes but it can be up to 128 bytes long in future BIOS versions.

/sys/class/firmware-attributes/*/attributes/debug_cmd

Defined on file *sysfs-class-firmware-attributes*

This write only attribute can be used to send debug commands to the BIOS. This should only be used when recommended by the BIOS vendor. Vendors may use it to enable extra debug attributes or BIOS features for testing purposes.

Note that any changes to this attribute requires a reboot for changes to take effect.

HP specific class extensions - Secure Platform Manager (SPM)

/sys/class/firmware-attributes/*/attributes/pending_reboot

Defined on file *sysfs-class-firmware-attributes*

A read-only attribute reads 1 if a reboot is necessary to apply pending BIOS attribute changes. Also, an uevent_KOBJ_CHANGE is generated when it changes to 1.

0	All BIOS attributes setting are current
1	A reboot is necessary to get pending BIOS attribute changes applied

Note, userspace applications need to follow below steps for efficient BIOS management,

1. Check if admin password is set. If yes, follow session method for password management as briefed under authentication section above.
2. Before setting any attribute, check if it has any modifiers or value_modifiers. If yes, incorporate them and then modify attribute.

Drivers may emit a CHANGE uevent when this value changes and userspace may check it again.

/sys/class/firmware-attributes/*/attributes/reset_bios

Defined on file *sysfs-class-firmware-attributes*

This attribute can be used to reset the BIOS Configuration. Specifically, it tells which type of reset BIOS configuration is being requested on the host.

Reading from it returns a list of supported options encoded as:

- 'builtinsafe' (Built in safe configuration profile)
- 'lastknowngood' (Last known good saved configuration profile)
- 'factory' (Default factory settings configuration profile)
- 'custom' (Custom saved configuration profile)

The currently selected option is printed in square brackets as shown below:

```
# echo "factory" > /sys/class/firmware-attributes/*/device/attributes/reset_
↪bios
# cat /sys/class/firmware-attributes/*/device/attributes/reset_bios
builtinsafe lastknowngood [factory] custom
```

Note that any changes to this attribute requires a reboot for changes to take effect.

/sys/class/firmware-attributes/*/attributes/save_settings

Defined on file *sysfs-class-firmware-attributes*

On Lenovo platforms there is a limitation in the number of times an attribute can be saved. This is an architectural limitation and it limits the number of attributes that can be modified to 48. A solution for this is instead of the attribute being saved after every modification, to allow a user to bulk set the attributes, and then trigger a final save. This allows unlimited attributes.

Read the attribute to check what save mode is enabled (single or bulk). E.g: # cat /sys/class/firmware-attributes/thinklmi/attributes/save_settings single

Write the attribute with 'bulk' to enable bulk save mode. Write the attribute with 'single' to enable saving, after every attribute set. The default setting is single mode. E.g: # echo bulk > /sys/class/firmware-attributes/thinklmi/attributes/save_settings

When in bulk mode write 'save' to trigger a save of all currently modified attributes. Note, once a save has been triggered, in bulk mode, attributes can no longer be set and will return a permissions error. This is to prevent users hitting the 48+ save limitation (which requires entering the BIOS to clear the error condition) E.g: # echo save > /sys/class/firmware-attributes/thinklmi/attributes/save_settings

/sys/class/firmware-attributes/*/authentication/

Defined on file *sysfs-class-firmware-attributes*

Devices support various authentication mechanisms which can be exposed as a separate configuration object.

For example a "BIOS Admin" password and "System" Password can be set, reset or cleared using these attributes.

- An "Admin" password is used for preventing modification to the BIOS settings.
- A "System" password is required to boot a machine.

Change in any of these two authentication methods will also generate an uevent KOBJ_CHANGE.

is_enabled:
A file that can be read to obtain a 0/1 flag to see if <attr> authentication is enabled. This attribute is mandatory.

role:
The type of authentication used. This attribute is mandatory.

Known types:

bios-admin:
Representing BIOS administrator password

power-on:
Representing a password required to use the system

system-mgmt:
Representing System Management password. See Lenovo extensions section for details

HDD:
Representing HDD password See Lenovo extensions section for details

NVMe:
Representing NVMe password See Lenovo extensions section for details

mechanism:
The means of authentication. This attribute is mandatory. Only supported type currently is "password".

max_password_length:
A file that can be read to obtain the maximum length of the Password

min_password_length:
A file that can be read to obtain the minimum length of the Password

current_password:
A write only value used for privileged access such as setting attributes when a system or admin password is set or resetting to a new password

This attribute is mandatory when mechanism == "password".

new_password:
A write only value that when used in tandem with current_password will reset a system or admin password.

Note, password management is session specific. If Admin password is set, same password must be written into current_password file (required for password-validation) and must be cleared once the session is over. For example:

```
echo "password" > current_password
echo "disabled" > TouchScreen/current_value
echo "" > current_password
```

Drivers may emit a CHANGE uevent when a password is set or unset userspace may check it again.

On Dell, Lenovo and HP systems, if Admin password is set, then all BIOS attributes require password validation. On Lenovo systems if you change the Admin password the new password is not active until the next boot.

Lenovo specific class extensions

On Lenovo systems the following additional settings are available:

role: system-mgmt This gives the same authority as the bios-admin password to control
security related features. The authorities allocated can be set via the BIOS menu SMP Access Control Policy

role: HDD & NVMe This password is used to unlock access to the drive at boot. Note see
'level' and 'index' extensions below.

lenovo_encoding:
The encoding method that is used. This can be either ”ascii” or ”scancode”. Default is set to ”ascii”

lenovo_kbdlang:
The keyboard language method that is used. This is generally a two char code (e.g. ”us”, ”fr”, ”gr”) and may vary per platform. Default is set to ”us”

level:
Available for HDD and NVMe authentication to set 'user' or 'master' privilege level. If only the user password is configured then this should be used to unlock the drive at boot. If both master and user passwords are set then either can be used. If a master password is set a user password is required. This attribute defaults to 'user' level

index:
Used with HDD and NVME authentication to set the drive index that is being referenced (e.g hdd1, hdd2 etc) This attribute defaults to device 1.

certificate, signature, save_signature:
These attributes are used for certificate based authentication. This is used in conjunction with a signing server as an alternative to password based authentication. The user writes to the attribute(s) with a BASE64 encoded string obtained from the signing server. The attributes can be displayed to check the stored value.

Some usage examples:

Installing a certificate to enable feature:

```
echo "supervisor password" > authentication/Admin/current_password
echo "signed certificate" > authentication/Admin/certificate
```

Updating the installed certificate:

```
echo "signature" > authentication/Admin/signature
echo "signed certificate" > authentication/Admin/certificate
```

Removing the installed certificate:

```
echo "signature" > authentication/Admin/signature
echo "" > authentication/Admin/certificate
```

Changing a BIOS setting:

```
echo "signature" > authentication/Admin/signature
echo "save signature" > authentication/Admin/save_signature
echo Enable > attribute/PasswordBeep/current_value
```

You cannot enable certificate authentication if a supervisor password has not been set. Clearing the certificate results in no bios-admin authentication method being configured allowing anyone to make changes. After any of these operations the system must reboot for the changes to take effect.

certificate_thumbprint:
Read only attribute used to display the MD5, SHA1 and SHA256 thumbprints for the certificate installed in the BIOS.

certificate_to_password:
Write only attribute used to switch from certificate based authentication back to password based. Usage:

```
echo "signature" > authentication/Admin/signature
echo "password" > authentication/Admin/certificate_to_password
```

HP specific class extensions

On HP systems the following additional settings are available:

role: enhanced-bios-auth:
This role is specific to Secure Platform Management (SPM) attribute. It requires configuring an endorsement (kek) and signing certificate (sk).

/sys/class/firmware-attributes/*/authentication/SPM/kek

Defined on file *sysfs-class-firmware-attributes*

'kek' Key-Encryption-Key is a write-only file that can be used to configure the RSA public key that will be used by the BIOS to verify signatures when setting the signing key. When written, the bytes should correspond to the KEK certificate (x509 .DER format containing an OU). The size of the certificate must be less than or equal to 4095 bytes.

/sys/class/firmware-attributes/*/authentication/SPM/sk

Defined on file *sysfs-class-firmware-attributes*

'sk' Signature Key is a write-only file that can be used to configure the RSA public key that will be used by the BIOS to verify signatures when configuring BIOS settings and security features.

When written, the bytes should correspond to the modulus of the public key. The exponent is assumed to be 0x10001.

/sys/class/firmware-attributes/*/authentication/SPM/status

Defined on file *sysfs-class-firmware-attributes*

'status' is a read-only file that returns ASCII text in JSON format reporting the status information.

> "State": "not provisioned | provisioned | provisioning in progress", "Version": "Major.Minor", "Nonce": <16-bit unsigned number display in base 10>, "FeaturesInUse": <16-bit unsigned number display in base 10>, "EndorsementKeyMod": "<256 bytes in base64>", "SigningKeyMod": "<256 bytes in base64>"

/sys/class/firmware/.../cancel

Defined on file *sysfs-class-firmware*

Write-only. For firmware uploads, write a "1" to this file to request that the transfer of firmware data to the lower-level device be canceled. This request will be rejected (EBUSY) if the update cannot be canceled (e.g. a FLASH write is in progress) or (ENODEV) if there is no firmware update in progress.

/sys/class/firmware/.../data

Defined on file *sysfs-class-firmware*

The data sysfs file is used for firmware-fallback and for firmware uploads. Cat a firmware image to this sysfs file after you echo 1 to the loading sysfs file. When the firmware image write is complete, echo 0 to the loading sysfs file. This sequence will signal the completion of the firmware write and signal the lower-level driver that the firmware data is available.

/sys/class/firmware/.../error

Defined on file *sysfs-class-firmware*

Read-only. Returns a string describing a failed firmware upload. This string will be in the form of <STATUS>:<ERROR>, where <STATUS> will be one of the status strings described for the status sysfs file and <ERROR> will be one of the following: "hw-error", "timeout", "user-abort", "device-busy", "invalid-file-size", "read-write-error", "flash-wearout". The error sysfs file is only meaningful when the current firmware upload status is "idle". If this file is read while a firmware transfer is in progress, then the read will fail with EBUSY.

/sys/class/firmware/.../loading

Defined on file *sysfs-class-firmware*

The loading sysfs file is used for both firmware-fallback and for firmware uploads. Echo 1 onto the loading file to indicate you are writing a firmware file to the data sysfs node. Echo -1 onto this file to abort the data write or echo 0 onto this file to indicate that the write is complete.

For firmware uploads, the zero value also triggers the transfer of the firmware data to the lower-level device driver.

/sys/class/firmware/.../remaining_size

Defined on file *sysfs-class-firmware*

Read-only. For firmware upload, this file contains the size of the firmware data that remains to be transferred to the lower-level device driver. The size value is initialized to the full size of the firmware image that was previously written to the data sysfs file. This value is periodically updated during the "transferring" phase of the firmware upload. Format: "%u".

/sys/class/firmware/.../status

Defined on file *sysfs-class-firmware*

Read-only. Returns a string describing the current status of a firmware upload. The string will be one of the following: idle, "receiving", "preparing", "transferring", "programming".

/sys/class/firmware/.../timeout

Defined on file *sysfs-class-firmware*

This file supports the timeout mechanism for firmware fallback. This file has no affect on firmware uploads. For more information on timeouts please see the documentation for firmware fallback.

/sys/class/fpga_bridge/<bridge>/name

Defined on file *sysfs-class-fpga-bridge*

Name of low level FPGA bridge driver.

/sys/class/fpga_bridge/<bridge>/state

Defined on file *sysfs-class-fpga-bridge*

Show bridge state as "enabled" or "disabled"

/sys/class/fpga_manager/<fpga>/name

Defined on file *sysfs-class-fpga-manager*

Name of low level fpga manager driver.

/sys/class/fpga_manager/<fpga>/state

Defined on file *sysfs-class-fpga-manager*

Read fpga manager state as a string. The intent is to provide enough detail that if something goes wrong during FPGA programming (something that the driver can't fix) then userspace can

know, i.e. if the firmware request fails, that could be due to not being able to find the firmware file.

This is a superset of FPGA states and fpga manager driver states. The fpga manager driver is walking through these steps to get the FPGA into a known operating state. It's a sequence, though some steps may get skipped. Valid FPGA states will vary by manufacturer; this is a superset.

- unknown = can't determine state
- power off = FPGA power is off
- power up = FPGA reports power is up
- reset = FPGA held in reset state
- firmware request = firmware class request in progress
- firmware request error = firmware request failed
- write init = preparing FPGA for programming
- write init error = Error while preparing FPGA for programming
- write = FPGA ready to receive image data
- write error = Error while programming
- write complete = Doing post programming steps
- write complete error = Error while doing post programming
- operating = FPGA is programmed and operating

/sys/class/fpga_manager/<fpga>/status

Defined on file *sysfs-class-fpga-manager*

Read fpga manager status as a string. If FPGA programming operation fails, it could be caused by crc error or incompatible bitstream image. The intent of this interface is to provide more detailed information for FPGA programming errors to userspace. This is a list of strings for the supported status.

- **reconfig operation error - invalid operations detected by**
  reconfiguration hardware. e.g. start reconfiguration with errors not cleared
- **reconfig CRC error - CRC error detected by**
  reconfiguration hardware.
- **reconfig incompatible image - reconfiguration image is**
  incompatible with hardware
- **reconfig IP protocol error - protocol errors detected by**
  reconfiguration hardware
- **reconfig fifo overflow error - FIFO overflow detected by**
  reconfiguration hardware

/sys/class/fpga_region/<region>/compat_id

Defined on file *sysfs-class-fpga-region*

FPGA region id for compatibility check, e.g. compatibility of the FPGA reconfiguration hardware and image. This value is defined or calculated by the layer that is creating the FPGA region. This interface returns the compat_id value or just error code -ENOENT in case compat_id is not used.

/sys/class/genwqe/genwqe<n>_card/appid

Defined on file *sysfs-driver-genwqe*

Identifies the currently active card application e.g. 'GZIP' for compression/decompression.

/sys/class/genwqe/genwqe<n>_card/base_clock

Defined on file *sysfs-driver-genwqe*

Base clock frequency of the card.

/sys/class/genwqe/genwqe<n>_card/curr_bitstream

Defined on file *sysfs-driver-genwqe*

Currently active bitstream. 1 is default, 0 is backup.

/sys/class/genwqe/genwqe<n>_card/device/sriov_numvfs

Defined on file *sysfs-driver-genwqe*

Enable VFs (1..15):

```
sudo sh -c 'echo 15 > \
  /sys/bus/pci/devices/0000\:1b\:00.0/sriov_numvfs'
```

Disable VFs:

```
Write a 0 into the same sysfs entry.
```

/sys/class/genwqe/genwqe<n>_card/freerunning_timer

Defined on file *sysfs-driver-genwqe*

Interface to read the cards free running timer. Used for performance and utilization measurements.

/sys/class/genwqe/genwqe<n>_card/next_bitstream

Defined on file *sysfs-driver-genwqe*

Interface to set the next bitstream to be used.

/sys/class/genwqe/genwqe<n>_card/queue_working_time

Defined on file *sysfs-driver-genwqe*

Interface to read queue working time. Used for performance and utilization measurements.

/sys/class/genwqe/genwqe<n>_card/reload_bitstream

Defined on file *sysfs-driver-genwqe*

Interface to trigger a PCIe card reset to reload the bitstream.

```
sudo sh -c 'echo 1 > \
  /sys/class/genwqe/genwqe0_card/reload_bitstream'
```

If successfully, the card will come back with the bitstream set on 'next_bitstream'.

/sys/class/genwqe/genwqe<n>_card/state

Defined on file *sysfs-driver-genwqe*

State of the card: ”unused”, ”used”, ”error”.

/sys/class/genwqe/genwqe<n>_card/tempsens

Defined on file *sysfs-driver-genwqe*

Interface to read the cards temperature sense register.

/sys/class/genwqe/genwqe<n>_card/type

Defined on file *sysfs-driver-genwqe*

Type of the card e.g. 'GenWQE5-A7'.

/sys/class/genwqe/genwqe<n>_card/version

Defined on file *sysfs-driver-genwqe*

Unique bitstream identification e.g. '0000000330336283.00000000475a4950'.

/sys/class/gnss/gnss<N>/type

Defined on file *sysfs-class-gnss*

The GNSS receiver type. The currently identified types reflect the protocol(s) supported by the receiver:

”NMEA”	NMEA 0183
”SiRF”	SiRF Binary
”UBX”	UBX

Note that also non-"NMEA" type receivers typically support a subset of NMEA 0183 with vendor extensions (e.g. to allow switching to a vendor protocol).

/sys/class/hwmon/hwmonX/cpuY_vid

Defined on file *sysfs-class-hwmon*

CPU core reference voltage.

Unit: millivolt

RO

Not always correct.

/sys/class/hwmon/hwmonX/currY_average

Defined on file *sysfs-class-hwmon*

Average current use

Unit: milliampere

RO

/sys/class/hwmon/hwmonX/currY_crit

Defined on file *sysfs-class-hwmon*

Current critical high value.

Unit: milliampere

RW

/sys/class/hwmon/hwmonX/currY_enable

Defined on file *sysfs-class-hwmon*

Enable or disable the sensors.

When disabled the sensor read will return -ENODATA.

- 1: Enable
- 0: Disable

RW

/sys/class/hwmon/hwmonX/currY_highest

Defined on file *sysfs-class-hwmon*

Historical maximum current Unit: milliampere RO

/sys/class/hwmon/hwmonX/currY_input

Defined on file *sysfs-class-hwmon*

Current input value

Unit: milliampere

RO

/sys/class/hwmon/hwmonX/currY_lcrit

Defined on file *sysfs-class-hwmon*

Current critical low value

Unit: milliampere

RW

/sys/class/hwmon/hwmonX/currY_lowest

Defined on file *sysfs-class-hwmon*

Historical minimum current

Unit: milliampere

RO

/sys/class/hwmon/hwmonX/currY_max

Defined on file *sysfs-class-hwmon*

Current max value

Unit: milliampere

RW

/sys/class/hwmon/hwmonX/currY_min

Defined on file *sysfs-class-hwmon*

Current min value.

Unit: milliampere

RW

/sys/class/hwmon/hwmonX/currY_rated_max

Defined on file *sysfs-class-hwmon*

Maximum rated current.

Unit: milliampere

RO

/sys/class/hwmon/hwmonX/currY_rated_min

Defined on file *sysfs-class-hwmon*

Minimum rated current.

Unit: milliampere

RO

/sys/class/hwmon/hwmonX/currY_reset_history

Defined on file *sysfs-class-hwmon*

Reset currX_lowest and currX_highest

WO

/sys/class/hwmon/hwmonX/curr_reset_history

Defined on file *sysfs-class-hwmon*

Reset currX_lowest and currX_highest for all sensors

WO

/sys/class/hwmon/hwmonX/device/pec

Defined on file *sysfs-class-hwmon*

PEC support on I2C devices

- 0, off, n: disable
- 1, on, y: enable

RW

/sys/class/hwmon/hwmonX/energyY_enable

Defined on file *sysfs-class-hwmon*

Enable or disable the sensors.

When disabled the sensor read will return -ENODATA.

- 1: Enable
- 0: Disable

RW

/sys/class/hwmon/hwmonX/energyY_input

Defined on file *sysfs-class-hwmon*

Cumulative energy use

Unit: microJoule

RO

/sys/class/hwmon/hwmonX/fanY_div

Defined on file *sysfs-class-hwmon*

Fan divisor.

Integer value in powers of two (1, 2, 4, 8, 16, 32, 64, 128).

RW

Some chips only support values 1, 2, 4 and 8. Note that this is actually an internal clock divisor, which affects the measurable speed range, not the read value.

/sys/class/hwmon/hwmonX/fanY_enable

Defined on file *sysfs-class-hwmon*

Enable or disable the sensors.

When disabled the sensor read will return -ENODATA.

- 1: Enable
- 0: Disable

RW

/sys/class/hwmon/hwmonX/fanY_fault

Defined on file *sysfs-class-hwmon*

Reports if a fan has reported failure.

- 1: Failed
- 0: Ok

RO

/sys/class/hwmon/hwmonX/fanY_input

Defined on file *sysfs-class-hwmon*

Fan input value.

Unit: revolution/min (RPM)

RO

/sys/class/hwmon/hwmonX/fanY_label

Defined on file *sysfs-class-hwmon*

Suggested fan channel label.

Text string

Should only be created if the driver has hints about what this fan channel is being used for, and user-space doesn't. In all other cases, the label is provided by user-space.

RO

/sys/class/hwmon/hwmonX/fanY_max

Defined on file *sysfs-class-hwmon*

Fan maximum value

Unit: revolution/min (RPM)

Only rarely supported by the hardware. RW

/sys/class/hwmon/hwmonX/fanY_min

Defined on file *sysfs-class-hwmon*

Fan minimum value

Unit: revolution/min (RPM)

RW

/sys/class/hwmon/hwmonX/fanY_pulses

Defined on file *sysfs-class-hwmon*

Number of tachometer pulses per fan revolution.

Integer value, typically between 1 and 4.

RW

This value is a characteristic of the fan connected to the device's input, so it has to be set in accordance with the fan model.

Should only be created if the chip has a register to configure the number of pulses. In the absence of such a register (and thus attribute) the value assumed by all devices is 2 pulses per fan revolution.

/sys/class/hwmon/hwmonX/fanY_target

Defined on file *sysfs-class-hwmon*

Desired fan speed

Unit: revolution/min (RPM)

RW

Only makes sense if the chip supports closed-loop fan speed control based on the measured fan speed.

/sys/class/hwmon/hwmonX/humidityY_alarm

Defined on file *sysfs-class-hwmon*

Humidity limit detection

- 0: OK
- 1: Humidity limit has been reached

RO

/sys/class/hwmon/hwmonX/humidityY_enable

Defined on file *sysfs-class-hwmon*

Enable or disable the sensors

When disabled the sensor read will return -ENODATA.

- 1: Enable
- 0: Disable

RW

/sys/class/hwmon/hwmonX/humidityY_fault

Defined on file *sysfs-class-hwmon*

Reports a humidity sensor failure.

- 1: Failed
- 0: Ok

RO

/sys/class/hwmon/hwmonX/humidityY_input

Defined on file *sysfs-class-hwmon*

Humidity

Unit: milli-percent (per cent mille, pcm)

RO

/sys/class/hwmon/hwmonX/humidityY_label

Defined on file *sysfs-class-hwmon*

Suggested humidity channel label.

Text string

Should only be created if the driver has hints about what this humidity channel is being used for, and user-space doesn't. In all other cases, the label is provided by user-space.

RO

/sys/class/hwmon/hwmonX/humidityY_max

Defined on file *sysfs-class-hwmon*

Humidity max value.

Unit: milli-percent (per cent mille, pcm)

RW

/sys/class/hwmon/hwmonX/humidityY_max_hyst

Defined on file *sysfs-class-hwmon*

Humidity hysteresis value for max limit.

Unit: milli-percent (per cent mille, pcm)

Must be reported as an absolute humidity, NOT a delta from the max value.

RW

/sys/class/hwmon/hwmonX/humidityY_min

Defined on file *sysfs-class-hwmon*

Humidity min value.

Unit: milli-percent (per cent mille, pcm)

RW

/sys/class/hwmon/hwmonX/humidityY_min_hyst

Defined on file *sysfs-class-hwmon*

Humidity hysteresis value for min limit.

Unit: milli-percent (per cent mille, pcm)

Must be reported as an absolute humidity, NOT a delta from the min value.

RW

/sys/class/hwmon/hwmonX/humidityY_rated_max

Defined on file *sysfs-class-hwmon*

Maximum rated humidity.

Unit: milli-percent (per cent mille, pcm)

RO

/sys/class/hwmon/hwmonX/humidityY_rated_min

Defined on file *sysfs-class-hwmon*

Minimum rated humidity.

Unit: milli-percent (per cent mille, pcm)

RO

/sys/class/hwmon/hwmonX/inY_average

Defined on file *sysfs-class-hwmon*

Average voltage

Unit: millivolt

RO

/sys/class/hwmon/hwmonX/inY_crit

Defined on file *sysfs-class-hwmon*

Voltage critical max value.

Unit: millivolt

RW

If voltage reaches or exceeds this limit, the system may take drastic action such as power down or reset. At the very least, it should report a fault.

/sys/class/hwmon/hwmonX/inY_enable

Defined on file *sysfs-class-hwmon*

Enable or disable the sensors.

When disabled the sensor read will return -ENODATA.

- 1: Enable
- 0: Disable

RW

/sys/class/hwmon/hwmonX/inY_highest

Defined on file *sysfs-class-hwmon*

Historical maximum voltage

Unit: millivolt

RO

/sys/class/hwmon/hwmonX/inY_input

Defined on file *sysfs-class-hwmon*

Voltage input value.

Unit: millivolt

RO

Voltage measured on the chip pin.

Actual voltage depends on the scaling resistors on the motherboard, as recommended in the chip datasheet.

This varies by chip and by motherboard. Because of this variation, values are generally NOT scaled by the chip driver, and must be done by the application. However, some drivers (notably lm87 and via686a) do scale, because of internal resistors built into a chip. These drivers will output the actual voltage. Rule of thumb: drivers should report the voltage values at the "pins" of the chip.

/sys/class/hwmon/hwmonX/inY_label

Defined on file *sysfs-class-hwmon*

Suggested voltage channel label.

Text string

Should only be created if the driver has hints about what this voltage channel is being used for, and user-space doesn't. In all other cases, the label is provided by user-space.

RO

/sys/class/hwmon/hwmonX/inY_lcrit

Defined on file *sysfs-class-hwmon*

Voltage critical min value.

Unit: millivolt

RW

If voltage drops to or below this limit, the system may take drastic action such as power down or reset. At the very least, it should report a fault.

/sys/class/hwmon/hwmonX/inY_lowest

Defined on file *sysfs-class-hwmon*

Historical minimum voltage

Unit: millivolt

RO

/sys/class/hwmon/hwmonX/inY_max

Defined on file *sysfs-class-hwmon*

Voltage max value.

Unit: millivolt

RW

/sys/class/hwmon/hwmonX/inY_min

Defined on file *sysfs-class-hwmon*

Voltage min value.

Unit: millivolt

RW

/sys/class/hwmon/hwmonX/inY_rated_max

Defined on file *sysfs-class-hwmon*

Maximum rated voltage.

Unit: millivolt

RO

/sys/class/hwmon/hwmonX/inY_rated_min

Defined on file *sysfs-class-hwmon*

Minimum rated voltage.

Unit: millivolt

RO

/sys/class/hwmon/hwmonX/inY_reset_history

Defined on file *sysfs-class-hwmon*

Reset inX_lowest and inX_highest

WO

/sys/class/hwmon/hwmonX/in_reset_history

Defined on file *sysfs-class-hwmon*

Reset inX_lowest and inX_highest for all sensors

WO

/sys/class/hwmon/hwmonX/intrusionY_alarm

Defined on file *sysfs-class-hwmon*

Chassis intrusion detection

- 0: OK
- 1: intrusion detected

RW

Contrary to regular alarm flags which clear themselves automatically when read, this one sticks until cleared by the user. This is done by writing 0 to the file. Writing other values is unsupported.

/sys/class/hwmon/hwmonX/intrusionY_beep

Defined on file *sysfs-class-hwmon*

Chassis intrusion beep

- 0: disable
- 1: enable

RW

/sys/class/hwmon/hwmonX/label

Defined on file *sysfs-class-hwmon*

A descriptive label that allows to uniquely identify a device within the system. The contents of the label are free-form.

RO

/sys/class/hwmon/hwmonX/name

Defined on file *sysfs-class-hwmon*

The chip name. This should be a short, lowercase string, not containing whitespace, dashes, or the wildcard character '*'. This attribute represents the chip name. It is the only mandatory attribute. I2C devices get this attribute created automatically.

RO

/sys/class/hwmon/hwmonX/powerY_accuracy

Defined on file *sysfs-class-hwmon*

Accuracy of the power meter.

Unit: Percent

RO

/sys/class/hwmon/hwmonX/powerY_average

Defined on file *sysfs-class-hwmon*

Average power use

Unit: microWatt

RO

/sys/class/hwmon/hwmonX/powerY_average_highest

Defined on file *sysfs-class-hwmon*

Historical average maximum power use

Unit: microWatt

RO

/sys/class/hwmon/hwmonX/powerY_average_interval

Defined on file *sysfs-class-hwmon*

Power use averaging interval. A poll notification is sent to this file if the hardware changes the averaging interval.

Unit: milliseconds

RW

/sys/class/hwmon/hwmonX/powerY_average_interval_max

Defined on file *sysfs-class-hwmon*

Maximum power use averaging interval

Unit: milliseconds

RO

/sys/class/hwmon/hwmonX/powerY_average_interval_min

Defined on file *sysfs-class-hwmon*

Minimum power use averaging interval

Unit: milliseconds

RO

/sys/class/hwmon/hwmonX/powerY_average_lowest

Defined on file *sysfs-class-hwmon*

Historical average minimum power use

Unit: microWatt

RO

/sys/class/hwmon/hwmonX/powerY_average_max

Defined on file *sysfs-class-hwmon*

A poll notification is sent to *powerY_average* when power use rises above this value.

Unit: microWatt

RW

/sys/class/hwmon/hwmonX/powerY_average_min

Defined on file *sysfs-class-hwmon*

A poll notification is sent to *powerY_average* when power use sinks below this value.

Unit: microWatt

RW

/sys/class/hwmon/hwmonX/powerY_cap

Defined on file *sysfs-class-hwmon*

If power use rises above this limit, the system should take action to reduce power use. A poll notification is sent to this file if the cap is changed by the hardware. The *_*cap* files only appear if the cap is known to be enforced by hardware.

Unit: microWatt

RW

/sys/class/hwmon/hwmonX/powerY_cap_hyst

Defined on file *sysfs-class-hwmon*

Margin of hysteresis built around capping and notification.

Unit: microWatt

RW

/sys/class/hwmon/hwmonX/powerY_cap_max

Defined on file *sysfs-class-hwmon*

Maximum cap that can be set.

Unit: microWatt

RO

/sys/class/hwmon/hwmonX/powerY_cap_min

Defined on file *sysfs-class-hwmon*

Minimum cap that can be set.

Unit: microWatt

RO

/sys/class/hwmon/hwmonX/powerY_crit

Defined on file *sysfs-class-hwmon*

Critical maximum power.

If power rises to or above this limit, the system is expected take drastic action to reduce power consumption, such as a system shutdown or a forced powerdown of some devices.

Unit: microWatt

RW

/sys/class/hwmon/hwmonX/powerY_enable

Defined on file *sysfs-class-hwmon*

Enable or disable the sensors.

When disabled the sensor read will return -ENODATA.

- 1: Enable
- 0: Disable

RW

/sys/class/hwmon/hwmonX/powerY_input

Defined on file *sysfs-class-hwmon*

Instantaneous power use

Unit: microWatt

RO

/sys/class/hwmon/hwmonX/powerY_input_highest

Defined on file *sysfs-class-hwmon*

Historical maximum power use

Unit: microWatt

RO

/sys/class/hwmon/hwmonX/powerY_input_lowest

Defined on file *sysfs-class-hwmon*

Historical minimum power use

Unit: microWatt

RO

/sys/class/hwmon/hwmonX/powerY_max

Defined on file *sysfs-class-hwmon*

Maximum power.

Unit: microWatt

RW

/sys/class/hwmon/hwmonX/powerY_rated_max

Defined on file *sysfs-class-hwmon*

Maximum rated power.

Unit: microWatt

RO

/sys/class/hwmon/hwmonX/powerY_rated_min

Defined on file *sysfs-class-hwmon*

Minimum rated power.

Unit: microWatt

RO

/sys/class/hwmon/hwmonX/powerY_reset_history

Defined on file *sysfs-class-hwmon*

Reset input_highest, input_lowest, average_highest and average_lowest.

WO

/sys/class/hwmon/hwmonX/pwmY

Defined on file *sysfs-class-hwmon*

Pulse width modulation fan control.

Integer value in the range 0 to 255

RW

255 is max or 100%.

/sys/class/hwmon/hwmonX/pwmY_auto_channels_temp

Defined on file *sysfs-class-hwmon*

Select which temperature channels affect this PWM output in auto mode.

Bitfield, 1 is temp1, 2 is temp2, 4 is temp3 etc... Which values are possible depend on the chip used.

RW

/sys/class/hwmon/hwmonX/pwmY_auto_pointZ_pwm
/sys/class/hwmon/hwmonX/pwmY_auto_pointZ_temp
/sys/class/hwmon/hwmonX/pwmY_auto_pointZ_temp_hyst

Defined on file *sysfs-class-hwmon*

Define the PWM vs temperature curve.

Number of trip points is chip-dependent. Use this for chips which associate trip points to PWM output channels.

RW

/sys/class/hwmon/hwmonX/pwmY_enable

Defined on file *sysfs-class-hwmon*

Fan speed control method:

- 0: no fan speed control (i.e. fan at full speed)
- 1: manual fan speed control enabled (using *pwmY*)
- 2+: automatic fan speed control enabled

Check individual chip documentation files for automatic mode details.

RW

/sys/class/hwmon/hwmonX/pwmY_freq

Defined on file *sysfs-class-hwmon*

Base PWM frequency in Hz.

Only possibly available when pwmN_mode is PWM, but not always present even then.

RW

/sys/class/hwmon/hwmonX/pwmY_mode

Defined on file *sysfs-class-hwmon*

- 0: DC mode (direct current)
- 1: PWM mode (pulse-width modulation)

RW

/sys/class/hwmon/hwmonX/tempY_auto_pointZ_pwm
/sys/class/hwmon/hwmonX/tempY_auto_pointZ_temp
/sys/class/hwmon/hwmonX/tempY_auto_pointZ_temp_hyst

Defined on file *sysfs-class-hwmon*

Define the PWM vs temperature curve.

Number of trip points is chip-dependent. Use this for chips which associate trip points to temperature channels.

RW

/sys/class/hwmon/hwmonX/tempY_crit

Defined on file *sysfs-class-hwmon*

Temperature critical max value, typically greater than corresponding temp_max values.

Unit: millidegree Celsius

RW

/sys/class/hwmon/hwmonX/tempY_crit_alarm

Defined on file *sysfs-class-hwmon*

Critical high temperature alarm flag.

- 0: OK
- 1: temperature has reached tempY_crit

RO

/sys/class/hwmon/hwmonX/tempY_crit_hyst

Defined on file *sysfs-class-hwmon*

Temperature hysteresis value for critical limit.

Unit: millidegree Celsius

Must be reported as an absolute temperature, NOT a delta from the critical value.

RW

/sys/class/hwmon/hwmonX/tempY_emergency

Defined on file *sysfs-class-hwmon*

Temperature emergency max value, for chips supporting more than two upper temperature limits. Must be equal or greater than corresponding temp_crit values.

Unit: millidegree Celsius

RW

/sys/class/hwmon/hwmonX/tempY_emergency_alarm

Defined on file *sysfs-class-hwmon*

Emergency high temperature alarm flag.

- 0: OK

- 1: temperature has reached tempY_emergency

RO

/sys/class/hwmon/hwmonX/tempY_emergency_hyst

Defined on file *sysfs-class-hwmon*

Temperature hysteresis value for emergency limit.

Unit: millidegree Celsius

Must be reported as an absolute temperature, NOT a delta from the emergency value.

RW

/sys/class/hwmon/hwmonX/tempY_enable

Defined on file *sysfs-class-hwmon*

Enable or disable the sensors.

When disabled the sensor read will return -ENODATA.

- 1: Enable
- 0: Disable

RW

/sys/class/hwmon/hwmonX/tempY_highest

Defined on file *sysfs-class-hwmon*

Historical maximum temperature

Unit: millidegree Celsius

RO

/sys/class/hwmon/hwmonX/tempY_input

Defined on file *sysfs-class-hwmon*

Temperature input value.

Unit: millidegree Celsius

RO

/sys/class/hwmon/hwmonX/tempY_label

Defined on file *sysfs-class-hwmon*

Suggested temperature channel label.

Text string

Should only be created if the driver has hints about what this temperature channel is being used for, and user-space doesn't. In all other cases, the label is provided by user-space.

RO

/sys/class/hwmon/hwmonX/tempY_lcrit

Defined on file *sysfs-class-hwmon*

Temperature critical min value, typically lower than corresponding temp_min values.

Unit: millidegree Celsius

RW

/sys/class/hwmon/hwmonX/tempY_lcrit_hyst

Defined on file *sysfs-class-hwmon*

Temperature hysteresis value for critical min limit.

Unit: millidegree Celsius

Must be reported as an absolute temperature, NOT a delta from the critical min value.

RW

/sys/class/hwmon/hwmonX/tempY_lowest

Defined on file *sysfs-class-hwmon*

Historical minimum temperature

Unit: millidegree Celsius

RO

/sys/class/hwmon/hwmonX/tempY_max

Defined on file *sysfs-class-hwmon*

Temperature max value.

Unit: millidegree Celsius (or millivolt, see below)

RW

/sys/class/hwmon/hwmonX/tempY_max_alarm

Defined on file *sysfs-class-hwmon*

Maximum temperature alarm flag.

- 0: OK
- 1: temperature has reached tempY_max

RO

/sys/class/hwmon/hwmonX/tempY_max_hyst

Defined on file *sysfs-class-hwmon*

Temperature hysteresis value for max limit.

Unit: millidegree Celsius

Must be reported as an absolute temperature, NOT a delta from the max value.

RW

/sys/class/hwmon/hwmonX/tempY_min

Defined on file *sysfs-class-hwmon*

Temperature min value.

Unit: millidegree Celsius

RW

/sys/class/hwmon/hwmonX/tempY_min_alarm

Defined on file *sysfs-class-hwmon*

Minimum temperature alarm flag.

- 0: OK
- 1: temperature has reached tempY_min

RO

/sys/class/hwmon/hwmonX/tempY_min_hyst

Defined on file *sysfs-class-hwmon*

Temperature hysteresis value for min limit. Unit: millidegree Celsius

Must be reported as an absolute temperature, NOT a delta from the min value.

RW

/sys/class/hwmon/hwmonX/tempY_offset

Defined on file *sysfs-class-hwmon*

Temperature offset which is added to the temperature reading by the chip.

Unit: millidegree Celsius

Read/Write value.

/sys/class/hwmon/hwmonX/tempY_rated_max

Defined on file *sysfs-class-hwmon*

Maximum rated temperature.

Unit: millidegree Celsius

RO

/sys/class/hwmon/hwmonX/tempY_rated_min

Defined on file *sysfs-class-hwmon*

Minimum rated temperature.

Unit: millidegree Celsius

RO

/sys/class/hwmon/hwmonX/tempY_reset_history

Defined on file *sysfs-class-hwmon*

Reset temp_lowest and temp_highest

WO

/sys/class/hwmon/hwmonX/tempY_type

Defined on file *sysfs-class-hwmon*

Sensor type selection.

Integers 1 to 6

RW

- 1: CPU embedded diode
- 2: 3904 transistor
- 3: thermal diode
- 4: thermistor
- 5: AMD AMDSI
- 6: Intel PECI

Not all types are supported by all chips

/sys/class/hwmon/hwmonX/temp_reset_history

Defined on file *sysfs-class-hwmon*

Reset temp_lowest and temp_highest for all sensors

WO

/sys/class/hwmon/hwmonX/update_interval

Defined on file *sysfs-class-hwmon*

The interval at which the chip will update readings. Unit: millisecond

RW

Some devices have a variable update rate or interval. This attribute can be used to change it to the desired value.

/sys/class/hwmon/hwmonX/vrm

Defined on file *sysfs-class-hwmon*

Voltage Regulator Module version number.

RW (but changing it should no more be necessary)

Originally the VRM standard version multiplied by 10, but now an arbitrary number, as not all standards have a version number.

Affects the way the driver calculates the CPU core reference voltage from the vid pins.

/sys/class/input/input(x)/device/function_row_physmap

Defined on file *sysfs-driver-input-cros-ec-keyb*

A space separated list of scancodes for the top row keys, ordered by the physical positions of the keys, from left to right.

/sys/class/input/input(x)/device/shutdown

Defined on file *sysfs-driver-input-axp-pek*

Shutdown time in us. Board is powered off if the button is pressed for more than <shutdown_time>

/sys/class/input/input(x)/device/startup

Defined on file *sysfs-driver-input-axp-pek*

Startup time in us. Board is powered on if the button is pressed for more than <startup_time>

/sys/class/intel_pmt/

Defined on file *sysfs-class-intel_pmt*

The intel_pmt/ class directory contains information for devices that expose hardware telemetry using Intel Platform Monitoring Technology (PMT)

/sys/class/intel_pmt/crashlog<x>

Defined on file *sysfs-class-intel_pmt*

The crashlog<x> directory contains files for configuring an instance of a PMT crashlog device that can perform crash data recording. Each crashlog<x> device has an associated crashlog

file. This file can be opened and mapped or read to access the resulting crashlog buffer. The register layout for the buffer can be determined from an XML file of specified GUID for the parent device.

/sys/class/intel_pmt/crashlog<x>/crashlog

Defined on file *sysfs-class-intel_pmt*

(RO) The crashlog buffer for this crashlog device. This file may be mapped or read to obtain the data.

/sys/class/intel_pmt/crashlog<x>/enable

Defined on file *sysfs-class-intel_pmt*

(RW) Boolean value controlling if the crashlog functionality is enabled for the crashlog device.

/sys/class/intel_pmt/crashlog<x>/guid

Defined on file *sysfs-class-intel_pmt*

(RO) The GUID for this crashlog device. The GUID identifies the version of the XML file for the parent device that should be used to determine the register layout.

/sys/class/intel_pmt/crashlog<x>/offset

Defined on file *sysfs-class-intel_pmt*

(RO) The offset of the buffer in bytes that corresponds to the mapping for the crashlog device.

/sys/class/intel_pmt/crashlog<x>/size

Defined on file *sysfs-class-intel_pmt*

(RO) The length of the result buffer in bytes that corresponds to the size for the crashlog buffer.

/sys/class/intel_pmt/crashlog<x>/trigger

Defined on file *sysfs-class-intel_pmt*

(RW) Boolean value controlling the triggering of the crashlog device node. When read it provides data on if the crashlog has been triggered. When written to it can be used to either clear the current trigger by writing false, or to trigger a new event if the trigger is not currently set.

/sys/class/intel_pmt/telem<x>

Defined on file *sysfs-class-intel_pmt*

The telem<x> directory contains files describing an instance of a PMT telemetry device that exposes hardware telemetry. Each telem<x> directory has an associated telem file. This file may be opened and mapped or read to access the telemetry space of the device. The register

layout of the telemetry space is determined from an XML file that matches the PCI device id and GUID for the device.

/sys/class/intel_pmt/telem<x>/guid

Defined on file *sysfs-class-intel_pmt*

(RO) The GUID for this telemetry device. The GUID identifies the version of the XML file for the parent device that is to be used to get the register layout.

/sys/class/intel_pmt/telem<x>/offset

Defined on file *sysfs-class-intel_pmt*

(RO) The offset of telemetry region in bytes that corresponds to the mapping for the telem file.

/sys/class/intel_pmt/telem<x>/size

Defined on file *sysfs-class-intel_pmt*

(RO) The size of telemetry region in bytes that corresponds to the mapping size for the telem file.

/sys/class/intel_pmt/telem<x>/telem

Defined on file *sysfs-class-intel_pmt*

(RO) The telemetry data for this telemetry device. This file may be mapped or read to obtain the data.

/sys/class/iommu/<iommu>/amd-iommu/cap

Defined on file *sysfs-class-iommu-amd-iommu*

IOMMU capability header as documented in the AMD IOMMU specification. Format: %x

/sys/class/iommu/<iommu>/amd-iommu/features

Defined on file *sysfs-class-iommu-amd-iommu*

Extended features of the IOMMU. Format: %llx

/sys/class/iommu/<iommu>/devices/

Defined on file *sysfs-class-iommu*

IOMMU drivers are able to link devices managed by a given IOMMU here to allow association of IOMMU to device.

/sys/class/iommu/<iommu>/intel-iommu/address

Defined on file *sysfs-class-iommu-intel-iommu*

Physical address of the VT-d DRHD for this IOMMU. Format: %llx. This allows association of a sysfs intel-iommu with a DMAR DRHD table entry.

/sys/class/iommu/<iommu>/intel-iommu/cap

Defined on file *sysfs-class-iommu-intel-iommu*

The cached hardware capability register value of this DRHD unit. Format: %llx.

/sys/class/iommu/<iommu>/intel-iommu/ecap

Defined on file *sysfs-class-iommu-intel-iommu*

The cached hardware extended capability register value of this DRHD unit. Format: %llx.

/sys/class/iommu/<iommu>/intel-iommu/version

Defined on file *sysfs-class-iommu-intel-iommu*

The architecture version as reported from the VT-d VER_REG. Format: %d:%d, major:minor

/sys/class/lcd/<lcd>/contrast

Defined on file *sysfs-class-lcd*

Current contrast of this LCD device. Value is between 0 and */sys/class/lcd/<lcd>/max_contrast*.

/sys/class/lcd/<lcd>/lcd_power

Defined on file *sysfs-class-lcd*

Control LCD power, values are FB_BLANK_* from fb.h

- FB_BLANK_UNBLANK (0) : power on.
- FB_BLANK_POWERDOWN (4) : power off

/sys/class/lcd/<lcd>/max_contrast

Defined on file *sysfs-class-lcd*

Maximum contrast for this LCD device.

/sys/class/leds/<led>/als_channel

Defined on file *sysfs-class-led-driver-lm3533*

Set the ALS output channel to use as input in ALS-current-control mode (1, 2), where:

1	out_current1
2	out_current2

/sys/class/leds/<led>/als_en

Defined on file *sysfs-class-led-driver-lm3533*

Enable ALS-current-control mode (0, 1).

/sys/class/leds/<led>/brightness

Defined on file *sysfs-class-led*

Set the brightness of the LED.

Most LEDs don't have hardware brightness support, so will just be turned on for non-zero brightness settings.

Note: For multicolor LEDs, writing to this file will update all LEDs within the group to a calculated percentage of what each color LED intensity is set to.

The percentage is calculated for each grouped LED via the equation below:

```
led_brightness = brightness * multi_intensity/max_brightness
```

For additional details please refer to /leds/leds-class-multicolor.

The value is between 0 and */sys/class/leds/<led>/max_brightness*.

Writing 0 to this file clears active trigger.

Writing non-zero to this file while trigger is active changes the top brightness trigger is going to use.

/sys/class/leds/<led>/brightness_hw_changed

Defined on file *sysfs-class-led*

Last hardware set brightness level for this LED. Some LEDs may be changed autonomously by hardware/firmware. Only LEDs where this happens and the driver can detect this, will have this file.

This file supports poll() to detect when the hardware changes the brightness.

Reading this file will return the last brightness level set by the hardware, this may be different from the current brightness. Reading this file when no hw brightness change event has happened will return an ENODATA error.

/sys/class/leds/<led>/cts

Defined on file *sysfs-class-led-trigger-tty*

CTS = Clear To Send DCE is ready to accept data from the DTE. If the line state is detected, the LED is switched on. If set to 0 (default), the LED will not evaluate CTS. If set to 1, the LED will evaluate CTS.

/sys/class/leds/<led>/dcd

Defined on file *sysfs-class-led-trigger-tty*

DCD = Data Carrier Detect DTE is receiving a carrier from the DCE. If the line state is detected, the LED is switched on. If set to 0 (default), the LED will not evaluate CAR (DCD). If set to 1, the LED will evaluate CAR (DCD).

/sys/class/leds/<led>/delay_off

Defined on file *sysfs-class-led-trigger-oneshot*

Specifies for how many milliseconds the LED has to stay at LED_OFF brightness after it has been armed. Defaults to 100 ms.

/sys/class/leds/<led>/delay_on

Defined on file *sysfs-class-led-trigger-oneshot*

Specifies for how many milliseconds the LED has to stay at LED_FULL brightness after it has been armed. Defaults to 100 ms.

/sys/class/leds/<led>/device/brightness

Defined on file *sysfs-class-led-driver-turris-omnia*

(RW) On the front panel of the Turris Omnia router there is also a button which can be used to control the intensity of all the LEDs at once, so that if they are too bright, user can dim them.

The microcontroller cycles between 8 levels of this global brightness (from 100% to 0%), but this setting can have any integer value between 0 and 100. It is therefore convenient to be able to change this setting from software.

Format: %i

/sys/class/leds/<led>/device/gamma_correction

Defined on file *sysfs-class-led-driver-turris-omnia*

(RW) Newer versions of the microcontroller firmware of the Turris Omnia router support gamma correction for the RGB LEDs. This feature can be enabled/disabled by writing to this file.

If the feature is not supported because the MCU firmware is too old, the file always reads as 0, and writing to the file results in the EOPNOTSUPP error.

Format: %i

/sys/class/leds/<led>/device_name

Defined on file *sysfs-class-led-trigger-netdev*

Specifies the network device name to monitor.

/sys/class/leds/<led>/dim

Defined on file *sysfs-class-led-driver-aw200xx*

64-level DIM current. If you write a negative value or "auto", the dim will be calculated according to the brightness.

/sys/class/leds/<led>/dsr

Defined on file *sysfs-class-led-trigger-tty*

DSR = Data Set Ready DCE is ready to receive and send data. If the line state is detected, the LED is switched on. If set to 0 (default), the LED will not evaluate DSR. If set to 1, the LED will evaluate DSR.

/sys/class/leds/<led>/falltime
/sys/class/leds/<led>/risetime

Defined on file *sysfs-class-led-driver-lm3533*

Set the pattern generator fall and rise times (0..7), where:

0	2048 us
1	262 ms
2	524 ms
3	1.049 s
4	2.097 s
5	4.194 s
6	8.389 s
7	16.78 s

/sys/class/leds/<led>/flash_brightness

Defined on file *sysfs-class-led-flash*

read/write Set the brightness of this LED in the flash strobe mode, in microamperes. The file is created only for the flash LED devices that support setting flash brightness.

The value is between 0 and */sys/class/leds/<led>/max_flash_brightness*.

/sys/class/leds/<led>/flash_fault

Defined on file *sysfs-class-led-flash*

read only Space separated list of flash faults that may have occurred. Flash faults are re-read after strobing the flash. Possible flash faults:

- **led-over-voltage**
  flash controller voltage to the flash LED has exceeded the limit specific to the flash controller

- **flash-timeout-exceeded**
  the flash strobe was still on when the timeout set by the user has expired; not all flash controllers may set this in all such conditions
- **controller-over-temperature**
  the flash controller has overheated
- **controller-short-circuit**
  the short circuit protection of the flash controller has been triggered
- **led-power-supply-over-current**
  current in the LED power supply has exceeded the limit specific to the flash controller
- **indicator-led-fault**
  the flash controller has detected a short or open circuit condition on the indicator LED
- **led-under-voltage**
  flash controller voltage to the flash LED has been below the minimum limit specific to the flash
- **controller-under-voltage**
  the input voltage of the flash controller is below the limit under which strobing the flash at full current will not be possible; the condition persists until this flag is no longer set
- **led-over-temperature**
  the temperature of the LED has exceeded its allowed upper limit

/sys/class/leds/<led>/flash_strobe

Defined on file *sysfs-class-led-flash*

read/write Flash strobe state. When written with 1 it triggers flash strobe and when written with 0 it turns the flash off.

On read 1 means that flash is currently strobing and 0 means that flash is off.

/sys/class/leds/<led>/flash_timeout

Defined on file *sysfs-class-led-flash*

read/write Hardware timeout for flash, in microseconds. The flash strobe is stopped after this period of time has passed from the start of the strobe. The file is created only for the flash LED devices that support setting flash timeout.

/sys/class/leds/<led>/full_duplex

Defined on file *sysfs-class-led-trigger-netdev*

Signal the link full duplex state of the named network device.

If set to 0 (default), the LED's normal state is off.

If set to 1, the LED's normal state reflects the link full duplex state of the named network device. Setting this value also immediately changes the LED state.

/sys/class/leds/<led>/gt683r/mode

Defined on file *sysfs-class-leds-gt683r*

Set the mode of LEDs. You should notice that changing the mode of one LED will update the mode of its two sibling devices as well. Possible values are:

0	normal
1	audio
2	breathing

Normal: LEDs are fully on when enabled Audio: LEDs brightness depends on sound level Breathing: LEDs brightness varies at human breathing rate

/sys/class/leds/<led>/half_duplex

Defined on file *sysfs-class-led-trigger-netdev*

Signal the link half duplex state of the named network device.

If set to 0 (default), the LED's normal state is off.

If set to 1, the LED's normal state reflects the link half duplex state of the named network device. Setting this value also immediately changes the LED state.

/sys/class/leds/<led>/hw_pattern

Defined on file *sysfs-class-led-trigger-pattern*

Specify a hardware pattern for the LED, for LED hardware that supports autonomously controlling brightness over time, according to some preprogrammed hardware patterns. It deactivates any active software pattern.

Since different LED hardware can have different semantics of hardware patterns, each driver is expected to provide its own description for the hardware patterns in their documentation file at Documentation/leds/.

/sys/class/leds/<led>/id

Defined on file *sysfs-class-led-driver-lm3533*

Get the id of this led (0..3).

/sys/class/leds/<led>/interval

Defined on file *sysfs-class-led-trigger-netdev*

Specifies the duration of the LED blink in milliseconds. Defaults to 50 ms.

When offloaded is true, the interval value MUST be set to the default value and cannot be changed. Trying to set any value in this specific mode will return an EINVAL error.

/sys/class/leds/<led>/invert

Defined on file *sysfs-class-led-trigger-oneshot*

Reverse the blink logic. If set to 0 (default) blink on for delay_on ms, then blink off for delay_off ms, leaving the LED normally off. If set to 1, blink off for delay_off ms, then blink on for delay_on ms, leaving the LED normally on. Setting this value also immediately changes the LED state.

/sys/class/leds/<led>/inverted

Defined on file *sysfs-class-led*

Invert the LED on/off state. This parameter is specific to gpio and backlight triggers. In case of the backlight trigger, it is useful when driving a LED which is intended to indicate a device in a standby like state.

/sys/class/leds/<led>/linear

Defined on file *sysfs-class-led-driver-lm3533*

Set the brightness-mapping mode (0, 1), where:

0	exponential mode
1	linear mode

/sys/class/leds/<led>/link

Defined on file *sysfs-class-led-trigger-netdev*

Signal the link state of the named network device.

If set to 0 (default), the LED's normal state is off.

If set to 1, the LED's normal state reflects the link state of the named network device. Setting this value also immediately changes the LED state.

/sys/class/leds/<led>/link_10

Defined on file *sysfs-class-led-trigger-netdev*

Signal the link speed state of 10Mbps of the named network device.

If set to 0 (default), the LED's normal state is off.

If set to 1, the LED's normal state reflects the link state speed of 10MBps of the named network device. Setting this value also immediately changes the LED state.

/sys/class/leds/<led>/link_100

Defined on file *sysfs-class-led-trigger-netdev*

Signal the link speed state of 100Mbps of the named network device.

If set to 0 (default), the LED's normal state is off.

If set to 1, the LED's normal state reflects the link state speed of 100Mbps of the named network device. Setting this value also immediately changes the LED state.

/sys/class/leds/<led>/link_1000

Defined on file *sysfs-class-led-trigger-netdev*

Signal the link speed state of 1000Mbps of the named network device.

If set to 0 (default), the LED's normal state is off.

If set to 1, the LED's normal state reflects the link state speed of 1000Mbps of the named network device. Setting this value also immediately changes the LED state.

/sys/class/leds/<led>/link_10000

Defined on file *sysfs-class-led-trigger-netdev*

Signal the link speed state of 10000Mbps of the named network device.

If set to 0 (default), the LED's normal state is off.

If set to 1, the LED's normal state reflects the link state speed of 10000Mbps of the named network device. Setting this value also immediately changes the LED state.

/sys/class/leds/<led>/link_2500

Defined on file *sysfs-class-led-trigger-netdev*

Signal the link speed state of 2500Mbps of the named network device.

If set to 0 (default), the LED's normal state is off.

If set to 1, the LED's normal state reflects the link state speed of 2500Mbps of the named network device. Setting this value also immediately changes the LED state.

/sys/class/leds/<led>/link_5000

Defined on file *sysfs-class-led-trigger-netdev*

Signal the link speed state of 5000Mbps of the named network device.

If set to 0 (default), the LED's normal state is off.

If set to 1, the LED's normal state reflects the link state speed of 5000Mbps of the named network device. Setting this value also immediately changes the LED state.

/sys/class/leds/<led>/max_brightness

Defined on file *sysfs-class-led*

Maximum brightness level for this LED, default is 255 (LED_FULL).

If the LED does not support different brightness levels, this should be 1.

/sys/class/leds/<led>/max_flash_brightness

Defined on file *sysfs-class-led-flash*

read only Maximum brightness level for this LED in the flash strobe mode, in microamperes.

/sys/class/leds/<led>/max_flash_timeout

Defined on file *sysfs-class-led-flash*

read only Maximum flash timeout for this LED, in microseconds.

/sys/class/leds/<led>/multi_index

Defined on file *sysfs-class-led-multicolor*

read The multi_index array, when read, will output the LED colors as an array of strings as they are indexed in the multi_intensity file.

For additional details please refer to /leds/leds-class-multicolor.

/sys/class/leds/<led>/multi_intensity

Defined on file *sysfs-class-led-multicolor*

read/write This file contains array of integers. Order of components is described by the multi_index array. The maximum intensity should not exceed */sys/class/leds/<led>/max_brightness*.

For additional details please refer to /leds/leds-class-multicolor.

/sys/class/leds/<led>/offloaded

Defined on file *sysfs-class-led-trigger-netdev*

Communicate whether the LED trigger modes are offloaded to hardware or whether software fallback is used.

If 0, the LED is using software fallback to blink.

If 1, the LED blinking in requested mode is offloaded to hardware.

/sys/class/leds/<led>/pattern

Defined on file *sysfs-class-led-trigger-pattern*

Specify a software pattern for the LED, that supports altering the brightness for the specified duration with one software timer. It can do gradual dimming and step change of brightness.

The pattern is given by a series of tuples, of brightness and duration (ms).

The exact format is described in: Documentation/devicetree/bindings/leds/leds-trigger-pattern.txt

/sys/class/leds/<led>/ports/<port>

Defined on file *sysfs-class-led-trigger-usbport*

Every dir entry represents a single USB port that can be selected for the USB port trigger. Selecting ports makes trigger observing them for any connected devices and lighting on LED if there are any.

Echoing ”1” value selects USB port. Echoing ”0” unselects it. Current state can be also read.

/sys/class/leds/<led>/pwm

Defined on file *sysfs-class-led-driver-lm3533*

Set the PWM-input control mask (5 bits), where:

bit 5	PWM-input enabled in Zone 4
bit 4	PWM-input enabled in Zone 3
bit 3	PWM-input enabled in Zone 2
bit 2	PWM-input enabled in Zone 1
bit 1	PWM-input enabled in Zone 0
bit 0	PWM-input enabled

/sys/class/leds/<led>/repeat

Defined on file *sysfs-class-led-trigger-pattern*

Specify a pattern repeat number. -1 means repeat indefinitely, other negative numbers and number 0 are invalid.

This file will always return the originally written repeat number.

It should be noticed that some leds, like EL15203000 may only support indefinitely patterns, so they always store -1.

/sys/class/leds/<led>/rng

Defined on file *sysfs-class-led-trigger-tty*

RNG = Ring Indicator DCE has detected an incoming ring signal on the telephone line. If the line state is detected, the LED is switched on. If set to 0 (default), the LED will not evaluate RNG. If set to 1, the LED will evaluate RNG.

/sys/class/leds/<led>/rx

Defined on file *sysfs-class-led-trigger-netdev*

Defined on file *sysfs-class-led-trigger-tty*

Signal reception of data on the named network device.

If set to 0 (default), the LED will not blink on reception.

If set to 1, the LED will blink for the milliseconds specified in interval to signal reception.

When offloaded is true, the blink interval is controlled by hardware and won't reflect the value set in interval.

Signal reception (rx) of data on the named tty device. If set to 0, the LED will not blink on reception. If set to 1 (default), the LED will blink on reception.

/sys/class/leds/<led>/shot

Defined on file *sysfs-class-led-trigger-oneshot*

Write any non-empty string to signal an events, this starts a blink sequence if not already running.

/sys/class/leds/<led>/trigger

Defined on file *sysfs-class-led*

Set the trigger for this LED. A trigger is a kernel based source of LED events.

You can change triggers in a similar manner to the way an IO scheduler is chosen. Trigger specific parameters can appear in /sys/class/leds/<led> once a given trigger is selected. For their documentation see *sysfs-class-led-trigger-**.

/sys/class/leds/<led>/ttyname

Defined on file *sysfs-class-led-trigger-tty*

Specifies the tty device name of the triggering tty

/sys/class/leds/<led>/tx

Defined on file *sysfs-class-led-trigger-netdev*

Defined on file *sysfs-class-led-trigger-tty*

Signal transmission of data on the named network device.

If set to 0 (default), the LED will not blink on transmission.

If set to 1, the LED will blink for the milliseconds specified in interval to signal transmission.

When offloaded is true, the blink interval is controlled by hardware and won't reflect the value set in interval.

Signal transmission (tx) of data on the named tty device. If set to 0, the LED will not blink on transmission. If set to 1 (default), the LED will blink on transmission.

/sys/class/leds/SRWS1::<serial>::RPM9
/sys/class/leds/SRWS1::<serial>::RPM10
/sys/class/leds/SRWS1::<serial>::RPM11
/sys/class/leds/SRWS1::<serial>::RPM12
/sys/class/leds/SRWS1::<serial>::RPM13
/sys/class/leds/SRWS1::<serial>::RPM14
/sys/class/leds/SRWS1::<serial>::RPM15
/sys/class/leds/SRWS1::<serial>::RPMALL

Defined on file *sysfs-driver-hid-srws1*

Provides a control for turning on/off the LEDs which form an RPM meter on the front of the controller

/sys/class/leds/dell::kbd_backlight/als_enabled

Defined on file *sysfs-platform-dell-laptop*

This file allows to control the automatic keyboard illumination mode on some systems that have an ambient light sensor. Write 1 to this file to enable the auto mode, 0 to disable it.

/sys/class/leds/dell::kbd_backlight/als_setting

Defined on file *sysfs-platform-dell-laptop*

This file allows to specify the on/off threshold value, as reported by the ambient light sensor.

/sys/class/leds/dell::kbd_backlight/start_triggers

Defined on file *sysfs-platform-dell-laptop*

This file allows to control the input triggers that turn on the keyboard backlight illumination that is disabled because of inactivity. Read the file to see the triggers available. The ones enabled are preceded by '+', those disabled by '-'.

To enable a trigger, write its name preceded by '+' to this file. To disable a trigger, write its name preceded by '-' instead.

For example, to enable the keyboard as trigger run:

```
echo +keyboard > /sys/class/leds/dell::kbd_backlight/start_triggers
```

To disable it:

```
echo -keyboard > /sys/class/leds/dell::kbd_backlight/start_triggers
```

Note that not all the available triggers can be configured.

/sys/class/leds/dell::kbd_backlight/stop_timeout

Defined on file *sysfs-platform-dell-laptop*

This file allows to specify the interval after which the keyboard illumination is disabled because of inactivity. The timeouts are expressed in seconds, minutes, hours and days, for which the symbols are 's', 'm', 'h' and 'd' respectively.

To configure the timeout, write to this file a value along with any the above units. If no unit is specified, the value is assumed to be expressed in seconds.

For example, to set the timeout to 10 minutes run:

```
echo 10m > /sys/class/leds/dell::kbd_backlight/stop_timeout
```

Note that when this file is read, the returned value might be expressed in a different unit than the one used when the timeout was set.

Also note that only some timeouts are supported and that some systems might fall back to a specific timeout in case an invalid timeout is written to this file.

/sys/class/mdio_bus/<bus>/<device>/attached_dev

Defined on file *sysfs-class-net-phydev*

Symbolic link to the network device this PHY device is attached to.

/sys/class/mdio_bus/<bus>/<device>/phy_dev_flags

Defined on file *sysfs-class-net-phydev*

32-bit hexadecimal number representing a bit mask of the configuration bits passed from the consumer of the PHY (Ethernet MAC, switch, etc.) to the PHY driver. The flags are only used internally by the kernel and their placement are not meant to be stable across kernel versions. This is intended for facilitating the debugging of PHY drivers.

/sys/class/mdio_bus/<bus>/<device>/phy_has_fixups

Defined on file *sysfs-class-net-phydev*

This attribute contains the boolean value whether a given PHY device has had any ”fixup” workaround running on it, encoded as a boolean. This information is provided to help troubleshooting PHY configurations.

/sys/class/mdio_bus/<bus>/<device>/phy_id

Defined on file *sysfs-class-net-phydev*

This attribute contains the 32-bit PHY Identifier as reported by the device during bus enumeration, encoded in hexadecimal. This ID is used to match the device with the appropriate driver.

/sys/class/mdio_bus/<bus>/<device>/phy_interface

Defined on file *sysfs-class-net-phydev*

This attribute contains the PHY interface as configured by the Ethernet driver during bus enumeration, encoded in string. This interface mode is used to configure the Ethernet MAC with the appropriate mode for its data lines to the PHY hardware.

Possible values are:

<empty> (not available), mii, gmii, sgmii, tbi, rev-mii, rmii, rgmii, rgmii-id, rgmii-rxid, rgmii-txid, rtbi, smii xgmii, moca, qsgmii, trgmii, 1000base-x, 2500base-x, rxaui, xaui, 10gbase-kr, unknown

/sys/class/mdio_bus/<bus>/<device>/phy_standalone

Defined on file *sysfs-class-net-phydev*

Boolean value indicating whether the PHY device is used in standalone mode, without a net_device associated, by PHYLINK. Attribute created only when this is the case.

/sys/class/mei/

Defined on file *sysfs-class-mei*

The mei/ class sub-directory belongs to mei device class

/sys/class/mei/mei<N>/

Defined on file *sysfs-class-mei*

The /sys/class/mei/meiN directory is created for each probed mei device

/sys/class/mei/mei<N>/dev_state

Defined on file *sysfs-class-mei*

Display the ME device state.

The device state can have following values: INITIALIZING INIT_CLIENTS ENABLED RESETTING DISABLED POWER_DOWN POWER_UP

/sys/class/mei/mei<N>/fw_status

Defined on file *sysfs-class-mei*

Display fw status registers content

The ME FW writes its status information into fw status registers for BIOS and OS to monitor fw health.

The register contains running state, power management state, error codes, and others. The way the registers are decoded depends on PCH or SoC generation. Also number of registers varies between 1 and 6 depending on generation.

/sys/class/mei/mei<N>/fw_ver

Defined on file *sysfs-class-mei*

Display the ME firmware version.

The version of the platform ME firmware is in format: <platform>:<major>.<minor>.<milestone>.<build_no>. There can be up to three such blocks for different FW components.

/sys/class/mei/mei<N>/hbm_ver

Defined on file *sysfs-class-mei*

Display the negotiated HBM protocol version.

The HBM protocol version negotiated between the driver and the device.

/sys/class/mei/mei<N>/hbm_ver_drv

Defined on file *sysfs-class-mei*

Display the driver HBM protocol version.

The HBM protocol version supported by the driver.

/sys/class/mei/mei<N>/kind

Defined on file *sysfs-class-mei*

Display kind of the device

Generic devices are marked as ”mei” while special purpose have their own names. Available options: - mei: generic mei device. - itouch: itouch (ipts) mei device.

/sys/class/mei/mei<N>/trc

Defined on file *sysfs-class-mei*

Display trc status register content

The ME FW writes Glitch Detection HW (TRC) status information into trc status register for BIOS and OS to monitor fw health.

/sys/class/mei/mei<N>/tx_queue_limit

Defined on file *sysfs-class-mei*

Configure tx queue limit

Set maximal number of pending writes per opened session.

/sys/class/mic/

Defined on file *sysfs-class-mic*

The mic class directory belongs to Intel MIC devices and provides information per MIC device. An Intel MIC device is a PCIe form factor add-in Coprocessor card based on the Intel Many Integrated Core (MIC) architecture that runs a Linux OS.

/sys/class/mic/mic<X>

Defined on file *sysfs-class-mic*

The directories /sys/class/mic/mic0, /sys/class/mic/mic1 etc., represent MIC devices (0,1,..etc). Each directory has information specific to that MIC device.

/sys/class/mic/mic<X>/bootmode

Defined on file *sysfs-class-mic*

When read, this sysfs entry provides the current bootmode for the card. This sysfs entry can be written with the following valid strings: a) linux - Boot a Linux image. b) flash - Boot an image for flash updates.

/sys/class/mic/mic<X>/cmdline

Defined on file *sysfs-class-mic*

An Intel MIC device runs a Linux OS during its operation. Before booting this card OS, it is possible to pass kernel command line options to configure various features in it, similar to self-bootable machines. When read, this entry provides information about the current kernel command line options set to boot the card OS. This entry can be written to change the existing kernel command line options. Typically, the user would want to read the current command line options, append new ones or modify existing ones and then write the whole kernel command line back to this entry.

/sys/class/mic/mic<X>/family

Defined on file *sysfs-class-mic*

Provides information about the Coprocessor family for an Intel MIC device. For example - ”x100”

/sys/class/mic/mic<X>/firmware

Defined on file *sysfs-class-mic*

When read, this sysfs entry provides the path name under /lib/firmware/ where the firmware image to be booted on the card can be found. The entry can be written to change the firmware image location under /lib/firmware/.

/sys/class/mic/mic<X>/heartbeat_enable

Defined on file *sysfs-class-mic*

The MIC drivers detect and inform user space about card crashes via a heartbeat mechanism (see the description of shutdown_status above). User space can turn off this notification by setting heartbeat_enable to 0 and enable it by setting this entry to 1. If this notification is disabled it is the responsibility of user space to detect card crashes via alternative means such as a network ping. This setting is enabled by default.

/sys/class/mic/mic<X>/log_buf_addr

Defined on file *sysfs-class-mic*

An Intel MIC device runs a Linux OS during its operation. For debugging purpose and early kernel boot messages, the user can access the card OS log buffer via debugfs. When read, this entry provides the kernel virtual address of the buffer where the card OS log buffer can be read. This entry is written by the host configuration daemon to set the log buffer address. The correct log buffer address to be written can be found in the System.map file of the card OS.

/sys/class/mic/mic<X>/log_buf_len

Defined on file *sysfs-class-mic*

An Intel MIC device runs a Linux OS during its operation. For debugging purpose and early kernel boot messages, the user can access the card OS log buffer via debugfs. When read, this entry provides the kernel virtual address where the card OS log buffer length can be read. This entry is written by host configuration daemon to set the log buffer length address. The correct log buffer length address to be written can be found in the System.map file of the card OS.

/sys/class/mic/mic<X>/ramdisk

Defined on file *sysfs-class-mic*

When read, this sysfs entry provides the path name under /lib/firmware/ where the ramdisk image to be used during card OS boot can be found. The entry can be written to change the ramdisk image location under /lib/firmware/.

/sys/class/mic/mic<X>/shutdown_status

Defined on file *sysfs-class-mic*

An Intel MIC device runs a Linux OS during its operation. This OS can shutdown because of various reasons. When read, this entry provides the status on why the card OS was shutdown. Possible values are:

”nop”	shutdown status is not applicable, when the card OS is ”online”
”crashed”	Shutdown because of a HW or SW crash.
”halted”	Shutdown because of a halt command.
”poweroff”	Shutdown because of a poweroff command.
”restart”	Shutdown because of a restart command.

/sys/class/mic/mic<X>/state

Defined on file *sysfs-class-mic*

When read, this entry provides the current state of an Intel MIC device in the context of the card OS. Possible values that will be read are:

”ready”	The MIC device is ready to boot the card OS. On reading this entry after an OSPM resume, a ”boot” has to be written to this entry if the card was previously shutdown during OSPM suspend.
”booting”	The MIC device has initiated booting a card OS.
”online”	The MIC device has completed boot and is online
”shutting_down”	The card OS is shutting down.
”resetting”	A reset has been initiated for the MIC device
”reset_failed”	The MIC device has failed to reset.

When written, this sysfs entry triggers different state change operations depending upon the current state of the card OS. Acceptable values are:

”boot”	Boot the card OS image specified by the combination of firmware, ramdisk, cmdline and bootmode sysfs entries.
”reset”	Initiates device reset.
”shutdown”	Initiates card OS shutdown.

/sys/class/mic/mic<X>/stepping

Defined on file *sysfs-class-mic*

Provides information about the silicon stepping for an Intel MIC device. For example - ”A0” or ”B0”

/sys/class/misc/drivers/dw-xdata-pcie.<device>/write

Defined on file *sysfs-driver-xdata*

Allows the user to enable the PCIe traffic generator which will create write TLPs frames - from the Root Complex to the Endpoint direction or to disable the PCIe traffic generator in all directions.

Write y/1/on to enable, n/0/off to disable

Usage e.g.
echo 1 > /sys/class/misc/dw-xdata-pcie.<device>/write

or
echo 0 > /sys/class/misc/dw-xdata-pcie.<device>/write

The user can read the current PCIe link throughput generated through this generator in MB/s.

Usage e.g.
cat /sys/class/misc/dw-xdata-pcie.<device>/write 204

The file is read and write.

/sys/class/misc/dw-xdata-pcie.<device>/read

Defined on file *sysfs-driver-xdata*

Allows the user to enable the PCIe traffic generator which will create read TLPs frames - from the Endpoint to the Root Complex direction or to disable the PCIe traffic generator in all directions.

Write y/1/on to enable, n/0/off to disable

Usage e.g.
echo 1 > /sys/class/misc/dw-xdata-pcie.<device>/read

or
echo 0 > /sys/class/misc/dw-xdata-pcie.<device>/read

The user can read the current PCIe link throughput generated through this generator in MB/s.

Usage e.g.
cat /sys/class/misc/dw-xdata-pcie.<device>/read 199

The file is read and write.

/sys/class/mtd/

Defined on file *sysfs-class-mtd*

The mtd/ class subdirectory belongs to the MTD subsystem (MTD core).

/sys/class/mtd/mtdX/

Defined on file *sysfs-class-mtd*

The /sys/class/mtd/mtd{0,1,2,3,...} directories correspond to each /dev/mtdX character device. These may represent physical/simulated flash devices, partitions on a flash device, or concatenated flash devices.

/sys/class/mtd/mtdX/bad_blocks

Defined on file *sysfs-class-mtd*

The number of blocks marked as bad, if any, in this partition.

/sys/class/mtd/mtdX/bbt_blocks

Defined on file *sysfs-class-mtd*

The number of blocks that are marked as reserved, if any, in this partition. These are typically used to store the in-flash bad block table (BBT).

/sys/class/mtd/mtdX/bitflip_threshold

Defined on file *sysfs-class-mtd*

This allows the user to examine and adjust the criteria by which mtd returns -EUCLEAN from mtd_read() and mtd_read_oob(). If the maximum number of bit errors that were corrected on any single region comprising an ecc step (as reported by the driver) equals or exceeds this

value, -EUCLEAN is returned. Otherwise, absent an error, 0 is returned. Higher layers (e.g., UBI) use this return code as an indication that an erase block may be degrading and should be scrutinized as a candidate for being marked as bad.

The initial value may be specified by the flash device driver. If not, then the default value is ecc_strength.

The introduction of this feature brings a subtle change to the meaning of the -EUCLEAN return code. Previously, it was interpreted to mean simply "one or more bit errors were corrected". Its new interpretation can be phrased as "a dangerously high number of bit errors were corrected on one or more regions comprising an ecc step". The precise definition of "dangerously high" can be adjusted by the user with bitflip_threshold. Users are discouraged from doing this, however, unless they know what they are doing and have intimate knowledge of the properties of their device. Broadly speaking, bitflip_threshold should be low enough to detect genuine erase block degradation, but high enough to avoid the consequences of a persistent return value of -EUCLEAN on devices where sticky bitflips occur. Note that if bitflip_threshold exceeds ecc_strength, -EUCLEAN is never returned by the read operations. Conversely, if bitflip_threshold is zero, -EUCLEAN is always returned, absent a hard error.

This is generally applicable only to NAND flash devices with ECC capability. It is ignored on devices lacking ECC capability; i.e., devices for which ecc_strength is zero.

/sys/class/mtd/mtdX/corrected_bits

Defined on file *sysfs-class-mtd*

The number of bits that have been corrected by means of the device's ECC.

It will always be a non-negative integer. In the case of devices lacking any ECC capability, it is 0.

/sys/class/mtd/mtdX/dev

Defined on file *sysfs-class-mtd*

Major and minor numbers of the character device corresponding to this MTD device (in <major>:<minor> format). This is the read-write device so <minor> will be even.

/sys/class/mtd/mtdX/ecc_failures

Defined on file *sysfs-class-mtd*

The number of failures reported by this device's ECC. Typically, these failures are associated with failed read operations.

It will always be a non-negative integer. In the case of devices lacking any ECC capability, it is 0.

/sys/class/mtd/mtdX/ecc_step_size

Defined on file *sysfs-class-mtd*

The size of a single region covered by ECC, known as the ECC step. Devices may have several equally sized ECC steps within each writesize region.

It will always be a non-negative integer. In the case of devices lacking any ECC capability, it is 0.

/sys/class/mtd/mtdX/ecc_strength

Defined on file *sysfs-class-mtd*

Maximum number of bit errors that the device is capable of correcting within each region covering an ECC step (see ecc_step_size). This will always be a non-negative integer.

In the case of devices lacking any ECC capability, it is 0.

/sys/class/mtd/mtdX/erasesize

Defined on file *sysfs-class-mtd*

"Major" erase size for the device. If numeraseregions is zero, this is the eraseblock size for the entire device. Otherwise, the MEMGETREGIONCOUNT/MEMGETREGIONINFO ioctls can be used to determine the actual eraseblock layout.

/sys/class/mtd/mtdX/flags

Defined on file *sysfs-class-mtd*

A hexadecimal value representing the device flags, ORed together:

0x0400: MTD_WRITEABLE - device is writable 0x0800: MTD_BIT_WRITEABLE - single bits can be flipped 0x1000: MTD_NO_ERASE - no erase necessary 0x2000: MTD_POWERUP_LOCK - always locked after reset

/sys/class/mtd/mtdX/name

Defined on file *sysfs-class-mtd*

A human-readable ASCII name for the device or partition. This will match the name in /proc/mtd .

/sys/class/mtd/mtdX/numeraseregions

Defined on file *sysfs-class-mtd*

For devices that have variable eraseblock sizes, this provides the total number of erase regions. Otherwise, it will read back as zero.

/sys/class/mtd/mtdX/offset

Defined on file *sysfs-class-mtd*

For a partition, the offset of that partition from the start of the parent (another partition or a flash device) in bytes. This attribute is absent on flash devices, so it can be used to distinguish them from partitions.

/sys/class/mtd/mtdX/oobavail

Defined on file *sysfs-class-mtd*

Number of bytes available for a client to place data into the out of band area.

/sys/class/mtd/mtdX/oobsize

Defined on file *sysfs-class-mtd*

Number of OOB bytes per page.

/sys/class/mtd/mtdX/size

Defined on file *sysfs-class-mtd*

Total size of the device/partition, in bytes.

/sys/class/mtd/mtdX/type

Defined on file *sysfs-class-mtd*

One of the following ASCII strings, representing the device type:

absent, ram, rom, nor, nand, mlc-nand, dataflash, ubi, unknown

/sys/class/mtd/mtdX/writesize

Defined on file *sysfs-class-mtd*

Minimal writable flash unit size. This will always be a positive integer.

In the case of NOR flash it is 1 (even though individual bits can be cleared).

In the case of NAND flash it is one NAND page (or a half page, or a quarter page).

In the case of ECC NOR, it is the ECC block size.

/sys/class/mtd/mtdXro/

Defined on file *sysfs-class-mtd*

These directories provide the corresponding read-only device nodes for */sys/class/mtd/mtdX/* .

/sys/class/mtd/mtdXro/dev

Defined on file *sysfs-class-mtd*

Major and minor numbers of the character device corresponding to the read-only variant of the MTD device (in <major>:<minor> format). In this case <minor> will be odd.

/sys/class/mux/

Defined on file *sysfs-class-mux*

The mux/ class sub-directory belongs to the Generic MUX Framework and provides a sysfs interface for using MUX controllers.

/sys/class/mux/muxchip<N>/

Defined on file *sysfs-class-mux*

A /sys/class/mux/muxchipN directory is created for each probed MUX chip where N is a simple enumeration.

/sys/class/net/<bridge iface>/bridge/group_fwd_mask

Defined on file *sysfs-class-net*

Bitmask to allow forwarding of link local frames with address 01-80-C2-00-00-0X on a bridge device. Only values that set bits not matching BR_GROUPFWD_RESTRICTED in net/bridge/br_private.h allowed. Default value 0 does not forward any link local frames.

Restricted bits:

0	01-80-C2-00-00-00 Bridge Group Address used for STP
1	01-80-C2-00-00-01 (MAC Control) 802.3 used for MAC PAUSE
2	01-80-C2-00-00-02 (Link Aggregation) 802.3ad

Any values not setting these bits can be used. Take special care when forwarding control frames e.g. 802.1X-PAE or LLDP.

/sys/class/net/<iface>/addr_assign_type

Defined on file *sysfs-class-net*

Indicates the address assignment type. Possible values are:

0	permanent address
1	randomly generated
2	stolen from another device
3	set using dev_set_mac_address

/sys/class/net/<iface>/addr_len

Defined on file *sysfs-class-net*

Indicates the hardware address size in bytes. Values vary based on the lower-level protocol used by the interface (Ethernet, FDDI, ATM, IEEE 802.15.4...). See include/uapi/linux/if_*.h for actual values.

/sys/class/net/<iface>/address

Defined on file *sysfs-class-net*

Hardware address currently assigned to this interface. Format is a string, e.g: 00:11:22:33:44:55 for an Ethernet MAC address.

/sys/class/net/<iface>/broadcast

Defined on file *sysfs-class-net*

Hardware broadcast address for this interface. Format is a string, e.g: ff:ff:ff:ff:ff:ff for an Ethernet broadcast MAC address.

/sys/class/net/<iface>/carrier

Defined on file *sysfs-class-net*

Indicates the current physical link state of the interface. Possible values are:

0	physical link is down
1	physical link is up

Note: some special devices, e.g: bonding and team drivers will allow this attribute to be written to force a link state for operating correctly and designating another fallback interface.

/sys/class/net/<iface>/carrier_changes

Defined on file *sysfs-class-net*

32-bit unsigned integer counting the number of times the link has seen a change from UP to DOWN and vice versa

/sys/class/net/<iface>/carrier_down_count

Defined on file *sysfs-class-net*

32-bit unsigned integer counting the number of times the link has been down

/sys/class/net/<iface>/carrier_up_count

Defined on file *sysfs-class-net*

32-bit unsigned integer counting the number of times the link has been up

/sys/class/net/<iface>/cdc_ncm/bmNtbFormatsSupported

Defined on file *sysfs-class-net-cdc_ncm*

- Bit 0: 16-bit NTB supported (set to 1)
- Bit 1: 32-bit NTB supported
- Bits 2 – 15: reserved (reset to zero; must be ignored by host)

/sys/class/net/<iface>/cdc_ncm/dwNtbInMaxSize

Defined on file *sysfs-class-net-cdc_ncm*

IN NTB Maximum Size in bytes

/sys/class/net/<iface>/cdc_ncm/dwNtbOutMaxSize

Defined on file *sysfs-class-net-cdc_ncm*

OUT NTB Maximum Size

/sys/class/net/<iface>/cdc_ncm/min_tx_pkt

Defined on file *sysfs-class-net-cdc_ncm*

The driver will pad NCM Transfer Blocks (NTBs) longer than this to tx_max, allowing the device to receive tx_max sized frames with no terminating short packet. NTBs shorter than this limit are transmitted as-is, without any padding, and are terminated with a short USB packet.

Padding to tx_max allows the driver to transmit NTBs back-to-back without any interleaving short USB packets. This reduces the number of short packet interrupts in the device, and represents a tradeoff between USB bus bandwidth and device DMA optimization.

Set to 0 to pad all frames. Set greater than tx_max to disable all padding.

/sys/class/net/<iface>/cdc_ncm/ndp_to_end

Defined on file *sysfs-class-net-cdc_ncm*

Boolean attribute showing the status of the ”NDP to end” quirk. Defaults to 'N', except for devices already known to need it enabled.

The ”NDP to end” quirk makes the driver place the NDP (the packet index table) after the payload. The NCM specification does not mandate this, but some devices are known to be more restrictive. Write 'Y' to this attribute for temporary testing of a suspect device failing to work with the default driver settings.

A device entry should be added to the driver if this quirk is found to be required.

/sys/class/net/<iface>/cdc_ncm/rx_max

Defined on file *sysfs-class-net-cdc_ncm*

The maximum NTB size for RX. Cannot exceed the maximum value supported by the device. Must allow at least one max sized datagram plus headers.

The actual limits are device dependent. See dwNtbInMaxSize.

Note: Some devices will silently ignore changes to this value, resulting in oversized NTBs and corresponding framing errors.

/sys/class/net/<iface>/cdc_ncm/tx_max

Defined on file *sysfs-class-net-cdc_ncm*

The maximum NTB size for TX. Cannot exceed the maximum value supported by the device. Must allow at least one max sized datagram plus headers.

The actual limits are device dependent. See dwNtbOutMaxSize.

/sys/class/net/<iface>/cdc_ncm/tx_timer_usecs

Defined on file *sysfs-class-net-cdc_ncm*

Datagram aggregation timeout in µs. The driver will wait up to 3 times this timeout for more datagrams to aggregate before transmitting an NTB frame.

Valid range: 5 to 4000000

Set to 0 to disable aggregation.

The following read-only attributes all represent fields of the structure defined in section 6.2.1 ”GetNtbParameters” of ”Universal Serial Bus Communications Class Subclass Specifications for Network Control Model Devices” (CDC NCM), Revision 1.0 (Errata 1), November 24, 2010 from USB Implementers Forum, Inc. The descriptions are quoted from table 6-3 of CDC NCM: ”NTB Parameter Structure”.

/sys/class/net/<iface>/cdc_ncm/wNdpInAlignment

Defined on file *sysfs-class-net-cdc_ncm*

NDP alignment modulus for NTBs on the IN pipe. Shall be a power of 2, and shall be at least 4.

/sys/class/net/<iface>/cdc_ncm/wNdpInDivisor

Defined on file *sysfs-class-net-cdc_ncm*

Divisor used for IN NTB Datagram payload alignment

/sys/class/net/<iface>/cdc_ncm/wNdpInPayloadRemainder

Defined on file *sysfs-class-net-cdc_ncm*

Remainder used to align input datagram payload within the NTB: (Payload Offset) mod (wNdpInDivisor) = wNdpInPayloadRemainder

/sys/class/net/<iface>/cdc_ncm/wNdpOutAlignment

Defined on file *sysfs-class-net-cdc_ncm*

NDP alignment modulus for use in NTBs on the OUT pipe. Shall be a power of 2, and shall be at least 4.

/sys/class/net/<iface>/cdc_ncm/wNdpOutDivisor

Defined on file *sysfs-class-net-cdc_ncm*

OUT NTB Datagram alignment modulus

/sys/class/net/<iface>/cdc_ncm/wNdpOutPayloadRemainder

Defined on file *sysfs-class-net-cdc_ncm*

Remainder used to align output datagram payload offsets within the NTB: Padding, shall be transmitted as zero by function, and ignored by host. (Payload Offset) mod (wNdpOutDivisor) = wNdpOutPayloadRemainder

/sys/class/net/<iface>/cdc_ncm/wNtbOutMaxDatagrams

Defined on file *sysfs-class-net-cdc_ncm*

Maximum number of datagrams that the host may pack into a single OUT NTB. Zero means that the device imposes no limit.

/sys/class/net/<iface>/dev_id

Defined on file *sysfs-class-net*

Indicates the device unique identifier. Format is an hexadecimal value. This is used to disambiguate interfaces which might be stacked (e.g: VLAN interfaces) but still have the same MAC address as their parent device.

/sys/class/net/<iface>/dev_port

Defined on file *sysfs-class-net*

Indicates the port number of this network device, formatted as a decimal value. Some NICs have multiple independent ports on the same PCI bus, device and function. This attribute allows userspace to distinguish the respective interfaces.

Note: some device drivers started to use 'dev_id' for this purpose since long before 3.15 and have not adopted the new attribute ever since. To query the port number, some tools look exclusively at 'dev_port', while others only consult 'dev_id'. If a network device has multiple client adapter ports as described in the previous paragraph and does not set this attribute to its port number, it's a kernel bug.

/sys/class/net/<iface>/dormant

Defined on file *sysfs-class-net*

Indicates whether the interface is in dormant state. Possible values are: 0: interface is not dormant 1: interface is dormant

This attribute can be used by supplicant software to signal that the device is not usable unless some supplicant-based authentication is performed (e.g: 802.1x). 'link_mode' attribute will also reflect the dormant state.

/sys/class/net/<iface>/dsa/tagging

Defined on file *sysfs-class-net-dsa*

On read, this file returns a string indicating the type of tagging protocol used by the DSA network devices that are attached to this master interface. On write, this file changes the tagging protocol of the attached DSA switches, if this operation is supported by the driver. Changing the tagging protocol must be done with the DSA interfaces and the master interface all administratively down. See the "name" field of each registered struct dsa_device_ops for a list of valid values.

/sys/class/net/<iface>/duplex

Defined on file *sysfs-class-net*

Indicates the interface latest or current duplex value. Possible values are:

half	half duplex
full	full duplex

Note: This attribute is only valid for interfaces that implement the ethtool get_link_ksettings method (mostly Ethernet).

/sys/class/net/<iface>/flags

Defined on file *sysfs-class-net*

Indicates the interface flags as a bitmask in hexadecimal. See include/uapi/linux/if.h for a list of all possible values and the flags semantics.

/sys/class/net/<iface>/fwinfo

Defined on file *sysfs-class-net-janz-ican3*

Firmware stamp of ican3 module Read-only: 32 byte string identification of the ICAN3 module (known values: "JANZ-ICAN3 ICANOS 1.xx", "JANZ-ICAN3 CAL/CANopen 1.xx")

/sys/class/net/<iface>/grcan/enable0

Defined on file *sysfs-class-net-grcan*

Hardware configuration of physical interface 0. This file reads and writes the "Enable 0" bit of the configuration register. Possible values: 0 or 1. See the GRCAN chapter of the GRLIB IP core library documentation for details. The default value is 0 or set by the module parameter grcan.enable0 and can be read at /sys/module/grcan/parameters/enable0.

/sys/class/net/<iface>/grcan/enable1

Defined on file *sysfs-class-net-grcan*

Hardware configuration of physical interface 1. This file reads and writes the "Enable 1" bit of the configuration register. Possible values: 0 or 1. See the GRCAN chapter of the GRLIB IP core library documentation for details. The default value is 0 or set by the module parameter grcan.enable1 and can be read at /sys/module/grcan/parameters/enable1.

/sys/class/net/<iface>/grcan/select

Defined on file *sysfs-class-net-grcan*

Configuration of which physical interface to be used. Possible values: 0 or 1. See the GRCAN chapter of the GRLIB IP core library documentation for details. The default value is 0 or is set by the module parameter grcan.select and can be read at /sys/module/grcan/parameters/select.

/sys/class/net/<iface>/ifalias

Defined on file *sysfs-class-net*

Indicates/stores an interface alias name as a string. This can be used for system management purposes.

/sys/class/net/<iface>/ifindex

Defined on file *sysfs-class-net*

Indicates the system-wide interface unique index identifier as a decimal number. This attribute is used for mapping an interface identifier to an interface name. It is used throughout the networking stack for specifying the interface specific requests/events.

/sys/class/net/<iface>/iflink

Defined on file *sysfs-class-net*

Indicates the system-wide interface unique index identifier a the interface is linked to. Format is decimal. This attribute is used to resolve interfaces chaining, linking and stacking. Physical interfaces have the same 'ifindex' and 'iflink' values.

/sys/class/net/<iface>/link_mode

Defined on file *sysfs-class-net*

Indicates the interface link mode, as a decimal number. This attribute should be used in conjunction with 'dormant' attribute to determine the interface usability. Possible values:

0	default link mode
1	dormant link mode

/sys/class/net/<iface>/mtu

Defined on file *sysfs-class-net*

Indicates the interface currently configured MTU value, in bytes, and in decimal format. Specific values depends on the lower-level interface protocol used. Ethernet devices will show a 'mtu' attribute value of 1500 unless changed.

/sys/class/net/<iface>/name_assign_type

Defined on file *sysfs-class-net*

Indicates the name assignment type. Possible values are:

1	enumerated by the kernel, possibly in an unpredictable way
2	predictably named by the kernel
3	named by userspace
4	renamed

/sys/class/net/<iface>/netdev_group

Defined on file *sysfs-class-net*

Indicates the interface network device group, as a decimal integer. Default value is 0 which corresponds to the initial network devices group. The group can be changed to affect routing decisions (see: net/ipv4/fib_rules and net/ipv6/fib6_rules.c).

/sys/class/net/<iface>/operstate

Defined on file *sysfs-class-net*

Indicates the interface RFC2863 operational state as a string.

Possible values are:

"unknown", "notpresent", "down", "lowerlayerdown", "testing", "dormant", "up".

/sys/class/net/<iface>/peak_usb/can_channel_id

Defined on file *sysfs-class-net-peak_usb*

PEAK PCAN-USB devices support user-configurable CAN channel identifiers. Contrary to a USB serial number, these identifiers are writable and can be set per CAN interface. This means that if a USB device exports multiple CAN interfaces, each of them can be assigned a unique channel ID. This attribute provides read-only access to the currently configured value of the channel identifier. Depending on the device type, the identifier has a length of 8 or 32 bit. The value read from this attribute is always an 8 digit 32 bit hexadecimal value in big endian format. If the device only supports an 8 bit identifier, the upper 24 bit of the value are set to zero.

/sys/class/net/<iface>/phydev

Defined on file *sysfs-class-net*

Symbolic link to the PHY device this network device is attached to.

/sys/class/net/<iface>/phys_port_id

Defined on file *sysfs-class-net*

Indicates the interface unique physical port identifier within the NIC, as a string.

/sys/class/net/<iface>/phys_port_name

Defined on file *sysfs-class-net*

Indicates the interface physical port name within the NIC, as a string.

/sys/class/net/<iface>/phys_switch_id

Defined on file *sysfs-class-net*

Indicates the unique physical switch identifier of a switch this port belongs to, as a string.

/sys/class/net/<iface>/qmi/add_mux

Defined on file *sysfs-class-net-qmi*

Unsigned integer.

Write a number ranging from 1 to 254 to add a qmap mux based network device, supported by recent Qualcomm based modems.

The network device will be called qmimux.

Userspace is in charge of managing the qmux network device activation and data stream setup on the modem side by using the proper QMI protocol requests.

/sys/class/net/<iface>/qmi/del_mux

Defined on file *sysfs-class-net-qmi*

Unsigned integer.

Write a number ranging from 1 to 254 to delete a previously created qmap mux based network device.

/sys/class/net/<iface>/qmi/pass_through

Defined on file *sysfs-class-net-qmi*

Boolean. Default: 'N'

Set this to 'Y' to enable 'pass-through' mode, allowing packets in MAP format to be passed on to the stack.

Normally the rmnet driver (CONFIG_RMNET) is then used to process and demultiplex these packets.

'Pass-through' mode can be enabled when the device is in 'raw-ip' mode only.

/sys/class/net/<iface>/qmi/raw_ip

Defined on file *sysfs-class-net-qmi*

Boolean. Default: 'N'

Set this to 'Y' to change the network device link framing from '802.3' to 'raw-ip'.

The netdev will change to reflect the link framing mode. The netdev is an ordinary ethernet device in '802.3' mode, and the driver expects to exchange frames with an ethernet header over

the USB link. The netdev is a headerless p-t-p device in 'raw-ip' mode, and the driver expects to echange IPv4 or IPv6 packets without any L2 header over the USB link.

Userspace is in full control of firmware configuration through the delegation of the QMI protocol. Userspace is responsible for coordination of driver and firmware link framing mode, changing this setting to 'Y' if the firmware is configured for 'raw-ip' mode.

/sys/class/net/<iface>/queues/rx-<queue>/rps_cpus

Defined on file *sysfs-class-net-queues*

Mask of the CPU(s) currently enabled to participate into the Receive Packet Steering packet processing flow for this network device queue. Possible values depend on the number of available CPU(s) in the system.

/sys/class/net/<iface>/queues/rx-<queue>/rps_flow_cnt

Defined on file *sysfs-class-net-queues*

Number of Receive Packet Steering flows being currently processed by this particular network device receive queue.

/sys/class/net/<iface>/queues/tx-<queue>/byte_queue_limits/hold_time

Defined on file *sysfs-class-net-queues*

Indicates the hold time in milliseconds to measure the slack of this particular network device transmit queue. Default value is 1000.

/sys/class/net/<iface>/queues/tx-<queue>/byte_queue_limits/inflight

Defined on file *sysfs-class-net-queues*

Indicates the number of bytes (objects) in flight on this network device transmit queue.

/sys/class/net/<iface>/queues/tx-<queue>/byte_queue_limits/limit

Defined on file *sysfs-class-net-queues*

Indicates the current limit of bytes allowed to be queued on this network device transmit queue. This value is clamped to be within the bounds defined by limit_max and limit_min.

/sys/class/net/<iface>/queues/tx-<queue>/byte_queue_limits/limit_max

Defined on file *sysfs-class-net-queues*

Indicates the absolute maximum limit of bytes allowed to be queued on this network device transmit queue. See include/linux/dynamic_queue_limits.h for the default value.

/sys/class/net/<iface>/queues/tx-<queue>/byte_queue_limits/limit_min

Defined on file *sysfs-class-net-queues*

Indicates the absolute minimum limit of bytes allowed to be queued on this network device transmit queue. Default value is 0.

/sys/class/net/<iface>/queues/tx-<queue>/tx_maxrate

Defined on file *sysfs-class-net-queues*

A Mbps max-rate set for the queue, a value of zero means disabled, default is disabled.

/sys/class/net/<iface>/queues/tx-<queue>/tx_timeout

Defined on file *sysfs-class-net-queues*

Indicates the number of transmit timeout events seen by this network interface transmit queue.

/sys/class/net/<iface>/queues/tx-<queue>/xps_cpus

Defined on file *sysfs-class-net-queues*

Mask of the CPU(s) currently enabled to participate into the Transmit Packet Steering packet processing flow for this network device transmit queue. Possible values depend on the number of available CPU(s) in the system.

/sys/class/net/<iface>/queues/tx-<queue>/xps_rxqs

Defined on file *sysfs-class-net-queues*

Mask of the receive queue(s) currently enabled to participate into the Transmit Packet Steering packet processing flow for this network device transmit queue. Possible values depend on the number of available receive queue(s) in the network device. Default is disabled.

/sys/class/net/<iface>/speed

Defined on file *sysfs-class-net*

Indicates the interface latest or current speed value. Value is an integer representing the link speed in Mbits/sec.

Note: this attribute is only valid for interfaces that implement the ethtool get_link_ksettings method (mostly Ethernet).

/sys/class/net/<iface>/statistics/collisions

Defined on file *sysfs-class-net-statistics*

Indicates the number of collisions seen by this network device. This value might not be relevant with all MAC layers.

/sys/class/net/<iface>/statistics/multicast

Defined on file *sysfs-class-net-statistics*

Indicates the number of multicast packets received by this network device.

/sys/class/net/<iface>/statistics/rx_bytes

Defined on file *sysfs-class-net-statistics*

Indicates the number of bytes received by this network device. See the network driver for the exact meaning of when this value is incremented.

/sys/class/net/<iface>/statistics/rx_compressed

Defined on file *sysfs-class-net-statistics*

Indicates the number of compressed packets received by this network device. This value might only be relevant for interfaces that support packet compression (e.g: PPP).

/sys/class/net/<iface>/statistics/rx_crc_errors

Defined on file *sysfs-class-net-statistics*

Indicates the number of packets received with a CRC (FCS) error by this network device. Note that the specific meaning might depend on the MAC layer used by the interface.

/sys/class/net/<iface>/statistics/rx_dropped

Defined on file *sysfs-class-net-statistics*

Indicates the number of packets received by the network device but dropped, that are not forwarded to the upper layers for packet processing. See the network driver for the exact meaning of this value.

/sys/class/net/<iface>/statistics/rx_errors

Defined on file *sysfs-class-net-statistics*

Indicates the number of receive errors on this network device. See the network driver for the exact meaning of this value.

/sys/class/net/<iface>/statistics/rx_fifo_errors

Defined on file *sysfs-class-net-statistics*

Indicates the number of receive FIFO errors seen by this network device. See the network driver for the exact meaning of this value.

/sys/class/net/<iface>/statistics/rx_frame_errors

Defined on file *sysfs-class-net-statistics*

Indicates the number of received frames with error, such as alignment errors. Note that the specific meaning depends on on the MAC layer protocol used. See the network driver for the exact meaning of this value.

/sys/class/net/<iface>/statistics/rx_length_errors

Defined on file *sysfs-class-net-statistics*

Indicates the number of received error packet with a length error, oversized or undersized. See the network driver for the exact meaning of this value.

/sys/class/net/<iface>/statistics/rx_missed_errors

Defined on file *sysfs-class-net-statistics*

Indicates the number of received packets that have been missed due to lack of capacity in the receive side. See the network driver for the exact meaning of this value.

/sys/class/net/<iface>/statistics/rx_nohandler

Defined on file *sysfs-class-net-statistics*

Indicates the number of received packets that were dropped on an inactive device by the network core.

/sys/class/net/<iface>/statistics/rx_over_errors

Defined on file *sysfs-class-net-statistics*

Indicates the number of received packets that are oversized compared to what the network device is configured to accept (e.g: larger than MTU). See the network driver for the exact meaning of this value.

/sys/class/net/<iface>/statistics/rx_packets

Defined on file *sysfs-class-net-statistics*

Indicates the total number of good packets received by this network device.

/sys/class/net/<iface>/statistics/tx_aborted_errors

Defined on file *sysfs-class-net-statistics*

Indicates the number of packets that have been aborted during transmission by a network device (e.g: because of a medium collision). See the network driver for the exact meaning of this value.

/sys/class/net/<iface>/statistics/tx_bytes

Defined on file *sysfs-class-net-statistics*

Indicates the number of bytes transmitted by a network device. See the network driver for the exact meaning of this value, in particular whether this accounts for all successfully transmitted packets or all packets that have been queued for transmission.

/sys/class/net/<iface>/statistics/tx_carrier_errors

Defined on file *sysfs-class-net-statistics*

Indicates the number of packets that could not be transmitted because of carrier errors (e.g: physical link down). See the network driver for the exact meaning of this value.

/sys/class/net/<iface>/statistics/tx_compressed

Defined on file *sysfs-class-net-statistics*

Indicates the number of transmitted compressed packets. Note this might only be relevant for devices that support compression (e.g: PPP).

/sys/class/net/<iface>/statistics/tx_dropped

Defined on file *sysfs-class-net-statistics*

Indicates the number of packets dropped during transmission. See the driver for the exact reasons as to why the packets were dropped.

/sys/class/net/<iface>/statistics/tx_errors

Defined on file *sysfs-class-net-statistics*

Indicates the number of packets in error during transmission by a network device. See the driver for the exact reasons as to why the packets were dropped.

/sys/class/net/<iface>/statistics/tx_fifo_errors

Defined on file *sysfs-class-net-statistics*

Indicates the number of packets having caused a transmit FIFO error. See the driver for the exact reasons as to why the packets were dropped.

/sys/class/net/<iface>/statistics/tx_heartbeat_errors

Defined on file *sysfs-class-net-statistics*

Indicates the number of packets transmitted that have been reported as heartbeat errors. See the driver for the exact reasons as to why the packets were dropped.

/sys/class/net/<iface>/statistics/tx_packets

Defined on file *sysfs-class-net-statistics*

Indicates the number of packets transmitted by a network device. See the driver for whether this reports the number of all attempted or successful transmissions.

/sys/class/net/<iface>/statistics/tx_window_errors

Defined on file *sysfs-class-net-statistics*

Indicates the number of packets not successfully transmitted due to a window collision. The specific meaning depends on the MAC layer used. On Ethernet this is usually used to report late collisions errors.

/sys/class/net/<iface>/termination

Defined on file *sysfs-class-net-janz-ican3*

Value representing the can bus termination

Default: 1 (termination active) Reading: get actual termination state Writing: set actual termination state (0=no termination, 1=termination active)

/sys/class/net/<iface>/testing

Defined on file *sysfs-class-net*

Indicates whether the interface is under test. Possible values are:

0	interface is not being tested
1	interface is being tested

When an interface is under test, it cannot be expected to pass packets as normal.

/sys/class/net/<iface>/threaded

Defined on file *sysfs-class-net*

Boolean value to control the threaded mode per device. User could set this value to enable/disable threaded mode for all napi belonging to this device, without the need to do device up/down.

Possible values: == ========== 0 threaded mode disabled for this dev 1 threaded mode enabled for this dev == ==========

/sys/class/net/<iface>/tx_queue_len

Defined on file *sysfs-class-net*

Indicates the interface transmit queue len in number of packets, as an integer value. Value depend on the type of interface, Ethernet network adapters have a default value of 1000 unless configured otherwise

/sys/class/net/<iface>/type

Defined on file *sysfs-class-net*

Indicates the interface protocol type as a decimal value. See include/uapi/linux/if_arp.h for all possible values.

/sys/class/net/<qmimux iface>/qmap/mux_id

Defined on file *sysfs-class-net-qmi*

Unsigned integer

Indicates the mux id associated to the qmimux network interface during its creation.

/sys/class/ocxl/<afu name>/afu_version

Defined on file *sysfs-class-ocxl*

read only Version of the AFU, in the format <major>:<minor> Reflects what is read in the configuration space of the AFU

/sys/class/ocxl/<afu name>/contexts

Defined on file *sysfs-class-ocxl*

read only Number of contexts for the AFU, in the format <n>/<max> where:

n	number of currently active contexts, for debug
max	maximum number of contexts supported by the AFU

/sys/class/ocxl/<afu name>/global_mmio_area

Defined on file *sysfs-class-ocxl*

read/write Give access the global mmio area for the AFU

/sys/class/ocxl/<afu name>/global_mmio_size

Defined on file *sysfs-class-ocxl*

read only Size of the global mmio area, as defined in the configuration space of the AFU

/sys/class/ocxl/<afu name>/pp_mmio_size

Defined on file *sysfs-class-ocxl*

read only Size of the per-process mmio area, as defined in the configuration space of the AFU

/sys/class/ocxl/<afu name>/reload_on_reset

Defined on file *sysfs-class-ocxl*

read/write Control whether the FPGA is reloaded on a link reset. Enabled through a vendor-specific logic block on the FPGA.

0	Do not reload FPGA image from flash
1	Reload FPGA image from flash
unavailable	The device does not support this capability

/sys/class/pktcdvd/add
/sys/class/pktcdvd/remove
/sys/class/pktcdvd/device_map

Defined on file *sysfs-class-pktcdvd*

add	(WO) Write a block device id (major:minor) to create a new pktcdvd device and map it to the block device.
remove	(WO) Write the pktcdvd device id (major:minor) to remove the pktcdvd device.
device_map	(RO) Shows the device mapping in format: pktcdvd[0-7] <pktdevid> <blkdevid>

/sys/class/pktcdvd/pktcdvd[0-7]/dev
/sys/class/pktcdvd/pktcdvd[0-7]/uevent

Defined on file *sysfs-class-pktcdvd*

dev: (RO) Device id

uevent: (WO) To send a uevent

/sys/class/pktcdvd/pktcdvd[0-7]/stat/packets_started
/sys/class/pktcdvd/pktcdvd[0-7]/stat/packets_finished
/sys/class/pktcdvd/pktcdvd[0-7]/stat/kb_written
/sys/class/pktcdvd/pktcdvd[0-7]/stat/kb_read
/sys/class/pktcdvd/pktcdvd[0-7]/stat/kb_read_gather
/sys/class/pktcdvd/pktcdvd[0-7]/stat/reset

Defined on file *sysfs-class-pktcdvd*

packets_started: (RO) Number of started packets.

packets_finished: (RO) Number of finished packets.

kb_written: (RO) kBytes written.

kb_read: (RO) kBytes read.

kb_read_gather: (RO) kBytes read to fill write packets.

reset: (WO) Write any value to it to reset
pktcdvd device statistic values, like bytes read/written.

/sys/class/pktcdvd/pktcdvd[0-7]/write_queue/size
/sys/class/pktcdvd/pktcdvd[0-7]/write_queue/congestion_off
/sys/class/pktcdvd/pktcdvd[0-7]/write_queue/congestion_on

Defined on file *sysfs-class-pktcdvd*

size	(RO) Contains the size of the bio write queue.
congestion_off	(RW) If bio write queue size is below this mark, accept new bio requests from the block layer.
congestion_on	(RW) If bio write queue size is higher as this mark, do no longer accept bio write requests from the block layer and wait till the pktcdvd device has processed enough bio's so that bio write queue size is below congestion off mark. A value of <= 0 disables congestion control.

Example:

To use the pktcdvd sysfs interface directly, you can do:

```
# create a new pktcdvd device mapped to /dev/hdc
echo "22:0" >/sys/class/pktcdvd/add
cat /sys/class/pktcdvd/device_map
# assuming device pktcdvd0 was created, look at stat's
cat /sys/class/pktcdvd/pktcdvd0/stat/kb_written
# print the device id of the mapped block device
fgrep pktcdvd0 /sys/class/pktcdvd/device_map
# remove device, using pktcdvd0 device id   253:0
echo "253:0" >/sys/class/pktcdvd/remove
```

/sys/class/power/ds2760-battery.*/charge_full

Defined on file *sysfs-class-power*

This file is writeable and can be used to set the assumed battery 'full level'. As batteries age, this value has to be amended over time.

/sys/class/power/ds2760-battery.*/charge_now

Defined on file *sysfs-class-power*

This file is writeable and can be used to set the current coloumb counter value inside the battery monitor chip. This is needed for unavoidable corrections of aging batteries. A userspace daemon can monitor the battery charging logic and once the counter drops out of considerable bounds, take appropriate action.

/sys/class/power_supply/<battery_name>/eppid

Defined on file *sysfs-platform-dell-wmi-ddv*

Reports the Dell ePPID (electronic Piece Part Identification) of the ACPI battery.

See /wmi/devices/dell-wmi-ddv for details.

/sys/class/power_supply/<supply_name>/alarm

Defined on file *sysfs-class-power-surface*

Battery trip point. When the remaining battery capacity crosses this value in either direction, the system will be notified and if necessary woken.

Set to zero to clear/disable.

Access: Read, Write

Valid values: In micro-Wh or micro-Ah, depending on the power unit of the battery

/sys/class/power_supply/<supply_name>/capacity

Defined on file *sysfs-class-power*

Fine grain representation of battery capacity.

Access: Read

Valid values: 0 - 100 (percent)

/sys/class/power_supply/<supply_name>/capacity_alert_max

Defined on file *sysfs-class-power*

Maximum battery capacity trip-wire value where the supply will notify user-space of the event. This is normally used for the battery discharging scenario where user-space needs to know the battery has dropped to an upper level so it can take appropriate action (e.g. warning user that battery level is low).

Access: Read, Write

Valid values: 0 - 100 (percent)

/sys/class/power_supply/<supply_name>/capacity_alert_min

Defined on file *sysfs-class-power*

Minimum battery capacity trip-wire value where the supply will notify user-space of the event. This is normally used for the battery discharging scenario where user-space needs to know the battery has dropped to a lower level so it can take appropriate action (e.g. warning user that battery level is critically low).

Access: Read, Write

Valid values: 0 - 100 (percent)

/sys/class/power_supply/<supply_name>/capacity_error_margin

Defined on file *sysfs-class-power*

Battery capacity measurement becomes unreliable without recalibration. This values provides the maximum error margin expected to exist by the fuel gauge in percent. Values close to 0% will be returned after (re-)calibration has happened. Over time the error margin will increase. 100% means, that the capacity related values are basically completely useless.

Access: Read

Valid values: 0 - 100 (percent)

/sys/class/power_supply/<supply_name>/capacity_level

Defined on file *sysfs-class-power*

Coarse representation of battery capacity.

Access: Read

Valid values:
"Unknown", "Critical", "Low", "Normal", "High", "Full"

/sys/class/power_supply/<supply_name>/charge_behaviour

Defined on file *sysfs-class-power*

Represents the charging behaviour.

Access: Read, Write

Valid values:

auto:	Charge normally, respect thresholds
inhibit-charge:	Do not charge while AC is attached
force-discharge:	Force discharge while AC is attached

/sys/class/power_supply/<supply_name>/charge_control_end_threshold

Defined on file *sysfs-class-power*

Represents a battery percentage level, above which charging will stop. Not all hardware is capable of setting this to an arbitrary percentage. Drivers will round written values to the nearest supported value. Reading back the value will show the actual threshold set by the driver.

Access: Read, Write

Valid values: 0 - 100 (percent)

/sys/class/power_supply/<supply_name>/charge_control_limit

Defined on file *sysfs-class-power*

Maximum allowable charging current. Used for charge rate throttling for thermal cooling or improving battery health.

Access: Read, Write

Valid values: Represented in microamps

/sys/class/power_supply/<supply_name>/charge_control_limit_max

Defined on file *sysfs-class-power*

Maximum legal value for the charge_control_limit property.

Access: Read

Valid values: Represented in microamps

/sys/class/power_supply/<supply_name>/charge_control_start_threshold

Defined on file *sysfs-class-power*

Represents a battery percentage level, below which charging will begin.

Access: Read, Write Valid values: 0 - 100 (percent)

/sys/class/power_supply/<supply_name>/charge_term_current

Defined on file *sysfs-class-power*

Reports the charging current value which is used to determine when the battery is considered full and charging should end.

Access: Read

Valid values: Represented in microamps

/sys/class/power_supply/<supply_name>/charge_type

Defined on file *sysfs-class-power*

Represents the type of charging currently being applied to the battery. "Trickle", "Fast", and "Standard" all mean different charging speeds. "Adaptive" means that the charger uses some algorithm to adjust the charge rate dynamically, without any user configuration required. "Custom" means that the charger uses the charge_control_* properties as configuration for some different algorithm. "Long Life" means the charger reduces its charging rate in order to prolong the battery health. "Bypass" means the charger bypasses the charging path around the integrated converter allowing for a "smart" wall adaptor to perform the power conversion externally.

Access: Read, Write

Valid values:

"Unknown", "N/A", "Trickle", "Fast", "Standard", "Adaptive", "Custom", "Long Life", "Bypass"

/sys/class/power_supply/<supply_name>/current_avg

Defined on file *sysfs-class-power*

Battery:

Reports an average IBAT current reading for the battery, over a fixed period. Normally devices will provide a fixed interval in which they average readings to smooth out the reported value.

USB:

Reports an average IBUS current reading over a fixed period. Normally devices will provide a fixed interval in which they average readings to smooth out the reported value.

Access: Read

Valid values: Represented in microamps. Negative values are used for discharging batteries, positive values for charging batteries and for USB IBUS current.

/sys/class/power_supply/<supply_name>/current_max

Defined on file *sysfs-class-power*

Battery:

Reports the maximum IBAT current allowed into the battery.

USB:

Reports the maximum IBUS current the supply can support.

Access: Read Valid values: Represented in microamps

/sys/class/power_supply/<supply_name>/current_now

Defined on file *sysfs-class-power*

Battery:

Reports an instant, single IBAT current reading for the battery. This value is not averaged/smoothed.

Access: Read

USB:

Reports the IBUS current supplied now. This value is generally read-only reporting, unless the 'online' state of the supply is set to be programmable, in which case this value can be set within the reported min/max range.

Access: Read, Write

Valid values: Represented in microamps. Negative values are used for discharging batteries, positive values for charging batteries and for USB IBUS current.

/sys/class/power_supply/<supply_name>/cycle_count

Defined on file *sysfs-class-power*

Reports the number of full charge + discharge cycles the battery has undergone.

Access: Read

Valid values:
Integer > 0: representing full cycles Integer = 0: cycle_count info is not available

USB Properties

/sys/class/power_supply/<supply_name>/health

Defined on file *sysfs-class-power*

Reports the health of the battery or battery side of charger functionality.

Access: Read

Valid values:
"Unknown", "Good", "Overheat", "Dead", "Over voltage", "Unspecified failure", "Cold", "Watchdog timer expire", "Safety timer expire", "Over current", "Calibration required", "Warm", "Cool", "Hot", "No battery"

/sys/class/power_supply/<supply_name>/input_current_limit

Defined on file *sysfs-class-power*

Details the incoming IBUS current limit currently set in the supply. Normally this is configured based on the type of connection made (e.g. A configured SDP should output a maximum of 500mA so the input current limit is set to the same value). Use preferably input_power_limit, and for problems that can be solved using power limit use input_current_limit.

Access: Read, Write

Valid values: Represented in microamps

/sys/class/power_supply/<supply_name>/input_power_limit

Defined on file *sysfs-class-power*

This entry configures the incoming power limit currently set in the supply. Normally this is configured based on system-level knowledge or user input. Use preferably this feature to limit the incoming power and use current/voltage limit only for problems that can be solved using power limit.

Access: Read, Write

Valid values: Represented in microwatts

/sys/class/power_supply/<supply_name>/input_voltage_limit

Defined on file *sysfs-class-power*

This entry configures the incoming VBUS voltage limit currently set in the supply. Normally this is configured based on system-level knowledge or user input (e.g. This is part of the Pixel C's thermal management strategy to effectively limit the input power to 5V when the screen is on to meet Google's skin temperature targets). Note that this feature should not be used for safety critical things. Use preferably input_power_limit, and for problems that can be solved using power limit use input_voltage_limit.

Access: Read, Write

Valid values: Represented in microvolts

/sys/class/power_supply/<supply_name>/manufacture_day

Defined on file *sysfs-class-power*

Reports the day of month when the device has been manufactured.

Access: Read Valid values: 1-31

/sys/class/power_supply/<supply_name>/manufacture_month

Defined on file *sysfs-class-power*

Reports the month when the device has been manufactured.

Access: Read

Valid values: 1-12

/sys/class/power_supply/<supply_name>/manufacture_year

Defined on file *sysfs-class-power*

Reports the year (following Gregorian calendar) when the device has been manufactured.

Access: Read

Valid values: Reported as integer

/sys/class/power_supply/<supply_name>/manufacturer

Defined on file *sysfs-class-power*

Reports the name of the device manufacturer.

Access: Read Valid values: Represented as string

/sys/class/power_supply/<supply_name>/model_name

Defined on file *sysfs-class-power*

Reports the name of the device model.

Access: Read Valid values: Represented as string

/sys/class/power_supply/<supply_name>/online

Defined on file *sysfs-class-power*

Indicates if VBUS is present for the supply. When the supply is online, and the supply allows it, then it's possible to switch between online states (e.g. Fixed -> Programmable for a PD_PPS USB supply so voltage and current can be controlled).

Access: Read, Write

Valid values:

0:	Offline
1:	Online Fixed - Fixed Voltage Supply
2:	Online Programmable - Programmable Voltage Supply

/sys/class/power_supply/<supply_name>/precharge_current

Defined on file *sysfs-class-power*

Reports the charging current applied during pre-charging phase for a battery charge cycle.

Access: Read

Valid values: Represented in microamps

/sys/class/power_supply/<supply_name>/present

Defined on file *sysfs-class-power*

Reports whether a battery is present or not in the system. If the property does not exist, the battery is considered to be present.

Access: Read

Valid values:

0:	Absent
1:	Present

/sys/class/power_supply/<supply_name>/serial_number

Defined on file *sysfs-class-power*

Reports the serial number of the device.

Access: Read Valid values: Represented as string

/sys/class/power_supply/<supply_name>/status

Defined on file *sysfs-class-power*

Represents the charging status of the battery. Normally this is read-only reporting although for some supplies this can be used to enable/disable charging to the battery.

Access: Read, Write

Valid values:
"Unknown", "Charging", "Discharging", "Not charging", "Full"

/sys/class/power_supply/<supply_name>/technology

Defined on file *sysfs-class-power*

Describes the battery technology supported by the supply.

Access: Read

Valid values:
"Unknown", "NiMH", "Li-ion", "Li-poly", "LiFe", "NiCd", "LiMn"

/sys/class/power_supply/<supply_name>/temp

Defined on file *sysfs-class-power*

Battery:

Reports the current TBAT battery temperature reading.

USB:

Reports the current supply temperature reading. This would normally be the internal temperature of the device itself (e.g TJUNC temperature of an IC)

Access: Read

Valid values: Represented in 1/10 Degrees Celsius

/sys/class/power_supply/<supply_name>/temp_alert_max

Defined on file *sysfs-class-power*

Battery:

Maximum TBAT temperature trip-wire value where the supply will notify user-space of the event.

USB:

Maximum supply temperature trip-wire value where the supply will notify user-space of the event.

This is normally used for the charging scenario where user-space needs to know if the temperature has crossed an upper threshold so it can take appropriate action (e.g. warning user that the temperature is critically high, and charging has stopped).

Access: Read

Valid values: Represented in 1/10 Degrees Celsius

/sys/class/power_supply/<supply_name>/temp_alert_min

Defined on file *sysfs-class-power*

Battery:

Minimum TBAT temperature trip-wire value where the supply will notify user-space of the event.

USB:

Minimum supply temperature trip-wire value where the supply will notify user-space of the event.

This is normally used for the charging scenario where user-space needs to know if the temperature has crossed a lower threshold so it can take appropriate action (e.g. warning user that temperature level is high, and charging current has been reduced accordingly to remedy the situation).

Access: Read

Valid values: Represented in 1/10 Degrees Celsius

/sys/class/power_supply/<supply_name>/temp_max

Defined on file *sysfs-class-power*

Battery:

Reports the maximum allowed TBAT battery temperature for charging.

USB:

Reports the maximum allowed supply temperature for operation.

Access: Read

Valid values: Represented in 1/10 Degrees Celsius

/sys/class/power_supply/<supply_name>/temp_min

Defined on file *sysfs-class-power*

Battery:

Reports the minimum allowed TBAT battery temperature for charging.

USB:

Reports the minimum allowed supply temperature for operation.

Access: Read

Valid values: Represented in 1/10 Degrees Celsius

/sys/class/power_supply/<supply_name>/type

Defined on file *sysfs-class-power*

Describes the main type of the supply.

Access: Read Valid values: ”Battery”, ”UPS”, ”Mains”, ”USB”, ”Wireless”

Battery and USB properties

/sys/class/power_supply/<supply_name>/usb_type

Defined on file *sysfs-class-power*

Reports what type of USB connection is currently active for the supply, for example it can show if USB-PD capable source is attached.

Access: Read-Only

Valid values:
”Unknown”, ”SDP”, ”DCP”, ”CDP”, ”ACA”, ”C”, ”PD”, ”PD_DRP”, ”PD_PPS”, ”BrickID”

Device Specific Properties

/sys/class/power_supply/<supply_name>/voltage_avg

Defined on file *sysfs-class-power*

Reports an average VBAT voltage reading for the battery, over a fixed period. Normally devices will provide a fixed interval in which they average readings to smooth out the reported value.

Access: Read

Valid values: Represented in microvolts

/sys/class/power_supply/<supply_name>/voltage_max

Defined on file *sysfs-class-power*

Battery:

Reports the maximum safe VBAT voltage permitted for the battery, during charging.

USB:

Reports the maximum VBUS voltage the supply can support.

Access: Read

Valid values: Represented in microvolts

/sys/class/power_supply/<supply_name>/voltage_min

Defined on file *sysfs-class-power*

Battery:

Reports the minimum safe VBAT voltage permitted for the battery, during discharging.

USB:

Reports the minimum VBUS voltage the supply can support.

Access: Read

Valid values: Represented in microvolts

/sys/class/power_supply/<supply_name>/voltage_now

Defined on file *sysfs-class-power*

Battery:

Reports an instant, single VBAT voltage reading for the battery. This value is not averaged/smoothed.

Access: Read

USB:

Reports the VBUS voltage supplied now. This value is generally read-only reporting, unless the 'online' state of the supply is set to be programmable, in which case this value can be set within the reported min/max range.

Access: Read, Write

Valid values: Represented in microvolts

Battery Properties

/sys/class/power_supply/bq24257-charger/high_impedance_enable

Defined on file *sysfs-class-power*

This entry allows enabling the high-impedance mode of bq24257-type charger devices. If enabled, it places the charger IC into low power standby mode with the switch mode controller disabled. When disabled, the charger operates normally. See device datasheet for details.

Valid values:

- 1: enabled
- 0: disabled

/sys/class/power_supply/bq24257-charger/in_dpm_voltage

Defined on file *sysfs-class-power*

This entry configures the input dynamic power path management voltage of bq24257-type charger devices. Once the supply drops to the configured voltage, the input current limit is reduced down to prevent the further drop of the supply. When the IC enters this mode, the charge current is lower than the set value. See device datasheet for details.

Valid values:

- 4200000, 4280000, 4360000, 4440000, 4520000, 4600000, 4680000, 4760000 (all uV)

/sys/class/power_supply/bq24257-charger/ovp_voltage

Defined on file *sysfs-class-power*

This entry configures the overvoltage protection feature of bq24257- type charger devices. This feature protects the device and other components against damage from overvoltage on the input supply. See device datasheet for details.

Valid values:

- 6000000, 6500000, 7000000, 8000000, 9000000, 9500000, 10000000, 10500000 (all uV)

/sys/class/power_supply/bq24257-charger/sysoff_enable

Defined on file *sysfs-class-power*

This entry allows enabling the sysoff mode of bq24257-type charger devices. If enabled and the input is removed, the internal battery FET is turned off in order to reduce the leakage from the BAT pin to less than 1uA. Note that on some devices/systems this disconnects the battery from the system. See device datasheet for details.

Valid values:

- 1: enabled
- 0: disabled

/sys/class/power_supply/ltc4162-l/arm_ship_mode

Defined on file *sysfs-class-power-ltc4162l*

The charger will normally drain the battery while inactive, typically drawing about 54 microamps. Write a "1" to this property to arm a special "ship" mode that extends shelf life by reducing the leakage to about 2.8 microamps. The chip will remain in this mode (and no longer respond to I2C commands) until some external power-supply is attached raising the input voltage above 1V. It will then automatically revert to "0". Writing a "0" to the property cancels the "ship" mode request. The ship mode, when armed, activates once the input voltage drops below 1V.

Access: Read, Write

Valid values: 0 (disable) or 1 (enable)

/sys/class/power_supply/ltc4162-l/charge_status

Defined on file *sysfs-class-power-ltc4162l*

Detailed charge status information as reported by the chip.

Access: Read

Valid values:

ilim_reg_active thermal_reg_active vin_uvcl_active iin_limit_active constant_current constant_voltage charger_off

/sys/class/power_supply/ltc4162-l/force_telemetry

Defined on file *sysfs-class-power-ltc4162l*

To save battery current, the measurement system is disabled if the battery is the only source of power. This affects all voltage, current and temperature measurements. Write a "1" to this to keep performing telemetry once every few seconds, even when running on battery (as reported by the online property, which is "1" when external power is available and "0" when the system runs on battery).

Access: Read, Write

Valid values: 0 (disabled) or 1 (enabled)

/sys/class/power_supply/ltc4162-l/ibat

Defined on file *sysfs-class-power-ltc4162l*

Battery input current as measured by the charger. Negative value means that the battery is discharging.

Access: Read

Valid values: Signed value in microamps

/sys/class/power_supply/ltc4162-l/vbat

Defined on file *sysfs-class-power-ltc4162l*

Battery voltage as measured by the charger.

Access: Read

Valid values: In microvolts

/sys/class/power_supply/ltc4162-l/vbat_avg

Defined on file *sysfs-class-power-ltc4162l*

Battery voltage, averaged over time, as measured by the charger.

Access: Read

Valid values: In microvolts

/sys/class/power_supply/max14577-charger/device/fast_charge_timer

Defined on file *sysfs-class-power*

This entry shows and sets the maximum time the max14577 charger operates in fast-charge mode. When the timer expires the device will terminate fast-charge mode (charging current will drop to 0 A) and will trigger interrupt.

Valid values:

- 5, 6 or 7 (hours),
- 0: disabled.

/sys/class/power_supply/max77693-charger/device/fast_charge_timer

Defined on file *sysfs-class-power*

This entry shows and sets the maximum time the max77693 charger operates in fast-charge mode. When the timer expires the device will terminate fast-charge mode (charging current will drop to 0 A) and will trigger interrupt.

Valid values:

- 4 - 16 (hours), step by 2 (rounded down)
- 0: disabled.

/sys/class/power_supply/max77693-charger/device/top_off_threshold_current

Defined on file *sysfs-class-power*

This entry shows and sets the charging current threshold for entering top-off charging mode. When charging current in fast charge mode drops below this value, the charger will trigger interrupt and start top-off charging mode.

Valid values:

- 100000 - 200000 (microamps), step by 25000 (rounded down)
- 200000 - 350000 (microamps), step by 50000 (rounded down)

- 0: disabled.

/sys/class/power_supply/max77693-charger/device/top_off_timer

Defined on file *sysfs-class-power*

This entry shows and sets the maximum time the max77693 charger operates in top-off charge mode. When the timer expires the device will terminate top-off charge mode (charging current will drop to 0 A) and will trigger interrupt.

Valid values:

- 0 - 70 (minutes), step by 10 (rounded down)

/sys/class/power_supply/mp2629_battery/batt_impedance_compen

Defined on file *sysfs-class-power-mp2629*

Represents a battery impedance compensation to accelerate charging.

Access: Read, Write

Valid values: Represented in milli-ohms. Valid range is [0, 140].

/sys/class/power_supply/rt9467-*/sysoff_enable

Defined on file *sysfs-class-power-rt9467*

This entry allows enabling the sysoff mode of rt9467 charger devices. If enabled and the input is removed, the internal battery FET is turned off to reduce the leakage from the BAT pin. See device datasheet for details. It's commonly used when the product enter shipping stage. After entering shipping mode, only 'VBUS' or 'Power key" pressed can make it leave this mode. 'Disable' also can help to leave it, but it's more like to abort the action before the device really enter shipping mode.

Access: Read, Write Valid values: - 1: enabled - 0: disabled

/sys/class/power_supply/rt9471-*/port_detect_enable

Defined on file *sysfs-class-power-rt9471*

This entry allows enabling the USB BC12 port detect function of rt9471 charger devices. If enabled and VBUS is inserted, device will start to do the BC12 port detect and report the usb port type when port detect is done. See datasheet for details. Normally controlled when TypeC/USBPD port integrated.

Access: Read, Write Valid values: - 1: enabled - 0: disabled

/sys/class/power_supply/rt9471-*/sysoff_enable

Defined on file *sysfs-class-power-rt9471*

This entry allows enabling the sysoff mode of rt9471 charger devices. If enabled and the input is removed, the internal battery FET is turned off to reduce the leakage from the BAT pin. See device datasheet for details. It's commonly used when the product enter shipping stage.

After entering shipping mode, only 'VBUS' or 'Power key" pressed can make it leave this mode. 'Disable' also can help to leave it, but it's more like to abort the action before the device really enter shipping mode.

Access: Read, Write Valid values: - 1: enabled - 0: disabled

/sys/class/power_supply/twl4030_ac/mode

Defined on file *sysfs-class-power-twl4030*

Changing mode for 'ac' port. Writing to this can disable charging.

Possible values are:

"auto"	draw power as appropriate for detected power source and battery status.
"off"	do not draw any power.

/sys/class/power_supply/twl4030_usb/mode

Defined on file *sysfs-class-power-twl4030*

Changing mode for USB port. Writing to this can disable charging.

Possible values are:

"auto"	draw power as appropriate for detected power source and battery status.
"off"	do not draw any power.
"continuous"	activate mode described as "linear" in TWL data sheets. This uses whatever current is available and doesn't switch off when voltage drops. This is useful for unstable power sources such as bicycle dynamo, but care should be taken that battery is not over-charged.

/sys/class/power_supply/wilco-charger/charge_control_end_threshold

Defined on file *sysfs-class-power-wilco*

Used when charge_type="Custom", as described above. Measured in percentages. The valid range is [55, 100].

/sys/class/power_supply/wilco-charger/charge_control_start_threshold

Defined on file *sysfs-class-power-wilco*

Used when charge_type="Custom", as described above. Measured in percentages. The valid range is [50, 95].

/sys/class/power_supply/wilco-charger/charge_type

Defined on file *sysfs-class-power-wilco*

What charging algorithm to use:

Standard:
Fully charges battery at a standard rate.

Adaptive:
Battery settings adaptively optimized based on typical battery usage pattern.

Fast:
Battery charges over a shorter period.

Trickle:
Extends battery lifespan, intended for users who primarily use their Chromebook while connected to AC.

Custom:
A low and high threshold percentage is specified. Charging begins when level drops below charge_control_start_threshold, and ceases when level is above charge_control_end_threshold.

Long Life:
Customized charge rate for last longer battery life. On Wilco device this mode is pre-configured in the factory through EC's private PID. Switching to a different mode will be denied by Wilco EC when Long Life mode is enabled.

/sys/class/powercap/

Defined on file *sysfs-class-powercap*

The powercap/ class sub directory belongs to the power cap subsystem. Refer to /power/powercap/powercap for details.

/sys/class/powercap/.../<power zone>/constraint_X_max_time_window_us

Defined on file *sysfs-class-powercap*

Maximum allowed time window in micro seconds for this constraint. Here "X" can have values from 0 to max integer.

/sys/class/powercap/.../<power zone>/constraint_X_min_time_window_us

Defined on file *sysfs-class-powercap*

Minimum allowed time window in micro seconds for this constraint. Here "X" can have values from 0 to max integer.

/sys/class/powercap/.../<power zone>/constraint_X_name

Defined on file *sysfs-class-powercap*

Each power zone can define one or more constraints. Each constraint can have an optional name. Here "X" can have values from 0 to max integer.

/sys/class/powercap/.../<power zone>/constraint_X_power_limit_uw

Defined on file *sysfs-class-powercap*

Power limit in micro-watts should be applicable for the time window specified by "constraint_X_time_window_us". Here "X" can have values from 0 to max integer.

/sys/class/powercap/.../<power zone>/constraint_X_time_window_us

Defined on file *sysfs-class-powercap*

Time window in micro seconds. This is used along with constraint_X_power_limit_uw to define a power constraint. Here "X" can have values from 0 to max integer.

/sys/class/powercap/.../<power zone>/enabled

Defined on file *sysfs-class-powercap*

This allows to enable/disable power capping at power zone level. This applies to current power zone and its children.

/sys/class/powercap/.../<power zone>/energy_uj

Defined on file *sysfs-class-powercap*

Current energy counter in micro-joules. Write "0" to reset. If the counter can not be reset, then this attribute is read-only.

/sys/class/powercap/.../<power zone>/max_energy_range_uj

Defined on file *sysfs-class-powercap*

Range of the above energy counter in micro-joules.

/sys/class/powercap/.../<power zone>/max_power_range_uw

Defined on file *sysfs-class-powercap*

Range of the above power value in micro-watts.

/sys/class/powercap/.../<power zone>/name

Defined on file *sysfs-class-powercap*

Specifies the name of this power zone.

/sys/class/powercap/.../<power zone>/power_uw

Defined on file *sysfs-class-powercap*

Current power in micro-watts.

/sys/class/powercap/<control type>

Defined on file *sysfs-class-powercap*

A <control type> is a unique name under /sys/class/powercap. Here <control type> determines how the power is going to be controlled. A <control type> can contain multiple power zones.

/sys/class/powercap/<control type>/.../constraint_X_max_power_uw

Defined on file *sysfs-class-powercap*

Maximum allowed power in micro watts for this constraint. Here "X" can have values from 0 to max integer.

/sys/class/powercap/<control type>/.../constraint_X_min_power_uw

Defined on file *sysfs-class-powercap*

Minimum allowed power in micro watts for this constraint. Here "X" can have values from 0 to max integer.

/sys/class/powercap/<control type>/<power zone>

Defined on file *sysfs-class-powercap*

A power zone is a single or a collection of devices, which can be independently monitored and controlled. A power zone sysfs entry is qualified with the name of the <control type>. E.g. intel-rapl:0:1:1.

/sys/class/powercap/<control type>/<power zone>/<child power zone>

Defined on file *sysfs-class-powercap*

Power zones may be organized in a hierarchy in which child power zones provide monitoring and control for a subset of devices under the parent. For example, if there is a parent power zone for a whole CPU package, each CPU core in it can be a child power zone.

/sys/class/powercap/<control type>/enabled

Defined on file *sysfs-class-powercap*

This allows to enable/disable power capping for a "control type". This status affects every power zone using this "control_type.

/sys/class/pps/

Defined on file *sysfs-pps*

The */sys/class/pps/* directory will contain files and directories that will provide a unified interface to the PPS sources.

/sys/class/pps/ppsX/

Defined on file *sysfs-pps*

The */sys/class/pps/ppsX/* directory is related to X-th PPS source into the system. Each directory will contain files to manage and control its PPS source.

/sys/class/pps/ppsX/assert

Defined on file *sysfs-pps*

The */sys/class/pps/ppsX/assert* file reports the assert events and the assert sequence number of the X-th source in the form:

<secs>.<nsec>#<sequence>

If the source has no assert events the content of this file is empty.

/sys/class/pps/ppsX/clear

Defined on file *sysfs-pps*

The */sys/class/pps/ppsX/clear* file reports the clear events and the clear sequence number of the X-th source in the form:

<secs>.<nsec>#<sequence>

If the source has no clear events the content of this file is empty.

/sys/class/pps/ppsX/echo

Defined on file *sysfs-pps*

The */sys/class/pps/ppsX/echo* file reports if the X-th does or does not support an "echo" function.

/sys/class/pps/ppsX/mode

Defined on file *sysfs-pps*

The */sys/class/pps/ppsX/mode* file reports the functioning mode of the X-th source in hexadecimal encoding.

Please, refer to linux/include/linux/pps.h for further info.

/sys/class/pps/ppsX/name

Defined on file *sysfs-pps*

The */sys/class/pps/ppsX/name* file reports the name of the X-th source.

/sys/class/pps/ppsX/path

Defined on file *sysfs-pps*

The */sys/class/pps/ppsX/path* file reports the path name of the device connected with the X-th source.

If the source is not connected with any device the content of this file is empty.

/sys/class/ptp/

Defined on file *sysfs-ptp*

This directory contains files and directories providing a standardized interface to the ancillary features of PTP hardware clocks.

/sys/class/ptp/ptp<N>/

Defined on file *sysfs-ptp*

This directory contains the attributes of the Nth PTP hardware clock registered into the PTP class driver subsystem.

/sys/class/ptp/ptp<N>/clock_name

Defined on file *sysfs-ptp*

This file contains the name of the PTP hardware clock as a human readable string. The purpose of this attribute is to provide the user with a "friendly name" and to help distinguish PHY based devices from MAC based ones. The string does not necessarily have to be any kind of unique id.

/sys/class/ptp/ptp<N>/extts_enable

Defined on file *sysfs-ptp*

This write-only file enables or disables external timestamps. To enable external timestamps, write the channel index followed by a "1" into the file. To disable external timestamps, write the channel index followed by a "0" into the file.

/sys/class/ptp/ptp<N>/fifo

Defined on file *sysfs-ptp*

This file provides timestamps on external events, in the form of three integers: channel index, seconds, and nanoseconds.

/sys/class/ptp/ptp<N>/max_adjustment

Defined on file *sysfs-ptp*

This file contains the PTP hardware clock's maximum frequency adjustment value (a positive integer) in parts per billion.

/sys/class/ptp/ptp<N>/max_vclocks

Defined on file *sysfs-ptp*

This file contains the maximum number of ptp vclocks. Write integer to re-configure it.

/sys/class/ptp/ptp<N>/n_alarms

Defined on file *sysfs-ptp*

This file contains the number of periodic or one shot alarms offer by the PTP hardware clock.

/sys/class/ptp/ptp<N>/n_external_timestamps

Defined on file *sysfs-ptp*

This file contains the number of external timestamp channels offered by the PTP hardware clock.

/sys/class/ptp/ptp<N>/n_periodic_outputs

Defined on file *sysfs-ptp*

This file contains the number of programmable periodic output channels offered by the PTP hardware clock.

/sys/class/ptp/ptp<N>/n_pins

Defined on file *sysfs-ptp*

This file contains the number of programmable pins offered by the PTP hardware clock.

/sys/class/ptp/ptp<N>/n_vclocks

Defined on file *sysfs-ptp*

This file contains the number of virtual PTP clocks in use. By default, the value is 0 meaning that only the physical clock is in use. Setting the value creates the corresponding number of virtual clocks and causes the physical clock to become free running. Setting the value back to 0 deletes the virtual clocks and switches the physical clock back to normal, adjustable operation.

/sys/class/ptp/ptp<N>/period

Defined on file *sysfs-ptp*

This write-only file enables or disables periodic outputs. To enable a periodic output, write five integers into the file: channel index, start time seconds, start time nanoseconds, period seconds, and period nanoseconds. To disable a periodic output, set all the seconds and nanoseconds values to zero.

/sys/class/ptp/ptp<N>/pins

Defined on file *sysfs-ptp*

This directory contains one file for each programmable pin offered by the PTP hardware clock. The file name is the hardware dependent pin name. Reading from this file produces two numbers, the assigned function (see the *PTP_PF_* enumeration values in linux/ptp_clock.h) and the channel number. The function and channel assignment may be changed by two writing numbers into the file.

/sys/class/ptp/ptp<N>/pps_available

Defined on file *sysfs-ptp*

This file indicates whether the PTP hardware clock supports a Pulse Per Second to the host CPU. Reading "1" means that the PPS is supported, while "0" means not supported.

/sys/class/ptp/ptp<N>/pps_enable

Defined on file *sysfs-ptp*

This write-only file enables or disables delivery of PPS events to the Linux PPS subsystem. To enable PPS events, write a "1" into the file. To disable events, write a "0" into the file.

/sys/class/pwm/

Defined on file *sysfs-class-pwm*

The pwm/ class sub-directory belongs to the Generic PWM Framework and provides a sysfs interface for using PWM channels.

/sys/class/pwm/pwmchip<N>/

Defined on file *sysfs-class-pwm*

A /sys/class/pwm/pwmchipN directory is created for each probed PWM controller/chip where N is the base of the PWM chip.

/sys/class/pwm/pwmchip<N>/export

Defined on file *sysfs-class-pwm*

Exports a PWM channel from the PWM chip for sysfs control. Value is between 0 and /sys/class/pwm/pwmchipN/npwm - 1.

/sys/class/pwm/pwmchip<N>/npwm

Defined on file *sysfs-class-pwm*

The number of PWM channels supported by the PWM chip.

/sys/class/pwm/pwmchip<N>/pwmX

Defined on file *sysfs-class-pwm*

A /sys/class/pwm/pwmchipN/pwmX directory is created for each exported PWM channel where X is the exported PWM channel number.

/sys/class/pwm/pwmchip<N>/pwmX/capture

Defined on file *sysfs-class-pwm*

Capture information about a PWM signal. The output format is a pair unsigned integers (period and duty cycle), separated by a single space.

/sys/class/pwm/pwmchip<N>/pwmX/duty_cycle

Defined on file *sysfs-class-pwm*

Sets the PWM signal duty cycle in nanoseconds.

/sys/class/pwm/pwmchip<N>/pwmX/enable

Defined on file *sysfs-class-pwm*

Enable/disable the PWM signal. 0 is disabled 1 is enabled

/sys/class/pwm/pwmchip<N>/pwmX/period

Defined on file *sysfs-class-pwm*

Sets the PWM signal period in nanoseconds.

/sys/class/pwm/pwmchip<N>/pwmX/polarity

Defined on file *sysfs-class-pwm*

Sets the output polarity of the PWM signal to ”normal” or ”inversed”.

/sys/class/pwm/pwmchip<N>/unexport

Defined on file *sysfs-class-pwm*

Unexports a PWM channel.

/sys/class/rapidio_port

Defined on file *sysfs-class-rapidio*

On-chip RapidIO controllers and PCIe-to-RapidIO bridges (referenced as ”Master Port” or ”mport”) are presented in sysfs as the special class of devices: ”rapidio_port”. The */sys/class/rapidio_port* subdirectory contains individual subdirectories named as ”rapidioN” where N = mport ID registered with RapidIO subsystem.

NOTE: An mport ID is not a RapidIO destination ID assigned to a given local mport device.

/sys/class/rapidio_port/rapidio<N>/port_destid

Defined on file *sysfs-class-rapidio*

(RO) reports RapidIO destination ID assigned to the given RapidIO mport device. If value 0xFFFFFFFF is returned this means that no valid destination ID have been assigned to the mport (yet). Normally, before enumeration/discovery have been executed only fabric enumerating mports have a valid destination ID assigned to them using "hdid=..." rapidio module parameter.

After enumeration or discovery was performed for a given mport device, the corresponding subdirectory will also contain subdirectories for each child RapidIO device connected to the mport.

The example below shows mport device subdirectory with several child RapidIO devices attached to it:

```
[rio@rapidio ~]$ ls /sys/class/rapidio_port/rapidio0/ -l
total 0
drwxr-xr-x 3 root root    0 Feb 11 15:10 00:e:0001
drwxr-xr-x 3 root root    0 Feb 11 15:10 00:e:0004
drwxr-xr-x 3 root root    0 Feb 11 15:10 00:e:0007
drwxr-xr-x 3 root root    0 Feb 11 15:10 00:s:0002
drwxr-xr-x 3 root root    0 Feb 11 15:10 00:s:0003
drwxr-xr-x 3 root root    0 Feb 11 15:10 00:s:0005
lrwxrwxrwx 1 root root    0 Feb 11 15:11 device -> ../../../0000:01:00.0
-r--r--r-- 1 root root 4096 Feb 11 15:11 port_destid
drwxr-xr-x 2 root root    0 Feb 11 15:11 power
lrwxrwxrwx 1 root root    0 Feb 11 15:04 subsystem -> ../../../../../../class/
↪rapidio_port
-r--r--r-- 1 root root 4096 Feb 11 15:11 sys_size
-rw-r--r-- 1 root root 4096 Feb 11 15:04 uevent
```

/sys/class/rapidio_port/rapidio<N>/sys_size

Defined on file *sysfs-class-rapidio*

(RO) reports RapidIO common transport system size:

0 = small (8-bit destination ID, max. 256 devices),

1 = large (16-bit destination ID, max. 65536 devices).

/sys/class/rc/

Defined on file *sysfs-class-rc*

The rc/ class sub-directory belongs to the Remote Controller core and provides a sysfs interface for configuring infrared remote controller receivers.

/sys/class/rc/rc<N>/

Defined on file *sysfs-class-rc*

A /sys/class/rc/rcN directory is created for each remote control receiver device where N is the number of the receiver.

/sys/class/rc/rc<N>/filter

Defined on file *sysfs-class-rc*

Sets the scancode filter expected value.

Use in combination with /sys/class/rc/rcN/filter_mask to set the expected value of the bits set in the filter mask. If the hardware supports it then scancodes which do not match the filter will be ignored. Otherwise the write will fail with an error.

This value may be reset to 0 if the current protocol is altered.

/sys/class/rc/rc<N>/filter_mask

Defined on file *sysfs-class-rc*

Sets the scancode filter mask of bits to compare. Use in combination with /sys/class/rc/rcN/filter to set the bits of the scancode which should be compared against the expected value. A value of 0 disables the filter to allow all valid scancodes to be processed.

If the hardware supports it then scancodes which do not match the filter will be ignored. Otherwise the write will fail with an error.

This value may be reset to 0 if the current protocol is altered.

/sys/class/rc/rc<N>/protocols

Defined on file *sysfs-class-rc*

Reading this file returns a list of available protocols, something like:

```
"rc5 [rc6] nec jvc [sony]"
```

Enabled protocols are shown in [] brackets.

Writing ”+proto” will add a protocol to the list of enabled protocols.

Writing ”-proto” will remove a protocol from the list of enabled protocols.

Writing ”proto” will enable only ”proto”.

Writing ”none” will disable all protocols.

Write fails with EINVAL if an invalid protocol combination or unknown protocol name is used.

/sys/class/rc/rc<N>/wakeup_data

Defined on file *sysfs-class-rc-nuvoton*

Reading this file returns the stored CIR wakeup sequence. It starts with a pulse, followed by a space, pulse etc. All values are in microseconds. The same format can be used to store a wakeup sequence in the Nuvoton chip by writing to this file.

Note: Some systems reset the stored wakeup sequence to a factory default on each boot. On such systems store the wakeup sequence in a file and set it on boot using e.g. a udev rule.

/sys/class/rc/rc<N>/wakeup_filter

Defined on file *sysfs-class-rc*

Sets the scancode wakeup filter expected value.

Use in combination with /sys/class/rc/rcN/wakeup_filter_mask to set the expected value of the bits set in the wakeup filter mask to trigger a system wake event.

If the hardware supports it and wakeup_filter_mask is not 0 then scancodes which match the filter will wake the system from e.g. suspend to RAM or power off.

Otherwise the write will fail with an error.

This value may be reset to 0 if the wakeup protocol is altered.

/sys/class/rc/rc<N>/wakeup_filter_mask

Defined on file *sysfs-class-rc*

Sets the scancode wakeup filter mask of bits to compare.

Use in combination with /sys/class/rc/rcN/wakeup_filter to set the bits of the scancode which should be compared against the expected value to trigger a system wake event.

If the hardware supports it and wakeup_filter_mask is not 0 then scancodes which match the filter will wake the system from e.g. suspend to RAM or power off.

Otherwise the write will fail with an error.

This value may be reset to 0 if the wakeup protocol is altered.

/sys/class/rc/rc<N>/wakeup_protocols

Defined on file *sysfs-class-rc*

Reading this file returns a list of available protocols to use for the wakeup filter, something like:

```
"rc-5 nec nec-x rc-6-0 rc-6-6a-24 [rc-6-6a-32] rc-6-mce"
```

Note that protocol variants are listed, so ”nec”, ”sony”, ”rc-5”, ”rc-6” have their different bit length encodings listed if available.

The enabled wakeup protocol is shown in [] brackets.

Only one protocol can be selected at a time.

Writing ”proto” will use ”proto” for wakeup events.

Writing ”none” will disable wakeup.

Write fails with EINVAL if an invalid protocol combination or unknown protocol name is used, or if wakeup is not supported by the hardware.

/sys/class/regulator/.../bypass

Defined on file *sysfs-class-regulator*

Some regulator directories will contain a field called bypass. This indicates if the device is in bypass mode.

This will be one of the following strings:

- 'enabled'
- 'disabled'
- 'unknown'

'enabled' means the regulator is in bypass mode.

'disabled' means that the regulator is regulating.

'unknown' means software cannot determine the state, or the reported state is invalid.

/sys/class/regulator/.../fail

Defined on file *sysfs-class-regulator*

Some regulator directories will contain a field called fail. This indicates if the device reports an output failure (1) or not (0).

/sys/class/regulator/.../max_microamps

Defined on file *sysfs-class-regulator*

Some regulator directories will contain a field called max_microamps. This holds the maximum safe working regulator output current limit setting for this domain measured in microamps, for regulators which support current constraints.

NOTE: this will return the string 'constraint not defined' if the power domain has no max microamps constraint defined by platform code.

/sys/class/regulator/.../max_microvolts

Defined on file *sysfs-class-regulator*

Some regulator directories will contain a field called max_microvolts. This holds the maximum safe working regulator output voltage setting for this domain measured in microvolts, for regulators which support voltage constraints.

NOTE: this will return the string 'constraint not defined' if the power domain has no max microvolts constraint defined by platform code.

/sys/class/regulator/.../microamps

Defined on file *sysfs-class-regulator*

Some regulator directories will contain a field called microamps. This holds the regulator output current limit setting measured in microamps (i.e. E-6 Amps), for regulators which can report the control input for a current limit.

NOTE: This value should not be used to determine the regulator output current level as this value is the same regardless of whether the regulator is enabled or disabled.

/sys/class/regulator/.../microvolts

Defined on file *sysfs-class-regulator*

Some regulator directories will contain a field called microvolts. This holds the regulator output voltage setting measured in microvolts (i.e. E-6 Volts), for regulators which can report the control input for voltage.

NOTE: This value should not be used to determine the regulator output voltage level as this value is the same regardless of whether the regulator is enabled or disabled.

/sys/class/regulator/.../min_microamps

Defined on file *sysfs-class-regulator*

Some regulator directories will contain a field called min_microamps. This holds the minimum safe working regulator output current limit setting for this domain measured in microamps, for regulators which support current constraints.

NOTE: this will return the string 'constraint not defined' if the power domain has no min microamps constraint defined by platform code.

/sys/class/regulator/.../min_microvolts

Defined on file *sysfs-class-regulator*

Some regulator directories will contain a field called min_microvolts. This holds the minimum safe working regulator output voltage setting for this domain measured in microvolts, for regulators which support voltage constraints.

NOTE: this will return the string 'constraint not defined' if the power domain has no min microvolts constraint defined by platform code.

/sys/class/regulator/.../name

Defined on file *sysfs-class-regulator*

Each regulator directory will contain a field called name. This holds a string identifying the regulator for display purposes.

NOTE: this will be empty if no suitable name is provided by platform or regulator drivers.

/sys/class/regulator/.../num_users

Defined on file *sysfs-class-regulator*

Each regulator directory will contain a field called num_users. This holds the number of consumer devices that have called regulator_enable() on this regulator.

/sys/class/regulator/.../opmode

Defined on file *sysfs-class-regulator*

Some regulator directories will contain a field called opmode. This holds the current regulator operating mode, for regulators which can report that control input value.

The opmode value can be one of the following strings:

- 'fast'
- 'normal'
- 'idle'
- 'standby'
- 'unknown'

The modes are described in include/linux/regulator/consumer.h

NOTE: This value should not be used to determine the regulator output operating mode as this value is the same regardless of whether the regulator is enabled or disabled. A "status" attribute may be available to determine the actual mode.

/sys/class/regulator/.../over_current

Defined on file *sysfs-class-regulator*

Some regulator directories will contain a field called over_current. This indicates if the device reports an over-current fault (1) or not (0).

/sys/class/regulator/.../over_current_warn

Defined on file *sysfs-class-regulator*

Some regulator directories will contain a field called over_current_warn. This indicates if the device reports an over-current warning (1) or not (0).

/sys/class/regulator/.../over_temp

Defined on file *sysfs-class-regulator*

Some regulator directories will contain a field called over_temp. This indicates if the device reports an over-temperature fault (1) or not (0).

/sys/class/regulator/.../over_temp_warn

Defined on file *sysfs-class-regulator*

Some regulator directories will contain a field called over_temp_warn. This indicates if the device reports an over-temperature warning (1) or not (0).

/sys/class/regulator/.../over_voltage_warn

Defined on file *sysfs-class-regulator*

Some regulator directories will contain a field called over_voltage_warn. This indicates if the device reports an over-voltage warning (1) or not (0).

/sys/class/regulator/.../parent

Defined on file *sysfs-class-regulator*

Some regulator directories will contain a link called parent. This points to the parent or supply regulator if one exists.

/sys/class/regulator/.../regulation_out

Defined on file *sysfs-class-regulator*

Some regulator directories will contain a field called regulation_out. This indicates if the device reports an out-of-regulation fault (1) or not (0).

/sys/class/regulator/.../requested_microamps

Defined on file *sysfs-class-regulator*

Some regulator directories will contain a field called requested_microamps. This holds the total requested load current in microamps for this regulator from all its consumer devices.

/sys/class/regulator/.../state

Defined on file *sysfs-class-regulator*

Some regulator directories will contain a field called state. This reports the regulator enable control, for regulators which can report that input value.

This will be one of the following strings:

'enabled' 'disabled' 'unknown'

'enabled' means the regulator output is ON and is supplying power to the system (assuming no error prevents it).

'disabled' means the regulator output is OFF and is not supplying power to the system (unless some non-Linux control has enabled it).

'unknown' means software cannot determine the state, or the reported state is invalid.

NOTE: this field can be used in conjunction with microvolts or microamps to determine configured regulator output levels.

/sys/class/regulator/.../status

Defined on file *sysfs-class-regulator*

Some regulator directories will contain a field called "status". This reports the current regulator status, for regulators which can report that output value.

This will be one of the following strings:

- off
- on

- error
- fast
- normal
- idle
- standby

”off” means the regulator is not supplying power to the system.

”on” means the regulator is supplying power to the system, and the regulator can't report a detailed operation mode.

”error” indicates an out-of-regulation status such as being disabled due to thermal shutdown, or voltage being unstable because of problems with the input power supply.

”fast”, ”normal”, ”idle”, and ”standby” are all detailed regulator operation modes (described elsewhere). They imply ”on”, but provide more detail.

Note that regulator status is a function of many inputs, not limited to control inputs from Linux. For example, the actual load presented may trigger ”error” status; or a regulator may be enabled by another user, even though Linux did not enable it.

/sys/class/regulator/.../suspend_disk_microvolts

Defined on file *sysfs-class-regulator*

Some regulator directories will contain a field called suspend_disk_microvolts. This holds the regulator output voltage setting for this domain measured in microvolts when the system is suspended to disk, for voltage regulators implementing suspend voltage configuration constraints.

/sys/class/regulator/.../suspend_disk_mode

Defined on file *sysfs-class-regulator*

Some regulator directories will contain a field called suspend_disk_mode. This holds the regulator operating mode setting for this domain when the system is suspended to disk, for regulators implementing suspend mode configuration constraints.

/sys/class/regulator/.../suspend_disk_state

Defined on file *sysfs-class-regulator*

Some regulator directories will contain a field called suspend_disk_state. This holds the regulator operating state when suspended to disk, for regulators implementing suspend configuration constraints.

This will be one of the same strings reported by the ”state” attribute.

/sys/class/regulator/.../suspend_mem_microvolts

Defined on file *sysfs-class-regulator*

Some regulator directories will contain a field called suspend_mem_microvolts. This holds the regulator output voltage setting for this domain measured in microvolts when the system is

suspended to memory, for voltage regulators implementing suspend voltage configuration constraints.

/sys/class/regulator/.../suspend_mem_mode

Defined on file *sysfs-class-regulator*

Some regulator directories will contain a field called suspend_mem_mode. This holds the regulator operating mode setting for this domain when the system is suspended to memory, for regulators implementing suspend mode configuration constraints.

/sys/class/regulator/.../suspend_mem_state

Defined on file *sysfs-class-regulator*

Some regulator directories will contain a field called suspend_mem_state. This holds the regulator operating state when suspended to memory, for regulators implementing suspend configuration constraints.

This will be one of the same strings reported by the "state" attribute.

/sys/class/regulator/.../suspend_standby_microvolts

Defined on file *sysfs-class-regulator*

Some regulator directories will contain a field called suspend_standby_microvolts. This holds the regulator output voltage setting for this domain measured in microvolts when the system is suspended to standby, for voltage regulators implementing suspend voltage configuration constraints.

/sys/class/regulator/.../suspend_standby_mode

Defined on file *sysfs-class-regulator*

Some regulator directories will contain a field called suspend_standby_mode. This holds the regulator operating mode setting for this domain when the system is suspended to standby, for regulators implementing suspend mode configuration constraints.

/sys/class/regulator/.../suspend_standby_state

Defined on file *sysfs-class-regulator*

Some regulator directories will contain a field called suspend_standby_state. This holds the regulator operating state when suspended to standby, for regulators implementing suspend configuration constraints.

This will be one of the same strings reported by the "state" attribute.

/sys/class/regulator/.../type

Defined on file *sysfs-class-regulator*

Each regulator directory will contain a field called type. This holds the regulator type.

This will be one of the following strings:

- 'voltage'
- 'current'
- 'unknown'

'voltage' means the regulator output voltage can be controlled by software.

'current' means the regulator output current limit can be controlled by software.

'unknown' means software cannot control either voltage or current limit.

/sys/class/regulator/.../under_voltage

Defined on file *sysfs-class-regulator*

Some regulator directories will contain a field called under_voltage. This indicates if the device reports an under-voltage fault (1) or not (0).

/sys/class/regulator/.../under_voltage_warn

Defined on file *sysfs-class-regulator*

Some regulator directories will contain a field called under_voltage_warn. This indicates if the device reports an under-voltage warning (1) or not (0).

/sys/class/remoteproc/.../coredump

Defined on file *sysfs-class-remoteproc*

Remote processor coredump configuration

Reports the coredump configuration of the remote processor, which will be one of:

”disabled” ”enabled” ”inline”

”disabled” means no dump will be collected.

”enabled” means when the remote processor's coredump is collected it will be copied to a separate buffer and that buffer is exposed to userspace.

”inline” means when the remote processor's coredump is collected userspace will directly read from the remote processor's device memory. Extra buffer will not be used to copy the dump. Also recovery process will not proceed until all data is read by userspace.

/sys/class/remoteproc/.../firmware

Defined on file *sysfs-class-remoteproc*

Remote processor firmware

Reports the name of the firmware currently loaded to the remote processor.

To change the running firmware, ensure the remote processor is stopped (using /sys/class/remoteproc/.../state) and write a new filename.

/sys/class/remoteproc/.../name

Defined on file *sysfs-class-remoteproc*

Remote processor name

Reports the name of the remote processor. This can be used by userspace in exactly identifying a remote processor and ease up the usage in modifying the 'firmware' or 'state' files.

/sys/class/remoteproc/.../recovery

Defined on file *sysfs-class-remoteproc*

Remote processor recovery mechanism

Reports the recovery mechanism of the remote processor, which will be one of:

”enabled” ”disabled”

”enabled” means, the remote processor will be automatically recovered whenever it crashes. Moreover, if the remote processor crashes while recovery is disabled, it will be automatically recovered too as soon as recovery is enabled.

”disabled” means, a remote processor will remain in a crashed state if it crashes. This is useful for debugging purposes; without it, debugging a crash is substantially harder.

/sys/class/remoteproc/.../state

Defined on file *sysfs-class-remoteproc*

Remote processor state

Reports the state of the remote processor, which will be one of:

- ”offline”
- ”suspended”
- ”running”
- ”crashed”
- ”invalid”

”offline” means the remote processor is powered off.

”suspended” means that the remote processor is suspended and must be woken to receive messages.

”running” is the normal state of an available remote processor

”crashed” indicates that a problem/crash has been detected on the remote processor.

”invalid” is returned if the remote processor is in an unknown state.

Writing this file controls the state of the remote processor. The following states can be written:

- ”start”
- ”stop”

Writing "start" will attempt to start the processor running the firmware indicated by, or written to, /sys/class/remoteproc/.../firmware. The remote processor should transition to "running" state.

Writing "stop" will attempt to halt the remote processor and return it to the "offline" state.

/sys/class/rnbd-client

Defined on file *sysfs-class-rnbd-client*

Provide information about RNBD-client. All sysfs files that are not read-only provide the usage information on read:

Example:

```
# cat /sys/class/rnbd-client/ctl/map_device

> Usage: echo "sessname=<name of the rtrs session> path=<[srcaddr,]dstaddr>
> [path=<[srcaddr,]dstaddr>] device_path=<full path on remote side>
> [access_mode=<ro|rw|migration>] > map_device
>
> addr ::= [ ip:<ipv4> | ip:<ipv6> | gid:<gid> ]
```

/sys/class/rnbd-client/ctl/devices/

Defined on file *sysfs-class-rnbd-client*

For each device mapped on the client a new symbolic link is created as /sys/class/rnbd-client/ctl/devices/<device_id>@<session_name>, which points to the block device created by rnbd (/sys/block/rnbd<N>/). The <device_id> of each device is created as follows:

- If the 'device_path' provided during mapping contains slashes ("/"), they are replaced by exclamation mark ("!") and used as as the <device_id>. Otherwise, the <device_id> will be the same as the "device_path" provided.

/sys/class/rnbd-client/ctl/map_device

Defined on file *sysfs-class-rnbd-client*

Expected format is the following:

```
sessname=<name of the rtrs session>
path=<[srcaddr,]dstaddr> [path=<[srcaddr,]dstaddr> ...]
device_path=<full path on remote side>
[access_mode=<ro|rw|migration>]
```

Where:

sessname:
accepts a string not bigger than 256 chars, which identifies a given session on the client and on the server. I.e. "clt_hostname-srv_hostname" could be a natural choice.

path:
describes a connection between the client and the server by specifying destination and,

when required, the source address. The addresses are to be provided in the following format:

```
ip:<IPv6>
ip:<IPv4>
gid:<GID>
```

for example:

```
path=ip:10.0.0.66
```

The single addr is treated as the destination. The connection will be established to this server from any client IP address.

```
path=ip:10.0.0.66,ip:10.0.1.66
```

First addr is the source address and the second is the destination.

If multiple ”path=” options are specified multiple connection will be established and data will be sent according to the selected multipath policy (see RTRS mp_policy sysfs entry description).

device_path:
Path to the block device on the server side. Path is specified relative to the directory on server side configured in the 'dev_search_path' module parameter of the rnbd_server. The rnbd_server prepends the <device_path> received from client with <dev_search_path> and tries to open the <dev_search_path>/<device_path> block device. On success, a /dev/rnbd<N> device file, a /sys/block/rnbd<N>/ directory and an entry in /sys/class/rnbd-client/ctl/devices will be created.

If 'dev_search_path' contains '%SESSNAME%', then each session can have different devices namespace, e.g. server was configured with the following parameter ”dev_search_path=/run/rnbd-devs/%SESSNAME%”, client has this string ”sessname=blya device_path=sda”, then server will try to open: /run/rnbd-devs/blya/sda.

access_mode:
the access_mode parameter specifies if the device is to be mapped as ”ro” read-only or ”rw” read-write. The server allows a device to be exported in rw mode only once. The ”migration” access mode has to be specified if a second mapping in read-write mode is desired.

By default ”rw” is used.

nr_poll_queues
specifies the number of poll-mode queues. If the IO has HIPRI flag, the block-layer will send the IO via the poll-mode queue. For fast network and device the polling is faster than interrupt-base IO handling because it saves time for context switching, switching to another process, handling the interrupt and switching back to the issuing process.

Set -1 if you want to set it as the number of CPUs By default rnbd client creates only irq-mode queues.

NOTICE: MUST make a unique session for a device using the poll-mode queues.

Exit Codes:

If the device is already mapped it will fail with EEXIST. If the input has an invalid format it will return EINVAL. If the device path cannot be found on the server, it will fail with ENOENT.

Finding device file after mapping

After mapping, the device file can be found by: o The symlink /sys/class/rnbd-client/ctl/devices/<device_id>@<session_name> points to /sys/block/<dev-name>. The last part of the symlink destination is the same as the device name. By extracting the last part of the path the path to the device /dev/<dev-name> can be build.

- /dev/block/$(cat /sys/class/rnbd-client/ctl/devices/<device_id>@<session_name>/dev)

How to find the <device_id> of the device is described on the next section.

/sys/class/rnbd-server

Defined on file *sysfs-class-rnbd-server*

provide information about RNBD-server.

/sys/class/rnbd-server/ctl/

Defined on file *sysfs-class-rnbd-server*

When a client maps a device, a directory entry with the name of the block device is created under /sys/class/rnbd-server/ctl/devices/.

/sys/class/rnbd-server/ctl/devices/<device_name>/block_dev

Defined on file *sysfs-class-rnbd-server*

Is a symlink to the sysfs entry of the exported device.

Example: block_dev -> ../../../../class/block/ram0

/sys/class/rnbd-server/ctl/devices/<device_name>/sessions/

Defined on file *sysfs-class-rnbd-server*

For each client a particular device is exported to, following directory will be created:

/sys/class/rnbd-server/ctl/devices/<device_name>/sessions/<session-name>/

When the device is unmapped by that client, the directory will be removed.

/sys/class/rnbd-server/ctl/devices/<device_name>/sessions/<session-name>/access_mode

Defined on file *sysfs-class-rnbd-server*

Contains the device access mode: ro, rw or migration.

/sys/class/rnbd-server/ctl/devices/<device_name>/sessions/<session-name>/force_close

Defined on file *sysfs-class-rnbd-server*

Write "1" to the file to close the device on server side. Please note that the client side device will not be closed, read or write to the device will get -ENOTCONN.

/sys/class/rnbd-server/ctl/devices/<device_name>/sessions/<session-name>/mapping_path

Defined on file *sysfs-class-rnbd-server*

Contains the relative device path provided by the user during mapping.

/sys/class/rnbd-server/ctl/devices/<device_name>/sessions/<session-name>/read_only

Defined on file *sysfs-class-rnbd-server*

Contains '1' if device is mapped read-only, otherwise '0'.

/sys/class/rtc/

Defined on file *sysfs-class-rtc*

The rtc/ class subdirectory belongs to the RTC subsystem.

/sys/class/rtc/rtc0/device/rtc_calibration

Defined on file *sysfs-class-rtc-rtc0-device-rtc_calibration*

Attribute for calibrating ST-Ericsson AB8500 Real Time Clock The rtc_calibration attribute allows the userspace to calibrate the AB8500.s 32KHz Real Time Clock. Every 60 seconds the AB8500 will correct the RTC's value by adding to it the value of this attribute.

The range of the attribute is -127 to +127 in units of 30.5 micro-seconds (half-parts-per-million of the 32KHz clock)

Users: The /vendor/st-ericsson/base_utilities/core/rtc_calibration daemon uses this interface.

/sys/class/rtc/rtcX/

Defined on file *sysfs-class-rtc*

The /sys/class/rtc/rtc{0,1,2,3,...} directories correspond to each RTC device.

/sys/class/rtc/rtcX/date

Defined on file *sysfs-class-rtc*

(RO) RTC-provided date in YYYY-MM-DD format

/sys/class/rtc/rtcX/hctosys

Defined on file *sysfs-class-rtc*

(RO) 1 if the RTC provided the system time at boot via the CONFIG_RTC_HCTOSYS kernel option, 0 otherwise

/sys/class/rtc/rtcX/max_user_freq

Defined on file *sysfs-class-rtc*

(RW) The maximum interrupt rate an unprivileged user may request from this RTC.

/sys/class/rtc/rtcX/name

Defined on file *sysfs-class-rtc*

(RO) The name of the RTC corresponding to this sysfs directory

/sys/class/rtc/rtcX/offset

Defined on file *sysfs-class-rtc*

(RW) The amount which the rtc clock has been adjusted in firmware. Visible only if the driver supports clock offset adjustment. The unit is parts per billion, i.e. The number of clock ticks which are added to or removed from the rtc's base clock per billion ticks. A positive value makes a day pass more slowly, longer, and a negative value makes a day pass more quickly.

/sys/class/rtc/rtcX/range

Defined on file *sysfs-class-rtc*

Valid time range for the RTC, as seconds from epoch, formatted as [min, max]

/sys/class/rtc/rtcX/since_epoch

Defined on file *sysfs-class-rtc*

(RO) RTC-provided time as the number of seconds since the epoch

/sys/class/rtc/rtcX/time

Defined on file *sysfs-class-rtc*

(RO) RTC-provided time in 24-hour notation (hh:mm:ss)

/sys/class/rtc/rtcX/wakealarm

Defined on file *sysfs-class-rtc*

(RW) The time at which the clock will generate a system wakeup event. This is a one shot wakeup event, so must be reset after wake if a daily wakeup is required. Format is seconds since the epoch by default, or if there's a leading +, seconds in the future, or if there is a leading +=, seconds ahead of the current alarm.

/sys/class/rtrs-client

Defined on file *sysfs-class-rtrs-client*

When a user of RTRS API creates a new session, a directory entry with the name of that session is created under /sys/class/rtrs-client/<session-name>/

/sys/class/rtrs-client/<session-name>/add_path

Defined on file *sysfs-class-rtrs-client*

RW, adds a new path (connection) to an existing session. Expected format is the following:

```
<[source addr,]destination addr>
*addr ::= [ ip:<ipv4|ipv6> | gid:<gid> ]
```

/sys/class/rtrs-client/<session-name>/max_reconnect_attempts

Defined on file *sysfs-class-rtrs-client*

Maximum number reconnect attempts the client should make before giving up after connection breaks unexpectedly.

/sys/class/rtrs-client/<session-name>/mp_policy

Defined on file *sysfs-class-rtrs-client*

Multipath policy specifies which path should be selected on each IO:

round-robin (0):
select path in per CPU round-robin manner.

min-inflight (1):
select path with minimum inflights.

min-latency (2):
select path with minimum latency.

/sys/class/rtrs-client/<session-name>/paths/

Defined on file *sysfs-class-rtrs-client*

Each path belonging to a given session is listed here by its source and destination address. When a new path is added to a session by writing to the "add_path" entry, a directory <src@dst> is created.

/sys/class/rtrs-client/<session-name>/paths/<src@dst>/cur_latency

Defined on file *sysfs-class-rtrs-client*

RO, Contains the latency time calculated by the heart-beat messages. Whenever the client sends heart-beat message, it checks the time gap between sending the heart-beat message and receiving the ACK. This value can be changed regularly.

/sys/class/rtrs-client/<session-name>/paths/<src@dst>/disconnect

Defined on file *sysfs-class-rtrs-client*

Write "1" to the file in order to disconnect the path. Operation blocks until RTRS path is disconnected.

/sys/class/rtrs-client/<session-name>/paths/<src@dst>/dst_addr

Defined on file *sysfs-class-rtrs-client*

RO, Contains the destination address of the path

/sys/class/rtrs-client/<session-name>/paths/<src@dst>/hca_name

Defined on file *sysfs-class-rtrs-client*

RO, Contains the name of HCA the connection established on.

/sys/class/rtrs-client/<session-name>/paths/<src@dst>/hca_port

Defined on file *sysfs-class-rtrs-client*

RO, Contains the port number of active port traffic is going through.

/sys/class/rtrs-client/<session-name>/paths/<src@dst>/reconnect

Defined on file *sysfs-class-rtrs-client*

Write "1" to the file in order to reconnect the path. Operation is blocking and returns 0 if reconnect was successful.

/sys/class/rtrs-client/<session-name>/paths/<src@dst>/remove_path

Defined on file *sysfs-class-rtrs-client*

Write "1" to the file in order to disconnected and remove the path from the session. Operation blocks until the path is disconnected and removed from the session.

/sys/class/rtrs-client/<session-name>/paths/<src@dst>/src_addr

Defined on file *sysfs-class-rtrs-client*

RO, Contains the source address of the path

/sys/class/rtrs-client/<session-name>/paths/<src@dst>/state

Defined on file *sysfs-class-rtrs-client*

RO, Contains "connected" if the session is connected to the peer and fully functional. Otherwise the file contains "disconnected"

/sys/class/rtrs-client/<session-name>/paths/<src@dst>/stats/cpu_migration

Defined on file *sysfs-class-rtrs-client*

RTRS expects that each HCA IRQ is pinned to a separate CPU. If it's not the case, the processing of an I/O response could be processed on a different CPU than where it was originally submitted. This file shows how many interrupts where generated on a non expected CPU.

"from:"
is the CPU on which the IRQ was expected, but not generated.

"to:"
is the CPU on which the IRQ was generated, but not expected.

/sys/class/rtrs-client/<session-name>/paths/<src@dst>/stats/rdma

Defined on file *sysfs-class-rtrs-client*

Contains statistics regarding rdma operations and inflight operations. The output consists of 6 values:

```
<read-count> <read-total-size> <write-count> \
<write-total-size> <inflights> <failovered>
```

/sys/class/rtrs-client/<session-name>/paths/<src@dst>/stats/reconnects

Defined on file *sysfs-class-rtrs-client*

Contains 2 unsigned int values, the first one records number of successful reconnects in the path lifetime, the second one records number of failed reconnects in the path lifetime.

/sys/class/rtrs-client/<session-name>/paths/<src@dst>/stats/reset_all

Defined on file *sysfs-class-rtrs-client*

RW, Read will return usage help, write 0 will clear all the statistics.

/sys/class/rtrs-server

Defined on file *sysfs-class-rtrs-server*

When a user of RTRS API creates a new session on a client side, a directory entry with the name of that session is created in here.

/sys/class/rtrs-server/<session-name>/paths/

Defined on file *sysfs-class-rtrs-server*

When new path is created by writing to "add_path" entry on client side, a directory entry named as <source address>@<destination address> is created on server.

/sys/class/rtrs-server/<session-name>/paths/<src@dst>/disconnect

Defined on file *sysfs-class-rtrs-server*

When "1" is written to the file, the RTRS session is being disconnected. Operations is non-blocking and returns control immediately to the caller.

/sys/class/rtrs-server/<session-name>/paths/<src@dst>/dst_addr

Defined on file *sysfs-class-rtrs-server*

RO, Contains the destination address of the path

/sys/class/rtrs-server/<session-name>/paths/<src@dst>/hca_name

Defined on file *sysfs-class-rtrs-server*

RO, Contains the name of HCA the connection established on.

/sys/class/rtrs-server/<session-name>/paths/<src@dst>/hca_port

Defined on file *sysfs-class-rtrs-server*

RO, Contains the port number of active port traffic is going through.

/sys/class/rtrs-server/<session-name>/paths/<src@dst>/src_addr

Defined on file *sysfs-class-rtrs-server*

RO, Contains the source address of the path

/sys/class/rtrs-server/<session-name>/paths/<src@dst>/stats/rdma

Defined on file *sysfs-class-rtrs-server*

Contains statistics regarding rdma operations and inflight operations. The output consists of 5 values: <read-count> <read-total-size> <write-count> <write-total-size> <inflights>

/sys/class/scsi_device/*/device/dyn_cap_needed

Defined on file *sysfs-driver-ufs*

This file shows the amount of physical memory needed to be removed from the physical memory resources pool of the particular logical unit. The full information about the attribute could be found at UFS specifications 2.1.

The file is read only.

/sys/class/scsi_device/*/device/unit_descriptor/boot_lun_id

Defined on file *sysfs-driver-ufs*

This file shows boot LUN information. This is one of the UFS unit descriptor parameters. The full information about the descriptor could be found at UFS specifications 2.1.

The file is read only.

/sys/class/scsi_device/*/device/unit_descriptor/context_capabilities

Defined on file *sysfs-driver-ufs*

This file shows the context capabilities. This is one of the UFS unit descriptor parameters. The full information about the descriptor could be found at UFS specifications 2.1.

The file is read only.

/sys/class/scsi_device/*/device/unit_descriptor/data_reliability

Defined on file *sysfs-driver-ufs*

This file defines the device behavior when a power failure occurs during a write operation. This is one of the UFS unit descriptor parameters. The full information about the descriptor could be found at UFS specifications 2.1.

The file is read only.

/sys/class/scsi_device/*/device/unit_descriptor/erase_block_size

Defined on file *sysfs-driver-ufs*

This file shows the erase block size. This is one of the UFS unit descriptor parameters. The full information about the descriptor could be found at UFS specifications 2.1.

The file is read only.

/sys/class/scsi_device/*/device/unit_descriptor/large_unit_granularity

Defined on file *sysfs-driver-ufs*

This file shows the granularity of the LUN. This is one of the UFS unit descriptor parameters. The full information about the descriptor could be found at UFS specifications 2.1.

The file is read only.

/sys/class/scsi_device/*/device/unit_descriptor/logical_block_count

Defined on file *sysfs-driver-ufs*

This file shows total number of addressable logical blocks. This is one of the UFS unit descriptor parameters. The full information about the descriptor could be found at UFS specifications 2.1.

The file is read only.

/sys/class/scsi_device/*/device/unit_descriptor/logical_block_size

Defined on file *sysfs-driver-ufs*

This file shows the size of addressable logical blocks (calculated as an exponent with base 2). This is one of the UFS unit descriptor parameters. The full information about the descriptor could be found at UFS specifications 2.1.

The file is read only.

/sys/class/scsi_device/*/device/unit_descriptor/lun_memory_type

Defined on file *sysfs-driver-ufs*

This file shows LUN memory type. This is one of the UFS unit descriptor parameters. The full information about the descriptor could be found at UFS specifications 2.1.

The file is read only.

/sys/class/scsi_device/*/device/unit_descriptor/lun_queue_depth

Defined on file *sysfs-driver-ufs*

This file shows LUN queue depth. This is one of the UFS unit descriptor parameters. The full information about the descriptor could be found at UFS specifications 2.1.

The file is read only.

/sys/class/scsi_device/*/device/unit_descriptor/lun_write_protect

Defined on file *sysfs-driver-ufs*

This file shows LUN write protection status. This is one of the UFS unit descriptor parameters. The full information about the descriptor could be found at UFS specifications 2.1.

The file is read only.

/sys/class/scsi_device/*/device/unit_descriptor/physical_memory_resourse_count

Defined on file *sysfs-driver-ufs*

This file shows the total physical memory resources. This is one of the UFS unit descriptor parameters. The full information about the descriptor could be found at UFS specifications 2.1.

The file is read only.

/sys/class/scsi_device/*/device/unit_descriptor/provisioning_type

Defined on file *sysfs-driver-ufs*

This file shows the thin provisioning type. This is one of the UFS unit descriptor parameters. The full information about the descriptor could be found at UFS specifications 2.1.

The file is read only.

/sys/class/scsi_device/*/device/unit_descriptor/psa_sensitive

Defined on file *sysfs-driver-ufs*

This file shows PSA sensitivity. This is one of the UFS unit descriptor parameters. The full information about the descriptor could be found at UFS specifications 2.1.

The file is read only.

/sys/class/scsi_device/*/device/unit_descriptor/wb_buf_alloc_units

Defined on file *sysfs-driver-ufs*

This entry shows the configured size of WriteBooster buffer. 0400h corresponds to 4GB.

The file is read only.

/sys/class/scsi_host/hostX/acciopath_status

Defined on file *sysfs-class-scsi_host*

This file contains the current status of the "SSD Smart Path" feature of HP Smart Array RAID controllers using the hpsa driver. SSD Smart Path, when enabled permits the driver to send i/o requests directly to physical devices that are part of a logical drive, bypassing the controllers firmware RAID stack for a performance advantage when possible. A value of '1' indicates the feature is enabled, and the controller may use the direct i/o path to physical devices. A value of zero means the feature is disabled and the controller may not use the direct i/o path to physical devices. This setting is controller wide, affecting all configured logical drives on the controller. This file is readable and writable.

/sys/class/scsi_host/hostX/ahci_host_version

Defined on file *sysfs-class-scsi_host*

(RO) Display the version of the AHCI spec implemented by the host.

/sys/class/scsi_host/hostX/ahci_port_cmd
/sys/class/scsi_host/hostX/ahci_host_caps
/sys/class/scsi_host/hostX/ahci_host_cap2

Defined on file *sysfs-class-scsi_host*

[to be documented]

/sys/class/scsi_host/hostX/em_buffer

Defined on file *sysfs-class-scsi_host*

(RW) Allows access to AHCI EM (enclosure management) buffer directly if the host supports EM.

For eg. the AHCI driver supports SGPIO EM messages but the SATA/AHCI specs do not define the SGPIO message format of the EM buffer. Different hardware(HW) vendors may have different definitions. With the em_buffer attribute, this issue can be solved by allowing HW vendors to provide userland drivers and tools for their SGPIO initiators.

/sys/class/scsi_host/hostX/em_message_supported

Defined on file *sysfs-class-scsi_host*

(RO) Displays supported enclosure management message types.

/sys/class/scsi_host/hostX/em_message
/sys/class/scsi_host/hostX/em_message_type

Defined on file *sysfs-class-scsi_host*

em_message: (RW) Enclosure management support. For the LED protocol, writes and reads correspond to the LED message format as defined in the AHCI spec.

The user must turn sw_activity (under */sys/block/*/device/*) OFF it they wish to control the activity LED via the em_message file.

em_message_type: (RO) Displays the current enclosure management protocol that is being used by the driver (for eg. LED, SAF-TE, SES-2, SGPIO etc).

/sys/class/scsi_host/hostX/isci_id

Defined on file *sysfs-class-scsi_host*

This file contains the enumerated host ID for the Intel SCU controller. The Intel(R) C600 Series Chipset SATA/SAS Storage Control Unit embeds up to two 4-port controllers in a single PCI device. The controllers are enumerated in order which usually means the lowest number scsi_host corresponds with the first controller, but this association is not guaranteed. The 'isci_id' attribute unambiguously identifies the controller index: '0' for the first controller, '1' for the second.

/sys/class/scsi_host/hostX/link_power_management_policy

Defined on file *sysfs-class-scsi_host*

(RW) This parameter allows the user to read and set the link (interface) power management.

There are four possible options:

min_power: Tell the controller to try to make the link use the least possible power when possible. This may sacrifice some performance due to increased latency when coming out of lower power states.

max_performance: Generally, this means no power management. Tell the controller to have performance be a priority over power management.

medium_power: Tell the controller to enter a lower power state when possible, but do not enter the lowest power state, thus improving latency over min_power setting.

med_power_with_dipm: Identical to the existing medium_power setting except that it enables dipm (device initiated power management) on top, which makes it match the Windows IRST (Intel Rapid Storage Technology) driver settings. This setting is also close to min_power, except that:

a) It does not use host-initiated slumber mode, but it does allow device-initiated slumber

b) It does not enable low power device sleep mode (DevSlp).

/sys/class/scsi_tape/*/stats/in_flight

Defined on file *sysfs-class-scsi_tape*

Show the number of I/Os currently in-flight between the st module and the SCSI mid-layer.

/sys/class/scsi_tape/*/stats/io_ns

Defined on file *sysfs-class-scsi_tape*

Shows the total amount of time spent waiting for all I/O to and from the tape drive to complete. This includes all reads, writes, and other SCSI commands issued to the tape drive. An example of other SCSI commands would be tape movement such as a rewind when a rewind tape device is closed. This item is measured in nanoseconds.

To determine the amount of time spent waiting for other I/O to complete subtract read_ns and write_ns from this value.

/sys/class/scsi_tape/*/stats/other_cnt

Defined on file *sysfs-class-scsi_tape*

The number of I/O requests issued to the tape drive other than SCSI read/write requests.

/sys/class/scsi_tape/*/stats/read_byte_cnt

Defined on file *sysfs-class-scsi_tape*

Shows the total number of bytes requested from the tape drive. This value is presented in bytes because tape drives support variable length block sizes.

/sys/class/scsi_tape/*/stats/read_cnt

Defined on file *sysfs-class-scsi_tape*

Shows the total number of read requests issued to the tape drive.

/sys/class/scsi_tape/*/stats/read_ns

Defined on file *sysfs-class-scsi_tape*

Shows the total amount of time in nanoseconds waiting for read I/O requests to complete.

/sys/class/scsi_tape/*/stats/resid_cnt

Defined on file *sysfs-class-scsi_tape*

Shows the number of times we found that a residual >0 was found when the SCSI midlayer indicated that there was an error. For reads this may be a case of someone issuing reads greater than the block size.

/sys/class/scsi_tape/*/stats/write_byte_cnt

Defined on file *sysfs-class-scsi_tape*

Shows the total number of bytes written to the tape drive. This value is presented in bytes because tape drives support variable length block sizes.

/sys/class/scsi_tape/*/stats/write_cnt

Defined on file *sysfs-class-scsi_tape*

Shows the total number of write requests issued to the tape drive.

/sys/class/scsi_tape/*/stats/write_ms

Defined on file *sysfs-class-scsi_tape*

Shows the total amount of time in nanoseconds waiting for write I/O requests to complete.

/sys/class/spi_master/spi<bus>/spi<bus>.<dev>/fram

Defined on file *sysfs-class-spi-eeprom*

Contains the FRAM binary data. Same as EEPROM, just another file name to indicate that it employs ferroelectric process. It performs write operations at bus speed - no write delays.

/sys/class/spi_master/spi<bus>/spi<bus>.<dev>/sernum

Defined on file *sysfs-class-spi-eeprom*

Contains the serial number of the Cypress FRAM (FM25VN) if it is present. It will be displayed as a 8 byte hex string, as read from the device.

This is a read-only attribute.

/sys/class/stm/<stm>/channels

Defined on file *sysfs-class-stm*

Shows the number of channels per master on this STM device.

/sys/class/stm/<stm>/hw_override

Defined on file *sysfs-class-stm*

Reads as 0 if master numbers in the STP stream produced by this stm device will match the master numbers assigned by the software or 1 if the stm hardware overrides software assigned masters.

/sys/class/stm/<stm>/masters

Defined on file *sysfs-class-stm*

Shows first and last available to software master numbers on this STM device.

/sys/class/stm_source/<stm_source>/stm_source_link

Defined on file *sysfs-class-stm_source*

stm_source device linkage to stm device, where its tracing data is directed. Reads return an existing connection or "<none>" if this stm_source is not connected to any stm device yet. Write an existing (registered) stm device's name here to connect that device. If a device is already connected to this stm_source, it will first be disconnected.

/sys/class/switchtec

Defined on file *sysfs-class-switchtec*

The switchtec class subsystem folder. Each registered switchtec driver is represented by a switchtecX subfolder (X being an integer >= 0).

/sys/class/switchtec/switchtec[0-9]+/component_id

Defined on file *sysfs-class-switchtec*

Component identifier as stored in the hardware (eg. PM8543) (read only) Values: arbitrary string.

/sys/class/switchtec/switchtec[0-9]+/component_revision

Defined on file *sysfs-class-switchtec*

Component revision stored in the hardware (read only) Values: integer.

/sys/class/switchtec/switchtec[0-9]+/component_vendor

Defined on file *sysfs-class-switchtec*

Component vendor as stored in the hardware (eg. MICROSEM) (read only) Values: arbitrary string.

/sys/class/switchtec/switchtec[0-9]+/device_version

Defined on file *sysfs-class-switchtec*

Device version as stored in the hardware (read only) Values: integer.

/sys/class/switchtec/switchtec[0-9]+/fw_version

Defined on file *sysfs-class-switchtec*

Currently running firmware version (read only) Values: integer (in hexadecimal).

/sys/class/switchtec/switchtec[0-9]+/partition

Defined on file *sysfs-class-switchtec*

Partition number for this device in the switch (read only) Values: integer.

/sys/class/switchtec/switchtec[0-9]+/partition_count

Defined on file *sysfs-class-switchtec*

Total number of partitions in the switch (read only) Values: integer.

/sys/class/switchtec/switchtec[0-9]+/product_id

Defined on file *sysfs-class-switchtec*

Product identifier as stored in the hardware (eg. PSX 48XG3) (read only) Values: arbitrary string.

/sys/class/switchtec/switchtec[0-9]+/product_revision

Defined on file *sysfs-class-switchtec*

Product revision stored in the hardware (eg. RevB) (read only) Values: arbitrary string.

/sys/class/switchtec/switchtec[0-9]+/product_vendor

Defined on file *sysfs-class-switchtec*

Product vendor as stored in the hardware (eg. MICROSEM) (read only) Values: arbitrary string.

/sys/class/thermal/cooling_deviceX/cur_state

Defined on file *sysfs-class-thermal*

The current cooling state of this cooling device. The value can any integer numbers between 0 and max_state:

- cur_state == 0 means no cooling
- cur_state == max_state means the maximum cooling.

RW, Required

/sys/class/thermal/cooling_deviceX/max_state

Defined on file *sysfs-class-thermal*

The maximum permissible cooling state of this cooling device.

RO, Required

/sys/class/thermal/cooling_deviceX/stats/reset

Defined on file *sysfs-class-thermal*

Writing any value resets the cooling device's statistics.

WO, Required

/sys/class/thermal/cooling_deviceX/stats/time_in_state_ms:

Defined on file *sysfs-class-thermal*

The amount of time spent by the cooling device in various cooling states. The output will have "<state> <time>" pair in each line, which will mean this cooling device spent <time> msec of time at <state>.

Output will have one line for each of the supported states.

RO, Required

/sys/class/thermal/cooling_deviceX/stats/total_trans

Defined on file *sysfs-class-thermal*

A single positive value showing the total number of times the state of a cooling device is changed.

RO, Required

/sys/class/thermal/cooling_deviceX/stats/trans_table

Defined on file *sysfs-class-thermal*

This gives fine grained information about all the cooling state transitions. The cat output here is a two dimensional matrix, where an entry <i,j> (row i, column j) represents the number of transitions from State_i to State_j. If the transition table is bigger than PAGE_SIZE, reading this will return an -EFBIG error.

RO, Required

/sys/class/thermal/cooling_deviceX/type

Defined on file *sysfs-class-thermal*

String which represents the type of device, e.g:

- for generic ACPI: should be "Fan", "Processor" or "LCD"
- for memory controller device on intel_menlow platform: should be "Memory controller".

RO, Required

/sys/class/thermal/thermal_zoneX/available_policies

Defined on file *sysfs-class-thermal*

Available thermal governors which can be used for a particular zone.

RO, Required

/sys/class/thermal/thermal_zoneX/cdevY

Defined on file *sysfs-class-thermal*

Sysfs link to the thermal cooling device node where the sys I/F for cooling device throttling control represents.

RO, Optional

/sys/class/thermal/thermal_zoneX/cdevY_trip_point

Defined on file *sysfs-class-thermal*

The trip point in this thermal zone which *cdev[0-*]* is associated with; -1 means the cooling device is not associated with any trip point.

RO, Optional

/sys/class/thermal/thermal_zoneX/cdevY_weight

Defined on file *sysfs-class-thermal*

The influence of *cdev[0-*]* in this thermal zone. This value is relative to the rest of cooling devices in the thermal zone. For example, if a cooling device has a weight double than that of other, it's twice as effective in cooling the thermal zone.

RW, Optional

/sys/class/thermal/thermal_zoneX/emul_temp

Defined on file *sysfs-class-thermal*

Interface to set the emulated temperature method in thermal zone (sensor). After setting this temperature, the thermal zone may pass this temperature to platform emulation function if registered or cache it locally. This is useful in debugging different temperature threshold and its associated cooling action. This is write only node and writing 0 on this node should disable emulation.

Unit: millidegree Celsius

WO, Optional

WARNING:
Be careful while enabling this option on production systems, because userland can easily disable the thermal policy by simply flooding this sysfs node with low temperature values.

/sys/class/thermal/thermal_zoneX/integral_cutoff

Defined on file *sysfs-class-thermal*

Temperature offset from the desired temperature trip point above which the integral term of the power allocator governor's PID controller starts accumulating errors. For example, if integral_cutoff is 0, then the integral term only accumulates error when temperature is above the desired temperature trip point. For more information see /driver-api/thermal/power_allocator

Unit: millidegree Celsius

RW, Optional

/sys/class/thermal/thermal_zoneX/k_d

Defined on file *sysfs-class-thermal*

The derivative term of the power allocator governor's PID controller. For more information see /driver-api/thermal/power_allocator

RW, Optional

/sys/class/thermal/thermal_zoneX/k_i

Defined on file *sysfs-class-thermal*

The integral term of the power allocator governor's PID controller. This term allows the PID controller to compensate for long term drift. For more information see /driver-api/thermal/power_allocator

RW, Optional

/sys/class/thermal/thermal_zoneX/k_po

Defined on file *sysfs-class-thermal*

The proportional term of the power allocator governor's PID controller during temperature overshoot. Temperature overshoot is when the current temperature is above the "desired temperature" trip point. For more information see /driver-api/thermal/power_allocator

RW, Optional

/sys/class/thermal/thermal_zoneX/k_pu

Defined on file *sysfs-class-thermal*

The proportional term of the power allocator governor's PID controller during temperature undershoot. Temperature undershoot is when the current temperature is below the "desired temperature" trip point. For more information see /driver-api/thermal/power_allocator

RW, Optional

/sys/class/thermal/thermal_zoneX/mode

Defined on file *sysfs-class-thermal*

One of the predefined values in [enabled, disabled]. This file gives information about the algorithm that is currently managing the thermal zone. It can be either default kernel based algorithm or user space application.

enabled
: enable Kernel Thermal management.

disabled
: Preventing kernel thermal zone driver actions upon trip points so that user application can take full charge of the thermal management.

RW, Optional

/sys/class/thermal/thermal_zoneX/offset

Defined on file *sysfs-class-thermal*

The offset constant used in a linear extrapolation model to determine a hotspot temperature based off the sensor's raw readings. It is up to the device driver to determine the usage of these values.

RW, Optional

/sys/class/thermal/thermal_zoneX/policy

Defined on file *sysfs-class-thermal*

One of the various thermal governors used for a particular zone.

RW, Required

/sys/class/thermal/thermal_zoneX/slope

Defined on file *sysfs-class-thermal*

The slope constant used in a linear extrapolation model to determine a hotspot temperature based off the sensor's raw readings. It is up to the device driver to determine the usage of these values.

RW, Optional

/sys/class/thermal/thermal_zoneX/sustainable_power

Defined on file *sysfs-class-thermal*

An estimate of the sustained power that can be dissipated by the thermal zone. Used by the power allocator governor. For more information see /driver-api/thermal/power_allocator

Unit: milliwatts

RW, Optional

/sys/class/thermal/thermal_zoneX/temp

Defined on file *sysfs-class-thermal*

Current temperature as reported by thermal zone (sensor).

Unit: millidegree Celsius

RO, Required

/sys/class/thermal/thermal_zoneX/trip_point_Y_hyst

Defined on file *sysfs-class-thermal*

The hysteresis value for a trip point, represented as an integer.

Unit: Celsius

RW, Optional

/sys/class/thermal/thermal_zoneX/trip_point_Y_temp

Defined on file *sysfs-class-thermal*

The temperature above which trip point will be fired.

Unit: millidegree Celsius

RO, Optional

/sys/class/thermal/thermal_zoneX/trip_point_Y_type

Defined on file *sysfs-class-thermal*

Strings which indicate the type of the trip point.

E.g. it can be one of critical, hot, passive, *active[0-*]* for ACPI thermal zone.

RO, Optional

/sys/class/thermal/thermal_zoneX/type

Defined on file *sysfs-class-thermal*

Strings which represent the thermal zone type. This is given by thermal zone driver as part of registration. E.g: "acpitz" indicates it's an ACPI thermal device. In order to keep it consistent with hwmon sys attribute; this should be a short, lowercase string, not containing spaces nor dashes.

RO, Required

/sys/class/timecard/

Defined on file *sysfs-timecard*

This directory contains files and directories providing a standardized interface to the ancillary features of the OpenCompute timecard.

/sys/class/timecard/ocpN/

Defined on file *sysfs-timecard*

This directory contains the attributes of the Nth timecard registered.

/sys/class/timecard/ocpN/available_clock_sources

Defined on file *sysfs-timecard*

(RO) The list of available time sources that the PHC uses for clock adjustments.

NONE	no adjustments
PPS	adjustments come from the PPS1 selector (default)
TOD	adjustments from the GNSS/TOD module
IRIG	adjustments from external IRIG-B signal
DCF	adjustments from external DCF signal

/sys/class/timecard/ocpN/available_sma_inputs

Defined on file *sysfs-timecard*

(RO) Set of available destinations (sinks) for a SMA input signal.

10Mhz	signal is used as the 10Mhz reference clock
PPS1	signal is sent to the PPS1 selector
PPS2	signal is sent to the PPS2 selector
TS1	signal is sent to timestamper 1
TS2	signal is sent to timestamper 2
TS3	signal is sent to timestamper 3
TS4	signal is sent to timestamper 4
IRIG	signal is sent to the IRIG-B module
DCF	signal is sent to the DCF module
FREQ1	signal is sent to frequency counter 1
FREQ2	signal is sent to frequency counter 2
FREQ3	signal is sent to frequency counter 3
FREQ4	signal is sent to frequency counter 4
None	signal input is disabled

/sys/class/timecard/ocpN/available_sma_outputs

Defined on file *sysfs-timecard*

(RO) Set of available sources for a SMA output signal.

10Mhz	output is from the 10Mhz reference clock
PHC	output PPS is from the PHC clock
MAC	output PPS is from the Miniature Atomic Clock
GNSS1	output PPS is from the first GNSS module
GNSS2	output PPS is from the second GNSS module
IRIG	output is from the PHC, in IRIG-B format
DCF	output is from the PHC, in DCF format
GEN1	output is from frequency generator 1
GEN2	output is from frequency generator 2
GEN3	output is from frequency generator 3
GEN4	output is from frequency generator 4
GND	output is GND
VCC	output is VCC

/sys/class/timecard/ocpN/clock_source

Defined on file *sysfs-timecard*

(RW) Contains the current synchronization source used by the PHC. May be changed by writing one of the listed values from the available_clock_sources attribute set.

/sys/class/timecard/ocpN/clock_status_drift

Defined on file *sysfs-timecard*

(RO) Contains the current drift value used by the firmware for internal disciplining of the atomic clock.

/sys/class/timecard/ocpN/clock_status_offset

Defined on file *sysfs-timecard*

(RO) Contains the current offset value used by the firmware for internal disciplining of the atomic clock.

/sys/class/timecard/ocpN/freqX

Defined on file *sysfs-timecard*

(RO) Optional directory containing the sysfs nodes for frequency counter <X>.

/sys/class/timecard/ocpN/freqX/frequency

Defined on file *sysfs-timecard*

(RO) Contains the measured frequency over the specified measurement period.

/sys/class/timecard/ocpN/freqX/seconds

Defined on file *sysfs-timecard*

(RW) Specifies the number of seconds from 0-255 that the frequency should be measured over. Write 0 to disable.

/sys/class/timecard/ocpN/genX

Defined on file *sysfs-timecard*

(RO) Optional directory containing the sysfs nodes for frequency generator <X>.

/sys/class/timecard/ocpN/genX/duty

Defined on file *sysfs-timecard*

(RO) Specifies the signal duty cycle as a percentage from 1-99.

/sys/class/timecard/ocpN/genX/period

Defined on file *sysfs-timecard*

(RO) Specifies the signal period in nanoseconds.

/sys/class/timecard/ocpN/genX/phase

Defined on file *sysfs-timecard*

(RO) Specifies the signal phase offset in nanoseconds.

/sys/class/timecard/ocpN/genX/polarity

Defined on file *sysfs-timecard*

(RO) Specifies the signal polarity, either 1 or 0.

/sys/class/timecard/ocpN/genX/running

Defined on file *sysfs-timecard*

(RO) Either 0 or 1, showing if the signal generator is running.

/sys/class/timecard/ocpN/genX/signal

Defined on file *sysfs-timecard*

(RW) Used to start the signal generator, and summarize the current status.

The signal generator may be started by writing the signal period, followed by the optional signal values. If the optional values are not provided, they default to the current settings, which may be obtained from the other sysfs nodes.

> period [duty [phase [polarity]]]

echo 500000000 > signal # 1/2 second period echo 1000000 40 100 > signal echo 0 > signal # turn off generator

Period and phase are specified in nanoseconds. Duty cycle is a percentage from 1-99. Polarity is 1 or 0.

Reading this node will return:

> period duty phase polarity start_time

/sys/class/timecard/ocpN/genX/start

Defined on file *sysfs-timecard*

(RO) Shows the time in <sec>.<nsec> that the signal generator started running.

/sys/class/timecard/ocpN/gnss_sync

Defined on file *sysfs-timecard*

(RO) Indicates whether a valid GNSS signal is received, or when the signal was lost.

/sys/class/timecard/ocpN/i2c

Defined on file *sysfs-timecard*

This optional attribute links to the associated i2c device.

/sys/class/timecard/ocpN/irig_b_mode

Defined on file *sysfs-timecard*

(RW) An integer from 0-7 indicating the timecode format of the IRIG-B output signal: B00<n>

/sys/class/timecard/ocpN/pps

Defined on file *sysfs-timecard*

This optional attribute links to the associated PPS device.

/sys/class/timecard/ocpN/ptp

Defined on file *sysfs-timecard*

This attribute links to the associated PTP device.

/sys/class/timecard/ocpN/serialnum

Defined on file *sysfs-timecard*

(RO) Provides the serial number of the timecard.

/sys/class/timecard/ocpN/sma1
/sys/class/timecard/ocpN/sma2
/sys/class/timecard/ocpN/sma3
/sys/class/timecard/ocpN/sma4

Defined on file *sysfs-timecard*

(RW) These attributes specify the direction of the signal on the associated SMA connectors, and also the signal sink or source.

The display format of the attribute is a space separated list of signals, prefixed by the input/output direction.

The signal direction may be changed (if supported) by prefixing the signal list with either "in:" or "out:". If neither prefix is present, then the direction is unchanged.

The output signal may be changed by writing one of the listed values from the available_sma_outputs attribute set.

The input destinations may be changed by writing multiple values from the available_sma_inputs attribute set, separated by spaces. If there are duplicated input destinations between connectors, the lowest numbered SMA connector is given priority.

Note that not all input combinations may make sense.

The 10Mhz reference clock input is currently only valid on SMA1 and may not be combined with other destination sinks.

/sys/class/timecard/ocpN/tod_correction

Defined on file *sysfs-timecard*

(RW) The incoming GNSS signal is in UTC time, and the NMEA format messages do not provide a TAI offset. This sets the correction value for the incoming time.

If UBX_LS is enabled, this should be 0, and the offset is taken from the UBX-NAV-TIMELS message.

/sys/class/timecard/ocpN/ts_window_adjust

Defined on file *sysfs-timecard*

(RW) When retrieving the PHC with the PTP SYS_OFFSET_EXTENDED ioctl, a system timestamp is made before and after the PHC time is retrieved. The midpoint between the two system timestamps is usually taken to be the SYS time associated with the PHC time. This estimate may be wrong, as it depends on PCI latencies, and when the PHC time was latched

The attribute value reduces the end timestamp by the given number of nanoseconds, so the computed midpoint matches the retrieved PHC time.

The initial value is set based on measured PCI latency and the estimated point where the FPGA latches the PHC time. This value may be changed by writing an unsigned integer.

/sys/class/timecard/ocpN/ttyGNSS
/sys/class/timecard/ocpN/ttyGNSS2

Defined on file *sysfs-timecard*

These optional attributes link to the TTY serial ports associated with the GNSS devices.

/sys/class/timecard/ocpN/ttyMAC

Defined on file *sysfs-timecard*

This optional attribute links to the TTY serial port associated with the Miniature Atomic Clock.

/sys/class/timecard/ocpN/ttyNMEA

Defined on file *sysfs-timecard*

This optional attribute links to the TTY serial port which outputs the PHC time in NMEA ZDA format.

/sys/class/timecard/ocpN/utc_tai_offset

Defined on file *sysfs-timecard*

(RW) The DCF and IRIG output signals are in UTC, while the TimeCard operates on TAI. This attribute allows setting the offset in seconds, which is added to the TAI timebase for these formats.

The offset may be changed by writing an unsigned integer.

/sys/class/tpm/tpmX/ppi/

Defined on file *sysfs-driver-ppi*

This folder includes the attributes related with PPI (Physical Presence Interface). Only if TPM is supported by BIOS, this folder makes sense. The folder path can be got by command 'find /sys/ -name 'pcrs''. For the detail information of PPI, please refer to the PPI specification from

http://www.trustedcomputinggroup.org/

In Linux 4.2 ppi was moved to the character device directory. A symlink from tpmX/device/ppi to tpmX/ppi to provide backwards compatibility.

/sys/class/tpm/tpmX/ppi/request

Defined on file *sysfs-driver-ppi*

This attribute shows the request for an operation to be executed in the pre-OS environment. It is the only input from the OS to the pre-OS environment. The request should be an integer value range from 1 to 160, and 0 means no request. This file can be read and written.

/sys/class/tpm/tpmX/ppi/response

Defined on file *sysfs-driver-ppi*

This attribute shows the response to the most recent operation request it acted upon. The format is ”<request> <response num> : <response description>”. This file is readonly.

/sys/class/tpm/tpmX/ppi/tcg_operations

Defined on file *sysfs-driver-ppi*

This attribute shows whether it is allowed to request an operation to be executed in the pre-OS environment by the BIOS for the requests defined by TCG, i.e. requests from 1 to 22. The format is ”<request> <status num>: <status description>”. This attribute is only supported by PPI version 1.2+. This file is readonly.

/sys/class/tpm/tpmX/ppi/transition_action

Defined on file *sysfs-driver-ppi*

This attribute shows the platform-specific action that should take place in order to transition to the BIOS for execution of a requested operation. The format is ”<action num>: <action description>”. This file is readonly.

/sys/class/tpm/tpmX/ppi/version

Defined on file *sysfs-driver-ppi*

This attribute shows the version of the PPI supported by the platform. This file is readonly.

/sys/class/tpm/tpmX/ppi/vs_operations

Defined on file *sysfs-driver-ppi*

This attribute shows whether it is allowed to request an operation to be executed in the pre-OS environment by the BIOS for the verdor specific requests, i.e. requests from 128 to 255. The format is same with tcg_operations. This attribute is also only supported by PPI version 1.2+. This file is readonly.

/sys/class/tty/console/active

Defined on file *sysfs-tty*

Shows the list of currently configured console devices, like 'tty1 ttyS0'. The last entry in the file is the active device connected to /dev/console. The file supports poll() to detect virtual console switches.

/sys/class/tty/tty<x>/active

Defined on file *sysfs-tty*

Shows the currently active virtual console device, like 'tty1'. The file supports poll() to detect virtual console switches.

/sys/class/tty/ttyS<x>/close_delay

Defined on file *sysfs-tty*

Show the closing delay time for this port in centiseconds.

These sysfs values expose the TIOCGSERIAL interface via sysfs rather than via ioctls.

/sys/class/tty/ttyS<x>/closing_wait

Defined on file *sysfs-tty*

Show the close wait time for this port in centiseconds.

Waiting forever is represented as 0. If waiting on close is disabled then the value is 65535.

These sysfs values expose the TIOCGSERIAL interface via sysfs rather than via ioctls.

/sys/class/tty/ttyS<x>/console

Defined on file *sysfs-tty*

Allows user to detach or attach back the given device as kernel console. It shows and accepts a boolean variable.

/sys/class/tty/ttyS<x>/custom_divisor

Defined on file *sysfs-tty*

Show the custom divisor if any that is set on this port.

These sysfs values expose the TIOCGSERIAL interface via sysfs rather than via ioctls.

/sys/class/tty/ttyS<x>/flags

Defined on file *sysfs-tty*

Show the tty port status flags for this port.

These sysfs values expose the TIOCGSERIAL interface via sysfs rather than via ioctls.

/sys/class/tty/ttyS<x>/io_type

Defined on file *sysfs-tty*

Show the I/O type that is to be used with the iomem base address.

These sysfs values expose the TIOCGSERIAL interface via sysfs rather than via ioctls.

/sys/class/tty/ttyS<x>/iomem_base

Defined on file *sysfs-tty*

The I/O memory base for this port.

These sysfs values expose the TIOCGSERIAL interface via sysfs rather than via ioctls.

/sys/class/tty/ttyS<x>/iomem_reg_shift

Defined on file *sysfs-tty*

Show the register shift indicating the spacing to be used for accesses on this iomem address.

These sysfs values expose the TIOCGSERIAL interface via sysfs rather than via ioctls.

/sys/class/tty/ttyS<x>/irq

Defined on file *sysfs-tty*

Shows the current primary interrupt for this port.

These sysfs values expose the TIOCGSERIAL interface via sysfs rather than via ioctls.

/sys/class/tty/ttyS<x>/line

Defined on file *sysfs-tty*

Shows the current tty line number for this port.

These sysfs values expose the TIOCGSERIAL interface via sysfs rather than via ioctls.

/sys/class/tty/ttyS<x>/port

Defined on file *sysfs-tty*

Shows the current tty port I/O address for this port.

These sysfs values expose the TIOCGSERIAL interface via sysfs rather than via ioctls.

/sys/class/tty/ttyS<x>/rx_trig_bytes

Defined on file *sysfs-tty*

Shows current RX interrupt trigger bytes or sets the user specified value to change it for the FIFO buffer. Users can show or set this value regardless of opening the serial device file or not.

The RX trigger can be set one of four kinds of values for UART serials. When users input a meaning less value to this I/F, the RX trigger is changed to the nearest lower value for the device specification. For example, when user sets 7bytes on 16550A, which has 1/4/8/14 bytes trigger, the RX trigger is automatically changed to 4 bytes.

/sys/class/tty/ttyS<x>/type

Defined on file *sysfs-tty*

Shows the current tty type for this port.

These sysfs values expose the TIOCGSERIAL interface via sysfs rather than via ioctls.

/sys/class/tty/ttyS<x>/uartclk

Defined on file *sysfs-tty*

Shows the current uartclk value associated with the UART port in serial_core, that is bound to TTY like ttyS0. uartclk = 16 * baud_base

These sysfs values expose the TIOCGSERIAL interface via sysfs rather than via ioctls.

/sys/class/tty/ttyS<x>/xmit_fifo_size

Defined on file *sysfs-tty*

Show the transmit FIFO size for this port.

These sysfs values expose the TIOCGSERIAL interface via sysfs rather than via ioctls.

/sys/class/typec/<port>-<plug>/number_of_alternate_modes

Defined on file *sysfs-class-typec*

Shows the number of alternate modes which are advertised by the plug associated with a particular cable during Power Delivery discovery. This file remains hidden until a value greater than or equal to 0 is set by Type C port driver.

USB Type-C partner/cable Power Delivery Identity objects

NOTE: The following attributes will be applicable to both partner (e.g /sys/class/typec/port0-partner/) and cable (e.g /sys/class/typec/port0-cable/) devices. Consequently, the example file paths below are prefixed with "/sys/class/typec/<port>-{partner|cable}/" to reflect this.

/sys/class/typec/<port>-cable/plug_type

Defined on file *sysfs-class-typec*

Shows type of the plug on the cable:

- type-a - Standard A
- type-b - Standard B
- type-c
- captive

/sys/class/typec/<port>-cable/type

Defined on file *sysfs-class-typec*

USB Power Delivery Specification defines a set of product types for the cables. This file will show the product type of the cable if it is known. If the product type of the cable is not visible to the device driver, this file will not exist.

When the cable product type is detected, uvevent is also raised with PRODUCT_TYPE showing the product type of the cable.

Valid values:

undefined	•
active	Active Cable
passive	Passive Cable

/sys/class/typec/<port>-partner/accessory_mode

Defined on file *sysfs-class-typec*

Shows the Accessory Mode name when the partner is an Accessory. The Accessory Modes are defined in USB Type-C Specification.

/sys/class/typec/<port>-partner/identity/

Defined on file *sysfs-class-typec*

This directory appears only if the port device driver is capable of showing the result of Discover Identity USB power delivery command. That will not always be possible even when USB power delivery is supported, for example when USB power delivery communication for the port is mostly handled in firmware. If the directory exists, it will have an attribute file for every VDO in Discover Identity command result.

USB Type-C cable devices (eg. /sys/class/typec/port0-cable/)

Note: Electronically Marked Cables will have a device also for one cable plug (eg. /sys/class/typec/port0-plug0). If the cable is active and has also SOP Double Prime controller (USB Power Deliver specification ch. 2.4) it will have second device also for the other plug.

Both plugs may have alternate modes as described in USB Type-C and USB Power Delivery specifications.

/sys/class/typec/<port>-partner/number_of_alternate_modes

Defined on file *sysfs-class-typec*

Shows the number of alternate modes which are advertised by the partner during Power Delivery discovery. This file remains hidden until a value greater than or equal to 0 is set by Type C port driver.

/sys/class/typec/<port>-partner/supports_usb_power_delivery

Defined on file *sysfs-class-typec*

Shows if the partner supports USB Power Delivery communication: Valid values: yes, no

/sys/class/typec/<port>-partner/type

Defined on file *sysfs-class-typec*

USB Power Delivery Specification defines a set of product types for the partner devices. This file will show the product type of the partner if it is known. Dual-role capable partners will have both UFP and DFP product types defined, but only one that matches the current role will be active at the time. If the product type of the partner is not visible to the device driver, this file will not exist.

When the partner product type is detected, or changed with role swap, uvevent is also raised that contains PRODUCT_TYPE=<product type> (for example PRODUCT_TYPE=hub).

Valid values:

UFP / device role ========== ==========
undefined - hub PDUSB Hub peripheral PDUSB Peripheral psd Power Bank ama Alternate Mode Adapter ========== ==========

DFP / host role ========== ==========
undefined - hub PDUSB Hub host PDUSB Host power_brick Power Brick amc Alternate Mode Controller ========== ==========

/sys/class/typec/<port>-{partner|cable}/identity/

Defined on file *sysfs-class-typec*

This directory appears only if the port device driver is capable of showing the result of Discover Identity USB power delivery command. That will not always be possible even when USB power delivery is supported, for example when USB power delivery communication for the port is mostly handled in firmware. If the directory exists, it will have an attribute file for every VDO in Discover Identity command result.

/sys/class/typec/<port>-{partner|cable}/identity/cert_stat

Defined on file *sysfs-class-typec*

Cert Stat VDO part of Discover Identity command result. The value will show 0 until Discover Identity command result becomes available. The value can be polled.

/sys/class/typec/<port>-{partner|cable}/identity/id_header

Defined on file *sysfs-class-typec*

ID Header VDO part of Discover Identity command result. The value will show 0 until Discover Identity command result becomes available. The value can be polled.

/sys/class/typec/<port>-{partner|cable}/identity/product

Defined on file *sysfs-class-typec*

Product VDO part of Discover Identity command result. The value will show 0 until Discover Identity command result becomes available. The value can be polled.

/sys/class/typec/<port>-{partner|cable}/identity/product_type_vdo1

Defined on file *sysfs-class-typec*

1st Product Type VDO of Discover Identity command result. The value will show 0 until Discover Identity command result becomes available and a valid Product Type VDO is returned.

/sys/class/typec/<port>-{partner|cable}/identity/product_type_vdo2

Defined on file *sysfs-class-typec*

2nd Product Type VDO of Discover Identity command result. The value will show 0 until Discover Identity command result becomes available and a valid Product Type VDO is returned.

/sys/class/typec/<port>-{partner|cable}/identity/product_type_vdo3

Defined on file *sysfs-class-typec*

3rd Product Type VDO of Discover Identity command result. The value will show 0 until Discover Identity command result becomes available and a valid Product Type VDO is returned.

USB Type-C port alternate mode devices.

/sys/class/typec/<port>-{partner|cable}/usb_power_delivery_revision

Defined on file *sysfs-class-typec*

Revision number of the supported USB Power Delivery specification of the port partner or cable, or 0.0 when USB Power Delivery is not supported.

Example values: - ”2.0”: USB Power Delivery Release 2.0 - ”3.0”: USB Power Delivery Release 3.0 - ”3.1”: USB Power Delivery Release 3.1

/sys/class/typec/<port>/<alt mode>/supported_roles

Defined on file *sysfs-class-typec*

Space separated list of the supported roles.

Valid values: source, sink

/sys/class/typec/<port>/data_role

Defined on file *sysfs-class-typec*

The supported USB data roles. This attribute can be used for requesting data role swapping on the port. Swapping is supported as synchronous operation, so write(2) to the attribute will not return until the operation has finished. The attribute is notified about role changes so that poll(2) on the attribute wakes up. Change on the role will also generate uevent KOBJ_CHANGE on the port. The current role is show in brackets, for example "[host] device" when DRP port is in host mode.

Valid values: host, device

/sys/class/typec/<port>/orientation

Defined on file *sysfs-class-typec*

Indicates the active orientation of the Type-C connector. Valid values: - "normal": CC1 orientation - "reverse": CC2 orientation - "unknown": Orientation cannot be determined.

/sys/class/typec/<port>/port_type

Defined on file *sysfs-class-typec*

Indicates the type of the port. This attribute can be used for requesting a change in the port type. Port type change is supported as a synchronous operation, so write(2) to the attribute will not return until the operation has finished.

Valid values:

source	(The port will behave as source only DFP port)
sink	(The port will behave as sink only UFP port)
dual	(The port will behave as dual-role-data and dual-role-power port)

/sys/class/typec/<port>/power_operation_mode

Defined on file *sysfs-class-typec*

Shows the current power operational mode the port is in. The power operation mode means current level for VBUS. In case USB Power Delivery communication is used for negotiating the levels, power operation mode should show "usb_power_delivery".

Valid values:

- default
- 1.5A
- 3.0A

- usb_power_delivery

/sys/class/typec/<port>/power_role

Defined on file *sysfs-class-typec*

The supported power roles. This attribute can be used to request power role swap on the port. Swapping is supported as synchronous operation, so write(2) to the attribute will not return until the operation has finished. The attribute is notified about role changes so that poll(2) on the attribute wakes up. Change on the role will also generate uevent KOBJ_CHANGE. The current role is show in brackets, for example "[source] sink" when in source mode.

Valid values: source, sink

/sys/class/typec/<port>/preferred_role

Defined on file *sysfs-class-typec*

The user space can notify the driver about the preferred role. It should be handled as enabling of Try.SRC or Try.SNK, as defined in USB Type-C specification, in the port drivers. By default the preferred role should come from the platform.

Valid values: source, sink, none (to remove preference)

/sys/class/typec/<port>/select_usb_power_delivery

Defined on file *sysfs-class-typec*

Lists the USB Power Delivery Capabilities that the port can advertise to the partner. The currently used capabilities are in brackets. Selection happens by writing to the file.

USB Type-C partner devices (eg. /sys/class/typec/port0-partner/)

/sys/class/typec/<port>/supported_accessory_modes

Defined on file *sysfs-class-typec*

Space separated list of accessory modes, defined in the USB Type-C specification, the port supports.

/sys/class/typec/<port>/usb_power_delivery_revision

Defined on file *sysfs-class-typec*

Revision number of the supported USB Power Delivery specification, or 0.0 when USB Power Delivery is not supported.

Example values: - "2.0": USB Power Delivery Release 2.0 - "3.0": USB Power Delivery Release 3.0 - "3.1": USB Power Delivery Release 3.1

/sys/class/typec/<port>/usb_typec_revision

Defined on file *sysfs-class-typec*

Revision number of the supported USB Type-C specification.

/sys/class/typec/<port>/vconn_source

Defined on file *sysfs-class-typec*

Shows is the port VCONN Source. This attribute can be used to request VCONN swap to change the VCONN Source during connection when both the port and the partner support USB Power Delivery. Swapping is supported as synchronous operation, so write(2) to the attribute will not return until the operation has finished. The attribute is notified about VCONN source changes so that poll(2) on the attribute wakes up. Change on VCONN source also generates uevent KOBJ_CHANGE.

Valid values:

- ”no” when the port is not the VCONN Source
- ”yes” when the port is the VCONN Source

/sys/class/uacce/<dev_name>/algorithms

Defined on file *sysfs-driver-uacce*

Algorithms supported by this accelerator, separated by new line. Can be any string and up to userspace to parse.

/sys/class/uacce/<dev_name>/api

Defined on file *sysfs-driver-uacce*

Api of the device Can be any string and up to userspace to parse. Application use the api to match the correct driver

/sys/class/uacce/<dev_name>/available_instances

Defined on file *sysfs-driver-uacce*

Available instances left of the device Return -ENODEV if uacce_ops get_available_instances is not provided

/sys/class/uacce/<dev_name>/flags

Defined on file *sysfs-driver-uacce*

Attributes of the device, see UACCE_DEV_xxx flag defined in uacce.h

/sys/class/uacce/<dev_name>/isolate

Defined on file *sysfs-driver-uacce*

(R) A sysfs node that read the device isolated state. The value 1 means the device is unavailable. The 0 means the device is available.

/sys/class/uacce/<dev_name>/isolate_strategy

Defined on file *sysfs-driver-uacce*

(RW) A sysfs node that configure the error threshold for the hardware isolation strategy. This size is a configured integer value, which is the number of threshold for hardware errors occurred in one hour. The default is 0. 0 means never isolate the device. The maximum value is 65535. You can write a number of threshold based on your hardware.

/sys/class/uacce/<dev_name>/region_dus_size

Defined on file *sysfs-driver-uacce*

Size (bytes) of dus region queue file

/sys/class/uacce/<dev_name>/region_mmio_size

Defined on file *sysfs-driver-uacce*

Size (bytes) of mmio region queue file

/sys/class/udc/udc.name/device/gadget/video4linux/video.name/function_name

Defined on file *configfs-usb-gadget-uvc*

UVC configfs function instance name

/sys/class/usb_power_delivery

Defined on file *sysfs-class-usb_power_delivery*

Directory for USB Power Delivery devices.

/sys/class/usb_power_delivery/.../<capability>/1:fixed_supply/dual_role_data

Defined on file *sysfs-class-usb_power_delivery*

This file shows the value of the Dual-Role Data bit in vSafe5V Fixed Supply Object. Dual role data means ability act as both USB host and USB device.

/sys/class/usb_power_delivery/.../<capability>/1:fixed_supply/dual_role_power

Defined on file *sysfs-class-usb_power_delivery*

This file contains boolean value that tells does the device support both source and sink power roles.

/sys/class/usb_power_delivery/.../<capability>/1:fixed_supply/unchunked_extended_message

Defined on file *sysfs-class-usb_power_delivery*

This file shows the value of the Unchunked Extended Messages Supported bit in vSafe5V Fixed Supply Object.

/sys/class/usb_power_delivery/.../<capability>/1:fixed_supply/unconstrained_power

Defined on file *sysfs-class-usb_power_delivery*

This file shows the value of the Unconstrained Power bit in vSafe5V Fixed Supply Object. The bit is set when an external source of power, powerful enough to power the entire system on its own, is available for the device.

/sys/class/usb_power_delivery/.../<capability>/1:fixed_supply/usb_communication_capable

Defined on file *sysfs-class-usb_power_delivery*

This file shows the value of the USB Communication Capable bit in vSafe5V Fixed Supply Object.

/sys/class/usb_power_delivery/.../<capability>/<position>:battery

Defined on file *sysfs-class-usb_power_delivery*

Battery PDO.

/sys/class/usb_power_delivery/.../<capability>/<position>:battery/maximum_voltage

Defined on file *sysfs-class-usb_power_delivery*

Maximum Voltage in millivolts.

/sys/class/usb_power_delivery/.../<capability>/<position>:battery/minimum_voltage

Defined on file *sysfs-class-usb_power_delivery*

Minimum Voltage in millivolts.

/sys/class/usb_power_delivery/.../<capability>/<position>:fixed_supply

Defined on file *sysfs-class-usb_power_delivery*

Devices containing the attributes (the bit fields) defined for Fixed Supplies.

The device "1:fixed_supply" is special. USB Power Delivery Specification dictates that the first PDO (at object position 1), and the only mandatory PDO, is always the vSafe5V Fixed Supply Object. vSafe5V Object has additional fields defined for it that the other Fixed Supply Objects do not have and that are related to the USB capabilities rather than power capabilities.

/sys/class/usb_power_delivery/.../<capability>/<position>:fixed_supply/voltage

Defined on file *sysfs-class-usb_power_delivery*

The voltage the supply supports in millivolts.

/sys/class/usb_power_delivery/.../<capability>/<position>:programmable_supply

Defined on file *sysfs-class-usb_power_delivery*

Programmable Power Supply (PPS) Augmented PDO (APDO).

/sys/class/usb_power_delivery/.../<capability>/<position>:programmable_supply/maximum_

Defined on file *sysfs-class-usb_power_delivery*

Maximum Current in milliamperes.

/sys/class/usb_power_delivery/.../<capability>/<position>:programmable_supply/maximum_

Defined on file *sysfs-class-usb_power_delivery*

Maximum Voltage in millivolts.

/sys/class/usb_power_delivery/.../<capability>/<position>:programmable_supply/minimum_

Defined on file *sysfs-class-usb_power_delivery*

Minimum Voltage in millivolts.

/sys/class/usb_power_delivery/.../<capability>/<position>:variable_supply

Defined on file *sysfs-class-usb_power_delivery*

Variable Power Supply PDO.

/sys/class/usb_power_delivery/.../<capability>/<position>:variable_supply/maximum_voltag

Defined on file *sysfs-class-usb_power_delivery*

Maximum Voltage in millivolts.

/sys/class/usb_power_delivery/.../<capability>/<position>:variable_supply/minimum_voltag

Defined on file *sysfs-class-usb_power_delivery*

Minimum Voltage in millivolts.

/sys/class/usb_power_delivery/.../revision

Defined on file *sysfs-class-usb_power_delivery*

File showing the USB Power Delivery Specification Revision used in communication.

/sys/class/usb_power_delivery/.../sink-capabilities

Defined on file *sysfs-class-usb_power_delivery*

The sink capability message "Sink_Capabilities" contains a set of Power Data Objects (PDO) just like with source capabilities, but instead of describing the power capabilities, these objects describe the power requirements.

The order of the objects in the sink capability message is the same as with the source capabilities message.

Fixed Supplies

/sys/class/usb_power_delivery/.../sink-capabilities/1:fixed_supply/higher_capability

Defined on file *sysfs-class-usb_power_delivery*

This file shows the value of the Higher capability bit in vsafe5V Fixed Supply Object. If the bit is set, then the sink needs more than vsafe5V(eg. 12 V) to provide full functionality. Valid values: 0, 1

/sys/class/usb_power_delivery/.../sink-capabilities/<position>:battery/operational_power

Defined on file *sysfs-class-usb_power_delivery*

The operational power that the sink requires at the given voltage range.

Standard Power Range (SPR) Programmable Power Supplies

/sys/class/usb_power_delivery/.../sink-capabilities/<position>:fixed_supply/fast_role_swap_c

Defined on file *sysfs-class-usb_power_delivery*

This file contains the value of the "Fast Role Swap USB Type-C Current" field that tells the current level the sink requires after a Fast Role Swap. 0 - Fast Swap not supported" 1 - Default USB Power" 2 - 1.5A@5V" 3 - 3.0A@5V"

Variable Supplies

/sys/class/usb_power_delivery/.../sink-capabilities/<position>:fixed_supply/operational_curr

Defined on file *sysfs-class-usb_power_delivery*

Operational current of the sink in milliamperes.

/sys/class/usb_power_delivery/.../sink-capabilities/<position>:variable_supply/operational_c

Defined on file *sysfs-class-usb_power_delivery*

The operational current in milliamperes that the sink requires at the given Voltage range.

Battery Supplies

/sys/class/usb_power_delivery/.../source-capabilities

Defined on file *sysfs-class-usb_power_delivery*

The source capabilities message "Source_Capabilities" contains a set of Power Data Objects (PDO), each representing a type of power supply. The order of the PDO objects is defined in the USB Power Delivery Specification. Each PDO - power supply - will have its own device, and the PDO device name will start with the object position number as the first character followed by the power supply type name (":" as delimiter).

/sys/class/usb_power_delivery/.../source_capabilities/<position>:<type>

/sys/class/usb_power_delivery/.../source-capabilities/1:fixed_supply/usb_suspend_supported

Defined on file *sysfs-class-usb_power_delivery*

This file shows the value of the USB Suspend Supported bit in vSafe5V Fixed Supply Object. If the bit is set then the device will follow the USB 2.0 and USB 3.2 rules for suspend and resume.

/sys/class/usb_power_delivery/.../source-capabilities/<position>:battery/maximum_power

Defined on file *sysfs-class-usb_power_delivery*

Maximum allowable Power in milliwatts.

/sys/class/usb_power_delivery/.../source-capabilities/<position>:fixed_supply/maximum_cur

Defined on file *sysfs-class-usb_power_delivery*

Maximum current of the fixed source supply in milliamperes.

/sys/class/usb_power_delivery/.../source-capabilities/<position>:fixed_supply/peak_current

Defined on file *sysfs-class-usb_power_delivery*

This file shows the value of the Fixed Power Source Peak Current Capability field.

/sys/class/usb_power_delivery/.../source-capabilities/<position>:programmable_supply/pps_

Defined on file *sysfs-class-usb_power_delivery*

The PPS Power Limited bit indicates whether or not the source supply will exceed the rated output power if requested.

/sys/class/usb_power_delivery/.../source-capabilities/<position>:variable_supply/maximum_

Defined on file *sysfs-class-usb_power_delivery*

The maximum current in milliamperes that the source can supply at the given Voltage range.

/sys/class/usb_power_delivery/.../version

Defined on file *sysfs-class-usb_power_delivery*

This is an optional attribute file showing the version of the specific revision of the USB Power Delivery Specification. In most cases the specification version is not known and the file is not available.

/sys/class/usb_role/

Defined on file *sysfs-class-usb_role*

Place in sysfs for USB Role Switches. USB Role Switch is a device that can select the data role (host or device) for USB port.

/sys/class/usb_role/<switch>/role

Defined on file *sysfs-class-usb_role*

The current role of the switch. This attribute can be used for requesting role swapping with non-USB Type-C ports. With USB Type-C ports, the ABI defined for USB Type-C connector class must be used.

Valid values: - none - host - device

/sys/class/vduse/

Defined on file *sysfs-class-vduse*

The vduse/ class sub-directory belongs to the VDUSE framework and provides a sysfs interface for configuring VDUSE devices.

/sys/class/vduse/<device-name>/

Defined on file *sysfs-class-vduse*

This directory entry is created when a VDUSE device is created via the control device.

/sys/class/vduse/<device-name>/msg_timeout

Defined on file *sysfs-class-vduse*

(RW) The timeout (in seconds) for waiting for the control message's response from userspace. Default value is 30s. Writing a '0' to the file means to disable the timeout.

/sys/class/vduse/control/

Defined on file *sysfs-class-vduse*

This directory entry is created for the control device of VDUSE framework.

/sys/class/wakeup/

Defined on file *sysfs-class-wakeup*

The */sys/class/wakeup/* directory contains pointers to all wakeup sources in the kernel at that moment in time.

/sys/class/wakeup/.../active_count

Defined on file *sysfs-class-wakeup*

This file contains the number of times the wakeup source was activated.

/sys/class/wakeup/.../active_time_ms

Defined on file *sysfs-class-wakeup*

This file contains the amount of time the wakeup source has been continuously active, in milliseconds. If the wakeup source is not active, this file contains '0'.

/sys/class/wakeup/.../event_count

Defined on file *sysfs-class-wakeup*

This file contains the number of signaled wakeup events associated with the wakeup source.

/sys/class/wakeup/.../expire_count

Defined on file *sysfs-class-wakeup*

This file contains the number of times the wakeup source's timeout has expired.

/sys/class/wakeup/.../last_change_ms

Defined on file *sysfs-class-wakeup*

This file contains the monotonic clock time when the wakeup source was touched last time, in milliseconds.

/sys/class/wakeup/.../max_time_ms

Defined on file *sysfs-class-wakeup*

This file contains the maximum amount of time this wakeup source has been continuously active, in milliseconds.

/sys/class/wakeup/.../name

Defined on file *sysfs-class-wakeup*

This file contains the name of the wakeup source.

/sys/class/wakeup/.../prevent_suspend_time_ms

Defined on file *sysfs-class-wakeup*

The file contains the total amount of time this wakeup source has been preventing autosleep, in milliseconds.

/sys/class/wakeup/.../total_time_ms

Defined on file *sysfs-class-wakeup*

This file contains the total amount of time this wakeup source has been active, in milliseconds.

/sys/class/wakeup/.../wakeup_count

Defined on file *sysfs-class-wakeup*

This file contains the number of times the wakeup source might abort suspend.

/sys/class/watchdog/watchdog1/access_cs0

Defined on file *sysfs-class-watchdog*

It is a read/write file. This attribute exists only if the system has booted from the alternate flash chip due to expiration of a watchdog timer of AST2400/AST2500 when alternate boot function was enabled with 'aspeed,alt-boot' devicetree option for that watchdog or with an appropriate h/w strapping (for WDT2 only).

At alternate flash the 'access_cs0' sysfs node provides:

ast2400:
a way to get access to the primary SPI flash chip at CS0 after booting from the alternate chip at CS1.

ast2500:
a way to restore the normal address mapping from (CS0->CS1, CS1->CS0) to (CS0->CS0, CS1->CS1).

Clearing the boot code selection and timeout counter also resets to the initial state the chip select line mapping. When the SoC is in normal mapping state (i.e. booted from CS0), clearing those bits does nothing for both versions of the SoC. For alternate boot mode (booted from CS1 due to wdt2 expiration) the behavior differs as described above.

This option can be used with wdt2 (watchdog1) only.

When read, the current status of the boot code selection is shown. When written with any non-zero value, it clears the boot code selection and the timeout counter, which results in chipselect reset for AST2400/AST2500.

/sys/class/watchdog/watchdogn/bootstatus

Defined on file *sysfs-class-watchdog*

It is a read only file. It contains status of the watchdog device at boot. It is equivalent to WDIOC_GETBOOTSTATUS of ioctl interface.

/sys/class/watchdog/watchdogn/fw_version

Defined on file *sysfs-class-watchdog*

It is a read only file. It contains firmware version of watchdog device.

/sys/class/watchdog/watchdogn/identity

Defined on file *sysfs-class-watchdog*

It is a read only file. It contains identity string of watchdog device.

/sys/class/watchdog/watchdogn/nowayout

Defined on file *sysfs-class-watchdog*

It is a read/write file. While reading, it gives '1' if the device has the nowayout feature set, otherwise it gives '0'. Writing a '1' to the file enables the nowayout feature. Once set, the nowayout feature cannot be disabled, so writing a '0' either has no effect (if the feature was already disabled) or results in a permission error.

/sys/class/watchdog/watchdogn/options

Defined on file *sysfs-class-watchdog*

It is a read only file. It contains options of watchdog device.

/sys/class/watchdog/watchdogn/pretimeout

Defined on file *sysfs-class-watchdog*

It is a read only file. It specifies the time in seconds before timeout when the pretimeout interrupt is delivered. Pretimeout is an optional feature.

/sys/class/watchdog/watchdogn/pretimeout_avaialable_governors

Defined on file *sysfs-class-watchdog*

It is a read only file. It shows the pretimeout governors available for this watchdog.

/sys/class/watchdog/watchdogn/pretimeout_governor

Defined on file *sysfs-class-watchdog*

It is a read/write file. When read, the currently assigned pretimeout governor is returned. When written, it sets the pretimeout governor.

/sys/class/watchdog/watchdogn/state

Defined on file *sysfs-class-watchdog*

It is a read only file. It gives active/inactive status of watchdog device.

/sys/class/watchdog/watchdogn/status

Defined on file *sysfs-class-watchdog*

It is a read only file. It contains watchdog device's internal status bits. It is equivalent to WDIOC_GETSTATUS of ioctl interface.

/sys/class/watchdog/watchdogn/timeleft

Defined on file *sysfs-class-watchdog*

It is a read only file. It contains value of time left for reset generation. It is equivalent to WDIOC_GETTIMELEFT of ioctl interface.

/sys/class/watchdog/watchdogn/timeout

Defined on file *sysfs-class-watchdog*

It is a read only file. It is read to know about current value of timeout programmed.

/sys/class/zram-control/

Defined on file *sysfs-class-zram*

The zram-control/ class sub-directory belongs to zram device class

/sys/class/zram-control/hot_add

Defined on file *sysfs-class-zram*

RO attribute. Read operation will cause zram to add a new device and return its device id back to user (so one can use /dev/zram<id>), or error code.

/sys/class/zram-control/hot_remove

Defined on file *sysfs-class-zram*

WO attribute. Remove a specific /dev/zramX device, where X is a device_id provided by user.

5.2.33 Symbols under /sys/dev

/sys/dev

Defined on file *sysfs-dev*

The */sys/dev* tree provides a method to look up the sysfs path for a device using the information returned from stat(2). There are two directories, 'block' and 'char', beneath */sys/dev* containing symbolic links with names of the form "<major>:<minor>". These links point to the corresponding sysfs path for the given device.

Example:

```
$ readlink /sys/dev/block/8:32
../../block/sdc
```

Entries in /sys/dev/char and /sys/dev/block will be dynamically created and destroyed as devices enter and leave the system.

Users: mdadm <linux-raid@vger.kernel.org>

5.2.34 Symbols under /sys/devices

/sys/devices

Defined on file *sysfs-devices*

The */sys/devices* tree contains a snapshot of the internal state of the kernel device tree. Devices will be added and removed dynamically as the machine runs, and between different kernel versions, the layout of the devices within this tree will change.

Please do not rely on the format of this tree because of this. If a program wishes to find different things in the tree, please use the /sys/class structure and rely on the symlinks there to point to the proper location within the */sys/devices* tree of the individual devices. Or rely on the uevent messages to notify programs of devices being added and removed from this tree to find the location of those devices.

Note that sometimes not all devices along the directory chain will have emitted uevent messages, so userspace programs must be able to handle such occurrences.

Users:

udev <linux-hotplug-devel@lists.sourceforge.net>

/sys/devices/*/<our-device>/fuse

Defined on file *sysfs-driver-tegra-fuse*

read-only access to the efuses on Tegra20, Tegra30, Tegra114 and Tegra124 SoC's from NVIDIA. The efuses contain write once data programmed at the factory. The data is laid out in 32bit words in LSB first format. Each bit represents a single value as decoded from the fuse registers. Bits order/assignment exactly matches the HW registers, including any unused bits.

Users: any user space application which wants to read the efuses on Tegra SoC's

/sys/devices/*/<our-device>/nvmem

Defined on file *sysfs-driver-jz4780-efuse*

read-only access to the efuse on the Ingenic JZ4780 SoC The SoC has a one time programmable 8K efuse that is split into segments. The driver supports read only. The segments are:

0x000	64 bit	Random Number
0x008	128 bit	Ingenic Chip ID
0x018	128 bit	Customer ID
0x028	3520 bit	Reserved
0x1E0	8 bit	Protect Segment
0x1E1	2296 bit	HDMI Key
0x300	2048 bit	Security boot key

Users: any user space application which wants to read the Chip and Customer ID

/sys/devices/*/xenbus/event_channels

Defined on file *sysfs-devices-xenbus*

Number of Xen event channels associated with a kernel based paravirtualized device frontend or backend.

/sys/devices/*/xenbus/events

Defined on file *sysfs-devices-xenbus*

Total number of Xen events received for a Xen pv device frontend or backend.

/sys/devices/*/xenbus/jiffies_eoi_delayed

Defined on file *sysfs-devices-xenbus*

Summed up time in jiffies the EOI of an interrupt for a Xen pv device has been delayed in order to avoid stalls due to event storms. This value rising is a first sign for a rogue other end of the pv device.

/sys/devices/*/xenbus/spurious_events

Defined on file *sysfs-devices-xenbus*

Number of events received for a Xen pv device which did not require any action. Too many spurious events in a row will trigger delayed EOI processing.

/sys/devices/*/xenbus/spurious_threshold

Defined on file *sysfs-devices-xenbus*

Controls the tolerated number of subsequent spurious events before delayed EOI processing is triggered for a Xen pv device. Default is 1. This can be modified in case the other end of the pv device is issuing spurious events on a regular basis and is known not to be malicious on purpose. Raising the value for such cases can improve pv device performance.

/sys/devices/.../consumer:<consumer>

Defined on file *sysfs-devices-consumer*

The /sys/devices/.../consumer:<consumer> are symlinks to device links where this device is the supplier. <consumer> denotes the name of the consumer in that device link and is of the form bus:device name. There can be zero or more of these symlinks for a given device.

/sys/devices/.../coredump

Defined on file *sysfs-devices-coredump*

The /sys/devices/.../coredump attribute is only present when the device is bound to a driver, which provides the .coredump() callback. The attribute is write only. Anything written to this file will trigger the .coredump() callback.

Available when CONFIG_DEV_COREDUMP is enabled.

/sys/devices/.../firmware_node/

Defined on file *sysfs-devices-firmware_node*

The /sys/devices/.../firmware_node directory contains attributes allowing the user space to check and modify some firmware related properties of given device.

/sys/devices/.../firmware_node/description

Defined on file *sysfs-devices-firmware_node*

The /sys/devices/.../firmware/description attribute contains a string that describes the device as provided by the _STR method in the ACPI namespace. This attribute is read-only. If the device does not have an _STR method associated with it in the ACPI namespace, this attribute is not present.

/sys/devices/.../iommu

Defined on file *sysfs-class-iommu*

IOMMU drivers are able to link the IOMMU for a given device here to allow association of device to IOMMU.

/sys/devices/.../lpss_ltr/

Defined on file *sysfs-devices-lpss_ltr*

The /sys/devices/.../lpss_ltr/ directory is only present for devices included into the Intel Lynx-point Low Power Subsystem (LPSS). If present, it contains attributes containing the LTR mode and the values of LTR registers of the device.

/sys/devices/.../lpss_ltr/auto_ltr

Defined on file *sysfs-devices-lpss_ltr*

The /sys/devices/.../lpss_ltr/auto_ltr attribute contains the current value of the device's AUTO_LTR register (raw) represented as an 8-digit hexadecimal number.

This attribute is read-only. If the device's runtime PM status is not ”active”, attempts to read from this attribute cause -EAGAIN to be returned.

/sys/devices/.../lpss_ltr/ltr_mode

Defined on file *sysfs-devices-lpss_ltr*

The /sys/devices/.../lpss_ltr/ltr_mode attribute contains an integer number (0 or 1) indicating whether or not the devices' LTR functionality is working in the software mode (1).

This attribute is read-only. If the device's runtime PM status is not ”active”, attempts to read from this attribute cause -EAGAIN to be returned.

/sys/devices/.../lpss_ltr/sw_ltr

Defined on file *sysfs-devices-lpss_ltr*

The /sys/devices/.../lpss_ltr/auto_ltr attribute contains the current value of the device's SW_LTR register (raw) represented as an 8-digit hexadecimal number.

This attribute is read-only. If the device's runtime PM status is not "active", attempts to read from this attribute cause -EAGAIN to be returned.

/sys/devices/.../mmc_host/mmcX/mmcX:XXXX/enhanced_area_offset

Defined on file *sysfs-devices-mmc*

Enhanced area is a new feature defined in eMMC4.4 standard. eMMC4.4 or later card can support such feature. This kind of area can help to improve the card performance. If the feature is enabled, this attribute will indicate the start address of enhanced data area. If not, this attribute will be -EINVAL. Unit Byte. Format decimal.

/sys/devices/.../mmc_host/mmcX/mmcX:XXXX/enhanced_area_size

Defined on file *sysfs-devices-mmc*

Enhanced area is a new feature defined in eMMC4.4 standard. eMMC4.4 or later card can support such feature. This kind of area can help to improve the card performance. If the feature is enabled, this attribute will indicate the size of enhanced data area. If not, this attribute will be -EINVAL. Unit KByte. Format decimal.

/sys/devices/.../online

Defined on file *sysfs-devices-online*

The /sys/devices/.../online attribute is only present for devices whose bus types provide .online() and .offline() callbacks. The number read from it (0 or 1) reflects the value of the device's 'offline' field. If that number is 1 and '0' (or 'n', or 'N') is written to this file, the device bus type's .offline() callback is executed for the device and (if successful) its 'offline' field is updated accordingly. In turn, if that number is 0 and '1' (or 'y', or 'Y') is written to this file, the device bus type's .online() callback is executed for the device and (if successful) its 'offline' field is updated as appropriate.

After a successful execution of the bus type's .offline() callback the device cannot be used for any purpose until either it is removed (i.e. device_del() is called for it), or its bus type's .online() is executed successfully.

/sys/devices/.../physical_location

Defined on file *sysfs-devices-physical_location*

This directory contains information on physical location of the device connection point with respect to the system's housing.

/sys/devices/.../physical_location/dock

Defined on file *sysfs-devices-physical_location*

”Yes” if the device connection point resides in a docking station or a port replicator. ”No” otherwise.

/sys/devices/.../physical_location/horizontal_position

Defined on file *sysfs-devices-physical_location*

Describes horizontal position of the device connection point on the panel surface.

/sys/devices/.../physical_location/lid

Defined on file *sysfs-devices-physical_location*

”Yes” if the device connection point resides on the lid of laptop system. ”No” otherwise.

/sys/devices/.../physical_location/panel

Defined on file *sysfs-devices-physical_location*

Describes which panel surface of the system’s housing the device connection point resides on.

/sys/devices/.../physical_location/vertical_position

Defined on file *sysfs-devices-physical_location*

Describes vertical position of the device connection point on the panel surface.

/sys/devices/.../power/

Defined on file *sysfs-devices-power*

The /sys/devices/.../power directory contains attributes allowing the user space to check and modify some power management related properties of given device.

/sys/devices/.../power/async

Defined on file *sysfs-devices-power*

The /sys/devices/.../async attribute allows the user space to enable or diasble the device's suspend and resume callbacks to be executed asynchronously (ie. in separate threads, in parallel with the main suspend/resume thread) during system-wide power transitions (eg. suspend to RAM, hibernation).

All devices have one of the following two values for the power/async file:

- ”enabledn” to permit the asynchronous suspend/resume;
- ”disabledn” to forbid it;

The value of this attribute may be changed by writing either ”enabled”, or ”disabled” to it.

It generally is unsafe to permit the asynchronous suspend/resume of a device unless it is certain that all of the PM dependencies of the device are known to the PM core. However, for some

devices this attribute is set to ”enabled” by bus type code or device drivers and in that cases it should be safe to leave the default value.

/sys/devices/.../power/autosuspend_delay_ms

Defined on file *sysfs-devices-power*

The /sys/devices/.../power/autosuspend_delay_ms attribute contains the autosuspend delay value (in milliseconds). Some drivers do not want their device to suspend as soon as it becomes idle at run time; they want the device to remain inactive for a certain minimum period of time first. That period is called the autosuspend delay. Negative values will prevent the device from being suspended at run time (similar to writing ”on” to the power/control attribute). Values >= 1000 will cause the autosuspend timer expiration to be rounded up to the nearest second.

Not all drivers support this attribute. If it isn't supported, attempts to read or write it will yield I/O errors.

/sys/devices/.../power/control

Defined on file *sysfs-devices-power*

The /sys/devices/.../power/control attribute allows the user space to control the run-time power management of the device.

All devices have one of the following two values for the power/control file:

- ”auton” to allow the device to be power managed at run time;
- ”onn” to prevent the device from being power managed;

The default for all devices is ”auto”, which means that they may be subject to automatic power management, depending on their drivers. Changing this attribute to ”on” prevents the driver from power managing the device at run time. Doing that while the device is suspended causes it to be woken up.

/sys/devices/.../power/pm_qos_latency_tolerance_us

Defined on file *sysfs-devices-power*

The /sys/devices/.../power/pm_qos_latency_tolerance_us attribute contains the PM QoS active state latency tolerance limit for the given device in microseconds. That is the maximum memory access latency the device can suffer without any visible adverse effects on user space functionality. If that value is the string ”any”, the latency does not matter to user space at all, but hardware should not be allowed to set the latency tolerance for the device automatically.

Reading ”auto” from this file means that the maximum memory access latency for the device may be determined automatically by the hardware as needed. Writing ”auto” to it allows the hardware to be switched to this mode if there are no other latency tolerance requirements from the kernel side.

This attribute is only present if the feature controlled by it is supported by the hardware.

This attribute has no effect on runtime suspend and resume of devices and on system-wide suspend/resume and hibernation.

/sys/devices/.../power/pm_qos_no_power_off

Defined on file *sysfs-devices-power*

The /sys/devices/.../power/pm_qos_no_power_off attribute is used for manipulating the PM QoS "no power off" flag. If set, this flag indicates to the kernel that power should not be removed entirely from the device.

Not all drivers support this attribute. If it isn't supported, it is not present.

This attribute has no effect on system-wide suspend/resume and hibernation.

/sys/devices/.../power/pm_qos_resume_latency_us

Defined on file *sysfs-devices-power*

The /sys/devices/.../power/pm_qos_resume_latency_us attribute contains the PM QoS resume latency limit for the given device, which is the maximum allowed time it can take to resume the device, after it has been suspended at run time, from a resume request to the moment the device will be ready to process I/O, in microseconds. If it is equal to 0, however, this means that the PM QoS resume latency may be arbitrary and the special value "n/a" means that user space cannot accept any resume latency at all for the given device.

Not all drivers support this attribute. If it isn't supported, it is not present.

This attribute has no effect on system-wide suspend/resume and hibernation.

/sys/devices/.../power/runtime_active_kids

Defined on file *sysfs-devices-power*

Reports the runtime PM children usage count of a device, or 0 if the children will be ignored.

/sys/devices/.../power/runtime_active_time

Defined on file *sysfs-devices-power*

Reports the total time that the device has been active. Used for runtime PM statistics.

/sys/devices/.../power/runtime_enabled

Defined on file *sysfs-devices-power*

Is runtime PM enabled for this device? States are "enabled", "disabled", "forbidden" or a combination of the latter two.

/sys/devices/.../power/runtime_status

Defined on file *sysfs-devices-power*

The /sys/devices/.../power/runtime_status attribute contains the current runtime PM status of the device, which may be "suspended", "suspending", "resuming", "active", "error" (fatal error), or "unsupported" (runtime PM is disabled).

/sys/devices/.../power/runtime_suspended_time

Defined on file *sysfs-devices-power*

Reports total time that the device has been suspended. Used for runtime PM statistics.

/sys/devices/.../power/runtime_usage

Defined on file *sysfs-devices-power*

Reports the runtime PM usage count of a device.

/sys/devices/.../power/wakeup

Defined on file *sysfs-devices-power*

The /sys/devices/.../power/wakeup attribute allows the user space to check if the device is enabled to wake up the system from sleep states, such as the memory sleep state (suspend to RAM) and hibernation (suspend to disk), and to enable or disable it to do that as desired.

Some devices support "wakeup" events, which are hardware signals used to activate the system from a sleep state. Such devices have one of the following two values for the sysfs power/wakeup file:

- "enabledn" to issue the events;
- "disabledn" not to do so;

In that cases the user space can change the setting represented by the contents of this file by writing either "enabled", or "disabled" to it.

For the devices that are not capable of generating system wakeup events this file is not present. In that case the device cannot be enabled to wake up the system from sleep states.

/sys/devices/.../power/wakeup_abort_count

Defined on file *sysfs-devices-power*

The /sys/devices/.../wakeup_abort_count attribute contains the number of times the processing of a wakeup event associated with the device might have aborted system transition into a sleep state in progress. This attribute is read-only. If the device is not capable to wake up the system from sleep states, this attribute is not present. If the device is not enabled to wake up the system from sleep states, this attribute is empty.

/sys/devices/.../power/wakeup_active

Defined on file *sysfs-devices-power*

The /sys/devices/.../wakeup_active attribute contains either 1, or 0, depending on whether or not a wakeup event associated with the device is being processed (1). This attribute is read-only. If the device is not capable to wake up the system from sleep states, this attribute is not present. If the device is not enabled to wake up the system from sleep states, this attribute is empty.

/sys/devices/.../power/wakeup_active_count

Defined on file *sysfs-devices-power*

The /sys/devices/.../wakeup_active_count attribute contains the number of times the processing of wakeup events associated with the device was completed (at the kernel level). This attribute is read-only. If the device is not capable to wake up the system from sleep states, this attribute is not present. If the device is not enabled to wake up the system from sleep states, this attribute is empty.

/sys/devices/.../power/wakeup_count

Defined on file *sysfs-devices-power*

The /sys/devices/.../wakeup_count attribute contains the number of signaled wakeup events associated with the device. This attribute is read-only. If the device is not capable to wake up the system from sleep states, this attribute is not present. If the device is not enabled to wake up the system from sleep states, this attribute is empty.

/sys/devices/.../power/wakeup_expire_count

Defined on file *sysfs-devices-power*

The /sys/devices/.../wakeup_expire_count attribute contains the number of times a wakeup event associated with the device has been reported with a timeout that expired. This attribute is read-only. If the device is not capable to wake up the system from sleep states, this attribute is not present. If the device is not enabled to wake up the system from sleep states, this attribute is empty.

/sys/devices/.../power/wakeup_last_time_ms

Defined on file *sysfs-devices-power*

The /sys/devices/.../wakeup_last_time_ms attribute contains the value of the monotonic clock corresponding to the time of signaling the last wakeup event associated with the device, in milliseconds. This attribute is read-only. If the device is not enabled to wake up the system from sleep states, this attribute is not present. If the device is not enabled to wake up the system from sleep states, this attribute is empty.

/sys/devices/.../power/wakeup_max_time_ms

Defined on file *sysfs-devices-power*

The /sys/devices/.../wakeup_max_time_ms attribute contains the maximum time of processing a single wakeup event associated with the device, in milliseconds. This attribute is read-only. If the device is not capable to wake up the system from sleep states, this attribute is not present. If the device is not enabled to wake up the system from sleep states, this attribute is empty.

/sys/devices/.../power/wakeup_prevent_sleep_time_ms

Defined on file *sysfs-devices-power*

The /sys/devices/.../wakeup_prevent_sleep_time_ms attribute contains the total time the device has been preventing opportunistic transitions to sleep states from occurring. This attribute is read-only. If the device is not capable to wake up the system from sleep states, this attribute is not present. If the device is not enabled to wake up the system from sleep states, this attribute is empty.

/sys/devices/.../power/wakeup_total_time_ms

Defined on file *sysfs-devices-power*

The /sys/devices/.../wakeup_total_time_ms attribute contains the total time of processing wakeup events associated with the device, in milliseconds. This attribute is read-only. If the device is not capable to wake up the system from sleep states, this attribute is not present. If the device is not enabled to wake up the system from sleep states, this attribute is empty.

/sys/devices/.../power_resources_D0/

Defined on file *sysfs-devices-power_resources_D0*

The /sys/devices/.../power_resources_D0/ directory is only present for device objects representing ACPI device nodes that use ACPI power resources for power management.

If present, it contains symbolic links to device directories representing ACPI power resources that need to be turned on for the given device node to be in ACPI power state D0. The names of the links are the same as the names of the directories they point to.

/sys/devices/.../power_resources_D1/

Defined on file *sysfs-devices-power_resources_D1*

The /sys/devices/.../power_resources_D1/ directory is only present for device objects representing ACPI device nodes that use ACPI power resources for power management and support ACPI power state D1.

If present, it contains symbolic links to device directories representing ACPI power resources that need to be turned on for the given device node to be in ACPI power state D1. The names of the links are the same as the names of the directories they point to.

/sys/devices/.../power_resources_D2/

Defined on file *sysfs-devices-power_resources_D2*

The /sys/devices/.../power_resources_D2/ directory is only present for device objects representing ACPI device nodes that use ACPI power resources for power management and support ACPI power state D2.

If present, it contains symbolic links to device directories representing ACPI power resources that need to be turned on for the given device node to be in ACPI power state D2. The names of the links are the same as the names of the directories they point to.

/sys/devices/.../power_resources_D3hot/

Defined on file *sysfs-devices-power_resources_D3hot*

The /sys/devices/.../power_resources_D3hot/ directory is only present for device objects representing ACPI device nodes that use ACPI power resources for power management and support ACPI power state D3hot.

If present, it contains symbolic links to device directories representing ACPI power resources that need to be turned on for the given device node to be in ACPI power state D3hot. The names of the links are the same as the names of the directories they point to.

/sys/devices/.../power_resources_wakeup/

Defined on file *sysfs-devices-power_resources_wakeup*

The /sys/devices/.../power_resources_wakeup/ directory is only present for device objects representing ACPI device nodes that require ACPI power resources for wakeup signaling.

If present, it contains symbolic links to device directories representing ACPI power resources that need to be turned on for the given device node to be able to signal wakeup. The names of the links are the same as the names of the directories they point to.

/sys/devices/.../power_state

Defined on file *sysfs-devices-power_state*

The /sys/devices/.../power_state attribute is only present for device objects representing ACPI device nodes that provide power management methods.

If present, it contains a string representing the current ACPI power state of the given device node. Its possible values, "D0", "D1", "D2", "D3hot", and "D3cold", reflect the power state names defined by the ACPI specification (ACPI 4 and above).

If the device node uses shared ACPI power resources, this state determines a list of power resources required not to be turned off. However, some power resources needed by the device node in higher-power (lower-number) states may also be ON because of some other devices using them at the moment.

This attribute is read-only.

/sys/devices/.../real_power_state

Defined on file *sysfs-devices-real_power_state*

The /sys/devices/.../real_power_state attribute is only present for device objects representing ACPI device nodes that provide power management methods and use ACPI power resources for power management.

If present, it contains a string representing the real ACPI power state of the given device node as returned by the _PSC control method or inferred from the configuration of power resources. Its possible values, "D0", "D1", "D2", "D3hot", and "D3cold", reflect the power state names defined by the ACPI specification (ACPI 4 and above).

In some situations the value of this attribute may be different from the value of the /sys/devices/.../power_state attribute for the same device object. If that happens, some shared power resources used by the device node are only ON because of some other devices using them at the moment.

This attribute is read-only.

/sys/devices/.../removable

Defined on file *sysfs-devices-removable*

Information about whether a given device can be removed from the platform by the user. This is determined by its subsystem in a bus / platform-specific way. This attribute is only present for devices that can support determining such information:

"removable"	device can be removed from the platform by the user
"fixed"	device is fixed to the platform / cannot be removed by the user.
"unknown"	The information is unavailable / cannot be deduced.

Currently this is only supported by USB (which infers the information from a combination of hub descriptor bits and platform-specific data such as ACPI) and PCI (which gets this from ACPI / device tree).

/sys/devices/.../resource_in_use

Defined on file *sysfs-devices-resource_in_use*

The /sys/devices/.../resource_in_use attribute is only present for device objects representing ACPI power resources.

If present, it contains a number (0 or 1) representing the current status of the given power resource (0 means that the resource is not in use and therefore it has been turned off).

This attribute is read-only.

/sys/devices/.../software_node/

Defined on file *sysfs-devices-software_node*

This directory contains the details about the device that are assigned in kernel (i.e. software), as opposed to the firmware_node directory which contains the details that are assigned for the device in firmware. The main attributes in the directory will show the properties the device has, and the relationship it has to some of the other devices.

/sys/devices/.../state_synced

Defined on file *sysfs-devices-state_synced*

The /sys/devices/.../state_synced attribute is only present for devices whose bus types or driver provides the .sync_state() callback. The number read from it (0 or 1) reflects the value of the device's 'state_synced' field. A value of 0 means the .sync_state() callback hasn't been called yet. A value of 1 means the .sync_state() callback has been called.

Generally, if a device has sync_state() support and has some of the resources it provides enabled at the time the kernel starts (Eg: enabled by hardware reset or bootloader or anything that run before the kernel starts), then it'll keep those resources enabled and in a state that's compatible with the state they were in at the start of the kernel. The device will stop doing this only when

the sync_state() callback has been called -- which happens only when all its consumer devices are registered and have probed successfully. Resources that were left disabled at the time the kernel starts are not affected or limited in any way by sync_state() callbacks.

Writing "1" to this file will force a call to the device's sync_state() function if it hasn't been called already. The sync_state() call happens independent of the state of the consumer devices.

/sys/devices/.../sun

Defined on file *sysfs-devices-sun*

The file contains a Slot-unique ID which provided by the _SUN method in the ACPI namespace. The value is written in Advanced Configuration and Power Interface Specification as follows:

"The _SUN value is required to be unique among the slots of the same type. It is also recommended that this number match the slot number printed on the physical slot whenever possible."

So reading the sysfs file, we can identify a physical position of the slot in the system.

/sys/devices/.../supplier:<supplier>

Defined on file *sysfs-devices-supplier*

The /sys/devices/.../supplier:<supplier> are symlinks to device links where this device is the consumer. <supplier> denotes the name of the supplier in that device link and is of the form bus:device name. There can be zero or more of these symlinks for a given device.

/sys/devices/.../waiting_for_supplier

Defined on file *sysfs-devices-waiting_for_supplier*

The /sys/devices/.../waiting_for_supplier attribute is only present when fw_devlink kernel command line option is enabled and is set to something stricter than "permissive". It is removed once a device probes successfully (because the information is no longer relevant). The number read from it (0 or 1) reflects whether the device is waiting for one or more suppliers to be added and then linked to using device links before the device can probe.

A value of 0 means the device is not waiting for any suppliers to be added before it can probe. A value of 1 means the device is waiting for one or more suppliers to be added before it can probe.

/sys/devices/../../gisb_arb_timeout

Defined on file *sysfs-platform-brcmstb-gisb-arb*

Returns the currently configured raw timeout value of the Broadcom Set Top Box internal GISB bus arbiter. Minimum value is 1, and maximum value is 0xffffffff.

/sys/devices/LNXSYSTM:00/LNXSYBUS:00/TOS620A:00/protection_level

Defined on file *sysfs-driver-toshiba_haps*

This file controls the built-in accelerometer protection level, valid values are:

- 0 -> Disabled
- 1 -> Low
- 2 -> Medium
- 3 -> High

The default potection value is set to 2 (Medium).

Users: KToshiba

/sys/devices/LNXSYSTM:00/LNXSYBUS:00/TOS620A:00/reset_protection

Defined on file *sysfs-driver-toshiba_haps*

This file turns off the built-in accelerometer for a few seconds and then restore normal operation. Accepting 1 as the only parameter.

/sys/devices/LNXSYSTM:00/LNXSYBUS:00/TOS{1900,620{0,7,8}}:00/available_kbd_modes

Defined on file *sysfs-driver-toshiba_acpi*

This file shows the supported keyboard backlight modes the system supports, which can be:

- 0x1 -> FN-Z
- 0x2 -> AUTO (also called TIMER)
- 0x8 -> ON
- 0x10 -> OFF

Note that not all keyboard types support the listed modes. See the entry named "available_kbd_modes"

Users: KToshiba

/sys/devices/LNXSYSTM:00/LNXSYBUS:00/TOS{1900,620{0,7,8}}:00/cooling_method

Defined on file *sysfs-driver-toshiba_acpi*

This file controls the Cooling Method feature. Reading this file prints two values, the first is the actual cooling method and the second is the maximum cooling method supported. When the maximum cooling method is ONE, valid values are:

- 0 -> Maximum Performance
- 1 -> Battery Optimized

When the maximum cooling method is TWO, valid values are:

- 0 -> Maximum Performance
- 1 -> Performance
- 2 -> Battery Optimized

Users: KToshiba

/sys/devices/LNXSYSTM:00/LNXSYBUS:00/TOS{1900,620{0,7,8}}:00/fan

Defined on file *sysfs-driver-toshiba_acpi*

This file controls the state of the internal fan, valid values are:

- 0 -> OFF
- 1 -> ON

/sys/devices/LNXSYSTM:00/LNXSYBUS:00/TOS{1900,620{0,7,8}}:00/kbd_backlight_mode

Defined on file *sysfs-driver-toshiba_acpi*

This file controls the keyboard backlight operation mode, valid values are:

- 0x1 -> FN-Z
- 0x2 -> AUTO (also called TIMER)
- 0x8 -> ON
- 0x10 -> OFF

Note that from kernel 3.16 onwards this file accepts all listed parameters, kernel 3.15 only accepts the first two (FN-Z and AUTO). Also note that toggling this value on type 1 devices, requires a reboot for changes to take effect.

Users: KToshiba

/sys/devices/LNXSYSTM:00/LNXSYBUS:00/TOS{1900,620{0,7,8}}:00/kbd_backlight_timeou

Defined on file *sysfs-driver-toshiba_acpi*

This file controls the timeout of the keyboard backlight whenever the operation mode is set to AUTO (or TIMER), valid values range from 0-60. Note that the kernel 3.15 only had support for the first keyboard type, the kernel 3.16 added support for the second type and the range accepted for type 2 is 1-60. See the entry named ”kbd_type”

Users: KToshiba

/sys/devices/LNXSYSTM:00/LNXSYBUS:00/TOS{1900,620{0,7,8}}:00/kbd_function_keys

Defined on file *sysfs-driver-toshiba_acpi*

This file controls the Special Functions (hotkeys) operation mode, valid values are:

- 0 -> Normal Operation
- 1 -> Special Functions

In the ”Normal Operation” mode, the F{1-12} keys are as usual and the hotkeys are accessed via FN-F{1-12}. In the ”Special Functions” mode, the F{1-12} keys trigger the hotkey and the F{1-12} keys are accessed via FN-F{1-12}. Note that toggling this value requires a reboot for changes to take effect.

Users: KToshiba

/sys/devices/LNXSYSTM:00/LNXSYBUS:00/TOS{1900,620{0,7,8}}:00/kbd_type

Defined on file *sysfs-driver-toshiba_acpi*

This file shows the current keyboard backlight type, which can be:

- 1 -> Type 1, supporting modes FN-Z and AUTO
- 2 -> Type 2, supporting modes TIMER, ON and OFF

Users: KToshiba

/sys/devices/LNXSYSTM:00/LNXSYBUS:00/TOS{1900,620{0,7,8}}:00/panel_power_on

Defined on file *sysfs-driver-toshiba_acpi*

This file controls whether the laptop should turn ON whenever the LID is opened, valid values are:

- 0 -> Disabled
- 1 -> Enabled

Note that toggling this value requires a reboot for changes to take effect.

Users: KToshiba

/sys/devices/LNXSYSTM:00/LNXSYBUS:00/TOS{1900,620{0,7,8}}:00/position

Defined on file *sysfs-driver-toshiba_acpi*

This file shows the absolute position of the built-in accelereometer.

/sys/devices/LNXSYSTM:00/LNXSYBUS:00/TOS{1900,620{0,7,8}}:00/sleep_functions_on_b

Defined on file *sysfs-driver-toshiba_acpi*

This file controls the USB Sleep Functions under battery, and set the level at which point they will be disabled, accepted values can be:

- 0 -> Disabled
- 1-100 -> Battery level to disable sleep functions

Currently it prints two values, the first one indicates if the feature is enabled or disabled, while the second one shows the current battery level set. Note that when the value is set to disabled, the sleep function will only work when connected to power.

Users: KToshiba

/sys/devices/LNXSYSTM:00/LNXSYBUS:00/TOS{1900,620{0,7,8}}:00/touchpad

Defined on file *sysfs-driver-toshiba_acpi*

This files controls the status of the touchpad and pointing stick (if available), valid values are:

- 0 -> OFF
- 1 -> ON

Users: KToshiba

/sys/devices/LNXSYSTM:00/LNXSYBUS:00/TOS{1900,620{0,7,8}}:00/usb_rapid_charge

Defined on file *sysfs-driver-toshiba_acpi*

This file controls the USB Rapid Charge state, which can be:

- 0 -> Disabled
- 1 -> Enabled

Note that toggling this value requires a reboot for changes to take effect.

Users: KToshiba

/sys/devices/LNXSYSTM:00/LNXSYBUS:00/TOS{1900,620{0,7,8}}:00/usb_sleep_charge

Defined on file *sysfs-driver-toshiba_acpi*

This file controls the USB Sleep & Charge charging mode, which can be:

- 0 -> Disabled (0x00)
- 1 -> Alternate (0x09)
- 2 -> Auto (0x21)
- 3 -> Typical (0x11)

Note that from kernel 4.1 onwards this file accepts all listed values, kernel 4.0 only supports the first three. Note that this feature only works when connected to power, if you want to use it under battery, see the entry named "sleep_functions_on_battery"

Users: KToshiba

/sys/devices/LNXSYSTM:00/LNXSYBUS:00/TOS{1900,620{0,7,8}}:00/usb_sleep_music

Defined on file *sysfs-driver-toshiba_acpi*

This file controls the Sleep & Music state, which values can be:

- 0 -> Disabled
- 1 -> Enabled

Note that this feature only works when connected to power, if you want to use it under battery, see the entry named "sleep_functions_on_battery"

Users: KToshiba

/sys/devices/LNXSYSTM:00/LNXSYBUS:00/TOS{1900,620{0,7,8}}:00/usb_three

Defined on file *sysfs-driver-toshiba_acpi*

This file controls the USB 3 functionality, valid values are:

- 0 -> Disabled (Acts as a regular USB 2)
- 1 -> Enabled (Full USB 3 functionality)

Note that toggling this value requires a reboot for changes to take effect.

Users: KToshiba

/sys/devices/LNXSYSTM:00/LNXSYBUS:00/TOS{1900,620{0,7,8}}:00/version

Defined on file *sysfs-driver-toshiba_acpi*

This file shows the current version of the driver

Users: KToshiba

/sys/devices/cpu/events/

Defined on file *sysfs-bus-event_source-devices-events*

Generic performance monitoring events

A collection of performance monitoring events that may be supported by many/most CPUs. These events can be monitored using the 'perf(1)' tool.

The contents of each file would look like:

event=0xNNNN

where 'N' is a hex digit and the number '0xNNNN' shows the "raw code" for the perf event identified by the file's "basename".

/sys/devices/hisi_ptt<sicl_id>_<core_id>/requester_filters

Defined on file *sysfs-devices-hisi_ptt*

This directory contains the files providing the PCIe Requester filters information used for PTT trace. Each file is named after the supported Endpoint device name <domain>:<bus>:<device>.<function>.

See the description of the "filter" in /trace/hisi-ptt for more information.

/sys/devices/hisi_ptt<sicl_id>_<core_id>/requester_filters/<bdf>

Defined on file *sysfs-devices-hisi_ptt*

(Read) Indicates the filter value of this Requester filter, which can be used to control the TLP headers to trace by the PTT trace.

/sys/devices/hisi_ptt<sicl_id>_<core_id>/requester_filters/multiselect

Defined on file *sysfs-devices-hisi_ptt*

(Read) Indicates if this kind of filter can be selected at the same time as others filters, or must be used on it's own. 1 indicates the former case and 0 indicates the latter.

/sys/devices/hisi_ptt<sicl_id>_<core_id>/root_port_filters

Defined on file *sysfs-devices-hisi_ptt*

This directory contains the files providing the PCIe Root Port filters information used for PTT trace. Each file is named after the supported Root Port device name <domain>:<bus>:<device>.<function>.

See the description of the "filter" in /trace/hisi-ptt for more information.

/sys/devices/hisi_ptt<sicl_id>_<core_id>/root_port_filters/<bdf>

Defined on file *sysfs-devices-hisi_ptt*

(Read) Indicates the filter value of this Root Port filter, which can be used to control the TLP headers to trace by the PTT trace.

/sys/devices/hisi_ptt<sicl_id>_<core_id>/root_port_filters/multiselect

Defined on file *sysfs-devices-hisi_ptt*

(Read) Indicates if this kind of filter can be selected at the same time as others filters, or must be used on it's own. 1 indicates the former case and 0 indicates the latter.

/sys/devices/hisi_ptt<sicl_id>_<core_id>/tune

Defined on file *sysfs-devices-hisi_ptt*

This directory contains files for tuning the PCIe link parameters(events). Each file is named after the event of the PCIe link.

See /trace/hisi-ptt for more information.

/sys/devices/hisi_ptt<sicl_id>_<core_id>/tune/qos_tx_cpl

Defined on file *sysfs-devices-hisi_ptt*

(RW) Controls the weight of Tx completion TLPs, which influence the proportion of outbound completion TLPs on the PCIe link. The available tune data is [0, 1, 2]. Writing a negative value will return an error, and out of range values will be converted to 2. The value indicates a probable level of the event.

/sys/devices/hisi_ptt<sicl_id>_<core_id>/tune/qos_tx_np

Defined on file *sysfs-devices-hisi_ptt*

(RW) Controls the weight of Tx non-posted TLPs, which influence the proportion of outbound non-posted TLPs on the PCIe link. The available tune data is [0, 1, 2]. Writing a negative value will return an error, and out of range values will be converted to 2. The value indicates a probable level of the event.

/sys/devices/hisi_ptt<sicl_id>_<core_id>/tune/qos_tx_p

Defined on file *sysfs-devices-hisi_ptt*

(RW) Controls the weight of Tx posted TLPs, which influence the proportion of outbound posted TLPs on the PCIe link. The available tune data is [0, 1, 2]. Writing a negative value will return an error, and out of range values will be converted to 2. The value indicates a probable level of the event.

/sys/devices/hisi_ptt<sicl_id>_<core_id>/tune/rx_alloc_buf_level

Defined on file *sysfs-devices-hisi_ptt*

(RW) Control the allocated buffer watermark for inbound packets. The packets will be stored in the buffer first and then transmitted either when the watermark reached or when timed out. The available tune data is [0, 1, 2]. Writing a negative value will return an error, and out of range values will be converted to 2. The value indicates a probable level of the event.

/sys/devices/hisi_ptt<sicl_id>_<core_id>/tune/tx_alloc_buf_level

Defined on file *sysfs-devices-hisi_ptt*

(RW) Control the allocated buffer watermark of outbound packets. The packets will be stored in the buffer first and then transmitted either when the watermark reached or when timed out. The available tune data is [0, 1, 2]. Writing a negative value will return an error, and out of range values will be converted to 2. The value indicates a probable level of the event.

/sys/devices/hv_24x7/cpumask

Defined on file *sysfs-bus-event_source-devices-hv_24x7*

read only This sysfs file exposes the cpumask which is designated to make HCALLs to retrieve hv-24x7 pmu event counter data.

/sys/devices/hv_24x7/interface/chipspersocket

Defined on file *sysfs-bus-event_source-devices-hv_24x7*

read only This sysfs interface exposes the number of chips per socket present in the system.

/sys/devices/hv_24x7/interface/coresperchip

Defined on file *sysfs-bus-event_source-devices-hv_24x7*

read only This sysfs interface exposes the number of cores per chip present in the system.

/sys/devices/hv_24x7/interface/sockets

Defined on file *sysfs-bus-event_source-devices-hv_24x7*

read only This sysfs interface exposes the number of sockets present in the system.

/sys/devices/hv_gpci/cpumask

Defined on file *sysfs-bus-event_source-devices-hv_gpci*

read only This sysfs file exposes the cpumask which is designated to make HCALLs to retrieve hv-gpci pmu event counter data.

/sys/devices/hv_gpci/interface/affinity_domain_via_domain

Defined on file *sysfs-bus-event_source-devices-hv_gpci*

admin read only This sysfs file exposes the system topology information by making HCALL H_GET_PERF_COUNTER_INFO. The HCALL is made with counter request value AFFINITY_DOMAIN_INFORMATION_BY_DOMAIN(0xB0).

- This sysfs file will be created only for power10 and above platforms.
- User needs root privileges to read data from this sysfs file.
- This sysfs file will be created, only when the HCALL returns "H_SUCCESS", "H_AUTHORITY" or "H_PARAMETER" as the return type.

  HCALL with return error type "H_AUTHORITY" can be resolved during runtime by setting "Enable Performance Information Collection" option.
- The end user reading this sysfs file must decode the content as per underlying platform/firmware.

Possible error codes while reading this sysfs file:

- **"-EPERM"**
  [Partition is not permitted to retrieve performance information,] required to set "Enable Performance Information Collection" option.
- **"-EIO"**
  [Can't retrieve system information because of invalid buffer length/invalid address] or because of some hardware error. Refer to getPerfCountInfo documentation for more information.
- "-EFBIG" : System information exceeds PAGE_SIZE.

/sys/devices/hv_gpci/interface/affinity_domain_via_partition

Defined on file *sysfs-bus-event_source-devices-hv_gpci*

admin read only This sysfs file exposes the system topology information by making HCALL H_GET_PERF_COUNTER_INFO. The HCALL is made with counter request value AFFINITY_DOMAIN_INFORMATION_BY_PARTITION(0xB1).

- This sysfs file will be created only for power10 and above platforms.
- User needs root privileges to read data from this sysfs file.
- This sysfs file will be created, only when the HCALL returns "H_SUCCESS", "H_AUTHORITY" or "H_PARAMETER" as the return type.

  HCALL with return error type "H_AUTHORITY" can be resolved during runtime by setting "Enable Performance Information Collection" option.
- The end user reading this sysfs file must decode the content as per underlying platform/firmware.

Possible error codes while reading this sysfs file:

- **"-EPERM"**
  [Partition is not permitted to retrieve performance information,] required to set "Enable Performance Information Collection" option.
- **"-EIO"**
  [Can't retrieve system information because of invalid buffer length/invalid address] or because of some hardware error. Refer to getPerfCountInfo documentation for more information.
- "-EFBIG" : System information exceeds PAGE_SIZE.

/sys/devices/hv_gpci/interface/affinity_domain_via_virtual_processor

Defined on file *sysfs-bus-event_source-devices-hv_gpci*

admin read only This sysfs file exposes the system topology information by making HCALL H_GET_PERF_COUNTER_INFO. The HCALL is made with counter request value AFFINITY_DOMAIN_INFORMATION_BY_VIRTUAL_PROCESSOR(0xA0).

- This sysfs file will be created only for power10 and above platforms.
- User needs root privileges to read data from this sysfs file.
- This sysfs file will be created, only when the HCALL returns "H_SUCCESS", "H_AUTHORITY" or "H_PARAMETER" as the return type.

  HCALL with return error type "H_AUTHORITY" can be resolved during runtime by setting "Enable Performance Information Collection" option.
- The end user reading this sysfs file must decode the content as per underlying platform/firmware.

Possible error codes while reading this sysfs file:

- **"-EPERM"**
  [Partition is not permitted to retrieve performance information,] required to set "Enable Performance Information Collection" option.
- **"-EIO"**
  [Can't retrieve system information because of invalid buffer length/invalid address] or because of some hardware error. Refer to getPerfCountInfo documentation for more information.
- "-EFBIG" : System information exceeds PAGE_SIZE.

/sys/devices/hv_gpci/interface/processor_bus_topology

Defined on file *sysfs-bus-event_source-devices-hv_gpci*

admin read only This sysfs file exposes the system topology information by making HCALL H_GET_PERF_COUNTER_INFO. The HCALL is made with counter request value PROCESSOR_BUS_TOPOLOGY(0xD0).

- This sysfs file will be created only for power10 and above platforms.
- User needs root privileges to read data from this sysfs file.

- This sysfs file will be created, only when the HCALL returns "H_SUCCESS", "H_AUTHORITY" or "H_PARAMETER" as the return type.

  HCALL with return error type "H_AUTHORITY" can be resolved during runtime by setting "Enable Performance Information Collection" option.

- The end user reading this sysfs file must decode the content as per underlying platform/firmware.

Possible error codes while reading this sysfs file:

- **"-EPERM"**
  [Partition is not permitted to retrieve performance information,] required to set "Enable Performance Information Collection" option.
- **"-EIO"**
  [Can't retrieve system information because of invalid buffer length/invalid address] or because of some hardware error. Refer to getPerfCountInfo documentation for more information.
- "-EFBIG" : System information exceeds PAGE_SIZE.

/sys/devices/hv_gpci/interface/processor_config

Defined on file *sysfs-bus-event_source-devices-hv_gpci*

admin read only This sysfs file exposes the system topology information by making HCALL H_GET_PERF_COUNTER_INFO. The HCALL is made with counter request value PROCESSOR_CONFIG(0x90).

- This sysfs file will be created only for power10 and above platforms.
- User needs root privileges to read data from this sysfs file.
- This sysfs file will be created, only when the HCALL returns "H_SUCCESS", "H_AUTHORITY" or "H_PARAMETER" as the return type.

  HCALL with return error type "H_AUTHORITY" can be resolved during runtime by setting "Enable Performance Information Collection" option.

- The end user reading this sysfs file must decode the content as per underlying platform/firmware.

Possible error codes while reading this sysfs file:

- **"-EPERM"**
  [Partition is not permitted to retrieve performance information,] required to set "Enable Performance Information Collection" option.
- **"-EIO"**
  [Can't retrieve system information because of invalid buffer length/invalid address] or because of some hardware error. Refer to getPerfCountInfo documentation for more information.
- "-EFBIG" : System information exceeds PAGE_SIZE.

/sys/devices/pci0000:00/*/QEMU0001:00/capability for MMIO

Defined on file *sysfs-bus-pci-devices-pvpanic*

Read-only attribute. Capabilities of pvpanic device which are supported by QEMU.

Format: %x.

Detailed bit definition refers to section <Bit Definition> from pvpanic device specification: https://git.qemu.org/?p=qemu.git;a=blob_plain;f=docs/specs/pvpanic.txt

/sys/devices/pci0000:00/*/QEMU0001:00/events

Defined on file *sysfs-bus-pci-devices-pvpanic*

RW attribute. Set/get which features in-use. This attribute is used to enable/disable feature(s) of pvpanic device. Notice that this value should be a subset of capability.

Format: %x.

Also refer to pvpanic device specification.

/sys/devices/pci0000:00/<dev>/fw_info

Defined on file *sysfs-bus-pci-devices-catpt*

Detailed AudioDSP firmware build information including build hash and log-providers hash. This information is obtained during initial handshake with firmware. Format: %s.

/sys/devices/pci0000:00/<dev>/fw_version

Defined on file *sysfs-bus-pci-devices-catpt*

Version of AudioDSP firmware ASoC catpt driver is communicating with.

Format: %d.%d.%d.%d, type:major:minor:build.

/sys/devices/platform/*/cnqf_enable

Defined on file *sysfs-amd-pmf*

Reading this file tells if the AMD Platform Management(PMF) Cool n Quiet Framework(CnQF) feature is enabled or not.

This feature is not enabled by default and gets only turned on if OEM BIOS passes a ”flag” to PMF ACPI function (index 11 or 12) or in case the user writes ”on”.

To turn off CnQF user can write ”off” to the sysfs node. Note: Systems that support auto mode will not have this sysfs file available.

/sys/devices/platform/.../power_on_reason

Defined on file *sysfs-platform-power-on-reason*

Shows system power on reason. The following strings/reasons can be read (the list can be extended): ”regular power-up”, ”RTC wakeup”, ”watchdog timeout”, ”software reset”, ”reset button action”, ”CPU clock failure”, ”crystal oscillator failure”, ”brown-out reset”, ”unknown reason”.

The file is read only.

/sys/devices/platform/8086<x>:00/firmware_version

Defined on file *sysfs-platform-sst-atom*

LPE Firmware version for SST driver on all atom platforms (BYT/CHT/Merrifield/BSW). If the FW has never been loaded it will display:

```
"FW not yet loaded"
```

If FW has been loaded it will display:

```
"v01.aa.bb.cc"
```

aa: Major version is reflecting SoC version:

0d:	BYT FW
0b:	BSW FW
07:	Merrifield FW

bb: Minor version

cc: Build version

/sys/devices/platform/<i2c-demux-name>/available_masters

Defined on file *sysfs-platform-i2c-demux-pinctrl*

Reading the file will give you a list of masters which can be selected for a demultiplexed bus. The format is "<index>:<name>". Example from a Renesas Lager board:

```
0:/i2c@e6500000 1:/i2c@e6508000
```

/sys/devices/platform/<i2c-demux-name>/current_master

Defined on file *sysfs-platform-i2c-demux-pinctrl*

This file selects/shows the active I2C master for a demultiplexed bus. It uses the <index> value from the file 'available_masters'.

/sys/devices/platform/<phy-name>/role

Defined on file *sysfs-platform-phy-rcar-gen3-usb2*

This file can be read and write. The file can show/change the phy mode for role swap of usb.

Write the following strings to change the mode:

- "host" - switching mode from peripheral to host.
- "peripheral" - switching mode from host to peripheral.

Read the file, then it shows the following strings:

- ”host” - The mode is host now.
- ”peripheral” - The mode is peripheral now.

/sys/devices/platform/<platform>/camera

Defined on file *sysfs-platform-asus-wmi*

Control the camera. 1 means on, 0 means off.

/sys/devices/platform/<platform>/cardr

Defined on file *sysfs-platform-asus-wmi*

Control the card reader. 1 means on, 0 means off.

/sys/devices/platform/<platform>/charge_mode

Defined on file *sysfs-platform-asus-wmi*

Get the current charging mode being used:

- 1 - Barrel connected charger,
- 2 - USB-C charging
- 3 - Both connected, barrel used for charging

/sys/devices/platform/<platform>/cpufv

Defined on file *sysfs-platform-asus-wmi*

Change CPU clock configuration (write-only). There are three available clock configuration:

- 0 -> Super Performance Mode
- 1 -> High Performance Mode
- 2 -> Power Saving Mode

/sys/devices/platform/<platform>/dgpu_disable

Defined on file *sysfs-platform-asus-wmi*

Disable discrete GPU:

- 0 - Enable dGPU,
- 1 - Disable dGPU

/sys/devices/platform/<platform>/egpu_connected

Defined on file *sysfs-platform-asus-wmi*

Show if the egpu (XG Mobile) is correctly connected:

- 0 - False,

- 1 - True

/sys/devices/platform/<platform>/egpu_enable

Defined on file *sysfs-platform-asus-wmi*

Enable the external GPU paired with ROG X-Flow laptops. Toggling this setting will also trigger ACPI to disable the dGPU:

- 0 - Disable,
- 1 - Enable

/sys/devices/platform/<platform>/etr3

Defined on file *sysfs-platform-intel-pmc*

The file exposes "Extended Test Mode Register 3" global reset bits. The bits are used during an Intel platform manufacturing process to indicate that consequent reset of the platform is a "global reset". This type of reset is required in order for manufacturing configurations to take effect.

Display global reset setting bits for PMC.

- bit 31 - global reset is locked
- bit 20 - global reset is set

Writing bit 20 value to the etr3 will induce a platform "global reset" upon consequent platform reset, in case the register is not locked. The "global reset bit" should be locked on a production system and the file is in read-only mode.

/sys/devices/platform/<platform>/fan_boost_mode

Defined on file *sysfs-platform-asus-wmi*

Fan boost mode:

- 0 - normal,
- 1 - overboost,
- 2 - silent

/sys/devices/platform/<platform>/force_power

Defined on file *sysfs-platform-intel-wmi-thunderbolt*

Modify the platform force power state, influencing Thunderbolt controllers to turn on or off when no devices are connected (write-only) There are two available states:

- 0 -> Force power disabled
- 1 -> Force power enabled

/sys/devices/platform/<platform>/gpu_mux_mode

Defined on file *sysfs-platform-asus-wmi*

Switch the GPU hardware MUX mode. Laptops with this feature can can be toggled to boot with only the dGPU (discrete mode) or in standard Optimus/Hybrid mode. On switch a reboot is required:

- 0 - Discrete GPU,
- 1 - Optimus/Hybrid,

/sys/devices/platform/<platform>/lid_resume

Defined on file *sysfs-platform-asus-wmi*

Resume on lid open. 1 means on, 0 means off.

/sys/devices/platform/<platform>/mini_led_mode

Defined on file *sysfs-platform-asus-wmi*

Change the mini-LED mode:

- 0 - Single-zone,
- 1 - Multi-zone

/sys/devices/platform/<platform>/nv_dynamic_boost

Defined on file *sysfs-platform-asus-wmi*

Set the dynamic boost limit of the Nvidia dGPU:

- min=5, max=25

/sys/devices/platform/<platform>/nv_temp_target

Defined on file *sysfs-platform-asus-wmi*

Set the target temperature limit of the Nvidia dGPU:

- min=75, max=87

/sys/devices/platform/<platform>/panel_od

Defined on file *sysfs-platform-asus-wmi*

Enable an LCD response-time boost to reduce or remove ghosting:

- 0 - Disable,
- 1 - Enable

/sys/devices/platform/<platform>/ppt_apu_sppt

Defined on file *sysfs-platform-asus-wmi*

Set the APU SPPT limit. Shown on full AMD systems only:

- min=5, max=130

/sys/devices/platform/<platform>/ppt_fppt

Defined on file *sysfs-platform-asus-wmi*

Set the Fast Package Power Tracking Limit of CPU. AMD+Nvidia only:

- min=5, max=250

/sys/devices/platform/<platform>/ppt_pl1_spl

Defined on file *sysfs-platform-asus-wmi*

Set the Package Power Target total of CPU: PL1 on Intel, SPL on AMD. Shown on Intel+Nvidia or AMD+Nvidia based systems:

- min=5, max=250

/sys/devices/platform/<platform>/ppt_pl2_sppt

Defined on file *sysfs-platform-asus-wmi*

Set the Slow Package Power Tracking Limit of CPU: PL2 on Intel, SPPT, on AMD. Shown on Intel+Nvidia or AMD+Nvidia based systems:

- min=5, max=250

/sys/devices/platform/<platform>/ppt_platform_sppt

Defined on file *sysfs-platform-asus-wmi*

Set the platform SPPT limit. Shown on full AMD systems only:

- min=5, max=130

/sys/devices/platform/<platform>/throttle_thermal_policy

Defined on file *sysfs-platform-asus-wmi*

Throttle thermal policy mode:

- 0 - default,
- 1 - overboost,
- 2 - silent

/sys/devices/platform/<platform>/tokens/*

Defined on file *sysfs-platform-dell-smbios*

A read-only description of Dell platform tokens available on the machine.

Each token attribute is available as a pair of sysfs attributes readable by a process with CAP_SYS_ADMIN.

For example the token ID "5" would be available as the following attributes:

- 0005_location
- 0005_value

Tokens will vary from machine to machine, and only tokens available on that machine will be displayed.

/sys/devices/platform/<platform>/touchpad

Defined on file *sysfs-platform-asus-wmi*

Control the card touchpad. 1 means on, 0 means off.

/sys/devices/platform/<renesas_usb3's name>/role

Defined on file *sysfs-platform-renesas_usb3*

This file can be read and write. The file can show/change the drd mode of usb.

Write the following string to change the mode:

- "host" - switching mode from peripheral to host.
- "peripheral" - switching mode from host to peripheral.

Read the file, then it shows the following strings:

- "host" - The mode is host now.
- "peripheral" - The mode is peripheral now.

/sys/devices/platform/HISI04Bx:00/chipX/all_linked
/sys/devices/platform/HISI04Bx:00/chipX/linked_full_lane
/sys/devices/platform/HISI04Bx:00/chipX/crc_err_cnt

Defined on file *sysfs-devices-platform-kunpeng_hccs*

The /sys/devices/platform/HISI04Bx:00/chipX/ directory contains read-only attributes exposing some summarization information of all HCCS ports under a specified chip. The X in 'chipX' indicates the Xth chip on platform.

There are following attributes in this directory:

all_linked:	(RO)	if all enabled ports on this chip are linked (bool).
linked_full_lane:	(RO)	if all linked ports on this chip are full lane (bool).
crc_err_cnt:	(RO)	total CRC err count for all ports on this chip.

/sys/devices/platform/HISI04Bx:00/chipX/dieY/all_linked
/sys/devices/platform/HISI04Bx:00/chipX/dieY/linked_full_lane
/sys/devices/platform/HISI04Bx:00/chipX/dieY/crc_err_cnt

Defined on file *sysfs-devices-platform-kunpeng_hccs*

The /sys/devices/platform/HISI04Bx:00/chipX/dieY/ directory contains read-only attributes exposing some summarization information of all HCCS ports under a specified die. The Y in 'dieY' indicates the hardware id of the die on chip who has chip id X.

There are following attributes in this directory:

all_linked:	(RO)	if all enabled ports on this die are linked (bool).
linked_full_lane:	(RO)	if all linked ports on this die are full lane (bool).
crc_err_cnt:	(RO)	total CRC err count for all ports on this die.

/sys/devices/platform/HISI04Bx:00/chipX/dieY/hccsN/type
/sys/devices/platform/HISI04Bx:00/chipX/dieY/hccsN/lane_mode
/sys/devices/platform/HISI04Bx:00/chipX/dieY/hccsN/enable
/sys/devices/platform/HISI04Bx:00/chipX/dieY/hccsN/cur_lane_num
/sys/devices/platform/HISI04Bx:00/chipX/dieY/hccsN/link_fsm
/sys/devices/platform/HISI04Bx:00/chipX/dieY/hccsN/lane_mask
/sys/devices/platform/HISI04Bx:00/chipX/dieY/hccsN/crc_err_cnt

Defined on file *sysfs-devices-platform-kunpeng_hccs*

The /sys/devices/platform/HISI04Bx/chipX/dieX/hccsN/ directory contains read-only attributes exposing information about a HCCS port. The N value in 'hccsN' indicates this port id. The X in 'chipX' indicates the ID of the chip to which the HCCS port belongs. For example, X ranges from to 'n - 1' if the chip number on platform is n. The Y in 'dieY' indicates the hardware id of the die to which the hccs port belongs. Note: type, lane_mode and enable are fixed attributes on running platform.

The HCCS port have the following attributes:

type:	(RO)	port type (string), e.g. HCCS-v1 -> H32
lane_mode:	(RO)	the lane mode of this port (string), e.g. x8
enable:	(RO)	indicate if this port is enabled (bool).
cur_lane_num:	(RO)	current lane number of this port.
link_fsm:	(RO)	link finite state machine of this port.
lane_mask:	(RO)	current lane mask of this port, every bit indicates a lane.
crc_err_cnt:	(RO)	CRC err count on this port.

/sys/devices/platform/_UDC_/gadget/gadget-lunX/nofua

Defined on file *sysfs-devices-platform-_UDC_-gadget*

Show or set the reaction on the FUA (Force Unit Access) bit in the SCSI WRITE(10,12) commands when a gadget in USB Mass Storage mode.

Possible values are:

- 1 -> ignore the FUA flag
- 0 -> obey the FUA flag

/sys/devices/platform/_UDC_/gadget/suspended

Defined on file *sysfs-devices-platform-_UDC_-gadget*

Show the suspend state of an USB composite gadget.

- 1 -> suspended
- 0 -> resumed

(_UDC_ is the name of the USB Device Controller driver)

/sys/devices/platform/amba_pl/<dev>/dis_block_break

Defined on file *sysfs-driver-xilinx-tmr-manager*

Write any value to it, This control file enables the break signal. This file is write only. Example: # echo <any value> > /sys/devices/platform/amba_pl/44a10000.tmr_manager/dis_block_break

/sys/devices/platform/amba_pl/<dev>/errcnt

Defined on file *sysfs-driver-xilinx-tmr-manager*

This control file provides the fault detection count. This file cannot be written. Example: # cat /sys/devices/platform/amba_pl/44a10000.tmr_manager/errcnt 1

/sys/devices/platform/asus_laptop/bluetooth

Defined on file *sysfs-platform-asus-laptop*

Control the bluetooth device. 1 means on, 0 means off. This may control the led, the device or both.

Users: Lapsus

/sys/devices/platform/asus_laptop/display

Defined on file *sysfs-platform-asus-laptop*

This file allows display switching. The value is composed by 4 bits and defined as follow:

```
4321
|||`- LCD
||`-- CRT
|`--- TV
`---- DVI
```

Ex:

- 0 (0000b) means no display
- 3 (0011b) CRT+LCD.

/sys/devices/platform/asus_laptop/gps

Defined on file *sysfs-platform-asus-laptop*

Control the gps device. 1 means on, 0 means off.

Users: Lapsus

/sys/devices/platform/asus_laptop/ledd

Defined on file *sysfs-platform-asus-laptop*

Some models like the W1N have a LED display that can be used to display several items of information. To control the LED display, use the following:

```
echo 0x0T000DDD > /sys/devices/platform/asus_laptop/
```

where T control the 3 letters display, and DDD the 3 digits display. The DDD table can be found in *Asus Laptop Extras*

/sys/devices/platform/asus_laptop/wimax

Defined on file *sysfs-platform-asus-laptop*

Control the wimax device. 1 means on, 0 means off.

/sys/devices/platform/asus_laptop/wlan

Defined on file *sysfs-platform-asus-laptop*

Control the wlan device. 1 means on, 0 means off. This may control the led, the device or both.

Users: Lapsus

/sys/devices/platform/asus_laptop/wwan

Defined on file *sysfs-platform-asus-laptop*

Control the wwan (3G) device. 1 means on, 0 means off.

/sys/devices/platform/at91_can/net/<iface>/mb0_id

Defined on file *sysfs-platform-at91*

Value representing the can_id of mailbox 0.

Default: 0x7ff (standard frame)

Due to a chip bug (errata 50.2.6.3 & 50.3.5.3 in "AT91SAM9263 Preliminary 6249H-ATARM-27-Jul-09") the contents of mailbox 0 may be send under certain conditions (even if disabled or in rx mode).

The workaround in the errata suggests not to use the mailbox and load it with an unused identifier.

In order to use an extended can_id add the CAN_EFF_FLAG (0x80000000U) to the can_id. Example:

- standard id 0x7ff:

```
echo 0x7ff      > /sys/class/net/can0/mb0_id
```

- extended id 0x1fffffff:

```
echo 0x9fffffff > /sys/class/net/can0/mb0_id
```

/sys/devices/platform/dmi-ipmi-ssif.*/hosed
/sys/devices/platform/dmi-ipmi-ssif.*/alerts
/sys/devices/platform/dmi-ipmi-ssif.*/sent_messages
/sys/devices/platform/dmi-ipmi-ssif.*/sent_messages_parts
/sys/devices/platform/dmi-ipmi-ssif.*/received_messages
/sys/devices/platform/dmi-ipmi-ssif.*/received_message_parts
/sys/devices/platform/dmi-ipmi-ssif.*/events
/sys/devices/platform/dmi-ipmi-ssif.*/watchdog_pretimeouts
/sys/devices/platform/dmi-ipmi-ssif.*/flag_fetches

/sys/devices/platform/dmi-ipmi-ssif.*/receive_retries
/sys/devices/platform/dmi-ipmi-ssif.*/send_errors
/sys/devices/platform/dmi-ipmi-ssif.*/receive_errors

Defined on file *sysfs-devices-platform-ipmi*

hosed	(RO) Number of times the hardware didn't follow the state machine.
alerts	(RO) Number of alerts received.
sent_messages	(RO) Number of total messages sent.
sent_message_parts	(RO) Number of message parts sent. Messages may be broken into parts if they are long.
received_messages	(RO) Number of message responses received.
received_message_parts	(RO) Number of message fragments received.
events	(RO) Number of received events.
watchdog_pretimeouts	(RO) Number of watchdog pretimeouts.
flag_fetches	(RO) Number of times a flag fetch was requested.
send_retries	(RO) Number of time a message was retried.
receive_retries	(RO) Number of times the receive of a message was retried.
send_errors	(RO) Number of times the send of a message failed.
receive_errors	(RO) Number of errors in receiving messages.

/sys/devices/platform/dmi-ipmi-ssif.*/type

Defined on file *sysfs-devices-platform-ipmi*

(RO) Shows the IMPI device interface type - ”ssif” here.

/sys/devices/platform/docg3/f[0-3]_dps[01]_is_keylocked

Defined on file *sysfs-devices-platform-docg3*

Show whether the floor (0 to 4), protection area (0 or 1) is keylocked. Each docg3 chip (or floor) has 2 protection areas, which can cover any part of it, block aligned, called DPS. The protection has information embedded whether it blocks reads, writes or both. The result is:

- 0 -> the DPS is not keylocked
- 1 -> the DPS is keylocked

Users: None identified so far.

/sys/devices/platform/docg3/f[0-3]_dps[01]_protection_key

Defined on file *sysfs-devices-platform-docg3*

Enter the protection key for the floor (0 to 4), protection area (0 or 1). Each docg3 chip (or floor) has 2 protection areas, which can cover any part of it, block aligned, called DPS. The protection has information embedded whether it blocks reads, writes or both. The protection key is a string of 8 bytes (value 0-255). Entering the correct value toggle the lock, and can be observed through f[0-3]_dps[01]_is_keylocked. Possible values are:

- 8 bytes

Typical values are:

- "00000000"
- "12345678"

Users: None identified so far.

/sys/devices/platform/dock.<N>/docked

Defined on file *sysfs-devices-platform-dock*

(RO) Value 1 or 0 indicates whether the software believes the laptop is docked in a docking station.

/sys/devices/platform/dock.<N>/flags

Defined on file *sysfs-devices-platform-dock*

(RO) Show dock station flags, useful for checking if undock request has been made by the user (from the immediate_undock option).

/sys/devices/platform/dock.<N>/type

Defined on file *sysfs-devices-platform-dock*

(RO) Display the dock station type- dock_station, ata_bay or battery_bay.

/sys/devices/platform/dock.<N>/uid

Defined on file *sysfs-devices-platform-dock*

(RO) Displays the docking station the laptop is docked to.

/sys/devices/platform/dock.<N>/undock

Defined on file *sysfs-devices-platform-dock*

(WO) Writing to this file causes the software to initiate an undock request to the firmware.

/sys/devices/platform/eeepc/available_cpufv

Defined on file *sysfs-platform-eeepc-laptop*

List available cpufv modes.

/sys/devices/platform/eeepc/camera

Defined on file *sysfs-platform-eeepc-laptop*

Control the camera. 1 means on, 0 means off.

/sys/devices/platform/eeepc/cardr

Defined on file *sysfs-platform-eeepc-laptop*

Control the card reader. 1 means on, 0 means off.

/sys/devices/platform/eeepc/cpufv

Defined on file *sysfs-platform-eeepc-laptop*

Change CPU clock configuration. On the Eee PC 1000H there are three available clock configuration:

- 0 -> Super Performance Mode
- 1 -> High Performance Mode
- 2 -> Power Saving Mode

On Eee PC 701 there is only 2 available clock configurations. Available configuration are listed in available_cpufv file. Reading this file will show the raw hexadecimal value which is defined as follow:

```
| 8 bit | 8 bit |
    |       `---- Current mode
    `------------ Availables modes
```

For example, 0x301 means: mode 1 selected, 3 available modes.

/sys/devices/platform/eeepc/disp

Defined on file *sysfs-platform-eeepc-laptop*

This file allows display switching.

- 1 = LCD
- 2 = CRT
- 3 = LCD+CRT

If you run X11, you should use xrandr instead.

/sys/devices/platform/hidma-*/chid

Defined on file *sysfs-platform-hidma*

Contains the ID of the channel within the HIDMA instance. It is used to associate a given HIDMA channel with the priority and weight calls in the management interface.

/sys/devices/platform/hidma-mgmt*/chanops/chan*/priority

Defined on file *sysfs-platform-hidma-mgmt*

Contains either 0 or 1 and indicates if the DMA channel is a low priority (0) or high priority (1) channel.

/sys/devices/platform/hidma-mgmt*/chanops/chan*/weight

Defined on file *sysfs-platform-hidma-mgmt*

Contains 0..15 and indicates the weight of the channel among equal priority channels during round robin scheduling.

/sys/devices/platform/hidma-mgmt*/chreset_timeout_cycles

Defined on file *sysfs-platform-hidma-mgmt*

Contains the platform specific cycle value to wait after a reset command is issued. If the value is chosen too short, then the HW will issue a reset failure interrupt. The value is platform specific and should not be changed without consultance.

/sys/devices/platform/hidma-mgmt*/dma_channels

Defined on file *sysfs-platform-hidma-mgmt*

Contains the number of dma channels supported by one instance of HIDMA hardware. The value may change from chip to chip.

/sys/devices/platform/hidma-mgmt*/hw_version_major

Defined on file *sysfs-platform-hidma-mgmt*

Version number major for the hardware.

/sys/devices/platform/hidma-mgmt*/hw_version_minor

Defined on file *sysfs-platform-hidma-mgmt*

Version number minor for the hardware.

/sys/devices/platform/hidma-mgmt*/max_rd_xactions

Defined on file *sysfs-platform-hidma-mgmt*

Contains a value between 0 and 31. Maximum number of read transactions that can be issued back to back. Choosing a higher number gives better performance but can also cause performance reduction to other peripherals sharing the same bus.

/sys/devices/platform/hidma-mgmt*/max_read_request

Defined on file *sysfs-platform-hidma-mgmt*

Size of each read request. The value needs to be a power of two and can be between 128 and 1024.

/sys/devices/platform/hidma-mgmt*/max_wr_xactions

Defined on file *sysfs-platform-hidma-mgmt*

Contains a value between 0 and 31. Maximum number of write transactions that can be issued back to back. Choosing a higher number gives better performance but can also cause performance reduction to other peripherals sharing the same bus.

/sys/devices/platform/hidma-mgmt*/max_write_request

Defined on file *sysfs-platform-hidma-mgmt*

Size of each write request. The value needs to be a power of two and can be between 128 and 1024.

/sys/devices/platform/i8042/.../draghys

Defined on file *sysfs-devices-platform-trackpoint*

(RW) The drag hysteresis controls how hard it is to drag with z-axis pressed.

/sys/devices/platform/i8042/.../drift_time

Defined on file *sysfs-devices-platform-trackpoint*

(RW) This parameter controls the period of time to test for a 'hands off' condition (i.e. when no force is applied) before a drift (noise) calibration occurs.

IBM Trackpoints have a feature to compensate for drift by recalibrating themselves periodically. By default, if for 0.5 seconds there is no change in position, it's used as the new zero. This duration is too low. Often, the calibration happens when the trackpoint is in fact being used.

/sys/devices/platform/i8042/.../ext_dev

Defined on file *sysfs-devices-platform-trackpoint*

(RW) Disable (0) or enable (1) external pointing device.

/sys/devices/platform/i8042/.../intertia

Defined on file *sysfs-devices-platform-trackpoint*

(RW) Negative inertia factor. High values cause the cursor to snap backward when the trackpoint is released.

/sys/devices/platform/i8042/.../jenks

Defined on file *sysfs-devices-platform-trackpoint*

(RW) Minimum curvature in degrees required to generate a double click without a release.

/sys/devices/platform/i8042/.../mindrag

Defined on file *sysfs-devices-platform-trackpoint*

(RW) Minimum amount of force needed to trigger dragging.

/sys/devices/platform/i8042/.../press_to_select

Defined on file *sysfs-devices-platform-trackpoint*

(RW) Writing a value of 1 to this file will enable the Press to Select functions like tapping the control stick to simulate a left click, and writing 0 will disable it.

/sys/devices/platform/i8042/.../reach

Defined on file *sysfs-devices-platform-trackpoint*

(RW) Backup range for z-axis press.

/sys/devices/platform/i8042/.../sensitivity

Defined on file *sysfs-devices-platform-trackpoint*

(RW) Trackpoint sensitivity.

/sys/devices/platform/i8042/.../skipback

Defined on file *sysfs-devices-platform-trackpoint*

(RW) When the skipback bit is set, backup cursor movement during releases from drags will be suppressed. The default value for this bit is 0.

/sys/devices/platform/i8042/.../speed

Defined on file *sysfs-devices-platform-trackpoint*

(RW) Speed of the trackpoint cursor.

/sys/devices/platform/i8042/.../thresh

Defined on file *sysfs-devices-platform-trackpoint*

(RW) Minimum value for z-axis force required to trigger a press or release, relative to the running average.

/sys/devices/platform/i8042/.../upthresh

Defined on file *sysfs-devices-platform-trackpoint*

(RW) The offset from the running average required to generate a select (click) on z-axis on release.

/sys/devices/platform/i8042/.../ztime

Defined on file *sysfs-devices-platform-trackpoint*

(RW) This attribute determines how sharp a press has to be in order to be recognized.

/sys/devices/platform/ipmi_bmc.*/additional_device_support

Defined on file *sysfs-devices-platform-ipmi*

(RO) Lists the IPMI 'logical device' commands and functions that the controller supports that are in addition to the mandatory IPM and Application commands.

/sys/devices/platform/ipmi_bmc.*/aux_firmware_revision

Defined on file *sysfs-devices-platform-ipmi*

(RO) Holds additional information about the firmware revision, such as boot block or internal data structure version numbers. The meanings of the numbers are specific to the vendor identified by Manufacturer ID.

/sys/devices/platform/ipmi_bmc.*/device_id

Defined on file *sysfs-devices-platform-ipmi*

(RO) Device id is specified by the manufacturer identified by the Manufacturer ID field. This field allows controller specific software to identify the unique application command, OEM fields, and functionality that are provided by the controller

/sys/devices/platform/ipmi_bmc.*/firmware_revision

Defined on file *sysfs-devices-platform-ipmi*

(RO) The major and minor revision of the firmware.

/sys/devices/platform/ipmi_bmc.*/guid

Defined on file *sysfs-devices-platform-ipmi*

(RO) A GUID (Globally Unique ID), also referred to as a UUID (Universally Unique Identifier), for the management controller, as described in section 20.8 'Get Device GUID Command' of the IPMI specification v2.0.

/sys/devices/platform/ipmi_bmc.*/ipmi_version

Defined on file *sysfs-devices-platform-ipmi*

(RO) Displays the IPMI Command Specification Version.

/sys/devices/platform/ipmi_bmc.*/manufacturer_id

Defined on file *sysfs-devices-platform-ipmi*

(RO) Identifies the manufacturer responsible for the specification of functionality of the vendor (OEM)-specific commands, codes, and interfaces used in the controller.

/sys/devices/platform/ipmi_bmc.*/product_id

Defined on file *sysfs-devices-platform-ipmi*

(RO) Displays a number that identifies a particular system, module, add-in card, or board set. The number is specified according to the manufacturer given by Manufacturer ID.

For detailed definitions of the above attributes, refer to section 20.1 'Get Device ID Command' of the IPMI specification v2.0.

/sys/devices/platform/ipmi_bmc.*/provides_device_sdrs

Defined on file *sysfs-devices-platform-ipmi*

(RO) Indicates whether device provides device sensor data records (1) or not (0).

/sys/devices/platform/ipmi_bmc.*/revision

Defined on file *sysfs-devices-platform-ipmi*

(RO) Device revision. Useful for identifying if significant hardware changes have been made to the implementation of the management controller.

/sys/devices/platform/ipmi_si.*/idles
/sys/devices/platform/ipmi_si.*/watchdog_pretimeouts
/sys/devices/platform/ipmi_si.*/complete_transactions
/sys/devices/platform/ipmi_si.*/events
/sys/devices/platform/ipmi_si.*/interrupts
/sys/devices/platform/ipmi_si.*/hosed_count
/sys/devices/platform/ipmi_si.*/long_timeouts
/sys/devices/platform/ipmi_si.*/flag_fetches
/sys/devices/platform/ipmi_si.*/attentions
/sys/devices/platform/ipmi_si.*/incoming_messages
/sys/devices/platform/ipmi_si.*/short_timeouts

Defined on file *sysfs-devices-platform-ipmi*

idles	(RO) Number of times the interface was idle while being polled.
watchdog_pretimeouts	(RO) Number of watchdog pretimeouts.
complete_transactions	(RO) Number of completed messages.
events	(RO) Number of IPMI events received from the hardware.
interrupts	(RO) Number of interrupts the driver handled.
hosed_count	(RO) Number of times the hardware didn't follow the state machine.
long_timeouts	(RO) Number of times the driver requested a timer while nothing was in progress.
flag_fetches	(RO) Number of times the driver requested flags from the hardware.
attentions	(RO) Number of time the driver got an ATTN from the hardware.
incoming_messages	(RO) Number of asynchronous messages received.
short_timeouts	(RO) Number of times the driver requested a timer while an operation was in progress.

/sys/devices/platform/ipmi_si.*/interrupts_enabled

Defined on file *sysfs-devices-platform-ipmi*

(RO) Indicates whether interrupts are enabled or not. The driver disables interrupts when it gets into a situation where it cannot handle messages due to lack of memory. Once that situation clears up, it will re-enable interrupts.

/sys/devices/platform/ipmi_si.*/params

Defined on file *sysfs-devices-platform-ipmi*

[to be documented]

/sys/devices/platform/ipmi_si.*/type

Defined on file *sysfs-devices-platform-ipmi*

(RO) The device interface for IPMI ”kcs”, ”smic”, ”bt” or ”invalid”

/sys/devices/platform/kim/baud_rate

Defined on file *sysfs-platform-kim*

The maximum reliable baud-rate the host can support. Different platforms tend to have different high-speed UART configurations, so the baud-rate needs to be set locally and also sent across to the WL128x via a HCI-VS command. The entry is read and made use by the user-space daemon when the ldisc install is requested.

/sys/devices/platform/kim/dev_name

Defined on file *sysfs-platform-kim*

Name of the UART device at which the WL128x chip is connected. example: ”/dev/ttyS0”.

The device name flows down to architecture specific board initialization file from the ATAGS bootloader firmware. The name exposed is read from the user-space daemon and opens the device when install is requested.

/sys/devices/platform/kim/flow_cntrl

Defined on file *sysfs-platform-kim*

The WL128x makes use of flow control mechanism, and this entry most often should be 1, the host's UART is required to have the capability of flow-control, or else this entry can be made use of for exceptions.

/sys/devices/platform/kim/install

Defined on file *sysfs-platform-kim*

When one of the protocols Bluetooth, FM or GPS wants to make use of the shared UART transport, it registers to the shared transport driver, which will signal the user-space for opening, configuring baud and install line discipline via this sysfs entry. This entry would be polled upon by the user-space daemon managing the UART, and is notified about the change by the sysfs_notify. The value would be '1' when UART needs to be opened/ldisc installed, and would be '0' when UART is no more required and needs to be closed.

/sys/devices/platform/lg-laptop/battery_care_limit

Defined on file *sysfs-platform-lg-laptop*

Deprecated use /sys/class/power_supply/CMB0/charge_control_end_threshold Maximal battery charge level. Accepted values are 80 or 100.

/sys/devices/platform/lg-laptop/fan_mode

Defined on file *sysfs-platform-lg-laptop*

Control fan mode. 1 for performance mode, 0 for silent mode.

/sys/devices/platform/lg-laptop/fn_lock

Defined on file *sysfs-platform-lg-laptop*

Control FN lock mode. 1 means on, 0 means off.

/sys/devices/platform/lg-laptop/reader_mode

Defined on file *sysfs-platform-lg-laptop*

Control reader mode. 1 means on, 0 means off.

/sys/devices/platform/lg-laptop/usb_charge

Defined on file *sysfs-platform-lg-laptop*

Control USB port charging when device is turned off. 1 means on, 0 means off.

/sys/devices/platform/msi-laptop-pf/auto_brightness

Defined on file *sysfs-platform-msi-laptop*

Enable automatic brightness control: contains either 0 or 1. If set to 1 the hardware adjusts the screen brightness automatically when the power cord is plugged/unplugged.

/sys/devices/platform/msi-laptop-pf/auto_fan

Defined on file *sysfs-platform-msi-laptop*

Contains either 0 or 1 and indicates if fan speed is controlled automatically (1) or fan runs at maximal speed (0). Can be toggled in software.

/sys/devices/platform/msi-laptop-pf/bluetooth

Defined on file *sysfs-platform-msi-laptop*

Bluetooth subsystem enabled: contains either 0 or 1. Please note that this file is constantly 0 if no Bluetooth hardware is available.

/sys/devices/platform/msi-laptop-pf/eco_mode

Defined on file *sysfs-platform-msi-laptop*

Contains either 0 or 1 and indicates if ECO mode is turned on. In ECO mode power LED is green and userspace should do some powersaving actions. ECO mode is available only on battery power. ECO mode can only be toggled by pressing Fn+F10.

/sys/devices/platform/msi-laptop-pf/lcd_level

Defined on file *sysfs-platform-msi-laptop*

Screen brightness: contains a single integer in the range 0..8.

/sys/devices/platform/msi-laptop-pf/touchpad

Defined on file *sysfs-platform-msi-laptop*

Contains either 0 or 1 and indicates if touchpad is turned on. Touchpad state can only be toggled by pressing Fn+F3.

/sys/devices/platform/msi-laptop-pf/turbo_cooldown

Defined on file *sysfs-platform-msi-laptop*

Contains value in range 0..3:

- 0 -> Turbo mode is off
- 1 -> Turbo mode is on, cannot be turned off yet

- 2 -> Turbo mode is off, cannot be turned on yet
- 3 -> Turbo mode is on

/sys/devices/platform/msi-laptop-pf/turbo_mode

Defined on file *sysfs-platform-msi-laptop*

Contains either 0 or 1 and indicates if turbo mode is turned on. In turbo mode power LED is orange and processor is overclocked. Turbo mode is available only if charging. It is only possible to toggle turbo mode state by pressing Fn+F10, and there is a few seconds cooldown between subsequent toggles. If user presses Fn+F10 too frequent, turbo mode state is not changed.

/sys/devices/platform/msi-laptop-pf/wlan

Defined on file *sysfs-platform-msi-laptop*

WLAN subsystem enabled: contains either 0 or 1.

/sys/devices/platform/samsung/battery_life_extender

Defined on file *sysfs-driver-samsung-laptop*

Max battery charge level can be modified, battery cycle life can be extended by reducing the max battery charge level.

- 0 means normal battery mode (100% charge)
- 1 means battery life extender mode (80% charge)

/sys/devices/platform/samsung/lid_handling

Defined on file *sysfs-driver-samsung-laptop*

Some Samsung laptops handle lid closing quicker and only handle lid opening with this mode enabled. 1 means enabled, 0 means disabled.

/sys/devices/platform/samsung/performance_level

Defined on file *sysfs-driver-samsung-laptop*

Some Samsung laptops have different ”performance levels” that can be modified by a function key, and by this sysfs file. These values don't always make a whole lot of sense, but some users like to modify them to keep their fans quiet at all costs. Reading from this file will show the current performance level. Writing to the file can change this value.

Valid options:

- ”silent”
- ”normal”
- ”overclock”

Note that not all laptops support all of these options. Specifically, not all support the "overclock" option, and it's still unknown if this value even changes anything, other than making the user feel a bit better.

/sys/devices/platform/samsung/usb_charge

Defined on file *sysfs-driver-samsung-laptop*

Use your USB ports to charge devices, even when your laptop is powered off. 1 means enabled, 0 means disabled.

/sys/devices/platform/sh_mobile_lcdc_fb.[0-3]/graphics/fb[0-9]/ovl_alpha

Defined on file *sysfs-devices-platform-sh_mobile_lcdc_fb*

This file is only available on fb[0-9] devices corresponding to overlay planes.

Stores the alpha blending value for the overlay. Values range from 0 (transparent) to 255 (opaque). The value is ignored if the mode is not set to Alpha Blending.

/sys/devices/platform/sh_mobile_lcdc_fb.[0-3]/graphics/fb[0-9]/ovl_mode

Defined on file *sysfs-devices-platform-sh_mobile_lcdc_fb*

This file is only available on fb[0-9] devices corresponding to overlay planes.

Selects the composition mode for the overlay. Possible values are:

- 0 - Alpha Blending
- 1 - ROP3

/sys/devices/platform/sh_mobile_lcdc_fb.[0-3]/graphics/fb[0-9]/ovl_position

Defined on file *sysfs-devices-platform-sh_mobile_lcdc_fb*

This file is only available on fb[0-9] devices corresponding to overlay planes.

Stores the x,y overlay position on the display in pixels. The position format is *[0-9]+,[0-9]+*.

/sys/devices/platform/sh_mobile_lcdc_fb.[0-3]/graphics/fb[0-9]/ovl_rop3

Defined on file *sysfs-devices-platform-sh_mobile_lcdc_fb*

This file is only available on fb[0-9] devices corresponding to overlay planes.

Stores the raster operation (ROP3) for the overlay. Values range from 0 to 255. The value is ignored if the mode is not set to ROP3.

/sys/devices/platform/silicom-platform/efuse_status

Defined on file *sysfs-platform-silicom*

This file is read only. It returns the current OTP status:

0 - not programmed. 1 - programmed.

/sys/devices/platform/silicom-platform/power_cycle

Defined on file *sysfs-platform-silicom*

This file allow user to power cycle the platform. Default value is 0; when set to 1, it powers down the platform, waits 5 seconds, then powers on the device. It returns to default value after power cycle.

0 - default value.

/sys/devices/platform/silicom-platform/uc_version

Defined on file *sysfs-platform-silicom*

This file allows to read microcontroller firmware version of current platform.

/sys/devices/platform/soc@X/XXXXXXX.ipa/

Defined on file *sysfs-devices-platform-soc-ipa*

The /sys/devices/platform/soc@X/XXXXXXX.ipa/ directory contains read-only attributes exposing information about an IPA device. The X values could vary, but are typically "soc@0/1e40000.ipa".

/sys/devices/platform/stratix10-rsu.0/current_image

Defined on file *sysfs-devices-platform-stratix10-rsu*

(RO) the address in flash of currently running image.

/sys/devices/platform/stratix10-rsu.0/dcmf0

Defined on file *sysfs-devices-platform-stratix10-rsu*

(RO) Decision firmware copy 0 version information.

/sys/devices/platform/stratix10-rsu.0/dcmf1

Defined on file *sysfs-devices-platform-stratix10-rsu*

(RO) Decision firmware copy 1 version information.

/sys/devices/platform/stratix10-rsu.0/dcmf2

Defined on file *sysfs-devices-platform-stratix10-rsu*

(RO) Decision firmware copy 2 version information.

/sys/devices/platform/stratix10-rsu.0/dcmf3

Defined on file *sysfs-devices-platform-stratix10-rsu*

(RO) Decision firmware copy 3 version information.

/sys/devices/platform/stratix10-rsu.0/error_details

Defined on file *sysfs-devices-platform-stratix10-rsu*

(RO) error code.

/sys/devices/platform/stratix10-rsu.0/error_location

Defined on file *sysfs-devices-platform-stratix10-rsu*

(RO) the error offset inside the image that failed.

/sys/devices/platform/stratix10-rsu.0/fail_image

Defined on file *sysfs-devices-platform-stratix10-rsu*

(RO) the address in flash of failed image.

/sys/devices/platform/stratix10-rsu.0/max_retry

Defined on file *sysfs-devices-platform-stratix10-rsu*

(RO) max retry parameter is stored in the firmware decision IO section, as a byte located at offset 0x18c.

/sys/devices/platform/stratix10-rsu.0/notify

Defined on file *sysfs-devices-platform-stratix10-rsu*

(WO) client to notify firmware with different actions.

b[15:0]
inform firmware the current software execution stage.

0	the first stage bootloader didn't run or didn't reach the point of launching second stage bootloader.
1	failed in second bootloader or didn't get to the point of launching the operating system.
2	both first and second stage bootloader ran and the operating system launch was attempted.

b[16]

1	firmware to reset current image retry counter.
0	no action.

b[17]

1	firmware to clear RSU log
0	no action.

b[18]
this is negative logic

1	no action
0	firmware record the notify code defined in b[15:0].

/sys/devices/platform/stratix10-rsu.0/reboot_image

Defined on file *sysfs-devices-platform-stratix10-rsu*

(WO) the address in flash of image to be loaded on next reboot command.

/sys/devices/platform/stratix10-rsu.0/retry_counter

Defined on file *sysfs-devices-platform-stratix10-rsu*

(RO) the current image's retry counter, which is used by user to know how many times the images is still allowed to reload itself before giving up and starting RSU fail-over flow.

/sys/devices/platform/stratix10-rsu.0/state

Defined on file *sysfs-devices-platform-stratix10-rsu*

(RO) the state of RSU system. The state field has two parts: major error code in upper 16 bits and minor error code in lower 16 bits.

b[15:0]
Currently used only when major error is 0xF006 (CPU watchdog timeout), in which case the minor error code is the value reported by CPU to firmware through the RSU notify command before the watchdog timeout occurs.

b[31:16]
0xF001 bitstream error 0xF002 hardware access failure 0xF003 bitstream corruption 0xF004 internal error 0xF005 device error 0xF006 CPU watchdog timeout 0xF007 internal unknown error

/sys/devices/platform/stratix10-rsu.0/version

Defined on file *sysfs-devices-platform-stratix10-rsu*

(RO) the version number of RSU firmware. 19.3 or late version includes information about the firmware which reported the error.

pre 19.3:

b[31:0]
0x0 version number

19.3 or late:

b[15:0]
0x1 version number

b[31:16]
0x0 no error 0x0DCF Decision CMF error 0x0ACF Application CMF error

/sys/devices/platform/ts5500/adc

Defined on file *sysfs-platform-ts5500*

Indicates the presence of an A/D Converter. If it is present, it will display "1", otherwise "0".

/sys/devices/platform/ts5500/ereset

Defined on file *sysfs-platform-ts5500*

Indicates the presence of an external reset. If it is present, it will display "1", otherwise "0".

/sys/devices/platform/ts5500/id

Defined on file *sysfs-platform-ts5500*

Product ID of the TS board. TS-5500 ID is 0x60.

/sys/devices/platform/ts5500/jumpers

Defined on file *sysfs-platform-ts5500*

Bitfield showing the jumpers' state. If a jumper is present, the corresponding bit is set. For instance, 0x0e means jumpers 2, 3 and 4 are set.

/sys/devices/platform/ts5500/name

Defined on file *sysfs-platform-ts5500*

Model name of the TS board, e.g. "TS-5500".

/sys/devices/platform/ts5500/rs485

Defined on file *sysfs-platform-ts5500*

Indicates the presence of the RS485 option. If it is present, it will display "1", otherwise "0".

/sys/devices/platform/ts5500/sram

Defined on file *sysfs-platform-ts5500*

Indicates the presence of the SRAM option. If it is present, it will display "1", otherwise "0".

/sys/devices/platform/usbip-vudc.%d/dev_desc

Defined on file *sysfs-platform-usbip-vudc*

This file allows to read device descriptor of gadget driver which is currently bound to this controller. It is possible to read this file only if gadget driver is bound, otherwise error is returned.

/sys/devices/platform/usbip-vudc.%d/usbip_sockfd

Defined on file *sysfs-platform-usbip-vudc*

This file allows to export usb device to connection peer. It is done by writing to this file socket fd (as a string for example "8") associated with a connection to remote peer who would like to use this device. It is possible to close the connection by writing -1 instead of socked fd.

/sys/devices/platform/usbip-vudc.%d/usbip_status

Defined on file *sysfs-platform-usbip-vudc*

Current status of the device. Allowed values:

1	Device is available and can be exported
2	Device is currently exported
3	Fatal error occurred during communication with peer

/sys/devices/socX

Defined on file *sysfs-devices-soc*

The /sys/devices/ directory contains a sub-directory for each System-on-Chip (SoC) device on a running platform. Information regarding each SoC can be obtained by reading sysfs files. This functionality is only available if implemented by the platform.

The directory created for each SoC will also house information about devices which are commonly contained in /sys/devices/platform. It has been agreed that if an SoC device exists, its supported devices would be better suited to appear as children of that SoC.

/sys/devices/socX/family

Defined on file *sysfs-devices-soc*

Read-only attribute common to all SoCs. Contains SoC family name (e.g. DB8500).

On many of ARM based silicon with SMCCC v1.2+ compliant firmware this will contain the JEDEC JEP106 manufacturer's identification code. The format is "jep106:XXYY" where XX is identity code and YY is continuation code.

This manufacturer's identification code is defined by one or more eight (8) bit fields, each consisting of seven (7) data bits plus one (1) odd parity bit. It is a single field, limiting the possible number of vendors to 126. To expand the maximum number of identification codes, a continuation scheme has been defined.

The specified mechanism is that an identity code of 0x7F represents the "continuation code" and implies the presence of an additional identity code field, and this mechanism may be extended to multiple continuation codes followed by the manufacturer's identity code.

For example, ARM has identity code 0x7F 0x7F 0x7F 0x7F 0x3B, which is code 0x3B on the fifth 'page'. This is shortened as JEP106 identity code of 0x3B and a continuation code of 0x4 to represent the four continuation codes preceding the identity code.

/sys/devices/socX/machine

Defined on file *sysfs-devices-soc*

Read-only attribute common to all SoCs. Contains the SoC machine name (e.g. Ux500).

/sys/devices/socX/process

Defined on file *sysfs-devices-soc*

Read-only attribute supported ST-Ericsson's silicon. Contains the the process by which the silicon chip was manufactured.

/sys/devices/socX/revision

Defined on file *sysfs-devices-soc*

Read-only attribute supported by most SoCs. Contains the SoC's manufacturing revision number.

/sys/devices/socX/serial_number

Defined on file *sysfs-devices-soc*

Read-only attribute supported by most SoCs. Contains the SoC's serial number, if available.

/sys/devices/socX/soc_id

Defined on file *sysfs-devices-soc*

Read-only attribute supported by most SoCs. In the case of ST-Ericsson's chips this contains the SoC serial number.

On many of ARM based silicon with SMCCC v1.2+ compliant firmware this will contain the SOC ID appended to the family attribute to ensure there is no conflict in this namespace across various vendors. The format is "jep106:XXYY:ZZZZ" where XX is identity code, YY is continuation code and ZZZZ is the SOC ID.

/sys/devices/system/cpu/

Defined on file *sysfs-devices-system-cpu*

A collection of both global and individual CPU attributes

Individual CPU attributes are contained in subdirectories named by the kernel's logical CPU number, e.g.:

/sys/devices/system/cpu/cpuX/

/sys/devices/system/cpu/aarch32_el0

Defined on file *sysfs-devices-system-cpu*

Identifies the subset of CPUs in the system that can execute AArch32 (32-bit ARM) applications. If present, the same format as /sys/devices/system/cpu/{offline,online,possible,present} is used. If absent, then all or none of the CPUs can execute AArch32 applications and execve() will behave accordingly.

/sys/devices/system/cpu/cpu*/cache/index*/<set_of_attributes_mentioned_below>

Defined on file *sysfs-devices-system-cpu*

Parameters for the CPU cache attributes

allocation_policy:

- **WriteAllocate:**
  allocate a memory location to a cache line on a cache miss because of a write
- **ReadAllocate:**
  allocate a memory location to a cache line on a cache miss because of a read
- **ReadWriteAllocate:**
  both writeallocate and readallocate

coherency_line_size:
the minimum amount of data in bytes that gets transferred from memory to cache

level:
the cache hierarchy in the multi-level cache configuration

number_of_sets:
total number of sets in the cache, a set is a collection of cache lines with the same cache index

physical_line_partition:
number of physical cache line per cache tag

shared_cpu_list:
the list of logical cpus sharing the cache

shared_cpu_map:
logical cpu mask containing the list of cpus sharing the cache

size:
the total cache size in kB

type:

- Instruction: cache that only holds instructions
- Data: cache that only caches data

- Unified: cache that holds both data and instructions

ways_of_associativity:
degree of freedom in placing a particular block of memory in the cache

write_policy:

- **WriteThrough:**
  data is written to both the cache line and to the block in the lower-level memory
- **WriteBack:**
  data is written only to the cache line and the modified cache line is written to main memory only when it is replaced

/sys/devices/system/cpu/cpu*/cache/index*/id

Defined on file *sysfs-devices-system-cpu*

Cache id

The id provides a unique number for a specific instance of a cache of a particular type. E.g. there may be a level 3 unified cache on each socket in a server and we may assign them ids 0, 1, 2, ...

Note that id value can be non-contiguous. E.g. level 1 caches typically exist per core, but there may not be a power of two cores on a socket, so these caches may be numbered 0, 1, 2, 3, 4, 5, 8, 9, 10, ...

/sys/devices/system/cpu/cpu*/cache/index3/cache_disable_{0,1}

Defined on file *sysfs-devices-system-cpu*

Disable L3 cache indices

These files exist in every CPU's cache/index3 directory. Each cache_disable_{0,1} file corresponds to one disable slot which can be used to disable a cache index. Reading from these files on a processor with this functionality will return the currently disabled index for that node. There is one L3 structure per node, or per internal node on MCM machines. Writing a valid index to one of these files will cause the specified cache index to be disabled.

All AMD processors with L3 caches provide this functionality. For details, see BKDGs at https://www.amd.com/en/support/tech-docs?keyword=bios+kernel

/sys/devices/system/cpu/cpuX/cpu_capacity

Defined on file *sysfs-devices-system-cpu*

information about CPUs heterogeneity.

cpu_capacity: capacity of cpuX.

/sys/devices/system/cpu/cpuX/cpufreq/*

Defined on file *sysfs-devices-system-cpu*

Discover and change clock speed of CPUs

Clock scaling allows you to change the clock speed of the CPUs on the fly. This is a nice method to save battery power, because the lower the clock speed, the less power the CPU consumes.

There are many knobs to tweak in this directory.

See files in Documentation/cpu-freq/ for more information.

/sys/devices/system/cpu/cpuX/cpufreq/freqdomain_cpus

Defined on file *sysfs-devices-system-cpu*

Discover CPUs in the same CPU frequency coordination domain

freqdomain_cpus is the list of CPUs (online+offline) that share the same clock/freq domain (possibly at the hardware level). That information may be hidden from the cpufreq core and the value of related_cpus may be different from freqdomain_cpus. This attribute is useful for user space DVFS controllers to get better power/performance results for platforms using acpi-cpufreq.

This file is only present if the acpi-cpufreq or the cppc-cpufreq drivers are in use.

/sys/devices/system/cpu/cpuX/cpufreq/throttle_stats

Defined on file *sysfs-devices-system-cpu*

POWERNV CPUFreq driver's frequency throttle stats directory and attributes

'cpuX/cpufreq/throttle_stats' directory contains the CPU frequency throttle stat attributes for the chip. The throttle stats of a cpu is common across all the cpus belonging to a chip. Below are the throttle attributes exported in the 'throttle_stats' directory:

- turbo_stat : This file gives the total number of times the max frequency is throttled to lower frequency in turbo (at and above nominal frequency) range of frequencies.
- sub_turbo_stat : This file gives the total number of times the max frequency is throttled to lower frequency in sub-turbo(below nominal frequency) range of frequencies.
- unthrottle : This file gives the total number of times the max frequency is unthrottled after being throttled.
- powercap : This file gives the total number of times the max frequency is throttled due to 'Power Capping'.
- overtemp : This file gives the total number of times the max frequency is throttled due to 'CPU Over Temperature'.
- supply_fault : This file gives the total number of times the max frequency is throttled due to 'Power Supply Failure'.
- overcurrent : This file gives the total number of times the max frequency is throttled due to 'Overcurrent'.
- occ_reset : This file gives the total number of times the max frequency is throttled due to 'OCC Reset'.

The sysfs attributes representing different throttle reasons like powercap, overtemp, supply_fault, overcurrent and occ_reset map to the reasons provided by OCC firmware for throttling the frequency.

/sys/devices/system/cpu/cpuX/cpuidle/state<N>/default_status

Defined on file *sysfs-devices-system-cpu*

(RO) The default status of this state, "enabled" or "disabled".

/sys/devices/system/cpu/cpuX/cpuidle/state<N>/desc

Defined on file *sysfs-devices-system-cpu*

(RO) A small description about the idle state (string).

/sys/devices/system/cpu/cpuX/cpuidle/state<N>/disable

Defined on file *sysfs-devices-system-cpu*

(RW) Option to disable this idle state (bool). The behavior and the effect of the disable variable depends on the implementation of a particular governor. In the ladder governor, for example, it is not coherent, i.e. if one is disabling a light state, then all deeper states are disabled as well, but the disable variable does not reflect it. Likewise, if one enables a deep state but a lighter state still is disabled, then this has no effect.

/sys/devices/system/cpu/cpuX/cpuidle/state<N>/name

Defined on file *sysfs-devices-system-cpu*

The directory /sys/devices/system/cpu/cpuX/cpuidle contains per logical CPU specific cpuidle information for each online cpu X. The processor idle states which are available for use have the following attributes:

name:	(RO)	Name of the idle state (string).
latency:	(RO)	The latency to exit out of this idle state (in microseconds).
power:	(RO)	The power consumed while in this idle state (in milliwatts).
time:	(RO)	The total time spent in this idle state (in microseconds).
usage:	(RO)	Number of times this state was entered (a count).
above:	(RO)	Number of times this state was entered, but the observed CPU idle duration was too short for it (a count).
below:	(RO)	Number of times this state was entered, but the observed CPU idle duration was too long for it (a count).

/sys/devices/system/cpu/cpuX/cpuidle/state<N>/residency

Defined on file *sysfs-devices-system-cpu*

(RO) Display the target residency i.e. the minimum amount of time (in microseconds) this cpu should spend in this idle state to make the transition worth the effort.

/sys/devices/system/cpu/cpuX/cpuidle/state<N>/s2idle/

Defined on file *sysfs-devices-system-cpu*

Idle state usage statistics related to suspend-to-idle.

This attribute group is only present for states that can be used in suspend-to-idle with suspended timekeeping.

/sys/devices/system/cpu/cpuX/cpuidle/state<N>/s2idle/time

Defined on file *sysfs-devices-system-cpu*

Total time spent by the CPU in suspend-to-idle (with scheduler tick suspended) after requesting this state.

/sys/devices/system/cpu/cpuX/cpuidle/state<N>/s2idle/usage

Defined on file *sysfs-devices-system-cpu*

Total number of times this state has been requested by the CPU while entering suspend-to-idle.

/sys/devices/system/cpu/cpuX/crash_notes

Defined on file *sysfs-devices-system-cpu*

address and size of the percpu note.

crash_notes: the physical address of the memory that holds the note of cpuX.

crash_notes_size: size of the note of cpuX.

/sys/devices/system/cpu/cpuX/idle_purr

Defined on file *sysfs-devices-system-cpu*

PURR ticks for cpuX when it was idle.

This sysfs interface exposes the number of PURR ticks for cpuX when it was idle.

/sys/devices/system/cpu/cpuX/idle_spurr

Defined on file *sysfs-devices-system-cpu*

SPURR ticks for cpuX when it was idle.

This sysfs interface exposes the number of SPURR ticks for cpuX when it was idle.

/sys/devices/system/cpu/cpuX/mte_tcf_preferred

Defined on file *sysfs-devices-system-cpu*

Preferred MTE tag checking mode

When a user program specifies more than one MTE tag checking mode, this sysfs node is used to specify which mode should be preferred when scheduling a task on that CPU. Possible values:

”sync”	Prefer synchronous mode
”asymm”	Prefer asymmetric mode
”async”	Prefer asynchronous mode

See also: /arch/arm64/memory-tagging-extension

/sys/devices/system/cpu/cpuX/node

Defined on file *sysfs-devices-system-cpu*

Discover NUMA node a CPU belongs to

When CONFIG_NUMA is enabled, a symbolic link that points to the corresponding NUMA node directory.

For example, the following symlink is created for cpu42 in NUMA node 2:

/sys/devices/system/cpu/cpu42/node2 -> ../../node/node2

/sys/devices/system/cpu/cpuX/power/energy_perf_bias

Defined on file *sysfs-devices-system-cpu*

Intel Energy and Performance Bias Hint (EPB)

EPB for the given CPU in a sliding scale 0 - 15, where a value of 0 corresponds to a hint preference for highest performance and a value of 15 corresponds to the maximum energy savings.

In order to change the EPB value for the CPU, write either a number in the 0 - 15 sliding scale above, or one of the strings: ”performance”, ”balance-performance”, ”normal”, ”balance-power”, ”power” (that represent values reflected by their meaning), to this attribute.

This attribute is present for all online CPUs supporting the Intel EPB feature.

/sys/devices/system/cpu/cpuX/purr

Defined on file *sysfs-devices-system-cpu*

PURR ticks for this CPU since the system boot.

The Processor Utilization Resources Register (PURR) is a 64-bit counter which provides an estimate of the resources used by the CPU thread. The contents of this register increases monotonically. This sysfs interface exposes the number of PURR ticks for cpuX.

/sys/devices/system/cpu/cpuX/regs/

Defined on file *sysfs-devices-system-cpu*

AArch64 CPU registers

'identification' directory exposes the CPU ID registers for identifying model and revision of the CPU and SMCU.

/sys/devices/system/cpu/cpuX/spurr

Defined on file *sysfs-devices-system-cpu*

SPURR ticks for this CPU since the system boot.

The Scaled Processor Utilization Resources Register (SPURR) is a 64-bit counter that provides a frequency invariant estimate of the resources used by the CPU thread. The contents of this register increases monotonically. This sysfs interface exposes the number of SPURR ticks for cpuX.

/sys/devices/system/cpu/cpuX/topology/core_siblings

Defined on file *sysfs-devices-system-cpu*

CPU topology files that describe a logical CPU's relationship to other cores and threads in the same physical package.

One cpuX directory is created per logical CPU in the system, e.g. /sys/devices/system/cpu/cpu42/.

Briefly, the files above are:

core_siblings: internal kernel map of cpuX's hardware threads within the same physical_package_id.

core_siblings_list: human-readable list of the logical CPU numbers within the same physical_package_id as cpuX.

physical_package_id: physical package id of cpuX. Typically corresponds to a physical socket number, but the actual value is architecture and platform dependent.

thread_siblings: internal kernel map of cpuX's hardware threads within the same core as cpuX

thread_siblings_list: human-readable list of cpuX's hardware threads within the same core as cpuX

ppin: human-readable Protected Processor Identification Number of the socket the cpu# belongs to. There should be one per physical_package_id. File is readable only to admin.

See *How CPU topology info is exported via sysfs* for more information.

/sys/devices/system/cpu/cpufreq/boost

Defined on file *sysfs-devices-system-cpu*

Processor frequency boosting control

This switch controls the boost setting for the whole system. Boosting allows the CPU and the firmware to run at a frequency beyond its nominal limit.

More details can be found in *CPU Performance Scaling*

/sys/devices/system/cpu/cpufreq/policyX/throttle_stats

Defined on file *sysfs-devices-system-cpu*

POWERNV CPUFreq driver's frequency throttle stats directory and attributes

'policyX/throttle_stats' directory and all the attributes are same as the */sys/devices/system/cpu/cpuX/cpufreq/throttle_stats* directory and attributes which give the frequency throttle information of the chip.

/sys/devices/system/cpu/cpuidle/available_governors

Defined on file *sysfs-devices-system-cpu*

Discover cpuidle policy and mechanism

Various CPUs today support multiple idle levels that are differentiated by varying exit latencies and power consumption during idle.

Idle policy (governor) is differentiated from idle mechanism (driver).

available_governors: (RO) displays a space separated list of available governors.

current_driver: (RO) displays current idle mechanism.

current_governor: (RW) displays current idle policy. Users can switch the governor at runtime by writing to this file.

current_governor_ro: (RO) displays current idle policy.

See *CPU Idle Time Management* and /driver-api/pm/cpuidle for more information.

/sys/devices/system/cpu/crash_hotplug

Defined on file *sysfs-devices-system-cpu*

(RO) indicates whether or not the kernel directly supports modifying the crash elfcorehdr for CPU hot un/plug and/or on/offline changes.

/sys/devices/system/cpu/intel_pstate/max_perf_pct

Defined on file *sysfs-devices-system-cpu*

Parameters for the Intel P-state driver

Logic for selecting the current P-state in Intel Sandybridge+ processors. The three knobs control limits for the P-state that will be requested by the driver.

max_perf_pct: limits the maximum P state that will be requested by the driver stated as a percentage of the available performance.

min_perf_pct: limits the minimum P state that will be requested by the driver stated as a percentage of the available performance.

no_turbo: limits the driver to selecting P states below the turbo frequency range.

More details can be found in *intel_pstate CPU Performance Scaling Driver*

/sys/devices/system/cpu/isolated

Defined on file *sysfs-devices-system-cpu*

(RO) the list of CPUs that are isolated and don't participate in load balancing. These CPUs are set by boot parameter ”isolcpus=”.

/sys/devices/system/cpu/kernel_max

Defined on file *sysfs-devices-system-cpu*

CPU topology files that describe kernel limits related to hotplug. Briefly:

kernel_max: the maximum cpu index allowed by the kernel configuration.

offline: cpus that are not online because they have been HOTPLUGGED off or exceed the limit of cpus allowed by the kernel configuration (kernel_max above).

online: cpus that are online and being scheduled.

possible: cpus that have been allocated resources and can be brought online if they are present.

present: cpus that have been identified as being present in the system.

See *How CPU topology info is exported via sysfs* for more information.

/sys/devices/system/cpu/nohz_full

Defined on file *sysfs-devices-system-cpu*

(RO) the list of CPUs that are in nohz_full mode. These CPUs are set by boot parameter "nohz_full=".

/sys/devices/system/cpu/probe

Defined on file *sysfs-devices-system-cpu*

Dynamic addition and removal of CPU's. This is not hotplug removal, this is meant complete removal/addition of the CPU from the system.

probe: writes to this file will dynamically add a CPU to the system. Information written to the file to add CPU's is architecture specific.

release: writes to this file dynamically remove a CPU from the system. Information written to the file to remove CPU's is architecture specific.

/sys/devices/system/cpu/smt

Defined on file *sysfs-devices-system-cpu*

Control Symmetric Multi Threading (SMT)

active: Tells whether SMT is active (enabled and siblings online)

control: Read/write interface to control SMT. Possible
values:

"on"	SMT is enabled
"off"	SMT is disabled
"<N>"	SMT is enabled with N threads per core.
"forceoff"	SMT is force disabled. Cannot be changed.
"notsupported"	SMT is not supported by the CPU
"notimplemented"	SMT runtime toggling is not implemented for the architecture

If control status is "forceoff" or "notsupported" writes are rejected.

/sys/devices/system/cpu/svm

Defined on file *sysfs-devices-system-cpu*

Secure Virtual Machine

If 1, it means the system is using the Protected Execution Facility in POWER9 and newer processors. i.e., it is a Secure Virtual Machine.

/sys/devices/system/cpu/umwait_control

Defined on file *sysfs-devices-system-cpu*

Umwait control

enable_c02: Read/write interface to control umwait C0.2 state

Read returns C0.2 state status:
0: C0.2 is disabled 1: C0.2 is enabled

Write 'y' or '1' or 'on' to enable C0.2 state. Write 'n' or '0' or 'off' to disable C0.2 state.

The interface is case insensitive.

max_time: Read/write interface to control umwait maximum time
in TSC-quanta that the CPU can reside in either C0.1 or C0.2 state. The time is an unsigned 32-bit number. Note that a value of zero means there is no limit. Low order two bits must be zero.

/sys/devices/system/cpu/vulnerabilities

Defined on file *sysfs-devices-system-cpu*

Information about CPU vulnerabilities

The files are named after the code names of CPU vulnerabilities. The output of those files reflects the state of the CPUs in the system. Possible output values:

"Not affected"	CPU is not affected by the vulnerability
"Vulnerable"	CPU is affected and no mitigation in effect
"Mitigation: $M"	CPU is affected and mitigation $M is in effect

See also: *Hardware vulnerabilities*

/sys/devices/system/edac/mc/mc*/(dimm|rank)*/dimm_ce_count

Defined on file *sysfs-devices-edac*

This attribute file displays the total count of correctable errors that have occurred on this DIMM. This count is very important to examine. CEs provide early indications that a DIMM is beginning to fail. This count field should be monitored for non-zero values and report such information to the system administrator.

/sys/devices/system/edac/mc/mc*/(dimm|rank)*/dimm_dev_type

Defined on file *sysfs-devices-edac*

This attribute file will display what type of DRAM device is being utilized on this DIMM (x1, x2, x4, x8, ...).

/sys/devices/system/edac/mc/mc*/(dimm|rank)*/dimm_edac_mode

Defined on file *sysfs-devices-edac*

This attribute file will display what type of Error detection and correction is being utilized. For example: S4ECD4ED would mean a Chipkill with x4 DRAM.

/sys/devices/system/edac/mc/mc*/(dimm|rank)*/dimm_label

Defined on file *sysfs-devices-edac*

This control file allows this DIMM to have a label assigned to it. With this label in the module, when errors occur the output can provide the DIMM label in the system log. This becomes vital for panic events to isolate the cause of the UE event. DIMM Labels must be assigned after booting, with information that correctly identifies the physical slot with its silk screen label. This information is currently very motherboard specific and determination of this information must occur in userland at this time.

/sys/devices/system/edac/mc/mc*/(dimm|rank)*/dimm_location

Defined on file *sysfs-devices-edac*

This attribute file will display the location (csrow/channel, branch/channel/slot or channel/slot) of the dimm or rank.

/sys/devices/system/edac/mc/mc*/(dimm|rank)*/dimm_mem_type

Defined on file *sysfs-devices-edac*

This attribute file will display what type of memory is currently on this csrow. Normally, either buffered or unbuffered memory (for example, Unbuffered-DDR3).

/sys/devices/system/edac/mc/mc*/(dimm|rank)*/dimm_ue_count

Defined on file *sysfs-devices-edac*

This attribute file displays the total count of uncorrectable errors that have occurred on this DIMM. If panic_on_ue is set, this counter will not have a chance to increment, since EDAC will panic the system

/sys/devices/system/edac/mc/mc*/(dimm|rank)*/size

Defined on file *sysfs-devices-edac*

This attribute file will display the size of dimm or rank. For dimm*/size, this is the size, in MB of the DIMM memory stick. For rank*/size, this is the size, in MB for one rank of the DIMM memory stick. On single rank memories (1R), this is also the total size of the dimm. On dual rank (2R) memories, this is half the size of the total DIMM memories.

/sys/devices/system/edac/mc/mc*/ce_count

Defined on file *sysfs-devices-edac*

This attribute file displays the total count of correctable errors that have occurred on this memory controller. This count is very important to examine. CEs provide early indications that a DIMM is beginning to fail. This count field should be monitored for non-zero values and report such information to the system administrator.

/sys/devices/system/edac/mc/mc*/ce_noinfo_count

Defined on file *sysfs-devices-edac*

This attribute file displays the number of CEs that have occurred on this memory controller wherewith no information as to which DIMM slot is having errors. Memory is handicapped, but operational, yet no information is available to indicate which slot the failing memory is in. This count field should be also be monitored for non-zero values.

/sys/devices/system/edac/mc/mc*/max_location

Defined on file *sysfs-devices-edac*

This attribute file displays the information about the last available memory slot in this memory controller. It is used by userspace tools in order to display the memory filling layout.

/sys/devices/system/edac/mc/mc*/mc_name

Defined on file *sysfs-devices-edac*

This attribute file displays the type of memory controller that is being utilized.

/sys/devices/system/edac/mc/mc*/reset_counters

Defined on file *sysfs-devices-edac*

This write-only control file will zero all the statistical counters for UE and CE errors on the given memory controller. Zeroing the counters will also reset the timer indicating how long since the last counter were reset. This is useful for computing errors/time. Since the counters are always reset at driver initialization time, no module/kernel parameter is available.

/sys/devices/system/edac/mc/mc*/sdram_scrub_rate

Defined on file *sysfs-devices-edac*

Read/Write attribute file that controls memory scrubbing. The scrubbing rate used by the memory controller is set by writing a minimum bandwidth in bytes/sec to the attribute file. The rate will be translated to an internal value that gives at least the specified rate. Reading the file will

return the actual scrubbing rate employed. If configuration fails or memory scrubbing is not implemented, the value of the attribute file will be -1.

/sys/devices/system/edac/mc/mc*/seconds_since_reset

Defined on file *sysfs-devices-edac*

This attribute file displays how many seconds have elapsed since the last counter reset. This can be used with the error counters to measure error rates.

/sys/devices/system/edac/mc/mc*/size_mb

Defined on file *sysfs-devices-edac*

This attribute file displays, in count of megabytes, of memory that this memory controller manages.

/sys/devices/system/edac/mc/mc*/ue_count

Defined on file *sysfs-devices-edac*

This attribute file displays the total count of uncorrectable errors that have occurred on this memory controller. If panic_on_ue is set, this counter will not have a chance to increment, since EDAC will panic the system

/sys/devices/system/edac/mc/mc*/ue_noinfo_count

Defined on file *sysfs-devices-edac*

This attribute file displays the number of UEs that have occurred on this memory controller with no information as to which DIMM slot is having errors.

/sys/devices/system/ibm_rtl/state

Defined on file *sysfs-devices-system-ibm-rtl*

The state file allows a means by which to change in and out of Premium Real-Time Mode (PRTM), as well as the ability to query the current state.

- 0 => PRTM off
- 1 => PRTM enabled

Users: The ibm-prtm userspace daemon uses this interface.

/sys/devices/system/ibm_rtl/version

Defined on file *sysfs-devices-system-ibm-rtl*

The version file provides a means by which to query the RTL table version that lives in the Extended BIOS Data Area (EBDA).

Users: The ibm-prtm userspace daemon uses this interface.

/sys/devices/system/machinecheck/machinecheckX/

Defined on file *sysfs-mce*

(X = CPU number)

Machine checks report internal hardware error conditions detected by the CPU. Uncorrected errors typically cause a machine check (often with panic), corrected ones cause a machine check log entry.

For more details about the x86 machine check architecture see the Intel and AMD architecture manuals from their developer websites.

For more details about the architecture see http://one.firstfloor.org/~andi/mce.pdf

Each CPU has its own directory.

/sys/devices/system/machinecheck/machinecheckX/bank<Y>

Defined on file *sysfs-mce*

(Y bank number)

64bit Hex bitmask enabling/disabling specific subevents for bank Y.

When a bit in the bitmask is zero then the respective subevent will not be reported.

By default all events are enabled.

Note that BIOS maintain another mask to disable specific events per bank. This is not visible here

/sys/devices/system/machinecheck/machinecheckX/check_interval

Defined on file *sysfs-mce*

The entries appear for each CPU, but they are truly shared between all CPUs.

How often to poll for corrected machine check errors, in seconds (Note output is hexadecimal). Default 5 minutes. When the poller finds MCEs it triggers an exponential speedup (poll more often) on the polling interval. When the poller stops finding MCEs, it triggers an exponential backoff (poll less often) on the polling interval. The check_interval variable is both the initial and maximum polling interval. 0 means no polling for corrected machine check errors (but some corrected errors might be still reported in other ways)

/sys/devices/system/machinecheck/machinecheckX/cmci_disabled

Defined on file *sysfs-mce*

Disables the CMCI feature.

/sys/devices/system/machinecheck/machinecheckX/dont_log_ce

Defined on file *sysfs-mce*

Disables logging for corrected errors. All reported corrected errors will be cleared silently.

This option will be useful if you never care about corrected errors.

/sys/devices/system/machinecheck/machinecheckX/ignore_ce

Defined on file *sysfs-mce*

Disables polling and CMCI for corrected errors. All corrected events are not cleared and kept in bank MSRs.

/sys/devices/system/machinecheck/machinecheckX/monarch_timeout

Defined on file *sysfs-mce*

How long to wait for the other CPUs to machine check too on a exception. 0 to disable waiting for other CPUs.

Unit: us

/sys/devices/system/machinecheck/machinecheckX/trigger

Defined on file *sysfs-mce*

The entries appear for each CPU, but they are truly shared between all CPUs.

Program to run when a machine check event is detected. This is an alternative to running mcelog regularly from cron and allows to detect events faster.

/sys/devices/system/memory

Defined on file *sysfs-devices-memory*

The */sys/devices/system/memory* contains a snapshot of the internal state of the kernel memory blocks. Files could be added or removed dynamically to represent hot-add/remove operations.

Users: hotplug memory add/remove tools http://www.ibm.com/developerworks/wikis/display/LinuxP/powerpc-utils

/sys/devices/system/memory/crash_hotplug

Defined on file *sysfs-devices-memory*

(RO) indicates whether or not the kernel directly supports modifying the crash elfcorehdr for memory hot un/plug and/or on/offline changes.

/sys/devices/system/memory/hard_offline_page

Defined on file *sysfs-memory-page-offline*

Hard-offline the memory page containing the physical address written into this file. Input is a hex number specifying the physical address of the page. The kernel will then attempt to hard-offline the page, by trying to drop the page or killing any owner or triggering IO errors if needed. Note this may kill any processes owning the page. The kernel will avoid to access this page assuming it's poisoned by the hardware.

The offlining is done in kernel specific granularity. Normally it's the base page size of the kernel, but this might change.

Return value is the size of the number, or a error when the offlining failed. Reading the file is not allowed.

/sys/devices/system/memory/memoryX/phys_device

Defined on file *sysfs-devices-memory*

The file */sys/devices/system/memory/memoryX/phys_device* is read-only; it is a legacy interface only ever used on s390x to expose the covered storage increment.

Users: Legacy s390-tools lsmem/chmem

/sys/devices/system/memory/memoryX/phys_index

Defined on file *sysfs-devices-memory*

The file */sys/devices/system/memory/memoryX/phys_index* is read-only and contains the section ID in hexadecimal which is equivalent to decimal X contained in the memory section directory name.

/sys/devices/system/memory/memoryX/removable

Defined on file *sysfs-devices-memory*

The file */sys/devices/system/memory/memoryX/removable* is a legacy interface used to indicated whether a memory block is likely to be offlineable or not. Newer kernel versions return "1" if and only if the kernel supports memory offlining.

Users: hotplug memory remove tools http://www.ibm.com/developerworks/wikis/display/LinuxP/powerpc-utils lsmem/chmem part of util-linux

/sys/devices/system/memory/memoryX/state

Defined on file *sysfs-devices-memory*

The file */sys/devices/system/memory/memoryX/state* is read-write. When read, it returns the online/offline state of the memory block. When written, root can toggle the online/offline state of a memory block using the following commands:

```
# echo online > /sys/devices/system/memory/memoryX/state
# echo offline > /sys/devices/system/memory/memoryX/state
```

On newer kernel versions, advanced states can be specified when onlining to select a target zone: "online_movable" selects the movable zone. "online_kernel" selects the applicable kernel zone (DMA, DMA32, or Normal). However, after successfully setting one of the advanced states, reading the file will return "online"; the zone information can be obtained via "valid_zones" instead.

While onlining is unlikely to fail, there are no guarantees that offlining will succeed. Offlining is more likely to succeed if "valid_zones" indicates "Movable".

Users: hotplug memory remove tools http://www.ibm.com/developerworks/wikis/display/LinuxP/powerpc-utils

/sys/devices/system/memory/memoryX/valid_zones

Defined on file *sysfs-devices-memory*

The file */sys/devices/system/memory/memoryX/valid_zones* is read-only.

For online memory blocks, it returns in which zone memory provided by a memory block is managed. If multiple zones apply (not applicable for hotplugged memory), "None" is returned and the memory block cannot be offlined.

For offline memory blocks, it returns by which zone memory provided by a memory block can be managed when onlining. The first returned zone ("default") will be used when setting the state of an offline memory block to "online". Only one of the kernel zones (DMA, DMA32, Normal) is applicable for a single memory block.

/sys/devices/system/memory/soft_offline_page

Defined on file *sysfs-memory-page-offline*

Soft-offline the memory page containing the physical address written into this file. Input is a hex number specifying the physical address of the page. The kernel will then attempt to soft-offline it, by moving the contents elsewhere or dropping it if possible. The kernel will then be placed on the bad page list and never be reused.

The offlining is done in kernel specific granularity. Normally it's the base page size of the kernel, but this might change.

The page must be still accessible, not poisoned. The kernel will never kill anything for this, but rather fail the offline. Return value is the size of the number, or a error when the offlining failed. Reading the file is not allowed.

/sys/devices/system/memoryX/nodeY

Defined on file *sysfs-devices-memory*

When CONFIG_NUMA is enabled, a symbolic link that points to the corresponding NUMA node directory.

For example, the following symbolic link is created for memory section 9 on node0:

/sys/devices/system/memory/memory9/node0 -> ../../node/node0

/sys/devices/system/node/nodeX/memoryY

Defined on file *sysfs-devices-memory*

When CONFIG_NUMA is enabled */sys/devices/system/node/nodeX/memoryY* is a symbolic link that points to the corresponding /sys/devices/system/memory/memoryY memory section directory. For example, the following symbolic link is created for memory section 9 on node0.

/sys/devices/system/node/node0/memory9 -> ../../memory/memory9

/sys/devices/system/xen_cpu/

Defined on file *sysfs-devices-system-xen_cpu*

A collection of global/individual Xen physical cpu attributes

Individual physical cpu attributes are contained in subdirectories named by the Xen's logical cpu number, e.g.: /sys/devices/system/xen_cpu/xen_cpu#/

/sys/devices/system/xen_cpu/xen_cpu#/online

Defined on file *sysfs-devices-system-xen_cpu*

Interface to online/offline Xen physical cpus

When running under Xen platform, it provide user interface to online/offline physical cpus, except cpu0 due to several logic restrictions and assumptions.

/sys/devices/uncore_iio_x/dieX

Defined on file *sysfs-devices-mapping*

Each IIO stack (PCIe root port) has its own IIO PMON block, so each dieX file (where X is die number) holds "Segment:Root Bus" for PCIe root port, which can be monitored by that IIO PMON block. For example, on 4-die Xeon platform with up to 6 IIO stacks per die and, therefore, 6 IIO PMON blocks per die, the mapping of IIO PMON block 0 exposes as the following:

```
$ ls /sys/devices/uncore_iio_0/die*
-r--r--r-- /sys/devices/uncore_iio_0/die0
-r--r--r-- /sys/devices/uncore_iio_0/die1
-r--r--r-- /sys/devices/uncore_iio_0/die2
-r--r--r-- /sys/devices/uncore_iio_0/die3

$ tail /sys/devices/uncore_iio_0/die*
==> /sys/devices/uncore_iio_0/die0 <==
0000:00
==> /sys/devices/uncore_iio_0/die1 <==
0000:40
==> /sys/devices/uncore_iio_0/die2 <==
0000:80
==> /sys/devices/uncore_iio_0/die3 <==
0000:c0
```

Which means:

```
IIO PMU 0 on die 0 belongs to PCI RP on bus 0x00, domain 0x0000
IIO PMU 0 on die 1 belongs to PCI RP on bus 0x40, domain 0x0000
IIO PMU 0 on die 2 belongs to PCI RP on bus 0x80, domain 0x0000
IIO PMU 0 on die 3 belongs to PCI RP on bus 0xc0, domain 0x0000
```

/sys/devices/uncore_upi_x/dieX

Defined on file *sysfs-devices-mapping*

Each /sys/devices/uncore_upi_X/dieY file holds "upi_Z,die_W" value that means UPI link number X on die Y is connected to UPI link Z on die W and this link between sockets can be monitored by UPI PMON block. For example, 4-die Sapphire Rapids platform has the following UPI 0 topology:

```
# tail /sys/devices/uncore_upi_0/die*
==> /sys/devices/uncore_upi_0/die0 <==
upi_1,die_1
==> /sys/devices/uncore_upi_0/die1 <==
upi_0,die_3
==> /sys/devices/uncore_upi_0/die2 <==
upi_1,die_3
==> /sys/devices/uncore_upi_0/die3 <==
upi_0,die_1
```

Which means:

```
UPI link 0 on die 0 is connected to UPI link 1 on die 1
UPI link 0 on die 1 is connected to UPI link 0 on die 3
UPI link 0 on die 2 is connected to UPI link 1 on die 3
UPI link 0 on die 3 is connected to UPI link 0 on die 1
```

/sys/devices/virtual/memory_tiering/

Defined on file *sysfs-kernel-mm-memory-tiers*

A collection of all the memory tiers allocated.

Individual memory tier details are contained in subdirectories named by the abstract distance of the memory tier.

/sys/devices/virtual/memory_tiering/memory_tierN/

/sys/devices/virtual/memory_tiering/memory_tierN/

Defined on file *sysfs-kernel-mm-memory-tiers*

Directory with details of a specific memory tier

This is the directory containing information about a particular memory tier, memtierN, where N is derived based on abstract distance.

A smaller value of N implies a higher (faster) memory tier in the hierarchy.

nodelist: NUMA nodes that are part of this memory tier.

/sys/devices/virtual/misc/intel_ifs_<N>/current_batch

Defined on file *sysfs-platform-intel-ifs*

Write a number less than or equal to 0xff to load an IFS test image. The number written treated as the 2 digit suffix in the following file name: /lib/firmware/intel/ifs_<N>/ff-mm-ss-02x.scan

Reading the file will provide the suffix of the currently loaded IFS test image. This file is present only for device instances where a test image is applicable. Devices: intel_ifs_0

/sys/devices/virtual/misc/intel_ifs_<N>/details

Defined on file *sysfs-platform-intel-ifs*

Additional information regarding the last test. The details file reports the hex value of the STATUS MSR for this test. Note that the error_code field may contain driver defined software code not defined in the Intel SDM. Devices: all

/sys/devices/virtual/misc/intel_ifs_<N>/image_version

Defined on file *sysfs-platform-intel-ifs*

Version (hexadecimal) of loaded IFS test image. If no test image is loaded reports "none". Only present for device instances where a test image is applicable. Devices: intel_ifs_0

/sys/devices/virtual/misc/intel_ifs_<N>/run_test

Defined on file *sysfs-platform-intel-ifs*

Write <cpu#> to trigger IFS test for one online core. Note that the test is per core. The cpu# can be for any thread on the core. Running on one thread completes the test for the core containing that thread. Example: to test the core containing cpu5: echo 5 > */sys/devices/virtual/misc/intel_ifs_<N>/run_test* Devices: all

/sys/devices/virtual/misc/intel_ifs_<N>/status

Defined on file *sysfs-platform-intel-ifs*

The status of the last test. It can be one of "pass", "fail" or "untested". Devices: all

5.2.35 Symbols under /sys/firmware

/sys/firmware/acpi/bgrt/

Defined on file *sysfs-firmware-acpi*

The BGRT is an ACPI 5.0 feature that allows the OS to obtain a copy of the firmware boot splash and some associated metadata. This is intended to be used by boot splash applications in order to interact with the firmware boot splash in order to avoid jarring transitions.

image: The image bitmap. Currently a 32-bit BMP. status: 1 if the image is valid, 0 if firmware invalidated it. type: 0 indicates image is in BMP format.

version:	The version of the BGRT. Currently 1.
xoffset:	The number of pixels between the left of the screen and the left edge of the image.
yoffset:	The number of pixels between the top of the screen and the top edge of the image.

/sys/firmware/acpi/fpdt/

Defined on file *sysfs-firmware-acpi*

ACPI Firmware Performance Data Table (FPDT) provides information for firmware performance data for system boot, S3 suspend and S3 resume. This sysfs entry contains the performance data retrieved from the FPDT.

boot:

firmware_start_ns: Timer value logged at the beginning
of firmware image execution. In nanoseconds.

bootloader_load_ns: Timer value logged just prior to
loading the OS boot loader into memory. In nanoseconds.

bootloader_launch_ns: Timer value logged just prior to
launching the currently loaded OS boot loader image. In nanoseconds.

exitbootservice_start_ns: Timer value logged at the
point when the OS loader calls the ExitBootServices function for UEFI compatible firmware. In nanoseconds.

exitbootservice_end_ns: Timer value logged at the point
just prior to the OS loader gaining control back from the ExitBootServices function for UEFI compatible firmware. In nanoseconds.

suspend:

suspend_start_ns: Timer value recorded at the previous
OS write to SLP_TYP upon entry to S3. In nanoseconds.

suspend_end_ns: Timer value recorded at the previous
firmware write to SLP_TYP used to trigger hardware entry to S3. In nanoseconds.

resume:

resume_count: A count of the number of S3 resume cycles
since the last full boot sequence.

resume_avg_ns: Average timer value of all resume cycles
logged since the last full boot sequence, including the most recent resume. In nanoseconds.

resume_prev_ns: Timer recorded at the end of the previous
platform runtime firmware S3 resume, just prior to handoff to the OS waking vector. In nanoseconds.

/sys/firmware/acpi/hotplug/

Defined on file *sysfs-firmware-acpi*

There are separate hotplug profiles for different classes of devices supported by ACPI, such as containers, memory modules, processors, PCI root bridges etc. A hotplug profile for a given class of devices is a collection of settings defining the way that class of devices will be handled by the ACPI core hotplug code. Those profiles are represented in sysfs as subdirectories of */sys/firmware/acpi/hotplug/*.

The following setting is available to user space for each hotplug profile:

enabled:	If set, the ACPI core will handle notifications of hotplug events associated with the given class of devices and will allow those devices to be ejected with the help of the _EJ0 control method. Unsetting it effectively disables hotplug for the corresponding class of devices.

The value of the above attribute is an integer number: 1 (set) or 0 (unset). Attempts to write any other values to it will cause -EINVAL to be returned.

/sys/firmware/acpi/interrupts/

Defined on file *sysfs-firmware-acpi*

All ACPI interrupts are handled via a single IRQ, the System Control Interrupt (SCI), which appears as "acpi" in /proc/interrupts.

However, one of the main functions of ACPI is to make the platform understand random hardware without special driver support. So while the SCI handles a few well known (fixed feature) interrupts sources, such as the power button, it can also handle a variable number of a "General Purpose Events" (GPE).

A GPE vectors to a specified handler in AML, which can do a anything the BIOS writer wants from OS context. GPE 0x12, for example, would vector to a level or edge handler called _L12 or _E12. The handler may do its business and return. Or the handler may send send a Notify event to a Linux device driver registered on an ACPI device, such as a battery, or a processor.

To figure out where all the SCI's are coming from, /sys/firmware/acpi/interrupts contains a file listing every possible source, and the count of how many times it has triggered:

```
$ cd /sys/firmware/acpi/interrupts
$ grep . *
error:             0
ff_gbl_lock:       0   enable
ff_pmtimer:        0  invalid
ff_pwr_btn:        0   enable
ff_rt_clk:         2  disable
ff_slp_btn:        0  invalid
gpe00:             0  invalid
gpe01:             0   enable
gpe02:           108   enable
gpe03:             0  invalid
gpe04:             0  invalid
gpe05:             0  invalid
gpe06:             0   enable
gpe07:             0   enable
gpe08:             0  invalid
gpe09:             0  invalid
gpe0A:             0  invalid
gpe0B:             0  invalid
gpe0C:             0  invalid
gpe0D:             0  invalid
```

```
gpe0E:             0  invalid
gpe0F:             0  invalid
gpe10:             0  invalid
gpe11:             0  invalid
gpe12:             0  invalid
gpe13:             0  invalid
gpe14:             0  invalid
gpe15:             0  invalid
gpe16:             0  invalid
gpe17:          1084   enable
gpe18:             0   enable
gpe19:             0  invalid
gpe1A:             0  invalid
gpe1B:             0  invalid
gpe1C:             0  invalid
gpe1D:             0  invalid
gpe1E:             0  invalid
gpe1F:             0  invalid
gpe_all:        1192
sci:            1194
sci_not:           0
```

sci	The number of times the ACPI SCI has been called and claimed an interrupt.
sci_not	The number of times the ACPI SCI has been called and NOT claimed an interrupt.
gpe_all	count of SCI caused by GPEs.
gpeXX	count for individual GPE source
ff_gbl_lock	Global Lock
ff_pmtimer	PM Timer
ff_pwr_btn	Power Button
ff_rt_clk	Real Time Clock
ff_slp_btn	Sleep Button
error	an interrupt that can't be accounted for above.
invalid	it's either a GPE or a Fixed Event that doesn't have an event handler.
disable	the GPE/Fixed Event is valid but disabled.
enable	the GPE/Fixed Event is valid and enabled.

Root has permission to clear any of these counters. Eg.:

```
# echo 0 > gpe11
```

All counters can be cleared by clearing the total ”sci”:

```
# echo 0 > sci
```

None of these counters has an effect on the function of the system, they are simply statistics.

Besides this, user can also write specific strings to these files to enable/disable/clear ACPI interrupts in user space, which can be used to debug some ACPI interrupt storm issues.

Note that only writing to VALID GPE/Fixed Event is allowed, i.e. user can only change the status

of runtime GPE and Fixed Event with event handler installed.

Let's take power button fixed event for example, please kill acpid and other user space applications so that the machine won't shutdown when pressing the power button:

```
# cat ff_pwr_btn
0     enabled
# press the power button for 3 times;
# cat ff_pwr_btn
3     enabled
# echo disable > ff_pwr_btn
# cat ff_pwr_btn
3     disabled
# press the power button for 3 times;
# cat ff_pwr_btn
3     disabled
# echo enable > ff_pwr_btn
# cat ff_pwr_btn
4     enabled
/*
 * this is because the status bit is set even if the enable
 * bit is cleared, and it triggers an ACPI fixed event when
 * the enable bit is set again
 */
# press the power button for 3 times;
# cat ff_pwr_btn
7     enabled
# echo disable > ff_pwr_btn
# press the power button for 3 times;
# echo clear > ff_pwr_btn     /* clear the status bit */
# echo disable > ff_pwr_btn
# cat ff_pwr_btn
7     enabled
```

/sys/firmware/acpi/platform_profile

Defined on file *sysfs-platform_profile*

Reading this file gives the current selected profile for this device. Writing this file with one of the strings from platform_profile_choices changes the profile to the new value.

This file can be monitored for changes by polling for POLLPRI, POLLPRI will be signalled on any changes, independent of those changes coming from a userspace write; or coming from another source such as e.g. a hotkey triggered profile change handled either directly by the embedded-controller or fully handled inside the kernel.

/sys/firmware/acpi/platform_profile_choices

Defined on file *sysfs-platform_profile*

This file contains a space-separated list of profiles supported for this device.

Drivers must use the following standard profile-names:

low-power	Low power consumption
cool	Cooler operation
quiet	Quieter operation
balanced	Balance between low power consumption and performance
balanced-performance	Balance between performance and low power consumption with a slight bias towards performance
performance	High performance operation

Userspace may expect drivers to offer more than one of these standard profile names.

/sys/firmware/devicetree/*

Defined on file *sysfs-firmware-ofw*

When using OpenFirmware or a Flattened Device Tree to enumerate hardware, the device tree structure will be exposed in this directory.

It is possible for multiple device-tree directories to exist. Some device drivers use a separate detached device tree which have no attachment to the system tree and will appear in a different subdirectory under /sys/firmware/devicetree.

Userspace must not use the /sys/firmware/devicetree/base path directly, but instead should follow /proc/device-tree symlink. It is possible that the absolute path will change in the future, but the symlink is the stable ABI.

The /proc/device-tree symlink replaces the devicetree /proc filesystem support, and has largely the same semantics and should be compatible with existing userspace.

The contents of /sys/firmware/devicetree/ is a hierarchy of directories, one per device tree node. The directory name is the resolved path component name (node name plus address). Properties are represented as files in the directory. The contents of each file is the exact binary data from the device tree.

/sys/firmware/dmi/entries/

Defined on file *sysfs-firmware-dmi-entries*

Many machines' firmware (x86 and arm64) export DMI / SMBIOS tables to the operating system. Getting at this information is often valuable to userland, especially in cases where there are OEM extensions used.

The kernel itself does not rely on the majority of the information in these tables being correct. It equally cannot ensure that the data as exported to userland is without error either.

DMI is structured as a large table of entries, where each entry has a common header indicating the type and length of the entry, as well as a firmware-provided 'handle' that is supposed to be unique amongst all entries.

Some entries are required by the specification, but many others are optional. In general though, users should never expect to find a specific entry type on their system unless they know for certain what their firmware is doing. Machine to machine experiences will vary.

Multiple entries of the same type are allowed. In order to handle these duplicate entry types, each entry is assigned by the operating system an 'instance', which is derived from an entry

type's ordinal position. That is to say, if there are 'N' multiple entries with the same type 'T' in the DMI tables (adjacent or spread apart, it doesn't matter), they will be represented in sysfs as entries ”T-0” through ”T-(N-1)”:

Example entry directories:

```
/sys/firmware/dmi/entries/17-0
/sys/firmware/dmi/entries/17-1
/sys/firmware/dmi/entries/17-2
/sys/firmware/dmi/entries/17-3
...
```

Instance numbers are used in lieu of the firmware assigned entry handles as the kernel itself makes no guarantees that handles as exported are unique, and there are likely firmware images that get this wrong in the wild.

Each DMI entry in sysfs has the common header values exported as attributes:

handle	The 16bit 'handle' that is assigned to this entry by the firmware. This handle may be referred to by other entries.
length	The length of the entry, as presented in the entry itself. Note that this is _not the total count of bytes associated with the entry. This value represents the length of the ”formatted” portion of the entry. This ”formatted” region is sometimes followed by the ”unformatted” region composed of nul terminated strings, with termination signalled by a two nul characters in series.
raw	The raw bytes of the entry. This includes the ”formatted” portion of the entry, the ”unformatted” strings portion of the entry, and the two terminating nul characters.
type	The type of the entry. This value is the same as found in the directory name. It indicates how the rest of the entry should be interpreted.
instance	The instance ordinal of the entry for the given type. This value is the same as found in the parent directory name.
position	The ordinal position (zero-based) of the entry within the entirety of the DMI entry table.

Entry Specialization

Some entry types may have other information available in sysfs. Not all types are specialized.

Type 15 - System Event Log

This entry allows the firmware to export a log of events the system has taken. This information is typically backed by nvram, but the implementation details are abstracted by this table. This entry's data is exported in the directory:

```
/sys/firmware/dmi/entries/15-0/system_event_log
```

and has the following attributes (documented in the SMBIOS / DMI specification under ”System Event Log (Type 15)”:

- area_length
- header_start_offset
- data_start_offset
- access_method

- status
- change_token
- access_method_address
- header_format
- per_log_type_descriptor_length
- type_descriptors_supported_count

As well, the kernel exports the binary attribute:

raw_event_log	The raw binary bits of the event log as described by the DMI entry.

/sys/firmware/dmi/tables/

Defined on file *sysfs-firmware-dmi-tables*

The firmware provides DMI structures as a packed list of data referenced by a SMBIOS table entry point. The SMBIOS entry point contains general information, like SMBIOS version, DMI table size, etc. The structure, content and size of SMBIOS entry point is dependent on SMBIOS version. The format of SMBIOS entry point and DMI structures can be read in SMBIOS specification.

The dmi/tables provides raw SMBIOS entry point and DMI tables through sysfs as an alternative to utilities reading them from /dev/mem. The raw SMBIOS entry point and DMI table are presented as binary attributes and are accessible via:

/sys/firmware/dmi/tables/smbios_entry_point /sys/firmware/dmi/tables/DMI

The complete DMI information can be obtained using these two tables.

/sys/firmware/efi/config_table

Defined on file *sysfs-firmware-efi*

It shows the physical address of config table entry in the EFI system table.

Users: Kexec

/sys/firmware/efi/esrt/

Defined on file *sysfs-firmware-efi-esrt*

Provides userland access to read the EFI System Resource Table (ESRT), a catalog of firmware for which can be updated with the UEFI UpdateCapsule mechanism described in section 7.5 of the UEFI Standard.

Users: fwupdate - https://github.com/rhinstaller/fwupdate

/sys/firmware/efi/esrt/entries/entry<N>/

Defined on file *sysfs-firmware-efi-esrt*

Each ESRT entry is identified by a GUID, and each gets a subdirectory under entries/ . example: /sys/firmware/efi/esrt/entries/entry0/

/sys/firmware/efi/esrt/entries/entry<N>/capsule_flags

Defined on file *sysfs-firmware-efi-esrt*

Flags that must be passed to UpdateCapsule()

/sys/firmware/efi/esrt/entries/entry<N>/fw_class

Defined on file *sysfs-firmware-efi-esrt*

This is the entry's guid, and will match the directory name.

/sys/firmware/efi/esrt/entries/entry<N>/fw_type

Defined on file *sysfs-firmware-efi-esrt*

What kind of firmware entry this is:

0	Unknown
1	System Firmware
2	Device Firmware
3	UEFI Driver

/sys/firmware/efi/esrt/entries/entry<N>/fw_version

Defined on file *sysfs-firmware-efi-esrt*

The version of the firmware currently installed. This is a 32-bit unsigned integer.

/sys/firmware/efi/esrt/entries/entry<N>/last_attempt_status

Defined on file *sysfs-firmware-efi-esrt*

The result of the last firmware update attempt for the firmware resource entry.

0	Success
1	Insufficient resources
2	Incorrect version
3	Invalid format
4	Authentication error
5	AC power event
6	Battery power event

/sys/firmware/efi/esrt/entries/entry<N>/last_attempt_version

Defined on file *sysfs-firmware-efi-esrt*

The last firmware version for which an update was attempted.

/sys/firmware/efi/esrt/entries/entry<N>/lowest_supported_fw_version

Defined on file *sysfs-firmware-efi-esrt*

The lowest version of the firmware that can be installed.

/sys/firmware/efi/esrt/fw_resource_count

Defined on file *sysfs-firmware-efi-esrt*

The number of entries in the ESRT

/sys/firmware/efi/esrt/fw_resource_count_max

Defined on file *sysfs-firmware-efi-esrt*

The maximum number of entries that /could/ be registered in the allocation the table is currently in. This is really only useful to the system firmware itself.

/sys/firmware/efi/esrt/fw_resource_version

Defined on file *sysfs-firmware-efi-esrt*

The version of the ESRT structure provided by the firmware.

/sys/firmware/efi/fw_vendor

Defined on file *sysfs-firmware-efi*

It shows the physical address of firmware vendor field in the EFI system table.

Users: Kexec

/sys/firmware/efi/runtime

Defined on file *sysfs-firmware-efi*

It shows the physical address of runtime service table entry in the EFI system table.

Users: Kexec

/sys/firmware/efi/runtime-map/

Defined on file *sysfs-firmware-efi-runtime-map*

Switching efi runtime services to virtual mode requires that all efi memory ranges which have the runtime attribute bit set to be mapped to virtual addresses.

The efi runtime services can only be switched to virtual mode once without rebooting. The kexec kernel must maintain the same physical to virtual address mappings as the first kernel.

The mappings are exported to sysfs so userspace tools can reassemble them and pass them into the kexec kernel.

/sys/firmware/efi/runtime-map/ is the directory the kernel exports that information in.

subdirectories are named with the number of the memory range:

```
/sys/firmware/efi/runtime-map/0
/sys/firmware/efi/runtime-map/1
/sys/firmware/efi/runtime-map/2
/sys/firmware/efi/runtime-map/3
...
```

Each subdirectory contains five files:

attribute	The attributes of the memory range.
num_pages	The size of the memory range in pages.
phys_addr	The physical address of the memory range.
type	The type of the memory range.
virt_addr	The virtual address of the memory range.

Above values are all hexadecimal numbers with the '0x' prefix.

Users: Kexec

/sys/firmware/efi/systab

Defined on file *sysfs-firmware-efi*

Displays the physical addresses of all EFI Configuration Tables found via the EFI System Table. The order in which the tables are printed forms an ABI and newer versions are always printed first, i.e. ACPI20 comes before ACPI.

Users: dmidecode

/sys/firmware/efi/tables/rci2

Defined on file *sysfs-firmware-efi*

Displays the content of the Runtime Configuration Interface Table version 2 on Dell EMC PowerEdge systems in binary format

Users: It is used by Dell EMC OpenManage Server Administrator tool to populate BIOS setup page.

/sys/firmware/fdt

Defined on file *sysfs-firmware-ofw*

Exports the FDT blob that was passed to the kernel by the bootloader. This allows userland applications such as kexec to access the raw binary. This blob is also useful when debugging since it contains any changes made to the blob by the bootloader.

The fact that this node does not reside under /sys/firmware/device-tree is deliberate: FDT is also used on arm64 UEFI/ACPI systems to communicate just the UEFI and ACPI entry points, but the FDT is never unflattened and used to configure the system.

A CRC32 checksum is calculated over the entire FDT blob, and verified at late_initcall time. The sysfs entry is instantiated only if the checksum is valid, i.e., if the FDT blob has not been modified in the mean time. Otherwise, a warning is printed.

Users: kexec, debugging

/sys/firmware/gsmi

Defined on file *sysfs-firmware-gsmi*

Some servers used internally at Google have firmware that provides callback functionality via explicit SMI triggers. Some of the callbacks are similar to those provided by the EFI runtime services page, but due to historical reasons this different entry-point has been used.

The gsmi driver implements the kernel's abstraction for these firmware callbacks. Currently, this functionality is limited to handling the system event log and getting access to EFI-style variables stored in nvram.

Layout:

/sys/firmware/gsmi/vars:

> This directory has the same layout (and underlying implementation as /sys/firmware/efi/vars. See *Documentation/ABI/*/sysfs-firmware-efi-vars* for more information on how to interact with this structure.

/sys/firmware/gsmi/append_to_eventlog - write-only:

> This file takes a binary blob and passes it onto the firmware to be timestamped and appended to the system eventlog. The binary format is interpreted by the firmware and may change from platform to platform. The only kernel-enforced requirement is that the blob be prefixed with a 32bit host-endian type used as part of the firmware call.

/sys/firmware/gsmi/clear_config - write-only:

> Writing any value to this file will cause the entire firmware configuration to be reset to ”factory defaults”. Callers should assume that a reboot is required for the configuration to be cleared.

/sys/firmware/gsmi/clear_eventlog - write-only:

> This file is used to clear out a portion/the whole of the system event log. Values written should be values between 1 and 100 inclusive (in ASCII) representing the fraction of the log to clear. Not all platforms support fractional clearing though, and this writes to this file will error out if the firmware doesn't like your submitted fraction.
>
> Callers should assume that a reboot is needed for this operation to complete.

/sys/firmware/ibft/acpi_header

Defined on file *sysfs-ibft*

The */sys/firmware/ibft/acpi_header* directory will contain files that expose the SIGNATURE, OEM_ID, and OEM_TABLE_ID fields of the acpi table header of the iBFT structure. This will allow for identification of the creator of the table which is useful in determining quirks associated with some adapters when used in hardware vs software iscsi initiator mode.

/sys/firmware/ibft/ethernetX

Defined on file *sysfs-ibft*

The */sys/firmware/ibft/ethernetX* directory will contain files that expose the iSCSI Boot Firmware Table NIC data. Usually this contains the IP address, MAC, and gateway of the NIC.

/sys/firmware/ibft/initiator

Defined on file *sysfs-ibft*

The */sys/firmware/ibft/initiator* directory will contain files that expose the iSCSI Boot Firmware Table initiator data. Usually this contains the Initiator name.

/sys/firmware/ibft/targetX

Defined on file *sysfs-ibft*

The */sys/firmware/ibft/targetX* directory will contain files that expose the iSCSI Boot Firmware Table target data. Usually this contains the target's IP address, boot LUN, target name, and what NIC it is associated with. It can also contain the CHAP name (and password), the reverse CHAP name (and password)

/sys/firmware/initrd

Defined on file *sysfs-firmware-initrd*

When the kernel was booted with an initrd and the ”retain_initrd” option is set on the kernel command line, */sys/firmware/initrd* contains the contents of the initrd that the kernel was booted with.

/sys/firmware/lefi/boardinfo

Defined on file *sysfs-firmware-lefi-boardinfo*

Get mainboard and BIOS info easily on the Loongson platform, this is useful to point out the current used mainboard type and BIOS version when there exists problems related with hardware or firmware.

The related structures are already defined in the interface specification about firmware and kernel which are common requirement and specific for Loongson64, so only add a new boardinfo.c file in arch/mips/loongson64.

For example:

[loongson@linux ~]$ cat */sys/firmware/lefi/boardinfo* Board Info Manufacturer : LEMOTE Board Name : LEMOTE-LS3A4000-7A1000-1w-V01-pc Family : LOONGSON3

BIOS Info Vendor : Kunlun Version : Kunlun-A1901-V4.1.3-20200414093938 ROM Size : 4 KB Release Date : 2020-04-14

By the way, using dmidecode command can get the similar info if there exists SMBIOS in firmware, but the fact is that there is no SMBIOS on some machines, we can see nothing when execute dmidecode, like this:

[root@linux loongson]# dmidecode # dmidecode 2.12 # No SMBIOS nor DMI entry point found, sorry.

/sys/firmware/log

Defined on file *sysfs-firmware-log*

The */sys/firmware/log* is a binary file that represents a read-only copy of the firmware's log if one is available.

/sys/firmware/memmap/

Defined on file *sysfs-firmware-memmap*

On all platforms, the firmware provides a memory map which the kernel reads. The resources from that memory map are registered in the kernel resource tree and exposed to userspace via /proc/iomem (together with other resources).

However, on most architectures that firmware-provided memory map is modified afterwards by the kernel itself, either because the kernel merges that memory map with other information or just because the user overwrites that memory map via command line.

kexec needs the raw firmware-provided memory map to setup the parameter segment of the kernel that should be booted with kexec. Also, the raw memory map is useful for debugging. For that reason, /sys/firmware/memmap is an interface that provides the raw memory map to userspace.

The structure is as follows: Under /sys/firmware/memmap there are subdirectories with the number of the entry as their name:

```
/sys/firmware/memmap/0
/sys/firmware/memmap/1
/sys/firmware/memmap/2
/sys/firmware/memmap/3
...
```

The maximum depends on the number of memory map entries provided by the firmware. The order is just the order that the firmware provides.

Each directory contains three files:

start	The start address (as hexadecimal number with the '0x' prefix).
end	The end address, inclusive (regardless whether the firmware provides inclusive or exclusive ranges).
type	Type of the entry as string. See below for a list of valid types.

So, for example:

```
/sys/firmware/memmap/0/start
/sys/firmware/memmap/0/end
/sys/firmware/memmap/0/type
/sys/firmware/memmap/1/start
...
```

Currently following types exist:

- System RAM
- ACPI Tables
- ACPI Non-volatile Storage
- Unusable memory
- Persistent Memory (legacy)
- Persistent Memory
- Soft Reserved
- reserved

Following shell snippet can be used to display that memory map in a human-readable format:

```
#!/bin/bash
cd /sys/firmware/memmap
for dir in * ; do
    start=$(cat $dir/start)
    end=$(cat $dir/end)
    type=$(cat $dir/type)
    printf "%016x-%016x (%s)\n" $start $[ $end +1] "$type"
done
```

/sys/firmware/opal/powercap

Defined on file *sysfs-firmware-opal-powercap*

Powercap directory for Powernv (P8, P9) servers

Each folder in this directory contains a power-cappable component.

/sys/firmware/opal/powercap/system-powercap

Defined on file *sysfs-firmware-opal-powercap*

System powercap directory and attributes applicable for Powernv (P8, P9) servers

This directory provides powercap information. It contains below sysfs attributes:

- powercap-min : This file provides the minimum possible powercap in Watt units
- powercap-max : This file provides the maximum possible powercap in Watt units
- powercap-current : This file provides the current powercap set on the system. Writing to this file creates a request for setting a new-powercap. The powercap requested must be between powercap-min and powercap-max.

/sys/firmware/opal/psr

Defined on file *sysfs-firmware-opal-psr*

Power-Shift-Ratio directory for Powernv P9 servers

Power-Shift-Ratio allows to provide hints the firmware to shift/throttle power between different entities in the system. Each attribute in this directory indicates a settable PSR.

/sys/firmware/opal/psr/cpu_to_gpu_X

Defined on file *sysfs-firmware-opal-psr*

PSR sysfs attributes for Powernv P9 servers

Power-Shift-Ratio between CPU and GPU for a given chip with chip-id X. This file gives the ratio (0-100) which is used by OCC for power-capping.

/sys/firmware/opal/sensor_groups

Defined on file *sysfs-firmware-opal-sensor-groups*

Sensor groups directory for POWER9 powernv servers

Each folder in this directory contains a sensor group which are classified based on type of the sensor like power, temperature, frequency, current, etc. They can also indicate the group of sensors belonging to different owners like CSM, Profiler, Job-Scheduler

/sys/firmware/opal/sensor_groups/<sensor_group_name>/clear

Defined on file *sysfs-firmware-opal-sensor-groups*

Sysfs file to clear the min-max of all the sensors belonging to the group.

Writing 1 to this file will clear the minimum and maximum values of all the sensors in the group. In POWER9, the min-max of a sensor is the historical minimum and maximum value of the sensor cached by OCC.

/sys/firmware/papr/energy_scale_info

Defined on file *sysfs-firmware-papr-energy-scale-info*

Directory hosting a set of platform attributes like energy/frequency on Linux running as a PAPR guest.

Each file in a directory contains a platform attribute hierarchy pertaining to performance/energy-savings mode and processor frequency.

/sys/firmware/papr/energy_scale_info/<id>

Defined on file *sysfs-firmware-papr-energy-scale-info*

Energy, frequency attributes directory for POWERVM servers

/sys/firmware/papr/energy_scale_info/<id>/desc

Defined on file *sysfs-firmware-papr-energy-scale-info*

String description of the energy attribute of <id>

/sys/firmware/papr/energy_scale_info/<id>/value

Defined on file *sysfs-firmware-papr-energy-scale-info*

Numeric value of the energy attribute of <id>

/sys/firmware/papr/energy_scale_info/<id>/value_desc

Defined on file *sysfs-firmware-papr-energy-scale-info*

String value of the energy attribute of <id>

/sys/firmware/qemu_fw_cfg/

Defined on file *sysfs-firmware-qemu_fw_cfg*

Several different architectures supported by QEMU (x86, arm, sun4*, ppc/mac) are provisioned with a firmware configuration (fw_cfg) device, originally intended as a way for the host to provide configuration data to the guest firmware. Starting with QEMU v2.4, arbitrary fw_cfg file entries may be specified by the user on the command line, which makes fw_cfg additionally useful as an out-of-band, asynchronous mechanism for providing configuration data to the guest userspace.

The authoritative guest-side hardware interface documentation to the fw_cfg device can be found in "docs/specs/fw_cfg.rst" in the QEMU source tree, or online at: https://qemu-project.gitlab.io/qemu/specs/fw_cfg.html

SysFS fw_cfg Interface

The fw_cfg sysfs interface described in this document is only intended to display discoverable blobs (i.e., those registered with the file directory), as there is no way to determine the presence or size of "legacy" blobs (with selector keys between 0x0002 and 0x0018) programmatically.

All fw_cfg information is shown under:

/sys/firmware/qemu_fw_cfg/

The only legacy blob displayed is the fw_cfg device revision:

/sys/firmware/qemu_fw_cfg/rev

Discoverable fw_cfg blobs by selector key

All discoverable blobs listed in the fw_cfg file directory are displayed as entries named after their unique selector key value, e.g.:

/sys/firmware/qemu_fw_cfg/by_key/32 /sys/firmware/qemu_fw_cfg/by_key/33 /sys/firmware/qemu_fw_cfg/by_key/34 ...

Each such fw_cfg sysfs entry has the following values exported as attributes:

name	The 56-byte nul-terminated ASCII string used as the blob's 'file name' in the fw_cfg directory.
size	The length of the blob, as given in the fw_cfg directory.
key	The value of the blob's selector key as given in the fw_cfg directory. This value is the same as used in the parent directory name.
raw	The raw bytes of the blob, obtained by selecting the entry via the control register, and reading a number of bytes equal to the blob size from the data register.

Listing fw_cfg blobs by file name

While the fw_cfg device does not impose any specific naming convention on the blobs registered in the file directory, QEMU developers have traditionally used path name semantics to give each blob a descriptive name. For example:

```
"bootorder"
"genroms/kvmvapic.bin"
"etc/e820"
"etc/boot-fail-wait"
"etc/system-states"
"etc/table-loader"
"etc/acpi/rsdp"
"etc/acpi/tables"
"etc/smbios/smbios-tables"
"etc/smbios/smbios-anchor"
...
```

In addition to the listing by unique selector key described above, the fw_cfg sysfs driver also attempts to build a tree of directories matching the path name components of fw_cfg blob names, ending in symlinks to the by_key entry for each ”basename”, as illustrated below (assume current directory is /sys/firmware):

```
qemu_fw_cfg/by_name/bootorder -> ../by_key/38
qemu_fw_cfg/by_name/etc/e820 -> ../../by_key/35
qemu_fw_cfg/by_name/etc/acpi/rsdp -> ../../../by_key/41
...
```

Construction of the directory tree and symlinks is done on a ”best-effort” basis, as there is no guarantee that components of fw_cfg blob names are always ”well behaved”. I.e., there is the possibility that a symlink (basename) will conflict with a dirname component of another fw_cfg blob, in which case the creation of the offending /sys/firmware/qemu_fw_cfg/by_name entry will be skipped.

The authoritative list of entries will continue to be found under the /sys/firmware/qemu_fw_cfg/by_key directory.

/sys/firmware/secvar

Defined on file *sysfs-secvar*

This directory is created if the POWER firmware supports OS secureboot, thereby secure variables. It exposes interface for reading/writing the secure variables

/sys/firmware/secvar/config

Defined on file *sysfs-secvar*

This optional directory contains read-only config attributes as defined by the secure variable implementation. All data is in ASCII format. The directory is only created if the backing implementation provides variables to populate it, which at present is only PLPKS on the pseries platform.

/sys/firmware/secvar/config/max_object_size

Defined on file *sysfs-secvar*

Maximum allowed size of objects in the keystore in bytes, represented in ASCII decimal format.
